p16/Ki67 dual staining as an additional special circumstance recommendation for p16 immunohistochemistry in the diagnosis of HPV-associated lesions in cervical biopsy specimens: results from a 7-year study

K. Mazurec[1,2], M. Trzeszcz[1,2], M. Mazurec[1], R. Jach[3], A. Halon[4]
[1]Corfamed Woman's Health Centre, Wroclaw, Poland, [2]University Hospital in Wroclaw, Division of Pathology and Clinical Cytology, Wroclaw, Poland, [3]Jagiellonian University Medical College, Division of Gynaecologic Endocrinology, Krakow, Poland, [4]Wroclaw Medical University, Department of Clinical and Experimental Pathology, Division of Clinical Pathology, Wroclaw, Poland

Background & Objectives: p16 immunohistochemistry in diagnosing HPV-associated squamous lesions of the cervix follows the Lower Anogenital Squamous Terminology (LAST) criteria, which recommend its use in ≤IN1 surgical specimens with a high-risk for missed high-grade disease, defined as abnormal screening results (HSIL, ASC-H, ASC-US/HPV16+, AGC-NOS). p16/Ki67 dual staining (DS) has emerged as a promising HSIL/CIN2+ biomarker in secondary cervical cancer screening. This study evaluates whether DS-positive (DS+) status can serve as an equivalent diagnostic criterion to HSIL, ASC-H, and ASC-US/HPV16+ for p16 immunohistochemistry application in clinical practice.
Methods: A retrospective analysis included 28,525 cervical cancer screening tests and 602 histology results retrieved between 2015 and 2022. Among them, 314 patients had HR-HPV testing, liquid-based cytology, DS, histology diagnosis from colposcopy with biopsy, and p16 immunohistochemistry results. DS+ status was compared with HSIL, ASC-H, and ASC-US/HPV16+ regarding HSIL/CIN2+ results. Statistical methods included chi-square test, logistic regression, and ROC/AUC analysis. Machine learning models (Random Forest, XGBoost) were applied to explore the predictive potential of DS+. AGC-NOS cases (n=1) were excluded due to insufficient sample size.
Results: Among 314 patients, 227 were DS+, 19 had HSIL, 23 ASC-H, and 51 ASC-US/HPV16+. Chi-square test demonstrated the strongest association between DS+ and HSIL/CIN2+ (X^2=28.315, p<0.001), with higher values compared to HSIL, ASC-H, and ASC-US/HPV16+. Logistic regression confirmed DS+ as a significant HSIL/CIN2+ predictor (OR=2.14, p<0.001). ROC analysis revealed a higher AUC for DS+ (0.651) compared to HSIL (0.556), ASC-H (0.524), and ASC-US/HPV16+ (0.476), suggesting superior diagnostic performance.
Conclusion: The 7-year screening findings indicate that p16/Ki67+ is at least as strongly associated with HSIL/CIN2+ as the current LAST standardization criteria. Given its predictive value and higher AUC, DS+ may serve as a valuable additional criterion for p16 immunohistochemistry in HPV-associated squamous lesions of the cervix, alongside existing additional special circumstance recommendations.

OFP-01-002
WHO classification system in soft tissue cytopathology: diagnostic accuracy and malignancy risk assessment

S. Ahuja[1], A. Khan[1], C. Ahluwalia[1], M. Singh[1]
[1]Vardhman Mahavir Medical College and Safdarjung Hospital, Pathology, New Delhi, India

Background & Objectives: Diagnosing soft tissue tumours, which are intricate neoplasms, often necessitates precise identification through fine-needle aspiration (FNA). The World Health Organization (WHO) classification system seeks to standardize the cytopathological evaluation and assess the risk of malignancy (ROM) in these tumours. This manuscript aims to classify soft tissue FNA samples based on the recently proposed WHO classification for reporting soft tissue cytopathology and to assess this system's sensitivity, specificity, and diagnostic accuracy in diagnosing malignancies.
Methods: This retrospective analysis encompassed cytological specimens collected between January 2022 and June 2023. Specimens were classified into six categories following the WHO system: non-diagnostic (ND), benign, atypical, soft tissue neoplasm of uncertain malignant potential (STNUMP), suspicious for malignancy (SFM), and malignant. Histopathological comparisons were conducted, and the ROM, along with sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and diagnostic accuracy, were determined.
Results: The study analysed 203 samples, with findings showing 62.5% benign, 13.8% SFM, and 9.9% malignant cases. The ROMs were calculated as 33.3% for ND, 1.2% for benign, 40% for atypical, 25% for STNUMP, 80% for SFM, and 100% for malignant. Histopathological correlation was available for 117 cases. The highest sensitivity and diagnostic accuracy (77.3% and 93.9%, respectively) were observed when SFM and malignant categories were grouped as indicative of malignancy. Specificity peaked at 100% when only the malignant cases were classified as positive. The interobserver agreement was moderate, with a Cohen's kappa of 0.45.
Conclusion: The WHO classification system for soft tissue cytopathology enhances diagnostic accuracy and standardizes reporting. It serves as an effective tool for categorizing soft tissue tumours and guiding clinical management, though further refinements are necessary for its widespread application.

DICER1 mutations are mutually exclusive with the _BRAF_^{V600E} mutation: a retrospective study with 510 cases of Bethesda III nodules

W. Kong[1], Y. Wang[2], J. Lan[3], J. Wang[1]
[1]The Affiliated Hospital of Qingdao University, Department of Pathology, Qingdao, China, [2]Jining No. 1 People's Hospital, Department of Pathology, Jining, China, [3]Qingdao Academy, Qingdao, China

Background & Objectives: This study aimed to investigate the prevalence and cytological features of *DICER1*-mutant fine-needle aspiration (FNA) specimens in Bethesda III thyroid nodules and to explore the relationship between *DICER1* and *BRAF*^{V600E} mutations.
Methods: We collected 510 consecutive FNA cases diagnosed as Bethesda III from a single medical centre over one year. Mutations in *DICER1* (exons 24 and 25), *BRAF*^{V600E}, and *TERT* promoter were detected using Sanger sequencing. The association between DICER1 mutations and cytopathological features was also analysed.
Results: *DICER1* mutations were identified in 25 patients (4.9%, 25/510), while the *BRAF* ^{V600E}mutation was detected in 76 patients (14.9%, 76/510). The two mutations were mutually exclusive. No cases exhibited *TERT* promoter mutations. All *DICER1*-mutant cases were classified as AUS-other in this cohort. We found that the *DICER1*-mutant FNAs exhibited *RAS*-like nuclear features. Patients with *DICER1* mutations were younger than those in the wild-type group, and their tumours were significantly larger. However, *DICER1* mutation status was not associated with serum thyroid hormone levels.
Conclusion: Our findings suggest that *DICER1*-mutant Bethesda III nodules are unlikely to be *BRAF*-mutant carcinomas. Further study of the molecular characteristics of *DICER1*-mutant FNAs will contribute to more accurate cytological diagnosis.

A predictive mutation to identify endometrial carcinomas with better prognosis: *CCNB3*

A. Alpsoy[1], Z. Bayramoğlu[1], S. Aktaş[1]
[1]Dokuz Eylül University, Molecular Pathology, İzmir, Turkey

Background & Objectives: Endometrial carcinoma, the most common gynaecologic malignancy in developed countries, has undergone molecular classification. *POLE* mutant (*POLE*mut) subtype shows the highest survival rates, and its presence influences treatment decisions. These mutations cause disordered proofreading activity. Consequently, errors in replication cannot be rectified, and the accumulation of mutations contributes to clinicopathological features. To better understand the *POLE*mut subtype and develop a more targeted genomic approach, we performed an in-silico analysis of Cyclin B3 (*CCNB3*), a gene responsible for cell cycle control frequently mutated in *POLE*mut patients.
Methods: Data regarding *CCNB3* alterations in The Cancer Genome Atlas Pancancer Atlas dataset was acquired from cBioPortal. 507 cases with precise molecular subtyping were included in the study. Clinicopathologic analyses were conducted using cBioPortal.
Results: *CCNB3* mutant cases included 45 *POLE*mut, 12 MSI, 1 copy number-low, and 2 copy number-high subtype cases with a high frequency of *POLE*mut subtype ($p<10^{-10}$, $q<10^{-10}$). Mutation count (mean: 6695.63 vs 304.16) and tumour mutation burden (mean: 229.98 vs 10.28) were higher in *CCNB3* mutant cases compared to wild-type cases ($p<10^{-10}$, $q<10^{-10}$). *CCNB3* mutant cases had 95.20% overall, 90.50% progression-free, while *CCNB3* wild-type cases had 51.67% overall (p=3.132e-3, q=6.264e-3, HR: 6.295 [95% CI: 3.348-11.838]) and 59.01% progression-free (p=1.386e-3, q=5.543e-3, HR: 4.408 [95% CI: 2.588-7.509]) survival. *POLE*mut subtype had 73.3%, 91.75, and *POLE*wt group had 56.30%, and 59.13% overall (p=4.473e-3, q=8.945e-3, HR: 0.169 [95% CI: 0.088-0.321]) and progression-free (p=1.211e-3, q=4.845e-3, HR: 0.186 [95% CI: 0.107-0.323]) survival, respectively.
Conclusion: *CCNB3* mutant group included 45 out of 49 from *POLE*mut subtype and distinguished 15 *POLE*wt cases. Even with the addition of 15 cases from subtypes with worse prognoses, a slightly lower progression-free survival but a significantly improved overall survival were observed compared to the *POLE*mut subtype. Utilizing *CCNB3* evaluation can be valuable in selecting cases from heterogeneous subtypes, leading to more comprehensive and effective molecular classification.

OFP-01-005

Correlation between p53 immunohistochemical staining and *TP53* molecular testing in endometrial carcinomas: a detailed assessment of discrepant cases with implications for patient management

J. Machuca-Aguado[1], M. Catherwood[2], D. Gonzalez de Castro[3], G. McCluggage[4]
[1]Virgen Macarena University Hospital, Pathology, Seville, Spain, [2]Regional Molecular Diagnostics Service, Belfast Health and Social Care Trust, Belfast, United Kingdom, [3]Queen's University, Patrick G Johnston Centre for Cancer Research, Belfast, United Kingdom, [4]Belfast Health and Social Care Trust, Pathology, Belfast, United Kingdom

Background & Objectives: The TCGA molecular classification of endometrial carcinomas (ECs) has prognostic and predictive value. This study evaluates the concordance between p53 immunohistochemistry and *TP53* molecular testing in a consecutive cohort of ECs from a population-based setting.
Methods: A study was conducted on 386 consecutive ECs using NGS (83 genes, including *POLE* and *TP53* and microsatellite instability analysis) and immunohistochemistry for p53, hormone receptors, and MMR proteins. Cases with discrepancies between molecular and immunohistochemical p53 results were studied.
Results: Of the 386 carcinomas, 8% were *POLE*mut, 24.9% MMRd, 21.5% p53abn, and 45.6% NSMP. A total of 7% were multiple classifiers. The initial concordance between p53 immunohistochemistry and *TP53* NGS was 88.6% (44/386), increasing to 93.5% after reviewing the p53 stained slides of discordant cases. Among the 44 discordant cases, after review 19 were reclassified from p53 wild-type staining to mutation-type, including 13 with a subclonal p53 pattern of mutation-type immunoreactivity. Twenty-two cases (5.7%) with a subclonal pattern of mutation-type p53 immunoreactivity but with *TP53* mutations on NGS were identified, mostly low-grade endometrioid carcinomas (15/22;68.1%). Overall *TP53* mutations were detected in 9.6% of low-grade endometrioid carcinomas (25/260): 12 were of p53abn molecular type, all being low-risk carcinomas (Stage I).
Conclusion: The integrated use of NGS and immunohistochemistry enhances the accuracy of TCGA molecular classification. High concordance supports p53 immunohistochemistry as a *TP53* mutation surrogate, although the correlation is not perfect. Recognizing subclonal p53 immunohistochemical patterns is important for TCGA classification when molecular testing is not undertaken. Uncertainty persists regarding the classification and management of low-risk (low-grade and low-stage) endometrioid carcinomas in the p53abn subgroup.

Background & Objectives: The classification of vulvar squamous cell carcinoma (VSCC) distinguishes between human papillomavirus (HPV)-associated and HPV-independent types based on p16, a surrogate marker for high-risk HPV (hrHPV). p53 immunohistochemistry also has a key role, though its interpretation has varied over time. Recent studies, however, have identified six distinct p53 patterns. Using a large, unselected cohort of 1285 VSCC cases, we aimed to explore the robustness of this six-pattern p53 classification by evaluating inter-pathologist variation, map the pattern distribution and classify the cases by incorporating p16 and hrHPV DNA status.
Methods: In the Danish Pathology Data Bank, we identified 1285 women diagnosed with primary VSCC (1990–2017) and retrieved formalin-fixed paraffin-embedded tumour blocks. Eight gynaecological pathologists evaluated p53 immunohistochemistry, classifying cases as wild-type (scattered or mid-epithelial) or abnormal (basal overexpression, parabasal/diffuse overexpression, absent, or cytoplasmic). p16 had previously been scored, and p53 scoring was conducted with the corresponding p16 slide available for reference.
Results: Concordance across the six p53 immunohistochemical patterns was 66.6% (856/1285), increasing to 86.9% (1117/1285) when categorized as p53 wild-type or abnormal. Most discordances (313/429) involved cases where one pathologist assigned the 'scattered' pattern, while another classified it differently. Stratified by p16 status, concordance was 62.9% in p16-positive and 68.6% in p16-negative cases but increased to 94.5% and 82.8%, respectively, when categorized as wild-type or abnormal. A third evaluation of discordant pairs is ongoing.
Conclusion: This study represents the largest investigation to date on the robustness of the six-pattern-based p53 classification in VSCC. The overall concordance in scoring across the six patterns was 66.6%, increasing to 86.9% when simplified into abnormal versus wild-type categories. Concordance (wild-type/abnormal) was higher in p16-positive cases compared to p16-negative cases. The final distribution of p53 patterns and cohort classification, incorporating p16 and hrHPV DNA status, will be presented at the conference.

HPV-Independent CIN-lesions of the uterine cervix - a new concept cervix

L.-C. Prof. Horn[1], B. Gilks[2], L. Hoang[3], G.G.R. Hiller[4], M. Stiller[4], A.K. Hoehn[4]

[1]University Leipzig Hospital, Institute of Pathology, Leipzig, Germany, [2]Vancouver General Hospital, Pathology, Vancouver, Canada, [3]Vancouver General Hospital, University of British Columbia, Pathology, Vancouver, Canada, [4]University Hospital of Leipzig, Institute of Pathology, Leipzig, Germany

Background & Objectives: There is increasing evidence about HPV-independent (HPVI) squamous cell carcinomas of the uterine cervix (CSCC). While HPV-associated CSCC precursor lesions (i.e. high-grade squamous intraepithelial lesion, HSIL) are well characterised, features of HPVI-precursors are limited.
Methods: Histopathological and immunohistochemical evaluation (p16, p53) as well as mutational analysis by next generation sequencing performed on HPV high-risk DNA negative (HPVI) squamous precursor lesions.
Results: Six cases were available with a mean age of 74.5 years of age (range 64 to 83 years). Five precursors represented dVIN-like morphology, associated with aberrant p53-immunoepression (parabasal/diffuse overexpression), non-block-like p16 staining and pathogenic TP53-mutation, seen in patients with uterine prolapse. One case not associated with prolapsed uterus represented features similar to HPV-associated HSIL, no p16-overexpression but p53-wildtype staining pattern. On molecular level pathogentic *TERT* promotor mutation and a possible pathogenic mutation of *HRAS* occurred.
Conclusion: HPVI squamous precursor lesion of the uterine cervix are exceedingly rare and represent a range of morphologic findings. Some lesions represent features seen in differentiated vulvar intraepithelial neoplasia (dVIN-like) and others features similar to HPV high-risk associated HSIL. Molecular alterations are variable with *TP53*-mutation (dVIN-like HPVI precursors) and *TERT*- as well as *HRAS*-alteration (HSIL-like HPVI precursor).

Spatial Cancer-Immune Phenotypes in NSMP Endometrial Carcinomas: transcriptomic profiling reveals distinct pathways of immune evasion

A. De Leo[1], B. Donati[2], C.A. Coadă[3], M. Grillini[4], C. Ascione[2], C. Ravaioli[1], A.M. Perrone[1], C. Ceccarelli[1], T. Maloberti[5], D. de Biase[1], A. Ciarrocchi[2], G. Tallini[1]

[1]University of Bologna, Bologna, Italy, [2]Azienda USL-IRCCS di Reggio Emilia, Laboratory of Translational Research, Reggio Emilia, Italy, [3]University of Medicine and Pharmacy "Iuliu Hatieganu", Morpho-Functional Sciences, Cluj-Napoca, Romania, [4]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Pathology Unit, Bologna, Italy, [5]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Solid Tumour Molecular Pathology Laboratory, Bologna, Italy

Background & Objectives: The classification of the tumour immune microenvironment into spatial cancer-immune phenotypes (SCIs)—inflamed, excluded, and desert—is gaining recognition as a key determinant of immune response and prognosis in solid tumours. NSMP endometrial carcinomas (ECs), which lack a defining molecular alteration, represent a heterogeneous group with limited predictive biomarkers. The aim of this study was to define the immune transcriptomic landscape of SCIs within NSMP ECs to uncover immune-related mechanisms associated with prognosis.

Methods: 47 NSMP ECs, previously classified by molecular subtype and SCI using digital pathology and immunohistochemistry (CD3, CD8, CD68, CD20, PD-L1), were profiled using the NanoString PanCancer Immune panel. Gene expression data were analysed to identify differentially expressed genes across the three SCI groups.
Results: Nanostring profiling revealed distinct transcriptional signatures across SCI groups:

- Inflamed tumours showed broad activation of the immune response, with significant upregulation of genes involved in antigen presentation (HLA genes), T and NK cell cytotoxicity (PRF1, IL15), interferon signalling, and immune checkpoints (PDCD1, CTLA4).
- Excluded tumours exhibited partial immune activation, but with concurrent downregulation of MHC-related genes and components of the antigen processing machinery, indicating functional immune exclusion despite immune cell presence (HLA genes down; CDH1, MAGEA4 up).
- Desert tumours were characterized by overall immune silence and upregulation of genes associated with cell cycle progression and immune escape (TTK, ILF3, TNFRSF11A).

Pathway analysis confirmed a progressive loss of immune-related functions from inflamed to excluded to desert, with excluded tumours showing selective suppression of antigen presentation as a hallmark of immune evasion.
Conclusion: Transcriptomic profiling reveals that SCI subtypes in NSMP ECs represent biologically distinct immune states. The immune-excluded phenotype, in particular, is defined by a paradox of immune infiltration with silenced antigen presentation. These findings support the incorporation of SCI into molecular risk stratification and suggest new opportunities for targeted immune modulation.

Funding: The research leading to these results has received funding from AIRC under MFAG 2021 – ID. 26319 project – P.I. De Leo Antonio

Transcriptomic dysregulation of the epithelial-to-mesenchymal pathway defines a novel HPV-independent subset of vulvar squamous cell carcinoma with worse disease specific survival

L. Marimón Pérez de Villar[1], L. Diez-Ahijado[2], N. Peñuelas[2], B. Coloma[1], P. Pascual[2], N. Carreras-Dieguez[3], L. Sisuashvili[1], K. Darecka[1], M. Del Pino[3], J. Ordi[1], N. Rakislova[1], R. Albero[4]
[1]Hospital Clínic Barcelona, Pathology, Barcelona, Spain, [2]Instituto de Salut Global (ISGLOBAL), Barcelona, Spain, [3]Hospital Clínic Barcelona, Gynaecology and Obstetrics, Barcelona, Spain, [4]Instituto de Investigaciones Biomédicas August Pi i Sunyer (IDIBAPS), Barcelona, Spain

Background & Objectives: Vulvar squamous cell carcinoma (VSCC) is a rare malignancy with two distinct pathways: human papillomavirus-associated (HPV-A) and HPV-independent (HPV-I), with HPV-I tumours having impaired prognosis. We investigated the transcriptional networks differentially activated in VSCC tumours, to improve risk stratification and identify therapeutic targets.
Methods: Retrospective analysis of 73 primary VSCC (19 HPV-A, 54 HPV-I) surgically treated from 1996 to 2023 at the Hospital Clínic of Barcelona. Whole transcriptomic analysis (HTG Edge-Seq) in a clinically annotated series was performed on formalin-fixed, paraffin-embedded samples.
Results: The study of the top differential transcriptional pathways activated in HPV-I samples revealed three distinct molecular clusters: clusters 1 and 2 composed mainly of HPV-I VSCC, and cluster 3 composed mainly of HPV-A tumours. Cluster 1 exhibited epithelial features (CDH1 overexpression) and metabolic pathways (mTOR). Cluster 2 exhibited an epithelial-mesenchymal (EMT) signature (TWIST1/SNAI2/ZEB1 upregulation) with angiogenesis activation (VEGFC/MMPs). Cluster 3 showed an enrichment in IFN-gamma response pathway. Patients with EMT signature (cluster 2 tumours) showed worse disease-specific survival (DSS, p=0.044) and a trend toward reduced recurrence-free survival (RFS; p = 0.056). A simple H&E classifier based on the invasion patterns was established, including two categories, closed/ finger and spray patterns. Spray pattern predicted tumours with EMT signature (cluster 2) with a sensitivity of 84.4% and a specificity of 71.4%. This H&E-based classifier also correlated with survival, with tumours showing spray pattern having worse DSS than those having closed/finger pattern (p=0.0052).
Conclusion: Our study provides a complete overview of the transcriptional networks supporting HPV-I VSCC cases, identifying a subset of patients with high EMT expression signature correlating with poorer DSS. We have successfully translated these molecular findings into a practical H&E-based classification system using the invasion pattern, which correlates with DSS. The H&E-based classifier offers a globally accessible tool to identify tumours with EMT signature, addressing unmet needs in resource-limited settings.

Update on the interpretation of somatic *POLE* mutations in endometrial carcinomas

B. Tessier-Cloutier[1,2], A. Boroujeni-Momeni[3]
[1]McGill University Health Centre, Department of Pathology, Montreal, Canada, [2]McGill University, Department of Pathology, Montreal, Canada, [3]Memorial Sloan Kettering Cancer Centre, Department of Pathology, New York, USA

Background & Objectives: *POLE* mutation testing is essential for endometrial carcinomas (EC) molecular classification. Eleven hotspot mutations are considered canonical. While the POLE-score aids in evaluating rare variants, its use varies with testing methods. We present our interpretation of *POLE* and *POLD1* pathogenic mutations in a large, clinically and molecularly annotated EC cohort.
Methods: We analysed a cohort of EC cases previously sequenced using extended cancer gene panels (368–505 genes), assessing *POLE* and *POLD1* variants, tumour mutational burden (TMB), and microsatellite instability (MSI). Immunohistochemistry for p53 and MMR proteins completed the molecular profiling. Statistical analysis was used to correlate molecular and clinicopathological features.
Results: We surveyed a cohort of 2533 EC and identified 152 tumours with *POLE* variants involving the exonuclease domain of the gene (exons 9-14; 6%) and 16 cases with *POLD1* pathogenic variants (0.6%), among the *POLE* variants 84% were regarded as canonical. Within EC with canonical *POLE* variants, the median TMB was 52.7 mutations per megabase (m/mb) while for cases with non-canonical *POLE* exonuclease mutation the median TMB was 119 (m/mb) and for *POLD1* mutated cases it was 106 (m/mb; p=0.21). Among the cases with pathogenic *POLE* mutations, 5% had concurrent DNA mismatch repair deficiency (MMRd), while among the *POLD1* and non-canonical *POLE* mutated cases 80% and 47% had MMRd (p<0.001). No differences in histomorphologic features was identified. Survival analysis showed that the cases with non-canonical *POLE* had worse progression free and overall survival outcomes (log rank p<0.01).
Conclusion: Our analysis identified non-canonical *POLE* exonuclease domain and *POLD1* variants that show an ultramutated phenotype. They were more likely to be double classifiers (MMRd/*POLE* or

POLD1) and there may be clinical differences between their outcomes compared to canonical *POLE* mutated cases. These findings have implications for the testing methodology implemented in endometrial carcinoma molecular classification, as well as decisions regarding treatment de-escalation.

Endometrial and colorectal cancers: concordance between NGS-MSI and IHC-MMR

G. Scaglione[1], A. Santoro[1], B. Padial Urtueta[2], N. D'alessandris[1], D. Arciuolo[2], N. Narducci[2], F. Addante[2], A. Piermattei[2], M. Valente[2], A. Travaglino[3], L. Salvatore[2], S. Duranti[2], A. Minucci[2], C. Nero[2], F. Fanfani[2], G. Tortora[2], G.F. Zannoni[1]

[1]Catholic University of Sacred Heart, Rome, Italy, [2]Fondazione Policlinico A. Gemelli, Rome, Italy, [3]University of Insubria, Varese, Italy

Background & Objectives: Assessing mismatch repair (MMR) status is crucial for prognostic and predictive purposes, including Lynch syndrome screening. International guidelines recommend evaluating MMR status in newly diagnosed colorectal (CRC) and endometrial cancer (EC) patients. While immunohistochemistry (IHC) is the most commonly used method for MMR status assessment, other molecular tools, such NGS, can also be employed.
Methods: The aim of this study was to evaluate the concordance between NGS-MSI and IHC-MMR in a prospective cohort of CRC and EC patients from a large referral centre. We performed a detailed genomic and pathological analysis of discordant cases to explore reasons for discrepancies between methods.
Results: 520 patients were enrolled, 352 EC and 168 CRC. The overall concordance between IHC-MMR and NGS-MSI was 90% (CI: 87%-92%). Sensitivity was 62%, specificity 99%, with a positive predictive value of 98% and a negative predictive value of 88%. EC cases showed lower concordance rate (85%) compared to CRC cases (99%), largely due to microsatellite stable (MSS) status in MMR-deficient samples. Discordant CRC cases had poor responses to immunotherapy. In EC, 28% of discordant cases were linked to POLE mutations (10%), atypical IHC-MMR patterns (6%), MSH6 protein loss (18%). Around 60% of discordant EC cases involved Lynch syndrome (12%), MMR somatic variants (4%), MLH1 hypermethylation (37%). Differences in unstable loci among MMR phenotypes ($p = 0.003$) contributed to reduced MSI scores in cases with MLH1/PMS2 loss, accounting for 56% of discordant EC cases. Adjusting the MSI score threshold to 6.1 improved the AUC to 0.9 for predicting MMR status in EC.
Conclusion: The concordance between NGS-MSI and IHC-MMR was 90%, with a lower concordance in EC compared to CRC. Microsatellite instability assessed by NGS showed varying levels of concordance with MMR deficiency by IHC in CRC and EC patients. Tumour-specific thresholds may help reduce false negative cases and improve therapeutic decision-making.

Background & Objectives: KDM2B plays an important role in recruiting the polycomb repressive complex 1.1 (PRC1.1) to CpG islands, facilitating transcriptional repression. Recent studies have shown KDM2B to be highly expressed in soft tissue tumours harbouring alterations in *BCOR,* which is a core component of PRC1.1. The aim of this study was to evaluate the diagnostic value of KDM2B immunohistochemistry in the differential diagnosis of endometrial stromal neoplasms, including tumours with PRC1.1-associated alterations.
Methods: Formalin-fixed and paraffin-embedded (FFPE) tissue of endometrial stromal tumours of various genotypes was retrieved and a tissue microarray (TMA) constructed. A FFPE tissue section was stained on a Leica BOND RX stainer using a FBXL10 (KDM2B) antibody (clone D3T8J, Cell Signaling Technology) at 1:50 dilution. Only nuclear staining was evaluated, and the staining was quantified using an H-score.
Results: The series included 3 endometrial stromal nodules, 58 low-grade endometrial stromal sarcomas including tumours with confirmed *JAZF1::SUZ12* (n=9) and *EPC1::PHF1* (n=1) gene fusions, 11 high-grade endometrial stromal sarcomas including tumours with confirmed *ZC3H7B::BCOR/BCOR::LPP* (n=4) and *YWHAE::NUTM2* (n=5) gene fusions, 1 uterine tumour resembling ovarian sex cord tumour (UTROSCT) with an *ESR1::NCOA3*fusion, and 13 undifferentiated uterine sarcomas. An optimal cut-off value of H-score 10 was defined for KDM2B positivity. All endometrial stromal nodules, UTROSCT, and undifferentiated uterine sarcomas were negative for KDM2B. All but one low-grade endometrial stromal sarcomas were also negative. In contrast, all high-grade endometrial stromal sarcoma samples were positive for KDM2B (H-score range: 50 – 290).
Conclusion: In conclusion, our study shows that KDM2B is a highly sensitive and specific marker for high-grade endometrial stromal sarcoma, harbouring *ZC3H7B::BCOR* and *YWHAE::NUTM2* gene fusions. Future studies will aim to validate our findings and investigate additional molecular subtypes of uterine mesenchymal neoplasms to further confirm the specificity of KDM2B for HGESS.

OFP-01-013

Molecular profiling and tumour microenvironment in HPV-associated anogenital squamous cell carcinomas: detailed transcriptomic insights

M.A. Bani[1,2], L. El Khoury[1], D. Gentien[3], C. Kanaan[1], F. Griscelli[4], P. Dartigues[1], C. Genestie[1], C. Smolenschi[5], M. Aupomerol[6], L. Benhaim[7], N. Signolle[8], P. Saulnier[3], V. Marty[8], M. Ducreux[5,2], J. Michels[6], J. Durand-Labrunie[9], M. Lacroix-Triki[1], C. Badoual[1,8], L. Lacroix[10], B. Job[11], J.Y. Scoazec[1,2]

Background & Objectives: Human papillomavirus (HPV) infection plays a pivotal role in the pathogenesis of various anogenital squamous cell carcinomas (SCCs), including cervical, vulvar, and anal

cancers. Understanding the distinct molecular landscapes and immune microenvironments across these tumour sites may refine diagnostic accuracy and therapeutic approaches. We investigated transcriptomic profiles associated with tumour location and HPV genotypes to understand molecular distinctions and characterized the tumour immmune microenviroment.

Methods: We analysed 50 patients with HPV-associated SCC from cervix (n=19), vulva (n=16), and anal canal (n=15). HPV association was confirmed via p16 immunohistochemistry, high-risk HPV *in situ* hybridization, and PCR genotyping. Immune cell infiltration was assessed using multiplex immunohistochemistry (IRF1/CD20/CD3/CD68). Gene expression profiling employed Nanostring nCounter technology with the PanCancer Pathways panel covering 770 cancer-related genes.

Results: HPV16 was predominant across sites, while no HPV18 was detected. Transcriptomic profiling revealed two primary clusters distinguishing cervical from anal canal carcinomas, with vulvar cases distributed across both clusters. Cervical SCCs showed increased expression in inflammation, DNA repair, and FGF signalling. Anal canal tumours had elevated expression in epigenetic modulation and PI3K signalling. Vulvar tumours demonstrated mixed molecular features. GSEA further delineated HPV16-specific molecular characteristics. HPV16-driven SCCs exhibited suppressed DNA repair networks, senescence, and immune response pathways (CD8+ T-cell memory, activated CD4+ T cells), alongside activated extracellular matrix remodelling pathways. Cell cycle regulation was significantly altered, suggesting distinct proliferative dynamics compared to other HPV genotypes. The immune microenvironment showed higher intratumoral CD3+ T lymphocytes in cervical SCCs (p=0.028) and increased peri-tumoral CD68+ macrophages in vulvar carcinomas (p=0.012).

Conclusion: Distinct molecular signatures and immune profiles characterize HPV-associated anogenital SCCs according to tumour site and HPV genotype. Our transcriptomic analyses reveal molecular heterogeneity in HPV-associated anogenital SCCs based on location and HPV genotype. HPV16-driven tumours uniquely suppress DNA repair, immune responses, and cell cycle regulation while activating extracellular matrix remodelling.

OFP-01-014

YWHAE::NUTM2B-rearranged endometrial stromal sarcomas with pure low-grade morphology: a case series expanding the histologic spectrum

A. Alrwashdeh[1], S. Alvand[1], M. Hopkins[1], K. Halling[1], M. Shahi[1]
[1]Mayo Clinic, Laboratory Medicine and Pathology, Rochester, USA

Background & Objectives: The 2020 WHO classification categorizes endometrial stromal sarcomas (ESS) with YWHAE rearrangements as high-grade (HGESS). However, increased use of molecular diagnostics has expanded the recognized morphologic spectrum of YWHAE-rearranged ESS. Recent reports have described low-grade morphologies in these tumours. We present an additional case series highlighting unusual morphologic features in ESS harbouring YWHAE::NUTM2B fusions.

Methods: Cases with YWHAE gene fusions were identified from the institutional Sarcoma Targeted Gene Fusion Panel database. Pathology reports, and H&E slides were reviewed when available. Tumours with purely low-grade ESS (LGESS) morphology were selected. Detailed histologic features from one biopsy and five hysterectomy specimens were analysed, along with available clinical follow-up.

Results: Six patients with YWHAE::NUTM2B fusions were identified (median age: 43.5 years; range: 29–71). Tumour size ranged from 1.7 to 12.5 cm (median: 8.5 cm). All cases exhibited mild to moderate cytologic atypia with fibrous or fibromyxoid stroma, absent necrosis, and 1–3 mitoses per 10 high-power fields. Notably, three cases displayed pseudoangiomatoid features with dense hyalinized stroma lined by monolayer of cells, reminiscent of Masson's tumour. Immunohistochemically, cyclin D1 was positive in all cases (6/6); CD10 in 2/4; ER and PR in 4/4. Clinical follow-up was available for five patients (mean: 29 months). Two developed pulmonary metastases—one at diagnosis and one at 15 months—both alive at last follow-up. The remaining three showed no evidence of disease.

Conclusion: We describe a cohort of 6 ESS cases with YWHAE::NUTM2B fusions displaying purely low-grade morphology, including pseudoangiomatoid features and cyclin D1 co-expression with hormone receptors. CD10 expression was variable. These findings underscore the importance of molecular testing in morphologically low-grade ESS, as YWHAE rearrangement may not always correlate with high-grade histology but still carries metastatic potential.

OFP-02-001

The impact of congenital heart disease on hypoxic-ischemic encephalopathy: a comparative analysis

S. Quinones[1], C. Simón de Blas[2], G. De la Osa Hernández[3], C. Merino Argos[3], V. Macarrón[1], E.P. Sánchez-López[1], M. De Uribe-Viloria[4], J. Andrade-Restrepo[1], A. Andreu-Cervera[5], V. Company[5], M. Martínez-Sempere[5], E. Puelles[5], R.M. Regojo[1], I. Esteban-Rodríguez[1]
[1]La Paz University Hospital, Pathology, Madrid, Spain, [2]Universidad Rey Juan Carlos, Computer Science and Statistics Department, Madrid, Spain, [3]La Paz University Hospital, Cardiology, Madrid, Spain, [4]Clínico de Valladolid University Hospital, Pathology, Valladolid, Spain, [5]Institute of Neurosciences (CSIC-UMH), Campus de San Juan, Alicante, Spain

Background & Objectives: Cardiorespiratory abnormalities, such as congenital heart disease (CHD), have been associated with significant disruptions in white matter. However, in recent years, grey matter involvement has also been analysed, including neuronal necrosis and gliosis, and degeneration of the posterior columns. The aim of this study is to review acute neuronal necrosis in CHD patients and compare it to findings in non-CHD.

Methods: The anatomopathological reports of foetal clinical autopsies (from week 22), perinatal and infant from 2000 to 2019 inclusive were reviewed. Subsequently, all cases with selective acute neuronal necrosis (SANN) in more than one vascular territory were selected. A total of 205 cases were identified, including 28 patients with CHD and 177 patients without CHD. An expansion of sample size including autopsies from 1992 to 2024 was made, resulting on the identification of 47 CHD cases more. Therefore, we compared the SANN cases of 75 cases of CHD (between 1992 to 2024) and the 177 non-CHD (between 2000 to 2019).

Results: CHD patients presented a greater involvement of cerebral neocortex in grey matter lesions, including both SANN and grey gliosis, compared to non-CHD individuals (SANN: p-value<0.001, chi-square=12.085; Grey gliosis: p-value<0.001, chi-square=13.76).
However, non-CHD showed a larger involvement of the thalamus, including SANN and grey gliosis (SANN: p-value=0.014, chi-square=6.096; Grey gliosis: p-value=0.018, chi-square=5.64). Additionally, non-CHD presented a higher involvement of SANN in pons (p-value<0.001, chi-square=32.012).
Furthermore, cerebral neocortex and midbrain involvement was more pronounced in individuals older than 37 weeks (cerebral neocortex: p-value<0.001, t=-3.600; midbrain: 0.035, t=-2.121).

Conclusion: CHD were found to be associated with both white matter and grey matter lesions. Our study aligns with previous authors who have identified the cerebral neocortex as a region of higher lesion frequency in CHD individuals. However, our findings contrast with

the classical perspective, which posits a greater involvement of the thalamus and pons.

OFP-02-002

Post-mortem toxicology analysis in a young Sudden cardiac death cohort – an Irish perspective

C. Stacey[1], N. Shah[1]
[1]University Hospital Waterford, Histopathology, Waterford, Ireland

Background & Objectives: Sudden cardiac death (SCD) is one of the leading causes of death worldwide, accounting for 10-15% of all deaths. SCD can be caused by acquired heart disease in older adults, and in younger adults it is more likely caused by a genetically acquired defect or by ingestion of illicit substances. In cases of SCD, toxicological analysis at post-mortem is crucial to elucidate the cause of death and detect the presence of substances causing drug-induced arrhythmias.
Methods: We aimed to assess post-mortem forensic toxicology in young sudden cardiac deaths over a 5-year period. A retrospective analysis was performed of completed autopsy reports in our institution from 2019 to 2023, aged from 16 to 49 years old.
Results: 2975 autopsy reports were reviewed and 277 cases (9.3%) of SCD with toxicological analysis performed were identified, all of which were coroner's cases. Mean age was 38 (SD 7.8). Toxicology was positive in 83.8% of cases (n=232) and negative in 16.2% (n=45). Drug overdose causing SCD accounted for 45.8% of cases (n=127), alcohol overdose 7.9% of cases (N=22), cardiac disease 30% of cases (n=83), SADS/SUDEP accounted for 5.8% each (n= 16 & n=16) and other (respiratory/DKA) 4.7% (n=13). Average heart weight was 420g (range 160g-985g). Polypharmacy (the presence of 2 or more substances on toxicology) was identified in 82.3% (n=191). The average number of substances identified on toxicology in each case was 4.9 (range 1-15). History of drug & alcohol misuse was significantly more common among cases with a positive toxicology profile (n=132, 56.9% vs n=4, 8.9%, P<0.001).
Conclusion: Toxicology plays a critical role in assessing the underlying cause of death in SCD cases. In our cohort, toxicology was positive in 83.8%, which is higher than previously published European data (57%). The overwhelming majority displayed polypharmacy (82.3%). 5.8% of cases were SADS (sudden arrhythmic cardiac death).

OFP-02-003

Modernising pathology education: enhancing medical students' exposure through simulated multidisciplinary team meetings

S. Jones[1], K. Cooper[1], E. de Barra[1]
[1]Royal College of Surgeons in Ireland, Department of International Health and Tropical Medicine, Dublin, Ireland

Background & Objectives: Pathology, as a laboratory-based discipline, has traditionally been taught via didactic lectures and anatomy tutorials. While the growing emphasis on case-based learning and simulation in medical education fosters critical thinking and prepares students to contribute to multidisciplinary teams (MDTs) as junior doctors, this shift may reduce students' exposure to pathology, potentially influencing their interest in pursuing pathology as a career.
To increase medical students' exposure to pathology, while enhancing their readiness to contribute to MDTs as junior doctors, through the delivery of a simulated infectious diseases MDT meeting teaching session.
Methods: Four simulated cases were designed with an emphasis on teamwork and collaborative learning rather than solely on reaching the correct diagnosis. Students were divided into groups and assigned roles- clinician, pathologist and radiologist. Each group received a slide set relevant to their role and after a preparation period presented their findings in a simulated MDT meeting. Feedback on the session was obtained via a modified Readiness for Interprofessional Learning Scale (RIPLS), a validated questionnaire, to assess the students' readiness for interprofessional collaboration.
Results: Seventy-six medical students took part in the session. Of those who provided feedback, 97% agreed or strongly agreed that the event improved their understanding of the pathologist's role. Additional strengths included the team-based approach, with 91.2% of respondents stating that this helped them integrate clinical, pathological and radiological findings. 91.7% agreed or strongly agreed that the event would positively impact their approach to collaboration and diagnosis in future clinical practice.
Conclusion: This event was designed to enhance medical students' communication and teamwork skills, in keeping with current trends in medical education, while increasing their exposure to pathology. This approach aligns with the 37th European Congress of Pathology's theme, 'Tradition Meets Future' and offers a model to increase pathology exposure within the modern medical curriculum.

OFP-02-004

The Tumour Tissue Bank of the German National Cohort (NAKO): pilot of a centralized epidemiologically based biobanking

K. Hofmann[1], N. Großkinsky[2], K. Wirkner[3], H. Bläker[4], A. Brobeil[1,5], P. Schirmacher[1]
[1]Heidelberg University Hospital, Institute of Pathology, Heidelberg, Germany, [2]NAKO e.V., Heidelberg, Germany, [3]Leipzig University, Leipzig Research Centre for Civilization Diseases, Leipzig, Germany, [4]Leipzig University Hospital, Institute of Pathology, Leipzig, Germany, [5]Tissue Bank of the National Centre for Tumour Diseases (NCT), Heidelberg, Germany

Background & Objectives: The NAKO Health Study is a nationwide, long-term, population-based study. It contains 200,000 participants recruited by 18 study centres since 2014 and has the aim to gain knowledge of how widespread diseases develop, to improve prevention, early detection, and treatment. The centralized Tumour Tissue Bank (TTB) collects, characterizes, validates, and stores pseudonymized cancer tissue samples from participants of NAKO for future research. It's an integral infrastructure of NAKO, attached to the NCT tissue bank and the BioMaterialBank Heidelberg (BMBH) and represents a worldwide unique approach, combining structured epidemiological data with decentralized clinico-diagnostic tissue acquisition and expert-driven, quality-assured tissue biobanking.
Methods: Representative FFPE tumour tissues obtained in clinical context from NAKO participants are requested from the pathologies via NAKO study centres. To test the workflow and resulting tissue acquisition, a pilot project was carried out in December 2022 in cooperation with the Leipzig Cancer Registry and the Saxony State Cancer Registry.
Results: The successful pilot demonstrated correct data transfer from Leipzig Cancer Registry to TTB and enabled the implementation of all relevant processes. The consent rate from participants to tumour sample request was 42%, the response rate of requested cases was 50%. This resulted in 27 cases being acquired, processed, and validated in TTB, consisting of one tumour and one normal tissue sample. In addition, histopathological quality assessment as well as virtual microscopy was performed. The most frequently included tumour entity was breast cancer (52%).
Conclusion: The successfully implemented processes of TGB show the feasibility and potential of joining quality assured tissue biobanking with high-dimensional epidemiological studies. On the other side, regulatory issues pose significant challenges to efficient probe acquisition. A higher compliance from study participants as well as pathologies is aspired. This approach allows comprehensive analyses to multiple research issues due to the connection of structured epidemiologic data with high-quality tissue biobanking.

Funding: The NAKO is funded by the Federal Ministry of Education and Research (BMBF) [project funding reference numbers: 01ER1301A/B/C, 01ER1511D, 01ER1801A/B/C/D and 01ER2301A/B/C], federal states of Germany and the Helmholtz Association, the participating universities and the institutes of the Leibniz Association

OFP-02-005

The aromatic amino acids inhibit proteasome translocation and suppress tumour growth via selective mTOR activation

I. Livneh[1,2], V. Cohen-Kaplan[2], A. Zinger[3], Y. Shammai Vainer[4], G. Goldhirsh[2], B. Fabre[5], C. Lulu[2], M. Kaduri[4], A. Dahan[1], A. Schroeder[4], Y. Ben-Neriah[3], Y. Zohar[1], A. Ciechanover[2]
[1]Rambam Health Care Campus, Institute of Pathology and Cytology, Haifa, Israel, [2]Technion - Israel Institute of Technology, Faculty of Medicine, Haifa, Israel, [3]The Hebrew University, Medicine, Jerusalem, Israel, [4]Technion - Israel Institute of Technology, Faculty of Chemical Engineering, Haifa, Israel, [5]Université de Toulouse, CNRS, Auzeville-Tolosane, France

Background & Objectives: The proteasome, the catalytic arm of the ubiquitin system, undergoes translocation from the nucleus to the cytosol under stress. This adaptive response is regulated by newly identified mTOR-agonistic amino acids—tyrosine, tryptophan, and phenylalanine (YWF)—promoting proteasomal functions crucial for cell survival, including amino acid recycling and clearance of misfolded proteins. YWF-induced mTOR activation results in nuclear proteasome sequestration and subsequent cell death, positioning this pathway as a key stress-coping mechanism. Our objective was to investigate the role of YWF-mediated proteasome dynamics in vivo and explore its potential clinical relevance.
Methods: We analysed proteasome subcellular localization in tumours versus adjacent normal tissues using xenograft, endogenous, and metastatic tumour models. The effect of YWF on proteasome dynamics and tumour progression were evaluated across multiple cancer types. Human breast and uterine cervix xenografts, along with endogenous murine models of colorectal and urinary bladder carcinoma, sarcoma, and metastatic triple-negative breast cancer were employed. Proteasome localization and tumour response were assessed following YWF administration, either orally or subcutaneously to the tumour bed.
Results: Across all tumour models—sarcoma, breast, cervix, colorectal, and bladder—the proteasome predominantly localized to the cytosol, in stark contrast to adjacent non-neoplastic tissues. YWF administration triggered nuclear sequestration of the proteasome in tumour cells, leading to extensive apoptosis and marked tumour regression (sarcoma: 84.6% reduction, $p = 3.76\times10^{-5}$; breast: 81.2%, $p = 1\times10^{-7}$; cervix: 74.8%, $p = 1\times10^{-4}$; colorectal: 86.7%, $p = 0.006$; bladder: 87.8%, $p = 0.01$), as well as a significant decrease in metastatic burden (51.1% reduction, $p = 0.001$).
Conclusion: Our findings identify proteasome dynamics as a core mechanism of tumorigenesis and cellular stress tolerance. Modulating proteasome subcellular localization—particularly via nutrient-sensing pathways—emerges as a novel therapeutic strategy, effectively reprogramming the tumour cell's "satiety centre" and undermining its survival advantage under stress.

Contactless Traceability Automation in the Pathology Laboratory

M.M. Baron[1], A. Eccher[2], L.M. Terracciano[3,4], A. Repici[3,5], L. Di Tommaso[3,4], A.P. Dei Tos[6], A. Rizzo[1], S. Marletta[1,3]
[1]Humanitas Istituto Clinico Catanese, Division of Pathology, Catania, Italy, [2]University Hospital of Modena, Department of Medical and Sciences for Children and Adults, University of Modena and Reggio Emilia, Modena, Italy, [3]Humanitas University, Department of Biomedical Sciences, Milano, Italy, [4]IRCCS Humanitas Research Hospital, Department of Pathology, Milano, Italy, [5]IRCCS Humanitas Research Hospital, Endoscopy Unit, Milano, Italy, [6]Surgical Pathology and Cytopathology Unit, University of Padua School of Medicine, Department of Medicine-DIMED, Padova, Italy

Background & Objectives: Pathology laboratories are dealing with a constant increase in their workflow due to the shortage of dedicated professional figures and the overwhelming amount of data required in the era of personalized medicine. In this setting, automation, defined as the employment of devices meant to supplement or replace human efforts in a process, is pivotal.
Methods: In this work, we present a project for an automatic contactless traceability identification solution based on high-frequency alternating current electromagnetic wave technologies with real-time localization integrated with a dedicated dissection hood.
Results: The system depends on Tag/chip micro-transponders and 2.45 GHz RTLS-UWB labels, which can be interfaced through "pairing" between the tag and the receiver connected to the LIS. The tags may be implanted, among others, on fresh operator samples with a metallic "micro-tag" marker, slides, bio-cassettes, operator containers, and Eppendorf tubes. The whole system relies on contactless identification with a database that stores clinical records, IHC, FISH, and WSI results. This traceability system is integrated into an anatomical dissection hood capable of detecting the presence of biological tissue on the work surface and providing unique identification using next-generation transmitter modules with RTLS-UWB radio frequency signal reception functions coupled with GPS tracking hidden under the work surface. When the sample passes over the hood's workbench, it will be detected and identified via a touch monitor, displaying its complete related information. The subsequently created bio-cassettes will then be coded and placed in a basket inside an integrated compartment in the hood, constantly tracked through the coded tags in the block structure. The software will then perform a verification of the acquired images/data and, upon operator confirmation, transfer the information to the LIS.
Conclusion: The solutions proposed by the present project carry a disruptive potential to enhance sample management, lessen human-based mistakes, and increase timesaving and productivity of operators.

OFP-02-007

Beyond the microscope: introducing high school students to the medical world through pathology "Ege University Pathology Summer School Experience"

B. Doğanavşargil[1], G. Serin[1]
[1]Ege University Faculty of Medicine, Department of Pathology, İzmir, Turkey

Background & Objectives: Historically, physicians have been predominantly associated with treatment, while branches focused on disease mechanisms and diagnosis, such as pathology, remain less understood by the public. Modern medicine requires a multidisciplinary approach, and recognizing all branches as an integrated whole shapes the public's perception of the healthcare system, potentially preventing future issues. High school students are at a critical stage in career selection, and it is crucial that their foundational knowledge in medicine is shaped early and accurately. Moreover, this age group is most receptive to experimental learning.
Methods: We initiated a nonprofit one-day workshop to introduce high school students to the importance of pathology within the medical field. The theoretical section covered disease mechanisms, including neoplastic, infectious, and degenerative diseases, as well as their effects on tissues. Students also learned about materials examined and methods used in pathology. The practical section provided hands-on experience in some macroscopic examinations, tissue sectioning, preparing their

own mouth mucosal cytological preparations and staining, as well as examining common diseases under the microscope.
Results: A total of 126 students participated in the workshops (including 32 students in 2022, 50 in 2023, 44 in 2024). Pretests and posttests were performed and written informed consent was taken from the parents. Initially most students were unfamiliar with the role and outline of pathology. However, after the workshop, they reported gaining a deeper understanding of pathological processes, laboratory workflows, and diagnostic procedures, while also expressing enjoyment from their hands-on experiences.
Conclusion: Our study demonstrates that pathology, positioned at the intersection of clinical, surgical, laboratory, and basic medical sciences, serves as an excellent entry point for introducing high school students to medicine. Our three-year observation indicates that the program is sustainable, functional, and adaptable, suggesting it could be successfully repeated annually as part of a "Summer School" initiatives in collaboration with relevant institutions.

OFP-02-009

Exploring the spatial heterogeneity of antibody-mediated heart allograft injury through transcriptomic profiling

A. Sannier[1,2], I. Zouhry[1,2], N. Perlin[2], M. Para[2,3], G. Caligiuri[2], A. Nicoletti[2], G. Franck[2]
[1]Assistance Publique - Hôpitaux de Paris, Bichat Hospital, Pathology Department, Paris, France, [2]INSERM U 1148, Laboratory for Vascular Translational Science, Paris, France, [3]Assistance Publique - Hôpitaux de Paris, Bichat Hospital, Department of Cardiac Surgery, Paris, France

Background & Objectives: Antibody-mediated rejection (AMR) remains a major challenge to the long-term success of heart transplantation. Microvascular inflammation (MVI) and complement deposition are hallmark features of AMR, yet their spatial distribution is often heterogeneous. The molecular mechanisms underlying this heterogeneity remain poorly understood. We aimed to investigate the transcriptional basis of AMR heterogeneity through spatial transcriptomics, to better understand its pathophysiology and uncover potential therapeutic targets.
Methods: We analysed an explanted human heart diagnosed with AMR using histology, C4d immunostaining, immunofluorescence, and spatial transcriptomics (10X Genomics Visium). Regions with MVI and/or C4d deposition were annotated and correlated with spatially resolved gene expression patterns.
Results: MVI^+C4d^+ regions aligned with a distinct transcriptomic cluster, supporting a strong biological specificity of this injury pattern at the mRNA level. MVI^+C4d^- and MVI^-C4d^+ areas lacked unique clustering, suggesting more heterogeneous or transitional transcriptional states. These findings highlight the limitations of histology alone in capturing molecular complexity. MVI+C4d+ regions showed upregulation of genes associated with antigen presentation (*CD74*, *HLA-DQA1)*, classical complement activation (*C1QB*, *C1QC*), and interferon signalling (*GBP5*, *CXCL11*). Immunofluorescence showed local expression of C1q by $CD45^+$ leukocytes. MVI+C4d- areas were enriched in transcripts linked to T-cell activation (*IL7R*, *CD69*), lymphocyte chemotaxis (*CCL21*) and dendritic cell regulation (*WDFY4*). MVI-C4d+ regions showed a distinct profile with increased expression of genes associated with vascular injury (*PLAT*), matrix remodelling (*MMP9*), and myeloid cell activation (*SLAMF8*), indicating that complement deposition in these zones may reflect underlying vascular activation.
Conclusion: AMR is a spatially complex and transcriptionally diverse phenomenon. MVI^+C4d^+ regions aligned with a distinct molecular identity, while other histological patterns lacked clear transcriptomic boundaries. These findings redefine our understanding of AMR as a mosaic of immune processes and highlight the potential of spatial transcriptomics to uncover clinically relevant biological processes.

OFP-02-010

Histopathological features of different types of cardiac amyloidosis

Z. Gioeva[1], L. Mikhaleva[1], A. Volkov[1], N. Shakhpazyan[1], V. Pechnikova[1], K. Midiber[1]
[1]Avtsyn Research Institute of Human Morphology of Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Pathology, Moscow, Russia

Background & Objectives: Cardiac amyloidosis (CA) poses diagnostic challenges due to the non-specific nature of early symptoms and its rarity. The objective of this study is to identify histopathological characteristics of CA that influence outcomes, compare the percentage of the most common types of amyloidosis revealed by ante- and post-mortem examination, and to estimate the frequency of clinically underdiagnosed heart involvement in patients with amyloidosis.
Methods: The study describes the results of 46 endomyocardial biopsies and 56 autopsies in patients with CA. All tissue sections were stained with haematoxylin-eosin and Congo red and observed under a polarized light. A broad panel of antibodies against different types of amyloidosis was used for immunohistochemical (IHC) typing of amyloid.
Results: The study included 54 male and 48 female patients (mean age 76 years). Based on IHC typing, AL amyloidosis was detected in 40 cases (39%), ATTR in 45 (44%), and AA in 17 cases (17%). In most cases of AL amyloidosis, reticular or pericellular patterns of amyloid deposition were observed. Commonly, ATTR amyloidosis was characterized by multifocal interstitial amyloid deposits that may not cause early clinical symptoms. Patients with AA amyloidosis usually had intravascular amyloid deposition. This finding can explain why cardiac symptoms were not observed in such cases.
Conclusion: This study has demonstrated that AL amyloidosis can be accompanied by the diffuse intravascular and pericellular patterns of amyloid deposition with cardiomyocyte atrophy. Such patients may develop a rapid progression of CA leading to heart failure. Both in biopsy and autopsy specimens, the most extensive amyloid deposits were found in AL kappa amyloidosis. They caused an aggressive and rapidly progressing CA and a poorer outcome for these patients. The assessme nt of autopsy cases revealed that ATTRwt amyloidosis was frequently detected only at the post-mortem examination suggesting that it is a common underdiagnosed cause of heart failure in elderly patients.

Funding: This work was supported by the Russian Science Foundation, grant No 23-15-00138

Autophagy related proteins' immunohistochemical expression and their potential role as biomarkers in thymic epithelial tumours

C. Yfanti[1], G. Levidou[2], S. Kokkali[1], D. Rontogianni[1,3], S. Theocharis[1]
[1]National and Kapodistrian University of Athens, First Department of Pathology, Athens, Greece, [2]Paracelsus Medical University, Nuremberg Clinic, Department of Pathology, Nuremberg, Germany, [3]Evangelismos General Hospital, Department of Pathology, Athens, Greece

Background & Objectives: Thymic Epithelial Tumours (TETs) constitute the most frequent neoplasms in the anterior mediastinum exhibiting clinicopathological and molecular heterogeneity. Autophagy, a self-destructive cellular mechanism with a paradoxical nature, plays a part in both tumour suppression and induction by either providing cancer cells with metabolic substrates and nutrients as well as activating oncogenes and inhibiting tumour suppressor genes, resulting in cell proliferation and survival. The aim of the present study is to investigate the clinical significance of four autophagy pathway components (LC3b,

ATG3, BECLIN, p62) in pathogenetic mechanisms of TETs with possible prognostic importance.
Methods: Archival formalin-fixed and paraffin-embedded tissue from 99 patients with TETs resected between 2009 and 2020 at Evangelismos Hospital, were retrieved and immunohistochemical staining for LC3b, ATG3, BECLIN, p62 was performed. The possible correlations between the expression of the examined autophagy pathway components and patients' clinicopathological parameters, such as WHO histological subtype, Masaoka-Koga stage, overall survival and presence of relapse was examined.
Results: Higher cytoplasmic BECLIN and p62 expression was associated with male gender (p=0.027 and p=0.014, respectively). B3 thymomas and thymic carcinomas (TC) displayed higher cytoplasmic p62 expression (p=0.019), while cytoplasmic LC3b expression was marginally more often observed in non B3/TC TETs (p=0.098). A positive correlation between higher cytoplasmic BECLIN expression and advanced Masaoka-Koga stage was also observed (p=0.009). ATG3 was not associated with any of the investigated clinicopathological parameters (p>0.05). There was also no significant correlation between any of the four examined molecules and overall survival or relapse.
Conclusion: Our findings reveal definite associations between autophagy and clinicopathological aspects in TETs indicating autophagy activation in B3/TC and advanced Masaoka- Koga stage cases. Further studies are needed to explore the role of autophagy in TETs and its blockage as a potential therapy.

OFP-02-012
Clinicopathological analysis of thymoma: a 12-year retrospective study from a single institution
E.F. Kucuk[1], M. Cikrikcioglu[1], T. Okay[2], F. Aker[1]
[1]Haydarpasa Numune Training and Research Hospital, Department of Pathology, Istanbul, Turkey, [2]Dr. Siyami Ersek Thoracic and Cardiovascular Surgery Training and Research Hospital, Department of Thoracic Surgery, Istanbul, Turkey

Background & Objectives: Thymoma is a rare mediastinal tumour with diverse histopathological subtypes and variable clinical behaviours. A comprehensive understanding of its epidemiological and pathological characteristics is crucial for improving diagnosis and management. This study retrospectively analyzes 59 thymoma cases diagnosed at Istanbul Haydarpasa Numune Training and Research Hospital between 2013 and 2024. The objective is to evaluate patient demographics, histopathological and clinical findings (including paraneoplastic syndromes), and survival outcomes to identify potential prognostic factors.
Methods: A retrospective review was conducted on 59 thymoma cases, documenting patient age, sex, histologic type, tumour size, T stage, presence of paraneoplastic syndromes, and survival outcomes. Histopathological classification followed WHO criteria, and T staging was based on the TNM system. Immunohistochemical analysis was performed in 55 cases. Diagnosis was made through biopsy in 7 patients and surgical resection in 52 cases. Statistical analyses, including survival analysis and correlation tests, were performed to explore associations between these clinicopathological variables.
Results: The cohort included 36 males and 23 females, with a median age of 55 years (mean: 53.2). Tumour size was recorded in 49 cases (median: 6 cm, mean: 6.58 cm). Histologic subtypes included 7 type A, 6 type AB, 6 type B1, 18 type B2, 13 type B3, 5 thymic carcinoma, 3 microscopic thymoma, and 1 micronodular thymoma with lymphoid stroma. Among 46 cases with documented T stage; 35 were pT1a, 4 pT2, 6 pT3, and 1 pT4b. Myasthenia gravis was observed in 15 patients (25.42%). Survival analysis showed that 42 patients remain alive, while 17 succumbed within 1 to 10 years post-diagnosis.
Conclusion: This study provides a detailed analysis of thymoma cases over 12 years, emphasizing variations in tumour characteristics, paraneoplastic manifestations, and survival outcomes. Further statistical assessment will refine our understanding of key prognostic factors and support evidence-based clinical management strategies for thymoma patients.

OFP-02-013
Gallstones in the mummies of a monastic community in central Italy (17^{th}-18^{th} century)
L. Ventura[1], F. Bruno[2], A. Avitabile[2], A. Risdonna[2], I. Faenza[3], E. Petrella[4], G. Pasquinelli[5], M. Traversari[5]
[1]Pathology, San Salvatore Hospital, L'Aquila, Italy, [2]Neuroradiology and Interventional Radiology, San Salvatore Hospital, L'Aquila, Italy, [3]DIBINEM, University of Bologna, Bologna, Italy, [4]Radiology, Morgagni-Pierantoni Hospital, Forlì, Italy, [5]DIMEC, University of Bologna, Bologna, Italy

Background & Objectives: Gallstones were described in mummified/skeletal remains of 22 subjects from Egypt, Sweden, Greece, Italy, Sicily, Spain, China, Ohio, Chile, and Colombia, dating back from 2000 b. C. to 18^{th} century A. D. The age at death was comprised between 25 and 60 years old, with female predominance, and a 3:1 ratio of cholesterol:pigmented stones. The mummified bodies of the Poor Clares Hermits monastic community in Fara in Sabina belonged to Franciscan nuns who followed the first Rule of Saint Clare combined with strict seclusion and absolute loyalty to ecclesiastical hierarchies. Most of them came from wealthy Roman families.
Methods: The bodies were investigated by external examination and computed tomography (CT) scanning. 3D rendering and densitometry allowed to reconstruct the exact stone morphology and establish chemical composition. Written sources hosted in the current monastery library were examined to find information about the sisters who lived there.
Results: Cholesterol-based gallstones were found in 3 individuals (17.5%) and were probably linked to dietary factors and genetic predisposition. The age at death of the subjects ranged from 40 to >50 years. The Book of the Dead allowed to recognize 2 nuns with symptoms ascribed to cholelithiasis (Maria Francesca Romana, who died in 1730 at 75; Maria Giovanna Romana, who died in 1718 at 82) and 1 sister affected by sudden fever and an undefined deep lateral chest pain (Maria Isabella, who died in 1698 at 50).
Conclusion: In conclusion, gallstones may be easily recognized in natural mummies through CT scanning, whereas densitometry helps to establish their chemical composition. As its modern counterpart, ancient cholelithiasis was most frequently due to cholesterol-based stones and may thus represent a good bioanthropological marker of high social class. The presence of gallstones may also be a valid clue for the identification of the subject, when information recorded in textual sources are available.

OFP-02-014
Development of a virtual, on-line pathology curriculum for residency training in pathology: the OPEN experience to lower barriers for the developing world
L. Hassell[1], T. Ramsayer[1], R.S. Gonzalez[2], K. Mirza[3], N.T. Tran[4], A. Splitt[5]
[1]University of Oklahoma Health Sciences Centre, Pathology, Oklahoma City, USA, [2]Emory University, Pathology, Atlanta, USA, [3]University of Michigan, Pathology, Ann Arbor, USA, [4]Kaiser Permanente, Pathology, Berkeley, USA, [5]Open Pathology Education Network, Inc, Content Teams, Oklahoma City, USA

Background & Objectives: Current training models in pathology are poorly scalable in the developing world when compared to projected increases in demand for pathology services. The Open

Pathology Education Network (OPEN) was launched in 2022 as a means to address the global workforce shortage in pathology by lowering barriers to access. The training model consists of self-paced on-line materials sourced from largely extant materials, coupled with intermittent on-line live mentoring sessions. This study assesses the process of developing OPEN modules to date.
Methods: Teams of subject matter experts were recruited to curate and develop content for use on the OPEN learning management system (LMS). Each team consisted of six-eight individuals and included senior, junior and some trainee volunteers. Support for development was provided by OPEN leadership and staff via regular check-ins. A survey of participant experiences was sent to the 30 volunteers to date. Usage data from the LMS was also collected.
Results: To date, modules have been developed and presented live on the OPEN LMS in gynaecologic pathology (3), urine cytology, breast pathology, MMR testing, Basics of Pathology, and gynaecologic cytology. Additional teams in head and neck pathology, paediatric pathology, lung pathology, CNS pathology, dermatopathology, histology basics, and endocrine pathology have been formed or are pending launch. Survey results showed participants found OPEN goals matched personal values. Learners in 89 countries have accessed the LMS for one or more courses.
Conclusion: The OPEN module development process has succeeded using volunteers, but often requires lengthy development. Teams with strong leadership, and some intra-institution collaboration are more effective. Many disciplines have sufficient open-source content for a curriculum, while some require significant further development, slowing the process. Developers show ready transition to on-going mentorship roles. Trainee response to developed content and live mentorship shows promising results in developing competency.

OFP-02-015

A survey of molecular testing availability in Arab countries

O. Alayyan[1], R. Ibrahim[2], K. Oqbani[3], A. Joudeh[4], M. Al-Hussaini[5]
[1]King Hussein Cancer Centre, Office of Scientific Affairs and Research, Amman, Jordan, [2]Ain Shams University, Department of Pathology, Cairo, Egypt, [3]Souss Massa University Hospital, Faculty of Medicine and Pharmacy, Department of Pathology, Agadir, Morocco, [4]King Fahad Specialist Hospital, Department of Pathology, Dammam, Saudi Arabia, [5]King Hussein Cancer Centre, Department of Cell Therapy and Applied Genomics, Amman, Jordan

Background & Objectives: Molecular diagnostic testing is essential for accurate cancer diagnosis and targeted therapy, and is widely integrated in the current series of WHO Classification of Tumours, yet its availability across Arab countries remains unclear.
Methods: A cross-sectional survey targeting the status of molecular testing in healthcare facilities in Arab countries to assess the availability of molecular diagnostics. Centers were identified through an index-pathologist selected in each country. The survey included questions on availability of various inhouse molecular testing modalities, and infrastructure.
Results: 68 centres responded to the survey, 58 of which offered oncology services. Centers were distributed across 14 Arab countries, with the highest representation from Egypt (n=13), Morocco (n=10), and Saudi Arabia (n=9). Of the responding centres, 44 (75.9%) were located in large cities (population > 1 million), 13 (22.4%) in medium cities (population 100,000–1 million), and 1 (1.7%) in a small city (population < 100,000).
44 (75.9%) centres have PCR, 28 (48.3%) FISH, 26 (44.8%) karyotyping, 19 (32.8%) NGS, 16 (27.6%) Sanger sequencing, 8 (13.8%) methylation profiling, and 6 (10.3%) MLPA. Thirty-two centres lacked inhouse capability for some or all tests and opted for outsourcing—most commonly FISH and NGS.
Among 39 centres lacking specific tests, 27 (69.2%) cited high cost and 12 (30.8%) cited limited expert personnel as key barriers. Of 31 centres with inhouse testing, 11 (35.5%) adopted molecular diagnostics to improve diagnostic accuracy and treatment planning.
Conclusion: In the era of precision medicine and molecular-based classification of tumours, the availability of molecular diagnostic testing is increasing across Arab countries. However, a significant proportion of oncology-health centres still lack in-house testing capabilities, primarily due to high costs and limited specialized personnel. Expanding training programs and investing in molecular-diagnostic molecular infrastructure are essential steps toward achieving equitable access to precise diagnostics and personalized cancer treatment across the region.

Prognostic relevance of worst pattern of invasion in cutaneous squamous cell carcinoma: an analysis of 151 cases

A. Sert[1], İ. Özdemir[2], B. Öğüt[1], M. Öztaş[2], Ö. Erdem[1]
[1]Gazi University Faculty of Medicine, Department of Pathology, Ankara, Turkey, [2]Gazi University Faculty of Medicine, Department of Dermatology and Venereal Diseases, Ankara, Turkey

Background & Objectives: The "Worst Pattern of Invasion" (WPOI) scoring system is widely used in head and neck squamous cell carcinomas (SCC) to assess prognosis. In this study, we investigated the applicability and prognostic significance of this scoring system in cutaneous SCCs (cSCCs).
Methods: We retrospectively reviewed 151 cases of cSCC diagnosed between 2019 and 2024, all followed by the dermatology department. WPOI scores were assigned independently by two pathologists (AS, BÖ) and classified into two groups based on WPOI status: low (WPOI 1–3) and high (WPOI 4–5). These scores were compared with clinicopathological features (tumour size, tumour thickness, histological differentiation, perineural invasion (PNI), lymphovascular invasion (LVI), nodal metastasis, recurrence, subcutaneous extension, stage, T and N classification, and histologic subtype and demographic data extracted from the hospital information system. Prognostic assessment was made according to 'BWH T classification system' recommended by the European Dermatology Association. Associations were evaluated using chi-square tests and t-tests, with a significance level set at $p < 0.05$.
Results: A total of 144 patients with a median age of 71 (9-97) years were included in our study. High WPOI was found to be significantly associated with various adverse pathological features such as between high WPOI and PNI ($p < 0.000001$), subcutaneous tissue invasion ($p < 0.000001$), increased tumour size ($p < 0.00001$), and greater tumour thickness ($p < 0.0001$), poor differentiation ($p = 0.0003$), advanced stage ($p < 0.000001$), and higher pT classification ($p < 0.000001$).
WPOI was not significantly associated with nodal metastasis, recurrence, LVI, multiple SCCs, age, sex, or histological subtype.
Conclusion: Our findings suggest that the WPOI is a valuable histopathological marker in cutaneous SCC and could provide helpful insight into tumour behaviour. This may assist in identifying high-risk patients, treatment planning and long-term follow-up.

OFP-03-002

Diagnosing urticarial vasculitis and chronic urticaria: a critical evaluation of a histopathological algorithm and scoring system

D. Petrovic[1], N. Delic[2], M. Bosic[3], E. Manojlovic Gacic[3], J. Stojkovic Filipovic[2], A. Stefanovic[4]
[1]Institute of Oncology and Radiology of Serbia, Belgrade, Serbia, [2]University Clinical Centre of Serbia, Clinic for Dermatology and Venereology, Belgrade, Serbia, [3]Institute of Pathology, Faculty of Medicine,

University of Belgrade, Belgrade, Serbia, [4]Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background & Objectives: Urticarial vasculitis (UV) and chronic urticaria (CU) share clinical and histopathological features, complicating their distinction. Puhl et al. proposed a histopathological algorithm and UV score (UVS) based on leukocytoclasia, erythrocyte extravasation, and fibrin deposition (FD) in blood vessels to aid the diagnosis. This study applied and critically evaluated the proposed algorithm in archival cases.
Methods: Archival cases from 2016–2024 with a referral diagnosis of UV (n=141), CU (n=32), or both (n=34) were analysed. Biopsy specimens were scored for leukocytoclasia (3 points), erythrocyte extravasation (2 points), and FD based on the number of affected fields of view (FOV) (1–3 points). The UVS was calculated based on the proposed formula, and a cut-off of 2.75 was applied to classify cases as CU or UV. Histopathological features were assessed in detail for diagnostic value.
Results: The algorithm classified 49.8% of cases as CU and 50.2% as UV, with 46.1% of clinically suspected UV cases reclassified as CU. Leukocytoclasia, erythrocyte extravasation, and FD were significantly more frequent in UV (76%, 45.2%, and 97.1%, respectively) than in CU (6.8%, 9.7%, and 1.9%, respectively; $p<0.001$). FD was extensive (≥3 FOV) in 83.7% of UV cases, but in CU, it was mild (affecting <3 FOV) and rare (1.9%). While eosinophils were more common in CU ($p=0.036$), their presence did not exclude UV, nor did neutrophils rule out CU ($p=0.175$). Intravascular neutrophils/eosinophils were frequent in UV ($p<0.001$). Perivascular lymphocytes with leukocytoclasia and/or FD were characteristic of UV (31.7% and 29.8%, respectively). Exclusion of other skin diseases was needed in cases with a sole presence of lymphocytes, even though they were classified as CU.
Conclusion: Fibrin deposits in blood vessels are the most reliable marker for UV diagnosis. While the proposed algorithm aids classification, its clinical applicability in cases without fibrin deposits requires prospective validation.

Funding: This research was supported by the Ministry of Science, Technological Development and Innovation of the Republic of Serbia and the Faculty of Medicine, University of Belgrade, project No. 451-03-66/2024-03/200110

OFP-03-003

Cutaneous metastasis: an 18-year retrospective study in a tertiary hospital

J. Sobreiro Silva[1], C. Cerqueira[2], J. Pardal[1]
[1]Unidade Local de Saúde de Braga, Pathology, Braga, Portugal, [2]Unidade Local de Saúde de Braga, Dermatology & Venereology, Braga, Portugal

Background & Objectives: Cutaneous metastases account for approximately 2% of all skin tumours, affecting between 0.7% and 9% of patients with malignant neoplasms. Typically, there is a prolonged interval between the diagnosis of the primary tumour and the identification of cutaneous metastases. However, in some cases, such metastases may be the initial manifestation of occult primary malignancies.
Methods: A descriptive, retrospective study was conducted on patients diagnosed with cutaneous metastases between January 2007 and January 2025, whose histopathological examination was performed at Unidade Local de Saúde de Braga. Clinical and histopathological data were collected from electronic medical records.
Results: Seventy cases of cutaneous metastases were identified, which corresponds to 1% of all cutaneous neoplasias. Most patients were female (65.7%, n=24), and the mean age at diagnosis was 67.5 ± 13.8 years. Clinically, 88.6% (n=62) of the skin lesions presented as a nodule and 51.4% (n=36) had multiple skin lesions at the time of diagnosis. In our series, 38.6% (n=27) of cases were metastasis of primary breast carcinomas, 15.7% (n=11) of primary lung carcinomas, and 12.9% (n=9) of primary colorectal carcinomas. The most common site of cutaneous metastasis was the chest (n=25), followed by the abdomen (n=19). The mean time between the diagnosis of the primary tumour and cutaneous metastasis was 55.5 months. In seven cases, the diagnosis of metastases was synchronous with that of the primary tumour, and in nine patients, the primary tumour was diagnosed through histopathological/cytological examination of the skin lesions. Currently, only seven patients are alive, and the median survival after the diagnosis of cutaneous metastasis was 14.4 months.
Conclusion: Overall, the prognosis for patients with cutaneous metastases remains poor, as these are associated with the aggressiveness of the primary tumour. Understanding their clinical features and maintaining a low threshold for performing biopsies may be useful in such cases.

OFP-03-004

Skin neoplastic lesions in the "very old" Portuguese population: a retrospective study in a two-year period

M. de Brito Pereira[1,2], F. Oliveira[3], F. Gomes[3], M. Ferreira[1], J. Cruz[4], I. Viana[1,5], C. Alves-Vale[1]
[1]CUF Descobertas Hospital, Pathology Department, Lisbon, Portugal, [2]NOVA Medical School - Faculdade de Ciências Médicas, Lisbon, Portugal, [3]Faculdade de Ciências e Tecnologia da Universidade Nova de Lisboa, Caparica, Portugal, [4]CUF Descobertas Hospital, Pathology department, Lisbon, Portugal, [5]Hospital Egas Moniz - Centro Hospitalar Lisboa Ocidental, Dermatology, Lisbon, Portugal

Background & Objectives: Non-melanocytic skin tumours rank as the 5th most common cancer worldwide, while melanoma is less frequent. Due to an increase in life expectancy, the WHO defines individuals aged 85 and older as "very old". This study aimed to characterise skin tumours in this understudied segment of the Portuguese population.
Methods: We analysed anatomopathological reports of skin lesions received in our department from January 2023 to December 2024, from patients with 85 years or older. Specimens were collected in different institutions across Portugal. The data collection included age, gender, anatomical site, histopathological diagnosis (by WHO Classification of skin tumours, 5th ed.) and personal history.
Results: A total of 668 reports from 520 patients were reviewed. The median age was 89.2 years (85-103), with a sight female predominance (M/F ratio= 0.93). Malignant tumours constituted 63.17% of cases (n=422), mainly corresponding to epithelial tumours (n=390; 92.4%), with the most frequent being basal cell carcinoma. Melanocytic malignancies were less common (n=17; 4.03%), followed by sarcomas (n=8;1.90%), adnexal carcinomas (n=6;1.42%) and lymphoproliferative disorders (n=1; 0.24%).
Among the benign lesions/ precursor lesions (n=246; 36.83%), the most common were epithelial tumours (n=209; 85.00%), followed by melanocytic lesions (n=18; 7.32%) – 5 (27.78%) corresponding to blue nevi and 4 (22.22%) had dysplastic features; followed by mesenchymal lesions (n=13; 5.28%) and adnexal tumours (n=6; 2.44%).
Multiple reports were available in 22.16% of patients in this time period, with only 13 patients having the biopsy and excision of the same lesion. The remaining patients (n=102) had at least two different skin lesions submitted to analysis.
Conclusion: Skin tumours are prevalent in the "very old" group, yet remain understudied. Our findings corroborate the predominance of non-melanocytic malignancies. The higher incidence of blue nevi might be justified by the nature of the institution (private), yet further study is needed.

OFP-03-005

Histological melanoma findings in *POT1* germline carriers in a Swedish familial melanoma cohort

F. Portelli[1,2], K. Papadakis[1], K. Schultz[1,3], J. Lapins[4,5], M. Yang[1], B. Krynitz[2], I. Vassilaki[2], V. Höiom[1,3], H. Helgadottir[1,3]
[1]Karolinska Institutet, Oncology and Pathology, Stockholm, Sweden, [2]Karolinska University Hospital, Clinical Pathology and Cancer Diagnostics, Stockholm, Sweden, [3]Karolinska University Hospital, Theme Cancer, Stockholm, Sweden, [4]Karolinska University Hospital, Dermatology, Stockholm, Sweden, [5]Karolinska Institutet, Dermatology and Venereology Unit, Dept of Medicine Huddinge, Stockholm, Sweden

Background & Objectives: About 7 to 15% of cutaneous melanomas (CM) are familial melanoma (FM) cases. High-risk genes include *CDKN2A* (up to 40% of cases), *CDK4, BAP1* and the more recently identified telomerase maintenance genes (TMG) which are *POT1, TERF2IP, TERT* and *ACD*. Spitzoid morphology is commonly observed in patients with germline variants in TMG. This Swedish study represents the first report in the Nordic countries on the prevalence and pathogenicity of *POT1* variants along with the histopathology of melanoma cases in the identified carriers.
Methods: Since 2021, all the CM families in Stockholm have undergone *POT1* testing as an implementation of the routine panel. The SweGen Dataset and the gnomAD database were used to assess the frequency of pathogenic variants (PV). The melanoma cases were reviewed.
Results: Among 150 melanoma families negative for *CDKN2A, CDK4,* and *BAP1*, only one likely *POT1* PV (c.676C>A, p.His226Asn) was detected (0.7%). Population data confirmed its rarity. Three carriers were identified. Carrier 1 had two invasive melanomas in early 20s. One, in the head and neck area, showed 100% of spitzoid morphology, BRAF+, classified as a spitzoid melanoma, Breslow 0,6 mm, growing adjacent to a nevus, suggesting that the melanoma had arisen from a precursor lesion. The other on the leg was a superficial spreading melanoma with 90% of spitzoid cells, Breslow 1,2 mm, BRAF+. Carrier 2 was diagnosed on the leg with a melanoma in situ without spitzoid features, BRAF+. Carrier 3 was diagnosed on the leg with a superficial spreading melanoma without spitzoid features, Breslow 0,6 mm, NRAS mutated (p.Gln61Arg). There were several other tumours in the pedigree, including brain and soft tissue tumours.
Conclusion: *POT1* testing should be offered in high-risk FM cases, especially when negative for *CDKN2A, CDK4* and *BAP1,* with an early onset of melanoma exhibiting spitzoid features, and other tumours in the pedigree.

Gene expression profile comparison of atypical fibroxanthoma and undifferentiated pleomorphic sarcoma

G. Cazzato[1], A. Giubellino[2], N. Azmi[3], R. Sun[4], S. Munro[5], C. Lupo[6], F. Li[7]
[1]University of Bari "Aldo Moro", Department of Precision and Regenerative Medicine and Ionian Area (DiMePRe-J), Bari, Italy, [2]University of Minnesota, Department of Laboratory Medicine and Pathology, Minneapolis, Italy, [3]University of Minnesota, Department of Laboratory Medicine and Pathology, Minneapolis, USA, [4]University of Minnesota, Department of Laboratory Medicine and Pathology, Masonic Cancer Centre, Minneapolis, USA, [5]University of Minnesota, Minnesota Supercomputing Institute, Minneapolis, USA, [6]University of Bergamo, Department of Engineering and Applied Science, Bergamo, Italy, [7]University of Texas Health Science Centre at San Antonio, Department of Pathology and Laboratory Medicine, San Antonio, USA

Background & Objectives: Atypical fibroxanthoma is a dermal neoplasm of uncertain histogenesis with a relatively low-grade behaviour. However, AFX exists in a clinical and histopathologic spectrum and can show a more aggressive lesion as undifferentiated pleomorphic sarcoma/ pleomorphic dermal sarcoma. Recent literature has confirmed the overlap of AFX and UPS also at the molecular level, however, little is known about the gene expression profiles of these tumours.
Methods: We applied gene expression profiling through RNA sequencing of TruSight RNA Pan-Cancer Panel Kit (Illumina) to 9 cases of AFX and 3 cases of UPS.
Results: Unsupervised cluster analysis revealed a clear molecular distinction between AFX and PDS, despite both tumours sharing common DNA mutation profiles and a TP53 UV radiation signature. RNA sequencing identified unique gene expression patterns that help differentiate the two, particularly involving apoptosis and cell adhesion pathways. Receptor tyrosine kinases, such as FLT3, also showed differential expression between the groups. In AFX, both apoptosis and adhesion pathways were consistently upregulated across multiple platforms—BioPlanet2019, KEGG2019Human, and WikiPathways2019Human and these findings align with AFX's clinical behaviour, as increased apoptosis limits cellular survival, and enhanced adhesion restricts migration—traits that contribute to its less aggressive nature. Among these, apoptosis was the most frequently upregulated function, followed closely by adhesion. Additionally, three signalling pathways—PI3K-Akt, B-cell receptor/activation, and Ras—were found to be commonly altered in both tumour types, according to KEGG and WikiPathways analyses. These pathways are typically associated with cell proliferation and survival, and their downregulation in AFX further supports its limited growth potential.
Conclusion: Overall, while AFX and PDS share mutational similarities, their distinct transcriptomic profiles, especially in apoptosis and adhesion-related processes, suggest that RNA-based analysis may aid in distinguishing these closely related tumours.

OFP-03-007

Melanocytic lesions – correlation between margin status and residual pathology of wider excisions

K. Sheehan[1], L. Cheriyan[1], T. Dorman[1], E. Kay[1]
[1]Blackrock Clinic, Department of Pathology, Dublin, Ireland

Background & Objectives: Dermatological excisions are frequently performed for melanocytic lesions, where achieving clear histological margins is critical to reduce risk of recurrence. This retrospective study evaluates margin status and diagnostic changes in patients with melanocytic lesions discussed in a skin cancer multidisciplinary team (MDT) setting over a one-year period ('24-25).
Methods: 301 patients were discussed at the MDT. Of these, 191 patients with melanocytic pathology were included in analysis. Patients were categorized based on number of excisions of the same lesion: single excision (n=191), two excisions (n=146), and three or more excisions (n=25). Margin status and diagnostic alterations were assessed for each excision event.
Results: Mean age was 65 years (range 17-93). The most common diagnosis was in situ melanoma (n=118), followed by invasive melanoma (n=46). Frequently affected sites included upper limb (n=51), face (n=40), and back (n=28). Positive margins were observed in 90 patients following first biopsy/excision, 25 patients following a second and 4 after a third excision. The mean negative margin after each excision was 1.8mm, 3.25mm and 2.4mm respectively. Of the 90 patients with positive margins after initial excision,

75 proceeded to further surgery—12 (16%) had no residual disease. In contrast, among 101 patients with initially negative margins, 71 underwent further excision, and 14 (19.7%) were found to have residual melanocytic pathology. Thirteen patients (9%) had their diagnosis upgraded on subsequent excision (e.g., from benign to in situ, or in situ to invasive melanoma). Notably, the average clear margin in those with residual versus no residual disease differed by only 0.1 mm.

Conclusion: Some evidence exists correlating histological margins and residual disease in melanocytic lesions. However, this study underscores the sometimes paradoxical relationship, particularly in excisions that are <5mm. These insights reinforce the critical role of MDTs in optimizing patient outcomes, particularly when pathology and clinical context may not align.

OFP-03-008

A whole-lesion morphometric analysis in melanoma: towards a prognostic role for image analysis

D. Anconelli[1], F. Piccinini[2,3], L. Cardisciani[1,4], P. Sgubbi[5], G. Pasquinelli[3], M. Carroli[1,4], G. Castellani[3,6], L. Saragoni[1,3], F. Vasuri[1,3]
[1]Santa Maria delle Croci Hospital, Pathology Unit, Ravenna, Italy, [2]IRCCS Istituto Romagnolo per lo Studio del Tumori (IRST) "Dino Amadori", Meldola, Italy, [3]University of Bologna, Department of Medical and Surgical Sciences (DIMEC), Bologna, Italy, [4]University of Bologna, School of Anatomic Pathology, Department of Biomedical and Neuromotor Sciences (DIBINEM), Bologna, Italy, [5]Santa Maria delle Croci Hospital, Dermatology Unit, Ravenna, Italy, [6]IRCCS Azienda Ospedaliero-Universitaria di Bologna S. Orsola, Bologna, Italy

Background & Objectives: Previous morphometric studies in melanoma have proven useful in differentiating between melanoma and nevi. Correlations have been established between cell nuclear area, circularity, and optical density (OD), and p53 and Bcl-2 expression, mitotic index and tumour stage. In this study, we determined for the first time on whole-slide image (WSI) the prognostic significance of morphometric nuclear features in melanoma.

Methods: We evaluated 9 malignant melanomas, 4 metastatic(mM), with a mean progression-free survival (PFS) of 629 days, and 5 non-metastatic (nmM) with mean follow-up of 1637 days. All clinical and histopathological variables were collected.

We analysed the most representative slide for each case: following the digital slide acquisition by Aperio Scan Leica system, we selected all invasive tumour cells from the sections with the highest cell density and analysed 19 nuclear variables using the QuPath software analysis tools (ver. 0.5.1).

Results: In total, we extracted 782.793 cells(mean 86997/case, range 16967-236224/case). Mean nuclear area, nuclear perimeter, nuclear maximum and minimum caliper were positively correlated with melanoma diameter and Breslow thickness (all $p<0.05$); minimum nuclear calliper also correlated with the number of mitosis/mm^2 ($p=0.015$) and ulceration ($p=0.024$).

When the 503.788 cells from mM were compared with the 279.005 cells from nmM, many variables showed significant differences ($p<0.001$): nuclear max and min caliper, mean/sum/range of Haematoxylin OD, among others.

Conclusion: Our results strengthen the correlation of nuclear morphometric features (studied for the first time on WSI) and the prognostic variables in melanoma: mitotic index, tumour dimensions, ulceration, and Breslow thickness (the latter for the first time, to the best of our knowledge). Furthermore, our cell analysis revealed a correlation between the Haematoxylin OD features and metastatic potential, akin to cervix non-keratinising squamous cell carcinoma. While these findings necessitate a larger case series to establish PFS, they suggest that image analysis not only distinguishes nevi from malignant melanomas but also differentiates metastatic from non-metastatic cases.

OFP-03-010

Carcinoid-like pattern in basal cell carcinoma: a large series of 40 cases with detailed clinicopathological and immunohistochemical characterization

A. Erbağci[1], Ş. Özkanli[2], F. Aknar[1], D. Gül[1], B. Çobanoğlu Şimşek[2]
[1]Goztepe Prof. Dr. Suleyman Yalcin City Hospital, Istanbul Medeniyet University, Pathology, Istanbul, Turkey, [2]Istanbul Medeniyet University, Pathology, Istanbul, Turkey

Background & Objectives: Basal cell carcinoma (BCC) is histologically diverse, yet carcinoid-like architecture remains an extremely rare and under-recognized variant. This growth pattern may mimic sebaceous, neuroendocrine, or even melanocytic neoplasms, leading to potential diagnostic pitfalls. Our objective was to systematically characterize the largest known series of BCCs with carcinoid-like pattern, defining their clinicopathological spectrum and immunophenotypic profile.

Methods: We retrospectively reviewed 1373 BCC cases diagnosed between 2018 and 2025. Forty tumours (2.9%) demonstrated a carcinoid-like arrangement, characterized by branching and anastomosing trabeculae within fibrovascular stroma. Clinical parameters, histologic patterns, and ancillary features (ulceration, perineural invasion, recurrence) were evaluated. Immunohistochemistry (IHC) for BerEP4, EMA, CK20, synaptophysin, chromogranin, and vimentin was performed to delineate lineage and rule out mimics.

Results: The cohort comprised 21 females and 19 males (median age: 74, range: 40–103). Tumour size ranged from 4 to 65 mm. The majority (92.5%) were located on the head and neck region. Carcinoid-like pattern involved 5–90% of the tumour area, frequently coexisting with nodular and/or infiltrative components. Ulceration was present in 50% of cases. Perineural invasion and local recurrence were observed in only one case each. IHC revealed strong diffuse BerEP4 positivity in all tumours; CK20, EMA, synaptophysin, chromogranin, and vimentin were consistently negative.

Conclusion: Carcinoid-like BCC is a rare but distinct and recognizable histologic variant with characteristic morphology and a consistent immunoprofile. Awareness of this pattern is critical to prevent misclassification as adnexal, neuroendocrine, or melanocytic tumours. Our findings expand the histologic spectrum of BCC and reinforce the diagnostic utility of BerEP4 in challenging cases.

OFP-03-011

Evaluation of PRAME expression in dysplastic nevi: a comparative analysis of low- and high-grade lesions

H. İzol Özmen[1], G. Kolak Gözüküçük[1], F. Kuşku Çabuk[1]

[1]Basaksehir Cam and Sakura City Hospital, Pathology, Istanbul, Turkey

Background & Objectives: PRAME (PReferentially expressed Antigen in Melanoma) antibody is a crucial biomarker for differentiating melanoma from benign lesions. Although useful, its diagnostic value in dysplastic nevi (DN) remains controversial. This study investigates its diagnostic potential and clinicopathological correlations.

Methods: PRAME was immunohistochemically assessed in 115 low-grade dysplastic nevi (LG-DN) and 18 high-grade dysplastic nevi (HG-DN). Staining was scored from 0 (no staining) to 4+ (75% or more). The relationship of PRAME expression with age, gender, localization, and histological grade was examined.

Results: We analysed 133 DNs from 107 patients. Of these, 49.5% were female and 50.5% were male. The mean age was 36.6 years (range: 7-91). Lesions in females were observed to appear at an earlier age than males (mean: 31.7 vs 40.6, $p<0.001$). Histological grade increased with advancing age ($p=0.017$). Most lesions were located on the trunk (51.9% back, 27.1% chest) followed by the head and neck (7.5%). 27.8% of lesions were junctional, while 72.2% were compound.

PRAME was immunohistochemically assessed using a five-tiered system (0 to 4+). Among LG-DN 84.3% presented score 0, 5.2% score 1+, 0.9% score 2+, 2.6% score 3+, 7% score 4+. Among HG-DN 77.8% presented score 0, 5.6% score 1+, 0% score 2+, 5.6% score 3+, 11.2% score 4+. Although PRAME expression showed an increasing trend from LG-DN to HG-DN, the difference was not statistically significant. No correlation was found between PRAME expression and age, sex, localization, nevus subtype.
Conclusion: The findings indicate that PRAME expression is not associated with histological grade or clinical and histological parameters in DN, suggesting that this marker may have limited prognostic or diagnostic value in these lesions. These results need to be supported by larger sample-sized and comparative studies.

OFP-03-012
Comparative histological description between breast and abdominal skin territories with a special focus on erogenous sensation
R. Moiteiro da Cruz[1,2], A. Varanda Pereira[3,2], C. Fatal[2], V. Baranenko[2], S. Sanches-Fernandes[2], J. Beirolas[2], A.R. Henriques[2], S. Alves[4,5], D. Pinto[4], M.M. Novo[6]
[1]ULS de Santa Maria, Pathology, Lisbon, Portugal, [2]Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal, [3]Clínica Lmr - Cirurgia Plástica, Lisbon, Portugal, [4]ULS de São José, Pathology, Lisbon, Portugal, [5]NOVA Medical School, Lisboa, Portugal, [6]ULS de Amadora / Sintra, Pathology, Lisbon, Portugal

Background & Objectives: Sensory recovery constitutes an essential outcome of breast plastic surgery, either aesthetic or reconstructive. Abdominal wall-based flaps remain the gold standard for autologous breast reconstruction in most centres, and flap neurotization is increasingly popular since it has been shown to provide quicker and better postoperative sensation. Previous research shows that even with the neurotization of the flaps, full sensory recovery remains inconsistent. This study aims to address this issue by describing and comparing neurohistologically the skin of the breast and the infraumbilical abdominal wall.
Methods: An observational cross-sectional study was performed on 100 hemi-bodies from 35 mommy makeover patients (submitted to abdominoplasty + mastopexy/breast reduction) at the LMR – Plastic Surgery Clinic and 15 formalin-preserved adult cadavers at the Institute of Anatomy, Lisbon Faculty of Medicine, Portugal. From each hemi-body, 10x5mm full thickness skin biopsies have been collected: four from the infra-umbilical lower abdomen and five from each breast quadrant and from the areola. Samples were histologically prepared including staining with haematoxylin and eosin and immunohistochemistry using antibodies specific to neuronal markers S100, Peripherin (sympathetic nerve fibres), Annexin V (sensory nerve fibres), and PIEZO2 (erogenous sensation receptors). Microscopic analysis was focused on the comparisons between breast and abdomen skin histologic features, with a special focus on the skin layers, nerve endings and cutaneous sensory receptors, including the ones related to sexual function.
Results: Although skin thickness and epithelial layers are grossly similar, significant differences between these two anatomical regions were found in terms of nerve fibre distribution and density, especially concerning the PIEZO2 ion channel.
Conclusion: A comprehensive understanding of the skin neurohistology of the mammary and abdominal region can significantly influence surgical decisions, particularly in prioritizing flap areas with greater similarity to the breast. This understanding can potentially lead to improved sensory recovery, including erogenicity, and ultimately enhance patient outcomes in breast reconstruction.

OFP-04-001
The prognostic value of ATRX and TERT promoter status in the context of histopathological findings in conjunctival melanoma
K. Winkler[1], S. Nobacht[2], P. Groenen[1], J. van Ipenburg[1]
[1]Radboud University Medical Centre, Pathology, Nijmegen, The Netherlands, [2]Radboud University Medical Centre, Ophtalmology, Nijmegen, The Netherlands

Background & Objectives: Conjunctival Melanoma (CM) are rare melanocyte-derived malignancies with only partial overlap concerning biological background and clinical course compared to their cutaneous counterpart. While the recurrent and metastatic tendencies of CM call for literature-driven unified treatment and follow-up protocols, CM scarcity impedes reliable determination of regimen-deciding prognostic markers. Previous studies associated several clinicohistopathological features and a mutated *TERT* promoter (*TERTp*) with an adverse clinical course. This study builds upon prior research aiming to determine the prognostic value of ATRX status in CM patients.
Methods: A retrospective single-centre cohort study of Radboudumc CM patients between 1985 and 2022 is conducted to analyse the value of ATRX immunohistochemistry in additional to *TERTp* status using Sanger sequencing, correlated to clinicohistopathological context.
Results: Preliminary data of 32 CM patients include 9/32 (28%) male and 23/32 (72%) female patients, with 12/32 (38%) showing recurrent disease and 7/32 (22%) exhibiting metastases. Currently, ATRX immunohistochemistry was performed on 31 CM, showing ATRX loss in 7/31 (23%) instances. Recurrences were found in 4/7 (57%) ATRX-loss cases compared to 8/24 (33%) in the ATRX wild-type population. Metastases occurred in 3/7 (43%) ATRX-loss cases compared to 4/24 (17%) in the ATRX wild-type cohort.
So far, prior routine diagnostic molecular analyses show 2 *TERTp* wild-type cases and 1 mutated sample. Remarkably, the *TERTp*-mutated case showed concomitant ATRX loss and multiple hotspot mutations.
Conclusion: These preliminary findings of higher percentages of recurrences and metastases in ATRX-loss CM cases align with previously reported findings. Furthermore, 1 case showed both a *TERTp* mutation and ATRX loss, bringing prior propositions of its mutual exclusive occurrence into question. In addition to incorporation of upcoming data concerning *TERTp* status and clinical parameters, collaborations with other centres to increase the examined population will be of utmost importance in identifying prognostic parameters aiding in adequate personalized treatment.

Conjunctival melanocytic lesions: does simplifying WHO grading improve reproducibility?
S. Çolak[1], Ö. Gököz[1], E. Gezmiş[1], B. Babaoğlu[1], D. Ateş Özdemir[1]
[1]Hacettepe University Faculty of Medicine, Department of Pathology, Ankara, Turkey

Background & Objectives: Accurate grading of conjunctival melanocytic intraepithelial lesions is essential for predicting melanoma risk and guiding treatment. Three systems are commonly used: Primary Acquired Melanosis with atypia (PAM), Conjunctival Melanocytic Intraepithelial Neoplasia (C-MIN), and the 2022 World Health Organization (WHO) classification, which introduced the Conjunctival Melanocytic Intraepithelial Lesion (C-MIL) system. This study evaluated

interobserver agreement and correlations among these systems using real-life pathological cases.
Methods: Thirty-six conjunctival lesions diagnosed between March 2015 and January 2025 were reviewed independently by three experienced pathologists using PAM (0–3), C-MIN (quantitative score), and WHO 2022 C-MIL classifications. The C-MIL system was assessed in both its original format (four-tiered, including melanoma in situ as a separate category) and a simplified format (three-tiered, combining melanoma in situ with high-grade lesions). Fleiss' kappa was used to measure interobserver agreement, while Spearman correlation coefficients were used to assess relationships between the systems.
Results: Agreement was low for PAM ($\kappa = 0.270$) and C-MIL (four-tiered) ($\kappa = 0.272$), and moderate for the simplified three-tiered C-MIL ($\kappa = 0.467$). PAM and C-MIN showed higher agreement in "no atypia" and "severe atypia" categories, with lower consistency in intermediate grades. Among the original systems, C-MIN showed relatively higher agreement ($\kappa = 0.392$). The simplified WHO C-MIL format demonstrated the highest reproducibility. Correlation analysis revealed strong to very strong relationships across all systems (e.g., PAM vs C-MIN: $r = 0.819–0.854$; PAM vs C-MIL: $r = 0.908–0.947$; C-MIN vs C-MIL: $r = 0.824–1.000$; all $p < 0.001$).
Conclusion: The simplified WHO 2022 C-MIL classification improves diagnostic consistency while maintaining strong alignment with previous systems. Reducing the number of grading categories enhances reproducibility, especially in borderline lesions. These findings support the simplified C-MIL as a practical and standardized tool for routine reporting.

OFP-04-003
Integrating snRNAseq and Spatial Transcriptome (ST) shows diverse transcriptomic landscape for Tumour Microenvironment (TME) in intracranial germinomas
H.-K. Ng[1]
[1]Chinese University of Hong Kong, Pathology, Hong Kong, Hong Kong, SAR of China

Background & Objectives: The incidence of intracranial germ cell tumours is 5-8 times higher in East Asia and histologically, germinoma is well known to show intense lymphocytic infiltrates. The latter can be so marked that the malignant germ cells can be masked. However, there have only been a few studies on its tumour micro-environment (TME). The lack of studies is attributed to the unavailability of tumour specimens in western countries. There has been no study using the recent and comprehensive techniques of single nucleus sequencing or spatial transcriptomics to study its TME.
Methods: We studied snRNAseq (Chromium 10X) of FFPE tissues of 51 intracranial germinomas, and spatial transcriptoms (STs) (Visium Spatial) from fresh tissues from 12 matched cases.
Results: For the TME, in contrast to common belief, macrophages and fibroblasts were equally represented as T- and B-cells as immune cells. There was no correlation with proportion of tumour cells with either focal vs bifocal disease or clinical stage. Common gene modules (metaprograms) were epithelial-mesenchymal transition, cell cycle and immune cells. Cell interaction analysis showed strong interaction between germ cells and macrophages involving CXCL, MIF and MK pathways. By ligand-receptor analysis, MIF combined with CD74 might promote tumour development. For twelve cases, we studied STs with fresh tissues and integrated the results with snRNSeq, deconvoluting the spots for ST using snRNAseq cell types. Multimodal Intersection Analysis integrated significant genes based on snRNAseq and different regions' significant genes based on STs. Ligand and receptor was expressed in close proximity. There was correlation between the expression of the four gene modules for tumour and immune cells for cell neighbourhood. Multichannel immunofluorescence (Hyperion) confirmed spatial distribution of cell types and cell neighbourhood findings.
Conclusion: We showed in details the expression landscape of TME of germinomas.

OFP-04-004
***TERT* promoter mutations in medulloblastoma: clinicopathological and molecular correlation**
K. Krishnakumar[1], S. Epari[1,2], N. Panchal[2], R. Rumde[2], P. Bapat[2], M. Gurav[2], A. Sahay[1,2], A. Shah[1,2], O. Shetty[2], A. Moiyadi[3], P. Shetty[3], G. Chinnaswamy[4], M. Prasad[4], T. Gupta[5], A. Chatterjee[5], A. Dasgupta[5], A. Sahu[6]
[1]Tata Memorial Hospital, Pathology, Mumbai, India, [2]Tata Memorial Hospital, Molecular Pathology, Mumbai, India, [3]Tata Memorial Hospital, Neurosurgical Division of Surgical Oncology, Mumbai, India, [4]Tata Memorial Hospital, Paediatric Oncology, Mumbai, India, [5]Tata Memorial Hospital, Radiation Oncology, Mumbai, India, [6]Tata Memorial Hospital, Radiology, Mumbai, India

Background & Objectives: *TERT* promoter(*TERT*p) mutation has emerged as one of the distinct marker of adult subtype of *SHH*-activated medulloblastoma(MB), which is associated with a better prognosis. The current study aims to evaluate the frequency of *TERT*p mutations and correlate it with various clinical, histoarchitectural and molecular features.
Methods: Cases of medulloblastoma diagnosed between 2021 and 2024, which were molecularly grouped by targeted gene expression profiling (GEP), and evaluated for *TERT*p mutation by Droplet digital PCR(DdPCR) were included
Results: Cohort of 142 cases; the age range was-0-3years: 21(14.8%), 4-6years: 36(25.4%), 7-18years: 58(40.8%), 19-25years: 13(9.2%), 26-39 years: 12(8.5%) and ≥40years: 2(1.4%).M:F ratio-2.2:1. The molecular grouping based on GEP and with additional p53 immunohistochemistry, the cases were molecularly grouped - 23(16.2%)*WNT*-activated, 44(30.9%)*SHH*-activated and *TP53* wildtype immunophenotype, 2(1.4%)*SHH*-activated and *TP53* mutant immunophenotype and 73(51.4%)non-*WNT*/non-*SHH* group [27(19%)group3, 35(24.6%) group4, 11(7.7%)unclassified]. Histologically, classic(n=97,68.3%) histoarchitecture was the most common followed by D/N (n=24,16.9%), LC/A(n=11,7.7%), with myogenic differentiation(NOS; n=6,4.2%) and MBEN(n=4, 2.8%) histoarchitecture. The overall frequency of *TERT*p mutation was 16.9% (n=24). 19 were of *C228T* and 5 were of *C250T* type of mutations. *TERT*p mutations were significantly seen in adults(≥19 years) and *SHH*-activated group($p<0.001$). The frequency of mutation was 4.3% (n=5) and 70.3% (n=19) in <19 years and ≥19 years age-group respectively. Of the 24 mutant cases, 22(91.6%) were *SHH*-activated (≥19 years:19, 86.4%; <19 years:3, 13.6%), 1(0.7%) was *WNT*-activated and 1(0.7%) was non-*WNT*/non-*SHH* group. 8(33.3%) were midline and 16(66.7%) were laterally localized.13(54.1%) cases showed classic and 11(45.8%) showed D/N histoarchitecture. None of the mutant cases showed *TP53*-mutant immunophenotype, monosomy 6, and *MYCN* amplification. The one-year OS for *TERT*p mutant cases (100%) was better than *TERT* promoter wild-type cases(94%).
Conclusion: *TERT*p mutations were highly frequent (86.4%) in adult *SHH*-activated MB patients, observed in classic and D/N histoarchitectural patterns, lateralized locations, absent in *MYCN*-amplified or *TP53*-mutated cases, and associated with better overall survival.

OFP-04-005
Real-life investigation of nanopore sequencing for rapid epigenomic classification of brain tumours
T. Roetzer-Pejrimovsky[1,2,3], E. Bondareva[1,2], S. Moser[1,2], R. Höftberger[1,2], C. Haberler[1,2,3], N. Amberg[1,2,3]
[1]Division of Neuropathology and Neurochemistry, Department of Neurology, Medical University of Vienna, Vienna, Austria, [2]Comprehensive Centre for Clinical Neurosciences and Mental Health, Medical

University of Vienna, Vienna, Austria, [3]Comprehensive Cancer Centre, Medical University of Vienna, Vienna, Austria

Background & Objectives: DNA methylation profiling has been established as a crucial diagnostic biomarker for the classification of brain tumours. In the routine diagnostic workflow, traditional histopathology must be interpreted in synopsis with molecular pathology findings for precision diagnostics. However, conventional molecular assays, such as EPIC DNA methylation profiling and NGS require 2-4 weeks, delaying comprehensive tumour board decision and initiation of personalized therapy. This study explored the feasibility of nanopore sequencing as a rapid diagnostic approach capable of epigenetically classifying brain tumours within 24 hours.
Methods: We analysed 45 brain tumour specimens using Nanopore sequencing. Nineteen different common and rare tumour types were included. DNA was extracted, quantified, and sequenced using the MinION platform. Methylation-based classification was conducted in parallel using the NanoDx pipeline and the neural network classifier Sturgeon.
Results: Nanopore-based classification was obtained within a few hours of workflow initiation. NanoDx yielded a classifiable result in 31 (71 %) and Sturgeon in 39 (89 %) samples. The predicted class matched the integrated diagnosis obtained by histological and molecular pathological analyses in 29 cases (94 % of classifiables) for NanoDx and in 29 cases (74 % of classifiables) for Sturgeon. For non-classifiable cases, the prediction with the highest score matched the integrated diagnosis in 46 % of the cases for NanoDx and 20 % for Sturgeon. For 30 samples that were classifiable by both algorithms, NanoDx and Sturgeon yielded concordant results for 29 samples.
Conclusion: Nanopore sequencing substantially accelerates the diagnostic timeline for brain tumours, offering the potential to initiate personalized therapy within five days. Despite its promise, further refinement is necessary to improve classification accuracy, particularly for specimens with low tumour cell content. Ongoing investigations will assess whether earlier integrated diagnosis translates to improved clinical outcomes. Overall, these findings underscore the clinical benefits of nanopore sequencing for rapid integrated histopathological and molecular diagnostics.

OFP-04-006
Dissecting the methylomes of *CDKN2A/B* deleted glioblastoma
T.F.J. Kraus[1], C.K. Langwieder[1], B. Alinger-Scharinger[1], K. Sotlar[1]
[1]Institute of Pathology, University Hospital Salzburg, Salzburg, Austria

Background & Objectives: Glioblastoma IDH wildtype is the most common brain tumour of adults in the western world. It is highly aggressive and shows a devastating outcome. Up to now, there is no targeted therapy available. A very interesting novel approach for individualized patient care is the tumour suppressor gene *cyclin dependent kinase inhibitor (CDKN) 2A/B* that is lost in a fraction of Glioblastomas.
Methods: In this study, we performed integrated epigenome-wide DNA-methylation analysis of 866,895 methylation specific sites in 100 glioblastoma IDH wildtype samples with known *CDKN2A/B* deletion status comparing the DNA methylome of deleted and retained glioblastomas.
Results: We found distinct significantly differentially methylated CpGs (DMCG) with $\Delta\beta \geq 0.1$ and p-value < 0.05 in *CDKN2A/B* deleted compared with *CDKN2A/B* retained. Of these DMCGs, we were able to allocate distinct loci with tiling, promoter, gene and CpG island locations. Interestingly, the list of differentially methylated genes allocated functionally relevant RNAs. Gene ontology (GO) analysis showed enrichment of distinct pathways in *CDKN2A/B* deleted glioblastomas.
Conclusion: In summary, dissecting the methylomes of *CDKN2A/B* deleted and retained glioblastomas revealed globally altered pathways that are associated with cellular proliferative activity.

OFP-04-007
Single-nucleus RNA sequencing and spatial transcriptomics reveal sustained microglial activation in Post COVID-19 condition
A. Sudy[1,2], J. Meinhardt[3], R.L. Chua[1], J. Liebig[1,2], K. Jechow[1], F. Bösl[4], C. Franke[4], P. Körtvélyessy[4], V. Farztdinov[5], M. Mülleder[5], R. Eils[1], H. Radbruch[3], C. Conrad[1]
[1]Berlin Institute of Health at Charité - Universitätsmedizin Berlin, Digital Health Centre, Berlin, Germany, [2]Freie Universität Berlin, Berlin, Germany, [3]Charité – Universitätsmedizin Berlin, Department of Neuropathology, Berlin, Germany, [4]Charité – Universitätsmedizin Berlin, Department of Neurology, Berlin, Germany, [5]Charité – Universitätsmedizin Berlin, Core Facility High Throughput Mass Spectrometry, Berlin, Germany
Background & Objectives: Post COVID-19 condition (PCC) resembles chronic fatigue syndrome, with cognitive impairment and fatigue as common symptoms. However, the underlying pathomechanisms remain poorly understood, and therapeutic options are limited. We aimed to investigate the role of neuroinflammation and innate immune activation in PCC by analysing cerebrospinal fluid (CSF) and brain tissue from affected individuals.
Methods: We analysed CSF from PCC patients (n=20) presenting with neurological impairments one year post SARS-CoV-2 infection. To investigate long-term effects in the central nervous system, we performed single-nucleus RNA sequencing (snRNAseq; n=12) on postmortem brain tissue from donors who had died months after infection. To validate and spatially contextualize these findings, we applied StereoSeq, a spatial transcriptomics method, to fresh-frozen brainstem sections from the same individuals (n=8). Transcript mapping to individual nuclei was combined with computational label transfer using snRNAseq data to classify cell types. Lower-resolution binning was used to delineate tissue niches.
Results: We observed activation of the innate immune system in the CSF, indicative of marked microglial activation in PCC patients compared to non-infected controls. This activation persisted in postmortem brain tissue, as shown by snRNAseq. Harnessing spatial information confirmed these findings and revealed distinct localization patterns and transcriptional states of parenchymal versus perivascular microglia. We identified differentially expressed genes between microglial subtypes and quantified their local abundances in diseased versus control tissue. Niche analysis further revealed altered spatial interactions between microglia and their microenvironment in the context of systemic viral infection.
Conclusion: Our results provide hints for sustained neuroinflammation in PCC, driven by long-term microglial activation. Spatial and transcriptomic profiling highlights distinct microglial states, offering insights into the cellular basis of persistent neurological symptoms following SARS-CoV-2 infection.

OFP-04-008
Pathological findings of triplet placentas associated with assisted reproductive technology: a study of 98 triplet pregnancies
E.M. Pena Burgos[1], M. De la Calle Fernández-Miranda[2], J.J. Pozo Kreilinger[3], R.M. Regojo Zapata[3]
[1]Hospital General Universitario Gregorio Marañón, Pathology, Madrid, Spain, [2]Hospital Universitario La Paz, Obstetrics and Gynaecology, Madrid, Spain, [3]Hospital Universitario La Paz, Pathology, Madrid, Spain

Background & Objectives: Triplet pregnancies have increased over the past few decades due to an increase in assisted reproductive technology (ART) and are considered high-risk pregnancies. Generally, ART pregnancies are associated with poorer obstetric outcomes. Placental pathological findings of ART pregnancies are not well known. Our aim is to determine if triplet placentas conceived by ART present more placental abnormalities than those conceived in vivo.

Methods: This is a retrospective case-control study. It includes all triplet pregnancies followed up in a tertiary referral hospital between 2000 and 2024 whose placentas were analysed in a Pathology Department. The control group were the in vivo conceived triplet pregnancies (natural conceptions and artificial insemination) and the case group were the ART-conceived triplet pregnancies (in vitro fertilization and intracytoplasmic sperm injection). Univariate and multivariate statistical studies were performed.
Results: 98 triplet pregnancies were analysed: 33 triplet pregnancies in the in vivo conceptions group and 65 triplet pregnancies in the ART group. After multivariate analysis, the monochorionic triamniotic percentage was significantly higher (p=0.02) in the in vivo group and the dichorionic triamniotic (p=0.03) in the ART group. The percentage of primiparous women in the ART group was significantly higher (p=0.02). The ART group placentas presented less placental weight (p=0.03) and more marginal (p=0.01) and velamentous (p<0.01) insertion. Higher rates of chronic villitis (p=0.02), accelerated villous maturation (p=0.01), intervillous fibrin deposits (p=0.01) and chorangiomas (p=0.04) were found in the ART group and more oedema (p=0.01) and the presence of nucleated red blood cells (p=0.02) were detected in the in vivo group.
Conclusion: Gross and pathological placental evaluation is key to understand pregnancy outcomes. Further studies analysing the possible immunological and vascular mechanisms of these findings; and if these differences between groups are related to a higher rate of maternal, obstetric, foetal or neonatal complications are needed.

OFP-04-009

Leveraging artificial intelligence for grading chorioamnionitis: diagnostic precision in inflammatory cell localization and quantification

O. Greenberg[1], L. Flayer[2], C. Wizeman[1], S. Tsuriel[1], R. Hagege[1], V. Hannes[1], D. Hershkovitz[1]
[1]Tel Aviv Sourasky Medical Centre, Pathology, Tel Aviv, Israel, [2]Tel Aviv University, Tel Aviv, Israel

Background & Objectives: Chorioamnionitis is an acute inflammation of the amniotic membranes, leading to severe maternal and foetal complications. Early diagnosis is essential but current clinical methods lack precision. This study developed an artificial intelligence (AI)-based algorithm for identifying chorioamnionitis at varying severity levels. The algorithm aims to identify the grade (GRADE) and stage (STAGE) of anatomical spread based on Amsterdam criteria using placental and umbilical cord tissue images. The study hypothesizes that AI can accurately identify these factors, measure inflammatory cells, and reveal connections between chorioamnionitis and foetal diseases.
Methods: A total of 102 placental patches were captured and amnion layer was manually segmented. A previously developed algorithm was used for nuclear segmentation. Statistical analysis compared cell counts across GRADE groups and the median distance of cells from the amnion layer between the algorithm and pathologist's STAGE groups.
Results: A strong correlation was found between GRADE ratings and the number of cells, with cell count increasing as severity rose: GRADE 0 had 21.6±14.73 cells, GRADE 1 had 29.46±11.56, and GRADE 2 had 56.19±38.41 (P<0.01). In STAGE 3, the distance between inflammatory cells and reference points significantly decreased to 123.78±73.13 pixels (P<0.01). However, an anomaly was found in STAGE 1, where the average distance (235.79±64.9 pixels) was lower than in STAGE 2 (269.66±92.3 pixels), warranting further investigation.
Conclusion: The algorithm successfully identified the severity grades of chorioamnionitis and stages, providing quantitative tools for measuring the quantity and distance of cells. The findings confirm the known associations between inflammation severity and cell count. The integration of artificial intelligence in pathology may improve diagnostic accuracy, reduce pathologist workload, and enhance medical intervention capabilities in cases of chorioamnionitis.

OFP-04-010

Comprehensive analysis of gene expression profiles in paediatric myofibroblastic neoplasms

E. Rullo[1], S. Vallese[1], S. Barresi[1], A. Stracuzzi[1], S. Scuderi[2], G.M. Milano[3], G. Bisogno[4], V. Costabile[5], R. Alaggio[1]
[1]Pathology Unit, Department of Laboratories, Bambino Gesù Children's Hospital and Research Institute, Rome, Italy, [2]Department of Clinical and Molecular Medicine, Sant'Andrea Hospital, Sapienza University of Rome, Rome, Italy, [3]Onco-Haematology, Cell Therapy, Gene Therapies and Hemopoietic Transplant, Bambino Gesù Children's Hospital and Research Institute, Rome, Italy, [4]Department of Women's and Children's Health, University of Padua, Padua, Italy, [5]Multimodal Research Area, Unit of Microbiology and Diagnostics in Immunology, Bambino Gesù Children's Hospital and Research Institute, Rome, Italy

Background & Objectives: Myofibroblastic lesions in children are a group of soft tissue proliferations including a full spectrum of benign, intermediate, and malignant neoplasms. The aim of our study was to characterize the gene expression profiles of paediatric myofibroblastic neoplasms carrying tyrosine receptor kinases (TRK) fusions and classified as Inflammatory Myofibroblastic Tumours (IMT), Infantile Fibrosarcoma (IFS) or TRK-driven mesenchymal tumours according to Paediatric tumours WHO classification 2022, in order to define their differences and the pathways responsible for their clinical diversity.
Methods: We performed unbiased transcriptome-wide RNA-sequencing analysis on all the cases of myofibroblastic neoplasms arrived at our institution in the period 2000-2023. Paired-end sequencing was performed using a NextSeq550 Illumina platform. Gene Set Enrichment Analysis was performed on DESeq2-normalized counts. Analysis results were validated using bulk transcriptomic datasets.
Results: Our analysis was performed on 46 samples including 15 IFS (7 with prominent vascular pattern, all with *ETV6::NTRK3* fusion), 4 vascular lesions from 2 patients, arising in the site of previous IFS or at a distance, all carrying the *ETV6::NTRK3* fusion, 9 IFS-like lesions, 6 TRK rearranged paediatric mesenchymal tumours and 12 IMT. RNA-seq analysis demonstrated three main groups with distinct expression profiles: IFS, IFS with prominent vascular pattern (IFSv), and IMT. Hemangiomas formed an additional small sub-cluster. IFS-like tumours (i.e. IFS showing TRK rearrangement different from *ETV6::NTRK3)* and TRK-rearranged mesenchymal tumours formed 2 heterogeneous clusters, one closely related to IMT and the other one very close to IFS. Interestingly, 2 *ETV6::NTRK3* rearranged IMT clustered with *ALK*-rearranged IMT, and 2 IFS-like lesions with *ALK* rearrangement clustered with other IFS-like lesions.
Conclusion: These preliminary results demonstrate how the molecular profile of IFS and IMT reflects and confirms their classification based on morphology and also highlight a different molecular profile in IFSv. This study may pave the way to an evolution towards an integrated classification of myofibroblastic neoplasms.

OFP-04-011

From slides to capturing the whole picture: visualization of the downstream behaviour of twin-twin anastomoses in dye-injected placentae with 3D virtual histology using X-rays

M. Utermöhlen[1,2], G. Turowski[3], M. Reichardt[2]
[1]Göttingen University Hospital, Göttingen, Germany, [2]Histomography GmbH, Göttingen, Germany, [3]Oslo University Hospital, Centre for Paediatric and Pregnancy Related Pathology, Department of Pathology, Oslo, Norway

Background & Objectives: Twin to twin transfusion syndrome (TTTS) is a complication occurring in 10-15% of monochorionic

twin pregnancies and in case of unbalanced blood flow often resulting in foetal loss without treatment. It is characterized by a disproportionate blood flow between twins due to vascular anastomoses leading to severe complications. To validate ultrasound findings and identify missed or newly developed anastomoses after laser coagulation in TTTS, dye can be injected into the umbilical cord vessels. However, deep anastomoses can be missed since gross pathology identification often does not provide the identification of both superficial and deep anastomoses in TTTS placentae. Through 3D virtual histology using X-rays and following segmentation work we are able to visualize vessel trees of dye injected TTTS placentae in 3D showcasing anastomoses with actual intersections which are important for determining a change in behaviour of said vessels.
Methods: Placentae were prepared, injected with dye, and fixed with formalin according to Turowski [3]. The FFPE samples were scanned using a laboratory phase-contrast X-ray tomography setup by Histomography GmbH. The FFPE samples were cut into histological slides and compared to the segmented vessel trees after. Segmentation was performed using the open source 3D Slicer software, marking the dyed vessels based on thresholding of the measured intensities, followed by cleaning up artifacts with Gaussian smoothing.
Results: Downstream, anastomoses were identifiable in both histological slides and the unedited tomography scans. The vessel tree can be visualized based on grey levels with VG Studio Max. The segmentation performed with 3D Slicer can be used for further analysis like intervascular connectivity and blood flow simulations.
Conclusion: Using 3D virtual histology and segmentation, we can visualize placental vessel trees in 3D, highlighting intersections critical to understanding vessel behaviour. This method can enhance understanding of TTTS and contribute to more accurate diagnostics, staging, and future research on vascular structures.

OFP-04-012
A novel pattern-based histological approach to IBD-like colitis in children with PID
H. Berber[1], N. Reisli Attar[1], S. Yüksel[1], E.F. Doğu[2], B. Savaş[1], A. Kansu Tanca[3], K.A. İkincioğulları[2], A. Ensari[1]
[1]Ankara University, Department of Pathology, Ankara, Turkey, [2]Ankara University, Department of Paediatric Allergy and Immunology, Ankara, Turkey, [3]Ankara University, Department of Paediatric Gastroenterology, Ankara, Turkey

Background & Objectives: Primary immunodeficiencies (PID) can present as very early-onset (VEO) IBD or monogenic disease (MD), associated with gene defects in mucosal immune response. We, hereby, present our PID case series using a novel pattern-based histological approach highlighting the IBD-like morphology in ileocolonic biopsies.
Methods: A total of 33(13 girls and 20 boys) PID cases with GI symptoms were retrospectively evaluated for inflammatory patterns categorized as UC-like, CD-like, enterocolitis-like, apoptotic, eosinophil-rich, IBD-unclassified (IBD-U), and mild colitis. Clinicopathological features including age at diagnosis, symptoms, genetic and survival data were assessed in correlation with histologic data.
Results: Mean age at diagnosis and symptom onset were 44 and 56.85 months, respectively. PID cases composed of 6 severe combined immunodeficiency(SCID), 4 chronic granulomatous disease, 3 common variable immunodeficiency(CVID), 2 IgA deficiency, 2 other Ig deficiencies, and 1 hyper-IgM syndrome while monogenic defects including 4 MEFV and 3 LRBA mutations, 1 IL10R deficiency, 1 IL21 deficiency, 1 DGAT mutation, 1 prolidase deficiency, 1 RIPK1 defect, 1 Bruton's tyrosine-kinase deficiency, and 2 DOCK8 deficiency were detected in the remaining 15 cases. MDs showed UC-like (n=2), CD-like (n=2), IBD-U (n=1), and 2 mixed (apoptotic+UC-like/CD-like), 1 apoptotic, 1 enterocolitis-like pattern and 2 mild colitis. Non-monogenic cases (50%) comprised of 3 UC-like, 4 CD-like, 1 IBD-U, 4 mild colitis, 2 mixed (apoptotic+IBD-U/eosinophilic), and 1 eosinophilic patterns. No significant difference was found between MD and non-MD cases for colitis patterns, age, and survival. MDs (12:3) showed a higher M/F ratio compared to non-MDs (8:10) (p=0,037). IBD-like patterns were significantly more common before the age of 6, compatible with a diagnosis of VEO-IBD (68,8%, p=0,024) which was associated with monogenic disease in 50% of the cases.
Conclusion: IBD-like colitis seems to be more common in young children with PID which emphasizes the need for a multidisciplinary approach for accurate diagnosis and treatment of monogenic disease.

OFP-05 Oral Free Paper Session Breast Pathology

OFP-05-001
Ki-67 and lymph node status as predictive biomarkers for chemotherapy decision-making in moderately differentiated breast cancer
J.C. Almeida[1,2], C. Leal[1,2], A. Marques[1,2]
[1]Unidade Local de Saúde (ULS) de São João, Department of Pathology, Porto, Portugal, [2]Faculty of Medicine of the University of Porto (FMUP), Porto, Portugal

Background & Objectives: The decision to offer or withhold adjuvant chemotherapy (aCT) in patients with moderately differentiated (grade 2) luminal breast cancer, particularly those with a Ki-67 index between 5% and 30%, remains a clinical challenge. Although molecular tests can provide helpful information, they are costly and may not be accessible. On the other hand, immunohistochemistry is a more affordable and widely accessible option.
We aim to evaluate the ability of immunohistochemistry to correctly determine molecular subgroups in grade 2 breast cancer. We also assessed the predictive value of Ki-67 expression and lymph node status (pN) in determining the need for chemotherapy.
Methods: A retrospective analysis was performed on 59 patients with grade 2 breast carcinoma who underwent surgery followed by adjuvant therapy between January 2019 and December 2022. Logistic regression models were used to evaluate the relationship between Ki-67 expression, pN, and aCT. The optimal Ki-67 cutoff for selecting patients who would benefit from chemotherapy was determined using the receiver operating characteristic (ROC) curve.
Results: The median age of the cohort was 54.3±11.9years, with a median tumour size of 18.9±13.1mm. Most tumours (86.4%) were "no special type" carcinomas, and ductal carcinoma in situ was observed in 84.7% of cases. Metastatic involvement was found in 35.1% of sentinel lymph nodes. Immunohistochemical classification using a Ki-67 cutoff of 22% showed strong agreement with PAM50/Prosigna's molecular subtypes (Cramér's V=0.476,*p=0.001*). The ROC analysis for Ki-67>19.5% showed moderate predictive ability for the benefit of aCT (AUC=0.660). Logistic regression revealed that Ki-67>19.5% (OR=9.996,*p=0.005*) and pN (OR=14.015,*p=0.002*) were significant predictors of aCT benefit.
Conclusion: Immunohistochemistry-based molecular subtyping offers a cost-effective and reliable alternative to molecular testing. Regarding aCT, our findings suggest that Ki-67>19.5% and positive pN status could potentially serve as useful biomarkers for deciding whether a patient should undergo aCT, particularly when molecular testing is not available.

OFP-05-002
Breast carcinomas with low oestrogen receptor expression (1-10%): characteristics and therapeutic implications
A.C. Santos[1], R. Rocha[1], A. Coutada[1], C. Leal[1]
[1]Portuguese Oncology Institute of Porto, Anatomic Pathology Department, Porto, Portugal

Background & Objectives: Invasive breast carcinomas with low oestrogen receptor (ER) expression (1-10%) represent a rare subgroup. The

2020 ASCO/CAP guidelines recommend reporting them separately, and the 2025 guidelines emphasize internal control assessment. This study characterizes these tumours and compares oestrogen receptor immunohistochemistry (IHC) between biopsy and surgical specimens.
Methods: We retrospectively analysed clinicopathological data of 3,851 primary invasive breast cancer biopsies at IPO Porto (July 2017–December 2024). Data included tumour size, histologic type, grade, HER2 status, hormonal receptor status, treatment modalities, and IHC reevaluation in surgical specimens.
Results: Fifty cases (1.30%) with ER 1-10% were identified in biopsy, all in females (29-92 years). Most tumours (88%) were ductal/non-special type (NST), all grade 2 and 3. Tumour size ranged from 0.6 to 7.5 cm (mean 4.1 cm). Thirty-three tumours were HER2-negative (0, 1+ and 2+ FISH negative). Posteriorly, surgical specimens from 39 patients were analysed (22 post-neoadjuvant chemotherapy [NAC], 8 with pathological complete response). Among NAC-treated patients with residual tumour, 5 lacked ER reevaluation, 2 retained ER 1-10%, 6 became ER-negative, and 1 had ER 75-100%. In the primary surgery group, 7 lacked reevaluation, 3 retained ER 1-10%, and 7 became ER-negative. Of the total 19 patients who repeated ER testing in the surgical specimen, only 5 (26.3%) retained ER 1-10%. Post-surgery, 25 patients received hormone therapy, 30 radiation therapy, and 15 anti-HER2 therapy. No local recurrence was observed; however, 11 developed distant metastases, and 7 died. In the case with ER 75-100% in the surgical specimen, biopsy was revised and internal controls were adequate, but fixation time exceeded 72 hours.
Conclusion: ER-low tumours were usually high grade and stage and significant IHC discordance between biopsy and surgical specimens was observed. Routine ER retesting in surgical specimens should be recommended to avoid losing true positive results, which could have treatment implications.

OFP-05-003
Clinicopathological and molecular features of Glycogen-Rich Breast Carcinomas
B. Karadal-Ferrena[1], J.P. Solomon[1], N. Lindeman[1], S.A. Hoda[1], B. Boyraz[1]
[1]New York-Presbyterian/Weill Cornell Medical Centre, Department of Pathology and Laboratory Medicine, New York, USA

Background & Objectives: Since its first description by Hull et al in 1981, several case series have described the clinicopathological features of glycogen-rich breast carcinoma (GRC); however, these studies often involved low number of cases, and no detailed genetic study has been performed. To enhance our understanding of this rare breast carcinoma, we conducted the largest molecular study to date with 10 GRCs to describe their genetic landscape.
Methods: 10 invasive GRCs were identified, diagnosed between 2001-2024. All were subjected to DNA sequencing using TruSight Oncology 500 panel (523 genes).
Results: All patients were female (ages: 32 to 74 years; median 51). Tumour size ranged from 0.7-3.8 cm (median 1.45). All GRCs showed relatively well-defined borders and its characteristic appearance with nests/cords formed by clear cells with glycogen accumulation in cytoplasm confirmed by PAS/PASD staining. Four were grade 2 and six were grade 3. Seven showed associated DCIS with glycogen-rich features. Lymph node metastasis was seen in 2. Eight were ER/PR+/HER2-, two were ER/PR/HER2-. Follow-up (available for 9/10) ranged from 6 to 186 months (median 38). Three patients had distant metastasis; six had no evidence of disease. DNA sequencing identified two major molecular subgroups: *GATA3*-mutant GRCs (5/10) with frequent *RPKSB1* copy number gain (4/5) and *TP53*-mutant GRCs (4/10) with a subset harbouring *BRCA1* alterations (2/4; one germline). *FGFR* family copy number gains were seen in 3/10. *TP53*-mutant GRCs were all grade 3, showed low/negative ER, and 3/4 patients showed distant metastasis while *GATA3*-mutant GRCs were mixed grade 2/3, all were ER+ without distant metastasis.
Conclusion: Two molecular subgroups of GRCs were identified: *GATA3*-mutant and *TP53*-mutant. The latter was associated with higher grade, ER-negativity and poor clinical outcome. Molecular studies or p53 immunohistochemistry as a surrogate could be helpful to identify this subgroup for closer follow-up and/or more aggressive treatment.

OFP-05-004
Integration of next-generation RNA sequencing-based MammaPrint and BluePrint analysis in clinical decision making: performance evaluation in the first 1278 cases
C. Poulios[1], B. Temmerman[2,3], S. Vander Borght[2,4], S. Claerhout[4], L. Spans[4], D. Renders[4], F. Claessens[4], P. Neven[5], H. Wildiers[6], A.-S. Van Rompuy[3,2], I. Vanden Bempt[4], G. Floris[3,2]
[1]European Society of Pathology, Brussels, Belgium, [2]University Hospitals Leuven, Pathology, Leuven, Belgium, [3]KU Leuven, Imaging and Pathology, Laboratory of Translational Cell&Tissue Research, Leuven, Belgium, [4]University Hospitals Leuven, Human Genetics, Leuven, Belgium, [5]University Hospitals Leuven, Gynaecology and Obstetrics, Leuven, Belgium, [6]University Hospitals Leuven, General Medical Oncology, Leuven, Belgium

Background & Objectives: MammaPrint and BluePrint can identify breast cancer patients with luminal disease who may forego adjuvant chemotherapy. We validated a decentralised Next-Generation RNA Sequencing-Based MammaPrint and BluePrint (RNA-seq MP/BP) using total RNA extracted from paraffin tissue. We aimed at evaluating the technical performance and feasibility of RNA-seq MP/BP in the context of a national multigene signatures (MGS) testing in Belgium.
Methods: Data on MP/BP RNA-seq tests conducted at University Hospitals Leuven (UHL) were obtained from December 2019 until December 2022. The collected metrics included failure rate, turnaround times, MP and BP indices.
Results: To date, 1278 MP/BP RNA-seq tests were analysed accounting for 40% (n=1278/3227) of total national MGS output during this period. The total test failure rate was 6.1% (n=78/1278), which was reduced to 3.8% (n=49/1278) after repetition of a failed test. The average turnaround time was 13 days [range: 9-27 days] in 2021. Tests requested by external breast clinics accounted for 73% (n=930/1278) while the remaining were requested in UHL (27%; n=348/1278). The MP/BP RNA-seq test was Low-risk/Luminal Type A in 57% (n=679/1200), High-risk/Luminal Type B in 42% (n=510/1200), High-risk/Basal type and High-risk/HER2-Type in 1% of the patients (respectively 9 and 2 cases). Further categorisation of the MP index showed MP High-risk 2 in 5.1% (n=61/1200), MP High-risk 1 in 38.3% (n=459/1200), MP Low-risk in 41.9% (n = 503/1200) and MP Ultra-low risk in 14.8% of patients (n=177/1200). Based on these results, 520/1200 patients (43.3%) would have been recommended adjuvant chemotherapy.
Conclusion: Decentralisation of the MP/BP RNA-seq test is feasible with low failure rates and acceptable turnaround time. Our results suggest that adjuvant chemotherapy could be omitted in nearly 57% of patients. Further analysis of the MP/BP RNA-seq test in clinical decision-making and clinical follow-up of patients is warranted.

OFP-05-005
PRAME expression in Triple Negative Breast Carcinomas
B. Virine[1,2], E. Slodkowska[1,2], F.-I Lu[1,2], S. Nofech-Mozes[1,2], R. Han[1,2]
[1]Sunnybrook Health Sciences Centre, Toronto, Canada, [2]University of Toronto, Department of Laboratory Medicine and Pathobiology, Toronto, Canada

Background & Objectives: Triple negative breast carcinoma (TNBC) represents a heterogenous group of neoplasms defined by the absence of hormone receptor expression and HER2 overexpression. Accurate diagnosis of TNBC can be challenging due to inconsistent expression of many breast-specific markers. PRAME has emerged as a useful diagnostic marker for melanoma, however recent studies have reported expression in breast carcinomas. Our study evaluates the expression of PRAME, in the context of other melanoma and breast-site specific markers in a large cohort of TNBCs.
Methods: Sections from tissue microarrays (TMAs) composed of 316 TNBC in triplicate 1 mm cores were immunostained for PRAME, pankeratin (AE1/AE3) (PANK), GATA3, K7, SOX10, S100, HMB45 and Melan-A using standardized protocols. PRAME was scored according to the proportion of tumour cells with positive expression. Staining intensity and the cellular compartment of staining were also assessed. Weak nuclear expression of PRAME in >25% of cells or moderate to strong nuclear expression in any portion of cells were classified as positive. The remaining markers were scored using a modified Allred method. Histologic tumour types were assigned according to the WHO classification.
Results: Over half (51.9%) of the TNBCs showed nuclear expression of PRAME. Of these, 77.4% expressed SOX10, 75.0% expressed S100, 3.7% expressed HMB45 and 1.2% expressed Melan-A. Only 1.2% of PRAME positive cases did not co-express PANK, K7, or GATA3. 11.1% of TNBCs expressed PRAME, but not SOX10, S100, HMB45 or Melan-A. Strong cytoplasmic PRAME expression was associated with apocrine carcinoma or tumours with apocrine features (specificity=98.9%, sensitivity=43.2%).
Conclusion: Nuclear expression of PRAME is common in TNBC, frequently occurring in cases co-expressing other melanoma markers and rarely in cases with no expression of PANK, CK7, or GATA3. The findings underscore the importance of utilizing a panel of markers in accurately distinguishing TNBC from melanoma.

OFP-05-006
Predicting therapy response in triple negative breast cancer by applying DNA methylation profiling
T.F.J. Kraus[1], O. Wehnert[1], B. Alinger-Scharinger[1], K. Sotlar[1]
[1]Institute of Pathology, University Hospital Salzburg, Salzburg, Austria

Background & Objectives: Breast cancer (BC) is the most prevalent form of cancer among women. Therapy is contingent upon the biological profile underlying the specific type of breast cancer, including factors such as hormone receptor expression, Her2 status, and proliferative activity. Depending on the tumour subtypes, patients with BC receive individualized treatments. Triple-negative breast cancer (TNBC) is characterized by its highly aggressive tumour biology. The standard systemic treatment for TNBC is chemotherapy. In many cases, TNBC undergoes neoadjuvant therapy prior to surgical intervention with the aim of reducing tumour mass. However, only a subset of tumours show therapeutic response that is characterized by the residual cancer burden (RCB). The present study aims to predict therapy response in patients diagnosed with TNBC by applying DNA methylation profiling.
Methods: In this study, we performed epigenome-wide methylation analysis on 24 TNBCs, with 12 cancers demonstrating good therapy response (RCB 0) and 12 exhibiting poor therapy response (RCB 2). Utilizing the Illumina Infinium EPIC V2 bead chip array, we were able to interrogate more than 935,000 methylation-sensitive CpG sites in parallel. Subsequent computational analyses were then performed to identify differentially methylated genes. Gene ontology (GO) analyses were processed to reveal altered pathways.
Results: A computational analysis revealed that there were distinct epigenomic differences in the two TNBC subgroups of RCB 0 and RCB 2. Differential methylation analysis revealed distinct differences in the DNA-methylation landscape. GO analysis indicated that RNA processing emerged as the most significantly differentially methylated pathway.
Conclusion: In summary, our findings demonstrate that DNA methylation profiling serves as a valuable tool in breast cancer research. Our findings reveal substantial disparities in the DNA methylation signatures between TNBC of RCO 0 and RCB 2. These findings have the potential to serve as valuable predictors of therapy response status.

OFP-05-007
Multi-site study of an AI solution as clinical decision-support tool for the identification of microinvasive and T1a carcinomas of the breast
R. Canas-Marques[1], C. Karakas[2], D. Mevorach[3], S.E. Bachert[4], M. Gomez[5], J. He[5], E. Shearon[6], R. Ziv[3], J. Sandbank[3,7], M. Vecsler[3], S.J. Schnitt[4]
[1]Champalimaud Foundation, Anatomic Pathology, Lisboa, Portugal, [2]Standford University, Department of Pathology, Palo Alto, USA, [3]Ibex Medical Analytics, Tel Aviv, Israel, [4]Brigham and Women's Hospital, Dana-Farber Cancer Institute, Harvard Medical School, Boston, USA, [5]University of Texas Medical Branch, Department of Pathology, Galveston, USA, [6]Alverno Laboratories, Hammond, USA, [7]Maccabi Healthcare Services, Institute of Pathology, Rehovot, Israel

Background & Objectives: Histologic identification of small foci of invasive breast cancer (BC) is challenging and time-consuming. We assessed the accuracy of pathologists supported by an artificial intelligence (AI) breast H&E solution vs. those not assisted in identifying microinvasive (MI) and T1a BC associated with DCIS.
Methods: This two-arm multi-reader study compared 4 pathologists' ("readers") performance in the evaluation of 200 digitized H&E slides of BC biopsies from two different US and EU centres, without and with a fully automated AI breast solution. Pathologists' accuracy in both arms compared to ground truth (GT) and review time were analysed. GT was established by 3 expert breast pathologists. Cases were enriched for DCIS with potential confounding features (e.g., stromal chronic inflammation, lobular involvement).
Results: The four pathologists evaluated each case twice, once in each study arm separated by a wash-out period of two weeks. Pathologists supported by AI showed significantly higher accuracy in identifying MI and invasive carcinoma or foci suspicious for invasive carcinoma compared to pathologists without AI (84.2% vs 78.8%, p=0.045). In addition, the use of AI reduced the time required to evaluate MI+pT1a cases from a mean of 92 seconds without AI to 79 seconds with AI.
Conclusion: The AI solution demonstrated significantly improved detection of MI and pT1a BC, despite coexistent DCIS enriched for potentially confounding alterations. In addition, the use of the AI solution reduced the time required for slide evaluation in MI and T1a cases by 14%. This approach holds promise for enhancing diagnostic accuracy and consistency in the detection of MI and T1a BC, enhancing pathologist workflow, and reducing the time spent identifying small foci of BC.

OFP-05-008
A model of sensitive tissue transfer for breast reconstruction - the rat neurotized epigastric flap
M. Patrício[1], R. Moiteiro da Cruz[2], A. Gião[1], A. Varanda Pereira[1], D. Casal[3,4], S. Alves[3,5], D. Pinto[5], M.M. Novo[6]
[1]Anatomy Department, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal, [2]Pathology Department, Hospital de Santa Maria, ULS Santa Maria, Lisbon, Portugal, [3]Anatomy Department, NOVA Medical School, Universidade NOVA de Lisboa, Lisbon, Portugal, [4]Plastic Surgery Department, Hospital de São José, Unidade Local de Saúde São José, Lisbon, Portugal, [5]Pathology Department, Hospital de São José, Unidade Local de Saúde São José, Lisbon, Portugal,

[6]Pathology Department, Hospital Professor Doutor Fernando Fonseca; Unidade Local de Saúde Amadora/Sintra, Lisbon, Portugal

Background & Objectives: Sensory recovery is a key outcome in breast reconstruction, with abdominal wall-based flaps being the gold standard for autologous tissue transfer. Although neurotization offers significant benefits, its technical complexity hinders widespread implementation. A precise histological understanding of these flaps is essential for optimizing sensory restoration. The rat epigastric flap is a widely used model due to its anatomical resemblance to humans, but its neurohistology remains poorly studied. This study aims to characterize the rat's neurotized epigastric flap, highlighting its sensory nerve components and relevance for surgical applications.
Methods: An observational cross-sectional study was conducted on twenty murine models. The caudal epigastric nerve and the 10th to 12th intercostal nerves as well as samples from the rats abdominal skin were dissected and histologically processed. Haematoxylin-eosin and Masson's trichrome staining were performed, along with immunohistochemistry using anti-neurofilament antibodies (neuronal identification), Peripherin (sympathetic fibres), Annexin V (sensory fibres), and anti-PIEZO2 (mechanoreceptors). Microscopic analysis focused on nerve fiber types and cutaneous receptor density, classification and distribution relative to the dermo-epidermal junction.
Results: Histological analysis enabled a detailed characterization of the neuronal structures within the flap skin, including nerve fiber density, type, and receptor distribution. Findings revealed significant similarities between the rat and human ventrolateral abdominal skin, supporting the validity of this model for sensate tissue transfer research.
Conclusion: The neurohistological features of the rat neurotized epigastric flap reinforce its relevance for studying sensory nerve restoration in reconstructive surgery. This detailed analysis enhances understanding of flap neuroanatomy, providing a foundation for optimizing neurotization techniques and enhancing microsurgical training.

OFP-05-009

Hypoxia-induced CAIX expression restricts CD8+ T-cell infiltration in breast cancer

P. Juhasz[1], D. Hasulyó[1], J. Bedekovics[1], L. Beke[1], N. Kacsala[2], M. Török[1], G. Méhes[1]
[1]University of Debrecen, Debrecen, Hungary, [2]University of Pécs, Pécs, Hungary

Background & Objectives: Hypoxia and necrosis are common features of invasive cancer. In solid tumours, including breast carcinoma, the dynamic upregulation of carbonic anhydrase IX (CAIX), induced by hypoxia-inducible factor 1 (HIF-1), supports cellular adaptation to hypoxia. CAIX activity contributes to extracellular acidosis and reshapes the tumour microenvironment, impacting tumour behaviour and prognosis. This study aimed to assess the mass and distribution of the immune infiltrate—specifically CD8+ effector T-cells—in relation to tumoral CAIX expression.
Methods: Formalin-fixed, paraffin-embedded breast carcinoma sections were analysed via double immunohistochemical staining for CAIX and CD8. Digital slides were evaluated using HistoQuant (3DHistech) image analysis software to quantify CD8+ signal within and outside CAIX-positive tumour areas. Statistical analysis was performed using GraphPad Prism.
Results: Among 34 breast carcinomas, 18 were partially CAIX-positive, and 16 were CAIX-negative controls. Necrotic foci were associated with CAIX overexpression, and tumours with necrosis showed significantly higher relative CAIX expression than those without (11.47 ± 5.51 vs. 3.77 ± 3.5; $P = 0.0216$). However, relative CD8+ lymphocyte counts did not differ significantly between necrotic and non-necrotic cases (134.7 ± 55.7 vs. 97.7 ± 57.25; $P = 0.1579$). Similarly, no significant difference was observed in overall CD8+ T-cell infiltration between CAIX-positive and -negative tumours (98.5 ± 37.3 vs. 96.0 ± 50; $P = 0.5928$). Notably, in CAIX-positive tumours, CD8+ T-cell distribution correlated with the extent of CAIX expression. Within individual tumours, CD8+ T-cell counts were significantly lower in CAIX-positive versus CAIX-negative areas (13.1 ± 9.4 vs. 135.6 ± 62.2; $P < 0.0001$).
Conclusion: These findings suggest that CAIX-expressing tumour regions may hinder CD8+ T-cell infiltration, and that the hypoxia-driven tumour microenvironment could limit the efficacy of immune and targeted therapies requiring intact T-cell responses.

OFP-05-010

Multi-centre NHS evaluation of artificial intelligence as a decision support solution for breast cancer diagnosis: accuracy and early efficiency results from the DEBORAH study

E. Provenzano[1], P. Schouten[1], D. Bailey[2], A. Abbas[3], A. Gunavardhan[4], A. Shaaban[5], S. Ambrogio[6], M. Vecsler[7]
[1]Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom, [2]North West Anglia NHS Foundation Trust, Peterborough, United Kingdom, [3]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom, [4]Betsi Cadwaladr University Health Board, Ysbyty Gwynedd, United Kingdom, [5]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom, [6]Ibex Medical Analytics, London, United Kingdom, [7]Ibex Medical Analytics, Tel Aviv, Israel

Background & Objectives: This study investigates the performance of a commercial AI solution across a prospective consecutive patient cohort from five NHS hospitals (UK), while exploring its accuracy and contribution to enhancing diagnostic efficiency in the breast pathway.
Methods: The diagnostic performance of the AI solution was evaluated in an observational study involving over 3,000 consecutive patients undergoing breast biopsy. Initial diagnoses were made by pathologists following standard of care procedures, without AI support, within digital pathways. After issuing a preliminary report, pathologists reviewed the AI-generated findings and compared outcomes specifically in the classification of Benign, Cancer, Invasive Cancer, and DCIS. Efficiency metrics, including number of patients, turnaround time (TAT) and immunohistochemistry (IHCs) tests, were extracted from operational data in the Laboratory Information Management Systems (LIMS). The study is ongoing and will compare results from six months prior to AI deployment with six months after its integration into the workflow.
Results: When differentiating between cancerous and benign cases, the AI system demonstrated a sensitivity of 100%, specificity of 99.6%, positive predictive value (PPV) of 99.5%, and negative predictive value (NPV) of 100%. For invasive carcinoma detection, it showed a sensitivity of 99.5%, specificity of 99.8%, PPV of 99.5%, and NPV of 99.8%, while for DCIS diagnosis, the AI's sensitivity was 98.9%, specificity of 99.9%, PPV of 98.9%, and NPV of 99.9%. Early efficiency findings from one hospital indicate a 21% increase in productivity and a 73% reduction in diagnostic IHCs for benign cases, such as p63, CK7, and CK5/6. User feedback suggests that the IHC reduction is driven by increased pathologist confidence in signing off benign cases without additional tests.
Conclusion: The AI solution demonstrated high diagnostic accuracy and encouraging improvements in efficiency, including increased productivity and reduced IHC requests, suggesting its potential to enhance workflow in breast cancer pathology, leading to improved patient outcomes.

Funding: This project has received funding from the Artificial Intelligence (AI) in Health and Care Award, which is an NHS AI Lab programme run by the Accelerated Access Collaborative (AAC) in partnership with the National Institute for Health Research (NIHR)

OFP-05-011

Different HER2 immunoreactivity in biopsies compared to corresponding surgical specimens of invasive breast carcinomas with potential therapeutic implications

S. Bracic Tomazic[1], O. Scheiber[1], D. Kriegl[2], H. Hauser[3], C. Suppan[4], G. Rinnerthaler[4], S. Lax[1,5]

[1]Hospital Graz II, Styrian Hospital Corporation, Academic Teaching Hospital of the Medical University of Graz, Department of Pathology, Graz, Austria, [2]Hospital Graz II, Styrian Hospital Corporation, Academic Teaching Hospital of the Medical University of Graz, Department of Radiology, Graz, Austria, [3]Hospital Graz II, Styrian Hospital Corporation, Academic Teaching Hospital of the Medical University of Graz, Department of Surgery, Graz, Austria, [4]University Clinic of Internal Medicine, Medical University Graz, Department of Oncology, Graz, Austria, [5]School of Medicine, Johannes Kepler University, Linz, Austria

Background & Objectives: HER2 analysis by immunohistochemistry and in situ hybridization (ISH) for immunoreactive score (IRS) 2+ is standard for invasive breast carcinomas (IBC) and performed on diagnostic biopsies. Recently, non-amplified HER2 was reclassified as HER2 low (IRS 1+ and IRS 2+/non-amplified) and HER2 ultralow (IRS 0 with <10% positivity), respectively, considering response to antibody-drug conjugates (ADC). We routinely repeat HER2 on the surgical specimen. The aim of this study was to compare HER2 expression between biopsies and surgical specimens with emphasis on HER2 low and ultralow categories.

Methods: We searched for breast biopsies and corresponding surgical specimens from 2024. The HER2 reports were retrieved and compared using 2023 ESMO guidelines. Discrepant cases were reviewed. In our lab, HER2 testing is highly standardized and regularly checked by robin round trials.

Results: For 158 patients corresponding biopsies and surgical specimens were available. In the biopsy group 6.9% were HER2 negative, 8.9% ultralow, 70.9% low and 13.3% positive whereas in the surgical group 12.6% were HER2 negative, 22.2% HER2 ultralow, 55.7% low and 9.5% positive. These differences were statistically significant (p=0.001; chi^2 test) with 51 cases (32.2%) discrepant cases: downgrade from biopsy to surgical in 44 cases, upgrade in 7 cases. Downgrade involved IRS 2+ (low) amplified to non-amplified (6; 3.8%), low to ultralow (26; 16.5%) and low to negative (8; 5%). Upgrades involved negative to ultralow (1.2%), negative to low (0.6%) and ultralow to low (2.4%). All IRS 3+ cases remained positive.

Conclusion: HER2 low and ultralow and low HER2 amplification is detected more frequently in IBC biopsies compared to surgical specimens, which may have therapeutic implications on adjuvant anti-HER2 and ADC therapy. These discrepancies may be influenced by preanalytical and analytical conditions and highlight the necessity of standardized companion testing. The use of artificial intelligence for HER2 assessment may be considered.

OFP-05-012

Can criteria from DCIS de-escalation trials be used to select for atypical ductal hyperplasia with low risk of upgrade to carcinoma?

C. Albarracin[1], S. Zaveri[2], S. Sun[3], T. Bevers[4], I. Bedrosian[31]Univ of Texas MD Anderson Cancer Centre, Pathology, Houston, USA, [2]Univ of Texas MD Anderson Cancer Centre, Surgery, Houston, USA, [3]Univ of Texas MD Anderson Cancer Centre, Breast Surgical Oncology, Houston, USA, [4]Univ of Texas MD Anderson Cancer Centre, Cancer Prevention, Houston, USA

Background & Objectives: De-escalation of surgical treatment of low-risk DCIS is under active investigation. However, surgical excision remains the standard of care in the management of atypical ductal hyperplasia (ADH) diagnosed on core biopsy. This study examines the use of criteria from the DCIS de-escalation trials to identify ADH cases with low risk of upgrade to carcinoma.

Methods: A registry of ADH patients from 2004 to 2022 was reviewed for cases treated with surgical excision. Criteria from the COMET DCIS surgical de-escalation trial applicable for ADH including age, imaging findings and personal history of breast cancer were evaluated and rates of upgrade to carcinoma were compared in patients who would and would not meet these criteria.

Results: Of 362 ADH cases treated with surgical excision, 233 (64.4%) met trial criteria for de-escalation (Cohort 1) (patient age >40y, no mass lesions, no previous cancer in the ipsilateral breast within the last 5 years, and no concurrent cancer) and 129 (35.6%) did not meet these criteria (Cohort 2). The age at surgical excision, race, breast density or lesion size on imaging was not significantly different between two cohorts. Cohort 1 patients were more likely to have been diagnosed by mammography (94% vs 72%, $p<0.0001$) and more likely to present with calcifications (82% vs 30.2%, $p<0.0001$). While there was no significant difference in rate of ADH upgrade to DCIS between the two cohorts, there was a significantly lower rate of ADH upgrade to invasive disease in Cohort 1 (3.43%) compared to the cohort that did not meet the selected trial criteria for surgical de-escalation (10.85%) ($p<0.010$).

Conclusion: Our data show a very low rate of ADH upgrade to invasive disease in patients who meet criteria from trials of surgical de-escalation for DCIS, suggesting that such patients could also be considered a low-risk cohort for whom observation may be appropriate.

OFP-06 Oral Free Paper Session Soft Tissue and Bone Pathology

OFP-06-001

A clinicopathological analysis of 42 cases of paratesticular tumours in orchiectomies

A. Noyan[1], G. Guner Gebes[1], K. Kosemehmetoglu[1]

[1]Hacettepe University Medical School, Department of Pathology, Ankara, Turkey

Background & Objectives: Due to their low incidence, paratesticular tumours pose a diagnostic challenge for many pathologists. Therefore, understanding the diagnostic spectrum is crucial. This study aims to showcase the cases retrieved from our archives and provide a detailed analysis of the clinicopathological characteristics of this rare group of tumours.

Methods: A retrospective analysis was conducted on orchiectomies from 2014 to 2025. Cases of paratesticular tumours were selected and reviewed in terms of clinical, morphological, and molecular characteristics.

Results: Paratesticular tumours comprised 42 of 567 (%0.07) orchiectomies. The mean age was 45.3 (5-89). Liposarcoma was the most common diagnosis (19 cases, 45%) followed by rhabdomyosarcoma (14 cases, 33%) and leiomyosarcoma (4 cases, 10%). Liposarcomas included dedifferentiated (11 cases), well-differentiated (7) and myxoid (1) subtypes. Rhabdomyosarcomas were mostly embryonal (11 cases), with spindle-cell (2) and pleomorphic (1) variants. Other diagnoses included mesothelioma (2), myeloid sarcoma (1), aggressive angiomyxoma (1), and cellular angiofibroma (1). Liposarcomas were more common in patients older than 50 (mean: 63), while rhabdomyosarcomas were commonly seen in younger patients (mean: 17). The average tumour size was 6.1 cm (26 cases). Surgical margins were positive in 12 cases (29%). In 7 cases, the diagnosis required a molecular test; RT-PCR for *PAX3/7::FOXO1A* or *MDM2* and *DDIT3* FISH. Follow-up data (n=29, median: 12.5 months) showed recurrence in 3 cases and metastases in 6 cases. Nine patients died of disease (3 rhabdomyosarcomas, 3 liposarcomas, 1 leiomyosarcoma, 1 mesothelioma, and 1 myeloid sarcoma).

Conclusion: Paratesticular tumours are rare comprising <1% of orchiectomies. In this large series, nearly 90% of the tumours are

liposarcomas, leiomyosarcomas, and rhabdomyosarcomas, depending on age. In selected cases, molecular support is helpful in differential diagnoses such as leiomyosarcoma versus liposarcoma, and subtypes of rhabdomyosarcomas and liposarcomas. Orchiectomy may not achieve clear surgical margins and prognosis is poor, with one-third of patients succumbing to disease.

OFP-06-002

Soft tissue and bone tumours in a sarcoma reference centre: a retrospective study of 4163 cases in its 8-year existence

A. Gradil[1], M. Pinho Fialho[1], J. Santos[1], D. López-Presa[1]
[1]Unidade Local de Saúde Santa Maria, Lisbon, Portugal

Background & Objectives: Soft tissue and bone tumours constitute a heterogeneous group with an often-overlapping morphology, making accurate diagnoses a challenge. This study aims to describe the caseload at our Sarcoma Reference Centre (SRC) and to assess the degree of agreement between biopsy and surgical specimens.
Methods: A retrospective analysis of soft tissue and bone tumours was performed at the ULSSM in Lisbon, Portugal, from 2017 until 2024, since becoming a SRC. Pathology reports with diagnoses currently listed in the WHO Soft tissue and bone tumour classification volume (5^{th} edition, 2020) were selected. For each case, patient demographics and tumour features (e.g. location, behaviour, histogenesis groups, entity, grade, immunohistochemistry - IHC - and molecular profiles) were analysed.
Results: During this timeframe, the exams performed at the SRC doubled. Among 3607 patients, 4163 diagnoses were made, of which 2947 were benign lesions, 855 malignant lesions, 305 showed intermediate behaviour; the remaining 56 cases were inadequate for diagnosis. Across all histogenesis groups listed in the WHO, benign adipocytic and vascular tumours were the most frequent. Of the 4163 diagnoses, 668 pertain to patients with over 1 exams/diagnosis, of which only 320 had matching biopsy-surgical specimen pairs reported at our SRC; of these, 97%, 86% and 86% were given matching behaviour, entity and grade, respectively. Of the 202 reviewed cases from other centres, 21 were different from the entity/differential diagnoses considered at our SRC.
Conclusion: The demographics and epidemiology reported in this study are similar to those documented in the literature for soft tissue and bone tumours. Most of these tumours can be diagnosed based on morphology alone, if evaluated by experienced soft tissue and bone tumour pathologists. Considering the increasing molecularly defined entities, access to IHC and molecular testing is often available only at SRC, enabling a more accurate and swift diagnosis, ultimately optimizing patient treatment and prognosis.

OFP-06-003

Giant Cell Granuloma of jaw: a study on demographics, aggressiveness, and recurrence of a benign hidden threat

A. Toklu[1], A. Coşkun[2], M. Sezak[1], H. Koca[2], A. Biçer[3], K. Öztürk[4], A. Veral[1], B. Doğanavşargil[1]
[1]Ege University Faculty of Medicine, Department of Pathology, Izmir, Turkey, [2]Ege University Faculty of Dentistry, Department of Oral And Maxillofacial Surgery, Izmir, Turkey, [3]Ege University Faculty of Medicine, Department of Plastic and Reconstructive Surgery, Izmir, Turkey, [4]Ege University Faculty of Medicine, Department of Ear Nose and Throat Disease, Izmir, Turkey

Background & Objectives: Giant cell (reparative) granuloma (GCG) is a benign but locally aggressive lesion primarily affecting the jawbones,with a risk of recurrence after treatment.
Methods: This study evaluates the clinicopathological characteristics of 302 cases analysed through 364 biopsies between 2010 and 2025 at a single pathology centre. Age, gender, localization, recurrence, and associated diseases were assessed using nonparametric statistical tests.
Results: Females constituted 59% (n=179) of cases, with a median age of 46±20.9 years (range: 3–95 years). The mandible was the most affected site (59.7%, n=92). Recurrence was observed in 55 cases (18.2%), with a higher frequency in females (70.9%, p=0.035, chi-square). The earliest recurrence occurred within one year, while the latest was ten years post-diagnosis. Six cases experienced multiple recurrences. Surgical management required mandibular resection (n=2) and maxillectomy (n=2). Parathyroid pathology was detected in seven recurring cases (five adenomas, one hyperplasia, one carcinoma). Two cases were initially misdiagnosed as pyogenic granuloma before a definitive GCG diagnosis. No significant correlation was found between recurrence and age or lesion localization.
Conclusion: Our findings align with previous literature regarding demographic distribution. The recurrence rate (18.2%) falls within the reported range of 5%–70.6%. Higher recurrence is often associated with incomplete excision, particularly in central GCGs. Cases with multiple recurrences should raise suspicion for hyperparathyroidism-related giant cell lesions, which histologically resemble GCG. Improved histological biomarkers and surgical techniques are needed to predict disease outcomes and reduce recurrence, as multiple recurrences complicate the clinical course.

OFP-06-004

Clinico-pathological analysis of 19 osteofibrous dysplasias and 25 adamantinomas with respect to the current WHO classification: a single institution experience over 12 years

R. Jayan[1], B. Rekhi[1], M. Ramadwar[1], P. Panjwani[1]
[1]Tata Memorial Hospital, Pathology, Mumbai, India

Background & Objectives: Osteofibrous dysplasia (OFD) and adamantinoma are rare bone tumours. The present study provides a detailed clinicopathological evaluation of these tumours.
Methods: OFDs and adamantinomas diagnosed from 2012 to 2024 were retrieved. Additionally, tumours diagnosed as fibrous dysplasia (FD) and intra-osseous synovial sarcoma of the tibia and the fibula were retrieved. Fifty-five tumours were reviewed. Finally, 19 OFDs and 25 adamantinomas were included. The initial diagnosis was revised in 12/55 (21.8%) tumours. In addition to the tibia and the fibula, a single adamantinoma occurred in the metatarsal bone.
Results: Among 25 adamantinomas, there was a single OFD-like adamantinoma and 24 classic adamantinomas with various morphological patterns, most frequently tubular and basaloid. OFD-like areas were noted in 6/24 (25%) classic adamantinomas. Pan keratin was positive in scattered cells in 18/19 (94.7%) OFDs and 16/17 (94%) adamantinomas. P40 (4/4,100%) and p63 (4/6,66.7%) were useful in diagnosing adamantinomas. None of the OFDs, on follow-up (n=16) progressed to an adamantinoma during a median follow-up duration of 51.15 months. Four patients harbouring adamantinomas developed recurrences (4/25,16%), and four developed metastasis (4/25,16%) to the lungs and regional lymph nodes.
Conclusion: This constitutes the largest series of OFDs and adamantinomas from our subcontinent as per the recent WHO classification. These tumours are associated with errors in interpretation. Testing FD, especially in the tibia/fibula for keratin, is useful to avoid missing an OFD. A cluster of 3 or more keratin-positive cells in a fibro-osseous neoplasm indicates an OFD-like adamantinoma, which is rare. Although a morphological continuum was seen between OFD and adamantinoma, no OFD progressed to an adamantinoma. Given treatment-related implications, it is crucial to distinguish an OFD, OFD-like adamantinoma, and classic adamantinoma, from their mimics, especially synovial sarcoma from spindle cell adamantinoma. The

risk factors for recurrence and metastasis in adamantinomas include an incomplete curettage and a spindle cell pattern.

OFP-06-005

RNA sequencing expands the molecular spectrum of chondromyxoid fibroma: a multicentric study within the ResOs french network

C. Bontoux[1], F. Larousserie[2], N. Weingertner[3], M. Csanyi[4], L. Galmiche[5], P. Drabent[6], C. Bouvier[7], A. Coulomb[8], C. Galant[9], A. Sassi-Benna[10], I. Pommepuy[11], S. Valmary-Degano[12], D. Grand[1], M. Larquier[1], H. Reboul[1], G. de Pinieux[13], S. Evrard[1], A. Gomez-Mascard[1]
[1]IUCT-Oncopole, Pathology, Toulouse, France, [2]Hôpital Cochin-APHP, Pathology, Paris, France, [3]CHU Strasbourg, Pathology, Strasbourg, France, [4]CHU Lille, Pathology, Lille, France, [5]CHU Nantes, Pathology, Nantes, France, [6]Hôpital Necker-APHP, Pathology, Paris, France, [7]Hôpital de la Timone-APHM, Pathology, Marseille, France, [8]Hôpital Trousseau-APHP, Pathology, Paris, France, [9]Cliniques Universitaires Saint-Luc (UCLouvain), Pathology, Bruxelles, France, [10]CHU Nancy, Pathology, Nancy, France, [11]CHU Limoges, Pathology, Limoges, France, [12]CHU Grenoble, Pathology, Grenoble, France, [13]CHU Tours, Pathology, Tours, France

Background & Objectives: Chondromyxoid fibroma (CMF) is a rare locally agressive bone tumour whose diagnosis could be difficult in small biopie samples. Previous studies have identified GRM1 overexpression as a hallmark of the tumour, which is associated with *GRM1* rearrangements in a subset of cases. However, the full spectrum of fusion partners remains only predicted. We aim to characterize the clinical, phenotypical, and molecular features of CMF, particularly focusing on identifying novel *GRM1* fusion partners.
Methods: We conducted a retrospective multicentric study including 95 CMF samples from 85 patients diagnosed in twelve centres. We analysed clinicopathological data and phenotypic features. Targeted RNA sequencing was performed using our in-house developed NGS assay, with validation through orthogonal molecular techniques (FISH) where applicable.
Results: Media age at diagnosis was 33 [IQR:20-43] with a female/male sex ratio of 0.85. Main localizations were long bones of lower limb (35%), feet bones (28%) and flat bones (22%). Median size at diagnosis was 28 mm [IQR:20-37.25]. Sensitivity of GRM1 immunohistochemistry was 95%.
RNA sequencing analysis was performed on 74 samples. We identified nineteen *GRM1* fusion partners in twenty-nine cases (39%) including previously reported *BCLAF* gene (five cases) and novel *AOPEP* gene fusion partner (five cases). 8/19 fusion partners (42%) were located on chromosome 6, same as *GRM1*. Eleven cases (15%) were wild-type (WT) and thirty-four cases (46%) were non-contributive due to decalcification process. Eight patients relapsed during follow-up, six out of them were WT. Additional molecular testing and validation using *GRM1* FISH, notably for WT cases, is ongoing.
Conclusion: Our study represents one of the largest CMF cohorts analysed to date and highlights the utility of GRM1 immunohistochemistry and RNA sequencing in aiding the differential diagnosis of CMF. Morevover, the identification of novel *GRM1* fusion partners expand the known molecular spectrum of CMF and may contribute to a deeper understanding of its pathogenesis.

OFP-06-006

A clinicopathologic and molecular characterization of 15 distinctive hyalinizing spindle cell neoplasms of soft tissue with MUC4 and beta-catenin co-expression and frequent biallelic inactivation of *APC*

F. Repetto[1], I. Odintsov[1], L.M. Sholl[1], J.L. Hornick[1], W.J. Anderson[1]
[1]Mass General Brigham and Harvard Medical School, Department of Pathology, Boston, USA

Background & Objectives: MUC4 and beta-catenin are two important immunohistochemical markers that have well established applications in the diagnosis of fibroblastic soft tissue tumours. The former is highly specific for the related entities low-grade fibromyxoid sarcoma and sclerosing epithelioid fibrosarcoma, while the latter is commonly positive in desmoid fibromatosis and Gardner fibroma. It is generally considered that expression of these markers is mutually exclusive. In this study, we describe the clinicopathologic and molecular features of a group of distinctive fibroblastic soft tissue neoplasms characterized by consistent co-expression of MUC4 and beta-catenin.
Methods: Fifteen hyalinized spindle cell neoplasms with MUC4 and beta-catenin co-expression were identified from our institutional archives. Targeted DNA sequencing was performed on 9 tumours. In a subset, FISH was performed to assess for *FUS* and/or *EWSR1* rearrangement.
Results: The cohort comprised 15 adult patients (6 female, 9 male) with a median age of 40 years (range 20–61). No patients had a known history of familial adenomatous polyposis. Tumours were located in the extremities (9), trunk (5), and retroperitoneum (1). The tumours consisted of a hypocellular proliferation of spindled-to-stellate fibroblastic cells in a variably hyalinized collagenous stroma. No atypia, fascicular growth, or myxoid stroma was present. Sequencing demonstrated biallelic *APC* inactivation in 7/8 (86%) tumours successfully assessed. Variant allele frequencies were consistent with somatic rather than germline events. No gene fusions were detected. None of the tumours assessed with FISH showed *FUS* (0/9) or *EWSR1* (0/8) rearrangement. Clinical follow-up data are pending.
Conclusion: We describe a novel fibroblastic neoplasm of soft tissue characterized by co-expression of MUC4 and beta-catenin and frequent underlying *APC* inactivation. Our findings support that this represents a distinct soft tissue tumour type that is important to distinguish from LGFMS/SEF, as well as desmoid fibromatosis and Gardner fibroma.

OFP-06-007

Tertiary lymphoid structures in soft tissue sarcomas: prognostic and molecular associations

A. Fedorova[1,2], A. Shvyrkova[2], K. Kryukov[2], L. Zuguo[3], M. Babak[4], V. Kushnarev[2,5]
[1]Dmitry Rogachev National Research Centre of Paediatric Haematology, Oncology and Immunology of Ministry of Healthcare of the Russia, Pathology Department, Moscow, Russia, [2]Higher School of Oncology, Pathology Department, St. Petersburg, Russia, [3]Southern Medical University Shenzhen Hospital, Department of Pathology, Shenzhen, China, [4]City University of Hong Kong, Department of Chemistry, Hong Kong, China, [5]BostonGene Technologies, Multiomics Data Integration Group, Yerevan, Armenia

Background & Objectives: Tertiary lymphoid structures (TLSs) have been linked to improved outcomes in several cancers, but their role in soft tissue sarcomas is unclear. We integrated histopathological TLSs evaluation on H&E with RNA-seq data, correlating morphometric and spatial features with survival, molecular profiles, and a 12-chemokine TLSs gene signature.
Methods: We evaluated tertiary lymphoid structures (TLSs) in 191 soft tissue sarcoma (STS) samples from The Cancer Genome Atlas, integrating whole-slide imaging in QuPath for morphological assessment on H&E. TLSs density and area were calculated per tumour region (intra-, border-, extratumoral), along with overall TLSs score (number of TLSs inside+border). For transcriptional analysis, RNA-seq count files were obtained from the Genomic Data Commons. Patient stratification was based on the median score of a summed 12-chemokine genes generated signature score (*CCL2*, *-3*, *-4*, *-5*, *-8*, *-18*, *-19*, *-21*, *CXCL9*, *-10*, *-11*, *-13*). Spearman correlation, Kaplan–Meier, and Cox proportional-hazard models were performed with Python libraries (lifelines 0.30).

Results: TLSs were present in 74 of 191 (39%) STS samples. Median TLSs density reached 0.0215/mm² (range 0.0032–0.4957), with dedifferentiated liposarcoma showing the highest burden. Only 2 TLSs-positive cases (2.7%) displayed germinal centres. TLSs score correlated moderately with the 12-chemokine signature (Spearman r=0.428, p=6.38×10^{-10}). TLSs absence trended toward worse overall and recurrence-free survival in Kaplan–Meier analyses, while higher TLSs density suggested more favourable outcomes. However, univariate Cox models showed no statistical significance for TLSs parameters (p=0.732). By contrast, the 12-chemokine signature approached borderline significance (HR=0.891, 95% CI 0.779–1.019, p=0.092).
Conclusion: Though not definitively significant, the robust correlation between TLSs burden and the 12-chemokine signature underscores an immune-mediated advantage in STS. Larger, multicentre cohorts with deeper immunophenotyping are essential to further confirm TLSs prognostic utility and inform prospective immune-targeted therapeutic interventions.

OFP-06-008

Comprehensive analysis of m6A RNA methylation regulators in soft tissue leiomyosarcoma

T. Iwasaki[1], M. Masunaga[1], Y. Oda[1]
[1]Kyushu University, Anatomic Pathology, Fukuoka, Japan

Background & Objectives: N6-methyladenosine (m6A) is a prevalent RNA modification involved in various biological processes, including carcinogenesis, tumour progression, and immune regulation. This study aimed to investigate the role of m6A regulatory genes—including METTL3, METTL14, WTAP, FTO, ALKBH5, and YTHDF1–3—and their associations with c-MYC and programmed death ligand 1 (PD-L1) expression in soft tissue leiomyosarcoma (LMS).
Methods: The expression levels of m6A regulators were analysed using next-generation sequencing data from 53 LMS cases obtained from a public database. We further examined the relationship between m6A regulators and c-MYC and PD-L1 expression in an LMS cell line. Immunohistochemical staining (IHC) was performed on 69 LMS tissue samples. Functional analyses included siRNA-mediated knockdown of selected m6A regulators in LMS cells.
Results: IHC revealed that high expression levels of METTL3, METTL14, ALKBH5, FTO, and WTAP were associated with elevated c-MYC expression, while high expression of ALKBH5, YTHDF2, and WTAP correlated with increased mitotic activity. Knockdown of METTL3, METTL14, and FTO led to reduced c-MYC target gene expression and decreased cell proliferation, underscoring the role of m6A modifications in c-MYC-driven oncogenesis. Furthermore, knockdown of YTHDF2 suppressed interferon-γ-induced PD-L1 expression, suggesting its involvement in immune evasion. Multivariate Cox regression analysis identified low YTHDF2 and high WTAP expression as independent poor prognostic factors.
Conclusion: Our findings highlight the oncogenic and immunoregulatory roles of m6A regulators in LMS. Targeting these molecules, especially in combination with immune checkpoint blockade, may offer novel therapeutic strategies. Further studies are warranted to clarify the mechanisms underlying m6A-mediated regulation of c-MYC and PD-L1 in LMS.

OFP-06-009

Multi-omics profiling identifies two epithelioid sarcoma molecular subtypes with distinct signalling and immune characteristics

C. Ngo[1], L. Colmet-Daage[2], J. Vibert[3], R. Brillet[2], C. Henon[2], A. Valent[1], J.X. Jin[4], L. Lecorgne[2], C. Astier[2], J.-y. Scoazec[1], M. Faron[5], C. Honore[5], A. Le Cesne[6], T. Grunewald[4], F. Bourdeaut[7], J.-Y. Blay[8], F. Tirode[8], S. Postel-Vinay[3]
[1]Institut Gustave Roussy, Department of Pathology, Villejuif, France, [2]Institut Gustave Roussy, Villejuif, France, [3]Institut Gustave Roussy, Drug Development Department, DITEP, Villejuif, France, [4]German Cancer Research Centre (DKFZ), Heidelberg, Germany, [5]Institut Gustave Roussy, Department of Surgery, Villejuif, France, [6]Institut Gustave Roussy, Department of Medical Oncology, Villejuif, France, [7]Institut Curie, Paris, France, [8]Centre Léon Bérard, Lyon, France

Background & Objectives: Epithelioid sarcoma (EpS) is an aggressive soft tissue sarcoma affecting young adults, characterized by SMARCB1 loss. Traditionnaly, EpS is classified into two histological subtypes (HS) — distal and proximal, which may co-exist ("hybrid" EpS) — with distinct clinical behaviours. Despite its phenotypic diversity, the molecular basis of EpS heterogeneity remains poorly understood. We aimed to build a molecular classification to improve our understanding of EpS biology and guide therapeutic decisions.
Methods: To establish an EpS molecular classification and uncover determinants of inter- and intra-patient heterogeneity in EpS, we used multi-omics profiling and integrated the genomic, transcriptional and methylome landscapes with single-cell RNA sequencing on fresh samples as well as spatial transcriptomics.
Results: We identified two molecular subtypes of EpS: "distal-like" and "proximal-like". Distal-like tumours (n = 20) include all distal HS, two proximal HS and four mixed HS. They express a specific molecular single-cell derived epithelial-to-mesenchymal transition signature, which associates with improved patient survival and includes Desmoglein 2 (DSG2), which we identify as a potential routine immunohistochemical biomarker to improve diagnosis. Distal-like EpS also display increased peri-tumoral CD8+ T cell infiltrates and specific tumour-immune cell interactions. Conversely, proximal-like EpS (n = 13) — comprising 12 proximal HS and one mixed HS — harbour a higher inter-tumoral molecular heterogeneity with some cases resembling other SMARCB1-deficient tumours by DNA methylation profiling, and increased intra-tumoral immunosuppresive macrophage infiltrates.
Conclusion: Our study introduces a novel molecular classification of EpS with prognostic value, potential diagnostic markers and distinct tumour immune microenvironments, that extends beyond traditional clinicopathological classification. These insights pave the way for more personalized and effective treatment strategies for patients with EpS.

OFP-06-010

Clinicopathologic features of clear cell sarcoma and the role of PRAME in differential diagnosis

T. Aydemir[1], B. Yaman[1], T. Akalin[1], H. Kaya[2]
[1]Ege University, Pathology, Izmir, Turkey, [2]Ege University, Orthopedics and Traumatology, Izmir, Turkey

Background & Objectives: Clear cell sarcoma(CCS) of soft tissue is a rare, aggressive malignancy that primarily arises within the deep soft tissues of the extremities. The genetic alteration (EWSR1-ATF1 fusion), caused by the t(12;22)(q13;q12) translocation has not been found in melanoma, highlighting the crucial role of molecular diagnostics in ensuring precise differentiation. Due to its resemblance to histopathological similarity to melanoma, distinguishing between the two can pose substantial diagnostic difficulties especially with immunohistochemistry.
Methods: In this study, 14 CCS cases diagnosed between 2000 and 2025 were reviewed and their clinicopathological features were evaluated. PRAME expression was investigated for the differential diagnosis of melanoma.
Results: Nine(%64,2) cases were female. Median age was 35,9 years(11-64 years). The average tumour size was 6.6 cm (range 3–10). The most common location were foot(n:5) followed by

thigh(n:4),hand(n:2), inguinal-gluteal(n:2), and cruris(n:1). Histopathologically, tumours showed lobular growth patern. Spindle, epithelioid cells with clear cytoplasm showed low mitotic activity. Immunohistochemically all tumours were positive with HMB45 and S100, and focally positivity with MelanA, whereas other mesenchymal and epithelial markers were negative.
FISH was performed in seven tumours with EWSR-1 break apart probe. Six cases showed positive results with approximately 80% signal. Immunohistochemically PRAME was negative in eight tumours, whereas only one tru-cut biopsy was positive. The median follow-up time of eight cases was 53.5 months(6-216 months). Recurrence/metastasis was observed in five cases; five cases were alive whereas three patients had died.
Conclusion: Clear cell sarcoma is a rare and highly malignant neoplasm primarily affecting young adults. The genetic signature EWSR-1-ATF1 fusion is absent in melanoma, which is the major entity in differential diagnosis.
The results of this study show that the use of PRAME immunohistochemistry presents a valuable approach to minimizing diagnostic uncertainty and enhancing accuracy in differentiating CCS from melanoma and other histologically similar tumours.

OFP-07-001

Early-onset colorectal cancers differ from later-onset colorectal cancers, analysis of 651 cases with special emphasis to DNA MMR protein expression loss

M. Ozcan[1,2], F. Yildirim[3], M. Sezak[4], S. Toprak[2], E. Ozsagir[5], A. Solmaz[6], U. Aydin[7], P. Gursoy[8], B. Doganavsargil[4]
[1]Ege University Health Sciences Institution, Molecular Pathology, Izmir, Turkey, [2]Inonu University, School of Medicine, Pathology, Malatya, Turkey, [3]Lokman Hekim University, Faculty of Medicine, Pathology, Ankara, Turkey, [4]Ege University, School of Medicine, Pathology, Izmir, Turkey, [5]Ege University, Health Sciences Institution, Molecular Pathology, Izmir, Turkey, [6]Ege University, School of Medicine, Genetics, Izmir, Turkey, [7]Inonu University, School of Medicine, Medical Oncology, Malatya, Turkey, [8]Ege University, School of Medicine, Medical Oncology, Izmir, Turkey

Background & Objectives: Early-onset colorectal cancer (CRC) is increasingly prevalent worldwide, yet its underlying causes remain unclear. Emerging evidence suggests that early-onset CRC exhibits distinct clinical, pathological, and molecular characteristics compared to late-onset disease. Younger patients are often diagnosed at more advanced stages and present with more aggressive histopathological features. We compared the clinicopathological characteristics and DNA mismatch repair (MMR) protein expression in early-onset and late-onset CRC cases.
Methods: A total of 651 CRC resection specimens were analysed, including 328 cases from patients under 50 years and 323 age-matched controls from patients over 50 years, randomized by including the subsequent resection following the study case collected from two reference centres. Tissue microarrays (5 mm) were extracted from tumour samples and immunohistochemically analysed for MMR proteins (MSH6, MSH2, MLH1, and PMS2). Tumour location, gender distribution, pT and pN stages, lymphovascular invasion (LVI), and perineural invasion (PNI) were statistically evaluated using parametric and non-parametric tests.
Results: Among the patients, 59.9% were male, and 40.1% were female. The median age for early onset cases were 43 years-old and 66 years-old for late onset ones. MMR protein loss was significantly higher in early-onset CRC cases ($p<0.05$, Chi-square). Most tumours (72.4%) were located in the left colon and predominantly exhibited moderately differentiated adenocarcinoma morphology. Stage T3 (70.4%) and N1 (60.4%) tumours were most common. N0 tumours were more frequent in younger patients than in the control group (43.3% vs. 35.8%, $p=0.05$, Chi-square). LVI was significantly lower in early-onset cases (41% vs. 51.6%, $p=0.007$).
Conclusion: Early-onset CRC differs significantly from late-onset CRC in terms of clinicopathological features and molecular profiles as higher ratio of MMR loss, lower likelyhood to lymphatic spread. These findings highlight the need for age-specific screening, diagnosis, and treatment strategies to improve patient outcomes.

OFP-07-002

Deep learning-based prediction scores in colorectal cancer and their association to tumour morphology, biology and predicted drug response

N.G. Reitsam[1,2], X. Jiang[3], B. Grosser[2,1,4], V. Grozdanov[5], C.M. Loeffler[3,6], W. Müller[7], N.P. West[8], H. Grabsch[9], B. Märkl[2,1], J.N. Kather[3,10,6]
[1]Faculty of Medicine, University of Augsburg, Pathology, Augsburg, Germany, [2]Bavarian Cancer Research Centre (BZKF), Augsburg, Germany, [3]Technical University Dresden, Else Kroener Fresenius Centre for Digital Health, Dresden, Germany, [4]Technical University Munich, Pathology, Munich, Germany, [5]Ulm University, Department of Neurology, Ulm, Germany, [6]University Hospital and Faculty of Medicine Carl Gustav Carus, Technische Universität Dresden, Medical Department 1, Dresden, Germany, [7]Pathologie Starnberg, Starnberg, Germany, [8]School of Medicine, University of Leeds, Division of Pathology and Data Analytics, Leeds, United Kingdom, [9]GROW Research Institute for Oncology and Reproduction, Maastricht University Medical Centre+, Department of Pathology, Maastricht, The Netherlands, [10]National Centre for Tumour Diseases (NCT), University Hospital Heidelberg, Medical Oncology, Heidelberg, Germany

Background & Objectives: Over the last few years, several deep learning (DL) models have been presented to predict colorectal cancer (CRC) patient survival directly from Haematoxylin-Eosin (H&E)-stained routine whole slide images (WSI). Unlike traditional studies, which require a predefined hypothesis and selection of features of interest, weakly supervised deep learning allows training on clinical endpoints without specifying in advance what the model should explicitly focus on. Such DL study results offer the unique opportunity to subsequently investigate tissue morphology and biology potentially driving these predictions, which may improve our understanding of the disease under investigation.
Methods: We performed a comparison of clinicopathological features, tumour morphology, biology, gene expression-based predicted drug response and H&E-inferred DL-based survival risk scores (low- vs high-risk as well as absolute risk scores) in 692 CRCs from two international cohorts.
Results: Clinicopathological risk factors such as grade of differentiation, lymph node status or percentage of tumour necrosis were significantly associated with higher DL-based risk scores (p-values < 0.05). CRCs with tumour cells located next to adipocytes were enriched in the DL-based high-risk group. The morphological review showed that spatial proximity of tumour cells to adipocytes, high degree of tumour budding, poor differentiation and signet-ring cell morphology were linked to DL-based high-risk scores. Transcriptomic and genetic subgroups showed no or only minimal association with H&E-inferred DL-based risk scores. Furthermore, DL-based low- vs high-risk CRCs were characterized by a differential drug sensitivity.
Conclusion: Our study highlights that DL-based risk scores derived from H&E-WSI closely align to established clinicopathological prognostic features, such as grading, lymph node status or spatial proximity of tumour cells and adipocytes. Moreover, DL-based risk groups seem

to be associated with a differential treatment response, underlining their potential to guide patient stratification in clinical routine.

OFP-07-003

Mucosal neural network alterations in HSV esophagitis: a semi-quantitative scoring analysis in comparison with gastroesophageal reflux esophagitis and healthy controls

H.K. Uzkuç[1], M. Sezak[1], S. Kıpçak[2], S. Bor[2], B. Doğanavşargil[1]
[1]Ege University F.aculty of Medicine, Department of Medical Pathology, İzmir, Turkey, [2]Ege University Faculty of Medicine, Department of Gastroenterology, İzmir, Turkey

Background & Objectives: Herpes simplex virus(HSV) esophagitis is rare and usually caused by latent infection in the neural ganglia in immunocompromised patients. We aimed to investigate the impact of HSV infection on the oesophageal mucosa and mucosal neural network(MNN).
Methods: A total of 27 cases were analysed, including 9 patients with HSV esophagitis, 9 with gastroesophageal reflux disease(GERD) (evaluated according to Los Angeles classification and Lyon consensus) and 9 healthy controls (confirmed by endoscopy, high-resolution oesophageal manometry and 24-h pH-impedance monitoring). All samples were stained with S100 antibody and assessed semi-quantitatively (grade 1-3) for nerve fiber localization, density and nerve branching patterns. Additionally, oesophageal mucosal activity (EMA) was also scored based on histopathological features such as the presence of ulceration/erosion, basal cell hyperplasia, papillary elongation, dilated intercellular space, inflammatory cell (lymphocytes, eosinophil, polymorphonuclear leukocyte) infiltration and vascular dilation.
Results: Patients with HSV esophagitis were significantly older than healthy controls (67 vs. 43 years, p=0.013). EMA scores showed significant differences among groups: healthy controls (median: 4, range: 2-7), GERD (median: 14, range: 8-15), and HSV esophagitis (median: 11, range: 5-17) (p=0.000, ANOVA). MNN scores were also significantly different: healthy controls (median: 4, range: 3-5), GERD (median: 5, range: 3-6), and HSV esophagitis (median: 3, range: 0-5) (p=0.002, ANOVA).
Conclusion: HSV esophagitis was associated with increased EMA scores compared to healthy controls while MNN scores were lower, suggesting possible neural damage independent of inflammation. This implies that HSV may have a direct cytotoxic effect on oesophageal neural structures. Although investigated in a small group of cases these findings provide new insights into the neuropathological effects of HSV on the oesophageal mucosa and highlight the importance of MNNs in oesophageal disease pathology. Further research is needed to explore the mechanisms of HSV-induced neural damage and its clinical implications as well as the relationship of MNNs in different oesophageal pathologies.

OFP-07-004

Claudin 18.2 as an emerging and independent biomarker in gastric and gastroesophageal junction adenocarcinomas: a dual-centre cohort study

P. Tornero-Piñero[1], P. Santiago-Díaz[1], P. Rauseo-Aristigueta[1], Y. Molina-Correa[1], E. Hinchado[2], D. Naranjo-Hans[1], S. Medina[2], X. Ara-Mancebo[1], J. Gimeno-Beltrán[1], M. Iglesias[1]
[1]Hospital del Mar, Pathology Department, Barcelona, Spain, [2]Consorci Sanitari del Maresme - Hospital de Mataró, Pathology Department, Mataró, Spain

Background & Objectives: Gastric cancer is characterized by molecular heterogeneity, with several biomarkers considered for therapeutic targeting, including HER2, mismatch repair proteins (MMR), and PD-L1. Claudin 18.2 has emerged as a therapeutically relevant biomarker. This study assesses its frequency and overlap with established biomarkers in a dual-centre cohort of gastric and gastroesophageal junction adenocarcinomas (G/GEJC) and related clinicopathological features.
Methods: A retrospective study included 126 patients diagnosed between 2019 and 2025 with G/GEJC from two institutions. HER2 (4B5, Ventana), MMR (Ventana), PD-L1 (28.8 and 22C3, Agilent), and Claudin 18.2 (43-14A, Ventana) were assessed by immunohistochemistry (IHC). HER2 was additionally evaluated by in situ hybridization (ISH) in 2+ cases. Claudin 18.2 was analysed in all cases for academic purposes. PD-L1 Combined Positive Score (CPS) was assessed in 36 patients, as it was not routinely tested in earlier cases due to lack of therapeutic indication. Associations were analysed using chi-square tests ($p < 0.05$).
Results: HER2 positivity was observed in 21 patients (16.7%), and deficient MMR (dMMR) in 28 (22.2%). Claudin 18.2 was positive in 44 patients (34.9%), and PD-L1 CPS $\geq$5 in 22 of 36 evaluated cases (61.1%). Among Claudin-positive patients, 15.9% were also HER2-positive, 13.6% were also dMMR, and 13.6% had PD-L1 CPS $\geq$5 (6 of 11 evaluated). HER2 positivity was more frequent in GEJ tumours ($p = 0.0031$). dMMR was significantly associated with HER2 negativity ($p = 0.022$), older age ($p = 0.008$), and non-GEJ tumours ($p = 0.021$). Claudin 18.2 and PD-L1 expression showed no significant association with other biomarkers or clinical features.
Conclusion: Claudin 18.2 was expressed in over one-third of cases and exhibited partial co-expression with HER2, dMMR, and PD-L1, without statistically significant associations. These findings support its role as an independent biomarker. Its integration into routine molecular profiling informs therapeutic stratification within multidisciplinary tumour board discussions.

OFP-07-005

Variation in p53 Immunohistochemistry assessment in Barrett's Oesophagus, a review of 1.150 patient cases by the Dutch Oesophageal Pathology Panel

S. Issa[1], Y.A. Weeda[1], H. Halfwerk[1], M. Botros[1], O.J. De Boer[1], L. Brosens[2,2], M. Doukas[3], G. Kats-Ugurlu[4], F.J. Ten Kate[5], J. Van Der Laan[6], I. Van Lijnschoten[7], A. Ooms[6], L. Oudijk[3], C. Van der Post[8], G. Raicu[9], W. Timens[4], B. Timmer[4], M.J. Van der Wel[1,5], S.L. Meijer[1], DEPP-study group
[1]Amsterdam UMC, Pathology, Amsterdam, The Netherlands, [2]UMC Utrecht, Pathology, Utrecht, The Netherlands, [3]Erasmus MC, Pathology, Rotterdam, The Netherlands, [4]UMC Groningen, Pathology, Groningen, The Netherlands, [5]ISALA, Pathology, Zwolle, The Netherlands, [6]Pathan, Pathology, Rotterdam, The Netherlands, [7]Eurofins Eindhoven, Pathology, Eindhoven, The Netherlands, [8]Radboud UMC, Pathology, Nijmegen, The Netherlands, [9]ST. Antonius, Pathology, Nieuwegein, The Netherlands

Background & Objectives: Assessing Barrett's Oesophagus (BE) related dysplasia is hampered by interobserver variability and guidelines advocate a second opinion. Ancillary P53-immunohistochemistry (IHC) has the potential to improve diagnostic consistency and clinical decision-making. Little is known however about the inter-pathologist variation assessing P53-IHC.
Methods: The Dutch oesophageal pathology panel accommodates centralized revision for BE-biopsies in The Netherlands, and consists of 15 pathologists who underwent a stringent training program. This study evaluates expert P53-IHC review in 1150 digitized consecutive panel revision patient cases between January 2015 and December 2024. Panel P53-IHC gold-standard (GS) assessment was determined as P53 wild-type, P53-overexpression, P53 null-mutation or P53 double-clone, when >75% of pathologists (minimum of 4) reached agreement, and otherwise discussed in monthly consensus meetings. If no consensus was reached, P53-IHC status was rendered equivocal. Referral P53-IHC assessment was compared to panel GS P53-IHC assessment.

Results: Of 1150 patient cases, 1690 P53-IHC assessments were reviewed. Overall accuracy of referral P53-IHC status compared to panel GS-P53 assessment was 75%. Highest agreement was observed in p53 wild-type (86%, 689/798) and P53 overexpression (81%, 515/634) cases, followed by double-clone (80%, 8/10) and null-mutation patterns (67%, 48/72). Referring hospital P53 wild-type were re-classified as P53 overexpression by panel revision in 7% (57/794) and vice versa in 9% (54/634). P53-IHC was assessed indeterminate by referring hospital in 180 of 1690 cases, and 166 of 180 were re-classified as wildtype (n=89), overexpression (n=59), null mutation (n=12) or double-clone (n=6); 14 were rendered equivocal. P53-IHC null-mutation was missed in 83/1690 of cases (5%).
Conclusion: Panel review of 1150 BE-patient cases shows inter-observer variation assessing P53-IHC. Wildtype is assessed as overexpression in 7% and vice versa in 9%. Null-mutations are missed in 5%, and initial P53 classification indeterminate in 11%. Clear guidelines for P53-IHC interpretation is needed, as accurate P53-IHC assessment has impact on diagnostic and clinical decision-making.

Funding: This research was funded with a grant by the MaagLeverDarmSticking (MLDS) with project number: MLDS-WO21-25

OFP-07-006

WNT1-Inducible Signaling Pathway Protein 3 (WISP3) as a biomarker for neoadjuvant CCRT response and prognostic indicator in rectal cancer: a retrospective cohort study

I-W. Chang[1,2]
[1]Wan Fang Hospital, Taipei Medical University, Department of Clinical Pathology, Taipei, Taiwan, [2]School of Medicine, College of Medicine, Taipei Medical University, Department of Pathology, Taipei, Taiwan

Background & Objectives: Colorectal cancer ranks as the third most common malignancy worldwide. Fundamentally, cancer is characterized by dysregulated cell proliferation. The *WISP3* gene, also known as *cellular communication network factor 6 (CCN6)*, encodes WNT1-inducible signalling pathway protein 3 (WISP3). In aggressive subtypes of breast cancer, such as inflammatory and metaplastic carcinoma, WISP3 is recognized as a tumour suppressor.
Methods: Transcriptomic analysis of the GSE35452 dataset, with a focus on the Gene Ontology term "regulation of cell growth" (GO:0001558), identified WISP3 as the most significantly upregulated transcript in non-responders. Tumour samples from 343 primary rectal cancer patients who underwent neoadjuvant concurrent chemoradiotherapy (CCRT) followed by surgical resection were analysed. WISP3 expression was semi-quantitatively assessed via immunohistochemical staining, and statistical analyses were performed to evaluate its correlation with clinicopathological features and survival outcomes.
Results: Elevated WISP3 expression was significantly associated with greater tumour invasiveness pre- and post-treatment ($P \leq .002$), lymph node metastasis before and after therapy ($P \leq .005$), vascular invasion ($P = .006$), perineural invasion ($P = .041$), and poor response to neoadjuvant CCRT ($P = .031$). High cytoplasmic WISP3 immunoreactivity correlated with worse clinical outcomes, including disease-specific survival (DSS), local recurrence-free survival (LRFS), and metastasis-free survival (MeFS) (all $P \leq .0017$) in univariate analysis. Additionally, WISP3 was identified as an independent prognostic factor for reduced DSS, LRFS, and MeFS in multivariate analysis (all $P \leq .003$).
Conclusion: WISP3 plays a crucial role in rectal cancer progression and response to neoadjuvant CCRT, emerging as a novel prognostic biomarker that may help guide treatment strategies.

OFP-07-007

Ki67 Index and tumour size as dual diagnostic criteria for stratifying gastric fundic gland neoplasms: a multicentre clinicopathological validation study

H. Li[1,2], X. Chen[1,2], L. Chen[3], G. Zhong[4]
[1]Fuzhou University Affiliated Provincial Hospital, Fuzhou, China, [2]Fujian Provincial Hospital, Pathology, Fuzhou, China, [3]The First Affiliated Hospital of Fujian Medical University, Pathology, Fuzhouu, China, [4]The Second Affiliated Hospital of Fujian Traditional Chinese Medical University, Pathology, Fuzhouu, China

Background & Objectives: Gastric fundic gland neoplasms (GF-GNs), including oxyntic gland adenoma (OGA), fundic gland type gastric adenocarcinoma (GA-FG) and fundic gland mucosa type gastric adenocarcinoma (GA-FGM), are rare gastric tumours with low-grade nuclear atypia and indolent behaviour. This indolent nature poses diagnostic challenges in small biopsy specimens where architectural assessment is limited, necessitating quantitative biomarkers for accurate subtyping.
Methods: This multicentre study analysed 47 GF-GN cases with NGS and immunohistochemical staining, with thorough histological evaluation. Genomic alterations were analysed across histological subtypes using a 1021-related genes panel in 17 cases. AI-based approach was employed to quantify Ki67. ROC curve analysis, Decision Curve Analysis (DCA), and a diagnostic workflow integrating tumour size and Ki67 index were performed.
Results: Patients ranged from 42 to 79 years (median 60), with 22 males and 25 females. Histologically, 24 OGAs, 21 GA-FGs, and 2 GA-FGMs were identified. The tumours demonstrated well-formed glands, expanding with dense growth patterns comprising pale, blue-grey columnar cells with mild nuclear atypia. GA-FG/GA-FGM exhibited larger sizes ($p<0.0001$) and higher Ki67 indices (median 7.5%, range 2-26%) than OGA (median 1.9%, range 1-5%) ($p<0.0001$). ROC analysis set a Ki67 cutoff of 2.5% (AUC=0.9476, 90% sensitivity, 90.48% specificity) and a size threshold of 4.5 mm (94.74% sensitivity, 92.37% specificity) for distinguishing advanced subtypes. DCA confirmed the clinical utility of Ki67 (net benefit up to 0.9 at 0.3-0.6) and Size (0.8 at 0.2-0.4) models. Molecular profiling highlighted conserved Wnt signalling (GNAS 44.4%, CTNNB1 5.6%) across subtypes, with GA-FGM showing unique BRAF, MLL3, and MSH3 mutations.
Conclusion: This study validates that tumour size and Ki67 index effectively stratify indolent (OGA) versus progressive (GA-FG/GA-FGM) GF-GNs. DCA confirms the clinical benefit of these thresholds, with Ki67 offering superior performance in moderate-risk ranges. Integrating AI-quantified Ki67 and macroscopic measurements provides a high-accuracy diagnostic framework for biopsy interpretation, enabling conservative management of low-risk lesions.

UPK2 expression in colorectal cancer is linked to aggressive tumour histomorphology and distinct molecular features

V. Äijälä[1], J. Härkönen[2,3], P. Sirniö[1], T. Mantere[4], A. Kehusmaa[1], H. Karjalainen[1], M. Kastinen[1], V.V. Tapiainen[1], H. Elomaa[5], M. Ahtiainen[6], J. Böhm[2], A. Tuomisto[1], M.J. Mäkinen[1], J.P. Väyrynen[1]
[1]Oulu University Hospital, and University of Oulu, Translational Medicine Research Unit, Medical Research Centre Oulu, Oulu, Finland, [2]Hospital Nova of Central Finland, Well Being Services County of Central Finland, Department of Pathology, Jyväskylä, Finland, [3]A.I. Virtanen Institute for Molecular Sciences, University of Eastern Finland, Faculty of Health Sciences, Kuopio, Finland, [4]University of Oulu, Laboratory of Cancer Genetics and Tumour Biology, Translational Medicine Research Unit, Medical Research Centre Oulu and Biocentre Oulu, Oulu, Finland, [5]University of Helsinki, Research Program in

Systems Oncology, Helsinki, Finland, [6]Hospital Nova of Central Finland, Well Being Services County of Central Finland, Central Finland Biobank, Jyväskylä, Finland

Background & Objectives: Uroplakin-2 (UPK2) is a marker primarily associated with urothelium and urothelial cancer, frequently utilized in differential diagnosis of tumours of unknown origin. This study examines the histopathological, immunological, molecular, and clinical characteristics of UPK2-expressing colorectal cancer (CRC).
Methods: Two independent CRC cohorts (N=1,851) were used to analyse UPK2 expression in relation to tumour histopathological features, immune cell densities analysed with multiplex immunohistochemistry, and chromosomal alterations evaluated using optical genome mapping. Additional molecular analyses were conducted in The Cancer Genome Atlas (TCGA) cohort (N=629) using bioinformatics approaches.
Results: UPK2 was expressed in 12% of CRCs. UPK2-positive CRCs were associated with poor prognostic factors, including advanced disease stage, lymphovascular invasion, tumour budding, and micropapillary growth pattern ($p<0.01$ for all). UPK2 positivity was associated with higher CRC-specific mortality in both cohorts (Cohort 1: HR for high vs. negative 1.97, 95% CI 1.00–3.88; Cohort 2: HR 3.33, 95% CI 2.15–5.16). In the larger cohort, this association remained independent of other prognostic parameters (multivariable HR for high vs. negative 2.31, 95% CI 1.46–3.65). Multiplex immunohistochemistry showed that UPK2 expression was linked to lower densities of $CD3^+$ T cells, $CD20^+CD79A^+$ B cells, $CD20^-CD79A^+$ plasma cells, and M2-like macrophages in both tumour epithelial and stromal regions. Optical genome mapping revealed that 33% of UPK2-positive CRCs (vs. 4.3% in others) exhibit copy number gain of the *UPK2* locus. UPK2-positive CRCs were associated with *TP53* mutation, Consensus Molecular Subtype 4, and the upregulation of genes related to keratinization and squamous differentiation, such as *KRT17* and *DSG3* ($p<0.01$ for all).
Conclusion: Our results indicate that UPK2 expression identifies a subset of CRCs characterized by poor prognosis, epithelial-mesenchymal transition, micropapillary architecture, and squamous-like differentiation. These findings advance the understanding of CRC heterogeneity and could contribute to the advancement of precision medicine.

OFP-07-009

Basal-like subtype of oesophageal adenocarcinoma and it's morphological, molecular and clinical characteristics

S.I. Lyu[1], C. Fretter[1], A.M. Hilmer[1], S. Hoppe[1], A.G. Simon[1], T. Zander[2], K. Knipper[3], W. Schroeder[3], C.J. Bruns[3], A. Quaas[1]
[1]Faculty of Medicine and University Hospital of Cologne, Institute of Pathology, Cologne, Germany, [2]University Hospital Cologne, Department of Internal Medicine I, Cologne, Germany, [3]Faculty of Medicine and University Hospital of Cologne, Department of General, Visceral and Cancer Surgery, Cologne, Germany

Background & Objectives: Oesophageal adenocarcinoma (EAC) and squamous cell carcinoma (ESCC) are the two main oesophageal malignancies, exhibiting distinct morphological and molecular characteristics that influence therapy response. The WHO classification also identifies adenosquamous carcinoma, which shares features of both entities. A basal-like subtype has been described in breast and pancreatic adenocarcinomas, characterized by cytokeratin 5 (CK5) or cytokeratin 6 (CK6) expression and associated with poor prognosis and chemoresistance. This study aimed to determine whether a basal-like subtype exists in EAC and to evaluate its prognostic impact and molecular characteristics.
Methods: Paraffin embedded tumour tissue from 953 operable EACs was analysed for CK5 and CK6 expression using immunohistochemistry. Cases exhibiting squamous tumour cell differentiation, including adenosquamous subtypes, were excluded. The remaining cases were then classified into three groups: negative, low-positive (<50% tumour cells), and high-positive (>50% tumour cells). Expression patterns were further analysed in primary-operated versus neoadjuvantly treated patients (CROSS or FLOT).
Results: Nine tumours exhibited high CK5 expression (0,9%), 27 had high CK6 expression (2,8%), and 4 showed high co-expression of CK5 and CK6 (0,4%). High CK5 expression correlated with worse survival (median OS: 11.93 vs. 22.57 months for negative and 13.90 months for low-positive; $p = 0.012$). In neoadjuvantly treated patients, high CK5 expression was an independent predictor of poor prognosis (n= 8, HR = 1.56, 95% CI = 1.08–2.24, $p = 0.017$). Co-expression of CK5 and CK6 also indicated worse survival (HR = 1.30, 95% CI = 1.08–1.56, $p = 0.005$).
Conclusion: This study is the first to identify a basal-like EAC subtype with poor prognosis, even post-neoadjuvant therapy. CK5 (alone or with CK6) is an accessible biomarker for this subtype, suggesting its potential for guiding personalized treatment strategies. Further research should explore its biological characteristics and therapeutic implications.

Biopsy is still the "gold standard" in the diagnosis of coeliac disease: the first validation study of the "coeliac algorithm"

N. Reisli Attar[1], T. Köktürk[1], H. Berber[1], E.N. Kozan[2], V. Yilmaz[3], A.M. Demir[4], C.T. Kirsaçlioğlu[4], Z. Kuloğlu[4], B. Savaş[1], A. Kansu Tanca[4], I. Soykan[3], A. Ensari[1]
[1]Ankara University Medical School, Department of Pathology, Ankara, Turkey, [2]Weill Cornell Medicine, Department of Pathology, New York, USA, [3]Ankara University Medical School, Department of Gastroenterology, Ankara, Turkey, [4]Ankara University Medical School, Department of Paediatric Gastroenterology, Ankara, Turkey

Background & Objectives: Diagnosis of coeliac disease (CD), due to heterogeneity in symptoms, serology and histology, can be difficult for all parties involved. Recently, a histologic diagnostic algorithm, namely, the "coeliac algorithm", based on TCRγδ intraepithelial lymphocytes (IEL) has been proposed. We, therefore, aimed to validate the algorithm prospectively in cases with flat mucosae and intraepithelial lymphocytosis.
Methods: Duodenal biopsies of 81 cases obtained for a suspicion of coeliac disease were studied for CD3 and TCRγδ IEL counts/100 enterocytes. The "coeliac algorithm" based on the TCRγδ IELs count>10.5 (step1) and TCRγδ+ IEL/CD3 ratio>14 (step2) was applied and diagnostic accuracy was determined in comparison to clinical and serologic data.
Results: Mean age was 22.6 (2-75) and 72.8%(n=59) were female, 27.2%(n=22) were male. Majority comprised of paediatric cases (61.7%) while 38.3% were adults. Using the algorithm, 59% of the cases were compatible with CD, 36% were in grey zone, and 5% were non-CD at step1 while step2 revealed that 96.5% were suggestive of CD and 3.5% of non-CD. Step1 classified 68% of the cases as type 3 and 54% as type 1 and through step2 evaluation, 3 additional type 1 cases and 25 more type 3 cases were detected. The diagnostic accuracy of step1 was 68.5% whereas step2, with the application of γδTCR/CD3 ratio, significantly improved the algorithm's accuracy up to 93.8% ($p<0.001$). When all cases were evaluated solely using step2 the diagnostic accuracy was 95,1% which was significantly higher compared to step1 ($p<0.001$). The algorithm yielded significantly higher diagnostic

accuracy compared to endoscopy (79.3%; p=0.007) and, though not significant, was even better than serology (91.4%).
Conclusion: Our findings highlighted the performance of the "coeliac algorithm", particularly, when TCRγδ+IEL/CD3 ratio is applied, ad therefore, successfully validated its use in the diagnosis of coeliac disease in a prospective cohort with high diagnostic accuracy superior to endoscopy.

OFP-07-012

Insights into the clinical prognosis of High-grade Appendiceal Mucinous Neoplasms: lymph node metastasis and peritoneal risks

N. Benzerdjeb[1,2], V. Kepenekian[3,2], C. Illac-Vauquelin[4], V. Verriele[5], J. Fontaine[1], S. Isaac[1], A. Chevallier[6], S. Valmary-Degano[7,8], M.-H. Laverriere[7], G. Avérous[9], F. Bibeau[10], O. Glehen[3,2], P. Dartigues[11]
[1]CHU Lyon Sud, Pathology, Lyon, France, [2]Université Lyon 1, CICLY, Lyon, France, [3]CHU Lyon Sud, Department of General Surgery and Surgical Oncology, Lyon, France, [4]IUTC Oncopôle, Department of Pathology, Claudius Regaud Institute, Toulouse, France, [5]CRLCC Paul Papin, Department of Pathology, Angers, France, [6]CHU Nice, Department of Pathology, Nice, France, [7]CHU Grenoble, Department of Pathology, Grenoble, France, [8]Université Grenoble, Inserm U 1209, Grenoble, France, [9]CHU Strasbourg, Department of Pathology, Strasbourg, France, [10]CHU Besançon, Department of Pathology, Besançon, France, [11]Gustave Roussy Institute, Department of Pathology, Villejuif, France

Background & Objectives: High-grade appendiceal mucinous neoplasm (HAMN) is a relatively recent term used to describe a rare epithelial neoplasm of the appendix characterized by pushing-type invasion and high-grade cytologic atypia. Its implications regarding lymph node spread and the necessity of right colectomy are subjects of ongoing debate. All cases undergoing right colectomy for pseudomyxoma were included from the French reference network for rare peritoneal cancers (RENAPE) database to explore lymph node and peritoneal spread.
Methods: We analysed data from 440 patients diagnosed with low or high appendicular mucinous neoplasm (LAMN, n=240 / HAMN, n=33) or appendicular adenocarcinoma (AA, n=167) who underwent right colectomy with lymph node dissection within the RENAPE network.
Results: Nearly 60% of the patients were female (n=249), with a mean age of 56.6 years (range: 21-83). No difference of number of appendiceal wall rupture among the three subsets. Lymph node metastases were identified only in 16.2% of AA (27/167), whereas none were found among LAMN/HAMN cases. In terms of peritoneal metastasis, a significantly higher proportion of cases were classified as high grade with/without signet cells in HAMN (69.2%) compared to LAMN (15.6%) and AA (44.0%). Following multimodal treatment, with no significant difference in terms of completeness of cytoreduction (p=0.429), In terms of peritoneal metastasis, a significantly higher proportion of cases were classified as high grade in HAMN, AA from HAMN, and AA compared to LAMN and LAMN from AA. HAMN and AA with appendicular perforation experienced significantly more peritoneal recurrences than LAMN. In cases confined to the appendiceal wall, HAMN and LAMN confined to the appendiceal wall had a lower tendency for peritoneal recurrences than AA ($p = 0.132$).
Conclusion: Our data suggest that HAMN is more prone to peritoneal dissemination as high-grade expansion rather than nodal spread.

OFP-07-013

Refining risk stratification in stage II colorectal cancer: the role of Stroma AReactive Invasion Front Areas (SARIFA)

E. Fischer[1], B. Märkl[2], F. Sommer[3], G. Schenkirsch[4], J. Waidhauser[1], N. Reitsam[2]
[1]Faculty of Medicine, University of Augsburg, Haematology and Oncology, Augsburg, Germany, [2]Faculty of Medicine, University of Augsburg, Pathology, Augsburg, Germany, [3]Faculty of Medicine, University of Augsburg, General, Visceral and Transplantation Surgery, Augsburg, Germany, [4]University Hospital Augsburg, Tumour Data Management, Augsburg, Germany

Background & Objectives: Colorectal carcinoma (CRC) remains a leading cause of cancer-related mortality. While adjuvant chemotherapy is recommended for high-risk stage II patients, its benefit remains uncertain, highlighting the need for novel prognostic markers. The Stroma AReactive Invasion Front Area (SARIFA), a zone where tumour cells interact with adipocytes without stromal reaction, has shown prognostic relevance. This study evaluates SARIFA's impact on risk stratification and therapy guidance in stage II CRC.
Methods: This retrospective cohort study included 293 stage II CRC patients who underwent curative-intent resection (2013–2023). SARIFA was assessed in H&E-stained slides. Clinicopathological characteristics, including established prognostic markers, were analysed. Univariate and multivariate analyses of recurrence-free survival (RFS) were performed using Kaplan-Meier curves and Cox regression models.
Results: SARIFA positivity was observed in 42.0% of patients and was associated with significantly worse RFS (median RFS: 28.1 vs. 31.0 months, HR: 1.85, 95% CI 1.03-3.33, $p = 0.040$). The combination of SARIFA-positive and at least one NCCN risk factor further worsened prognosis (HR = 2.43, 95% CI: 1.13–5.24, $p = 0.023$). SARIFA-positive cases had fewer examined lymph nodes ($p = 0.004$) and more frequent perineural invasion ($p = 0.004$). In the multivariate analysis, SARIFA showed a trend towards poorer RFS, maintaining its prognostic relevance (HR = 1.64, 95% CI: 0.91–2.96, $p = 0.102$). Additionally, older age (HR = 1.03, 95% CI: 1.001–1.07, $p = 0.043$) and higher lymph node count (HR = 0.96, 95% CI: 0.94–0.99, $p = 0.002$) were independent prognostic factors.
Conclusion: SARIFA is a promising prognostic biomarker in stage II CRC, providing cost-effective and reproducible risk stratification. It may aid therapy decisions by identifying patients who could benefit from adjuvant chemotherapy while minimizing overtreatment in low-risk cases. Prospective studies are now needed to validate SARIFA's role in optimizing personalized treatment strategies.

France, [16]Pierre Fabre Laboratories, Biometry, Boulogne Billancourt, France, [17]Charité-Universitätsmedizin, Haematology, Oncology and Cancer Immunology, Berlin, Germany

Background & Objectives: Between 8% and 12% of patients with metastatic colorectal cancer (mCRC) harbour $BRAF^{V600E}$ mutation, which is associated with poor prognosis and resistance to conventional therapies. BRAF testing is essential to identify this mutation and define optimal treatment sequence. This analysis used pooled data from 5 European studies to determine real-world management of patients with $BRAF^{V600E}$-mutant mCRC treated with encorafenib plus cetuximab (EC).
Methods: This retrospective, longitudinal, pooled analysis used data from real-world observational studies conducted across Europe between 2020 and 2024. Adult patients (age ≥18 years) who received an encorafenib-based regimen for $BRAF^{V600E}$ mutant mCRC were included. Pooled data included information collected at the start of treatment until the end of the observation period in each study. The primary objective was to assess baseline demographics and characteristics of patients initiating EC. Here, we describe BRAF testing practices in these patients, a secondary objective of the study.
Results: Among 709 patients, 54.4% were female, median age was 65 years, 33.7% were aged ≥70 years, 78.8% had ECOG PS 0–1, and 66.1% had right-sided primary tumour. At initial diagnosis, 70.9% of all patients presented with synchronous disease and the number of metastatic sites at EC initiation was 1 (36.6%), 2 (32.5%), or ≥3 (30.9%). All patients underwent BRAF testing, which was performed on archived tissue from primary tumour (76.8% of patients with available data) or metastasis (16.5%). The most common methods used for BRAF testing were next-generation sequencing (61.2% of patients with available data) and polymerase chain reaction (16.1% of patients with available data). EC was initiated as second-line therapy for 66.1% of patients, followed by third-line (21.3%) and fourth/later-line (7.9%); 4.7% initiated EC after prior systemic treatment (early relapse after adjuvant treatment).
Conclusion: BRAF testing should be conducted as early as possible at the time of mCRC diagnosis to optimize treatment decisions.

OFP-07-015

Enteroblastic differentiation in gastric adenocarcinoma: clinicopathological, immunohistochemical, and molecular findings

A. Erbağci[1], A. Toksöz Yıldırım[2], P. Engin Zerk[3], B. Çobanoğlu Şimşek[2]
[1]GOZTEPE PROF.DR. SULEYMAN YALCIN CITY HOSPITAL, Istanbul Medeniyet University, Pathology, Istanbul, Turkey, [2]Istanbul Medeniyet University, Pathology, Istanbul, Turkey, [3]National Institutes of Health, Pathology, Bethesda, USA

Background & Objectives: Gastric adenocarcinoma with enteroblastic differentiation (GAED) is a rare and aggressive subtype of gastric cancer, characterized by clear cytoplasm and the expression of oncofoetal markers. This study aims to evaluate the clinicopathological and immunophenotypic features of GAED and to explore potential therapeutic targets, integrating immunohistochemistry and molecular techniques.
Methods: Eleven patients diagnosed with GAED were retrospectively analysed. Histological evaluation included tumour morphology, grade, and invasion patterns. Immunohistochemical staining was performed for AFP, glypican-3, SALL4, HER2, PD-L1, FOLR1, and CLDN18.2. HER2 status was further assessed using fluorescence in situ hybridization (FISH) in all cases with IHC score 2. Molecular profiling was performed using next-generation sequencing (NGS) on formalin-fixed, paraffin-embedded (FFPE) tumour tissue.
Results: The median age was 77 years (range: 62–90), with a male predominance (8/11). Tumour sizes ranged from 3 to 10 cm, and the enteroblastic component comprised 30–75% of the tumour area. All tumours expressed at least one enteroblastic marker, with glypican-3 positivity in 10/11 cases. HER2 overexpression (IHC score 2 or 3) was observed in four cases; FISH confirmed amplification in two of them. PD-L1 positivity (CPS ≥1%) was detected in five cases. FOLR1 was positive in three patients, while all cases were negative for CLDN18.2. Lymphovascular invasion was present in nine patients. Follow-up data showed that seven patients died of disease within 1 to 21 months after diagnosis; four patients were alive at last follow-up.
Conclusion: GAED is an aggressive form of gastric carcinoma with distinct immunophenotypic features. The frequent expression of HER2, PD-L1, and FOLR1 suggests that targeted therapies and immune checkpoint inhibitors may be viable treatment options. Integration of molecular testing, including FISH and NGS, may aid in the identification of novel biomarkers and treatment strategies.

OFP-08-001

Clinicopathological behaviour of pancreatic neuroendocrine tumours (PanNETs) - subgrading G2 using Ki-67 proliferation index (Ki67PI) as G2a (3% to <10%) and G2b (10% to ≤20%)

M.L. Sacramento[1,2], M. Simplício[1,2], E. Campos[3], J. Lopes[1,2]
[1]ULS São João, Pathology, Porto, Portugal, [2]Faculty of Medicine of the University of Porto (FMUP), Pathology, Porto, Portugal, [3]ULS São João, Surgery, Porto, Portugal

Background & Objectives: PanNETs are neoplasms graded as G1, G2 and G3 with different prognostic stratification. Recently, Eren and colleagues proposed subgrading G2 PanNETs, using Ki-67PI, as G2a (3% to <10%) and G2b (10% to ≤20%). Their study concluded that G2b PanNETs behave similarly to G3, indicating the need for a closer follow-up. Aim: to evaluate the clinicopathological behaviour of G1, G2a, G2b and G3 PanNETs.
Methods: A retrospective study was conducted and patients diagnosed with PanNETs between 2019 to 2024 were selected. Clinicopathological data were collected.
Ki-67 immunohistochemistry was performed for each tumour and its index was evaluated by digital pathology (Sectra algorithm for Ki-67). Tumours were graded according to their Ki-67PI as G1 (<3%), G2a (3-<10%), G2b (10-≤20%) and G3 (>20%). IBM SPSS was used for statistical analysis.
Results: A total of 42 patients (57.1% male; mean age 58 years) were diagnosed with PanNETs. Tumour sizes were 0.6 to 12.5cm (mean, 2.6cm). Considering Ki-67PI, 61.9% were G1, 16.7% were G2a, 14.3% were G2b and 7.1% were G3. There was statistic association between grade and distant metastases (p=0.03), perineural invasion (p=0.03), pT stage (p=0.001) and pN stage (p=0.015). There was no statistic association between disease-related death and vascular invasion. Perineural invasion was observed in 15 PanNETs (G1:n=4; G2a:n=4; G2b:n=4 and G3:n=3) and vascular invasion in 18 PanNETs (G1:n=7; G2a:n=5; G2b:n=4 and G3:n=2). Twenty-one tumours were pT1 (G1:n=17; G2a:n=3; G2b:n=1), 14 were pT2 (G1:n=8; G2a:n=2; G2b:n=3 and G3:n=1), 3 were pT3 (G1:n=1 and G2a:n=2) and 4 were pT4 (G2b:n=2 and G3:n=2). Eight tumours were pN1 (G1:n=2; G2a:n=1; G2b:n=3 and G3:n=2). Two patients died from PanNETs (G2b:n=1 and G3:n=1) and six had distant metastases (G2a:n=2, G2b:n=2 and G3:n=2).
Conclusion: Our study revealed that G2b subgroup has identical clinincopathological behaviour to G3 group, indicating the need for subgrading G2 PanNETs and a closer management of this subgroup.

High performance deep-learning model for the diagnosis of autoimmune hepatitis based on histological whole slide images

P. Allaume[1], N. Rabilloud[2], J. Calderaro[3], T. Pecot[4], A. Sessa[5], M. Pierre-Jean[6], N. Rioux-Leclercq[1], O. Loreal[7], S.-F. Kammerer-Jacquet[1], E. Bardou-Jacquet[8], B. Turlin[1]

[1]Hôpital Universitaire de Rennes – Université de Rennes, Hôpital Pontchaillou, Service d'Anatomie et Cytologie Pathologique, Rennes, France, [2]Université de Rennes, Laboratoire Traitement du Signal et de l'Image, Unité Mixte de Recherche INSERM 1099, Rennes, France, [3]Assistance Publique Hôpitaux de Paris, Groupe Hospitalier Henri Mondor, Département de Pathologie, Créteil, France, [4]Université de Rennes, FAIIA, Biosit (UAR 3480 CNRS - US 18 Inserm), Rennes, France, [5]Assistance Publique Hôpitaux de Paris, Groupe Hospitalier Henri Mondor, Département de Hépatologie, Créteil, France, [6]Hôpital Universitaire de Rennes – Université de Rennes, Hôpital Pontchaillou, Direction de la Recherche et Investigation, Rennes, France, [7]Institut NuMeCan (Nutrition Metabolisms and Cancer), Rennes University, INSERM, Univ Rennes, INRAE, CHU Rennes, U 1241, Rennes, France, [8]Hôpital Universitaire de Rennes – Université de Rennes, Hôpital Pontchaillou, Service d'Hépatologie, Rennes, France

Background & Objectives: Autoimmune Hepatitis (AIH) is a liver disease with a wide clinical spectrum, driven by an abnormal immune response against the liver parenchyma. Challenges persist especially in terms of accurate early diagnosis of acute onsets and differential diagnosis. Our work falls within the goals set by the fifth research workshop of the International Autoimmune Hepatitis Group for improving AIH diagnosis through a Deep-Learning Model (DLM) approach on liver biopsy's histology, in a setting close to real life.

Methods: Our training cohort comprised 143 index cases of untreated AIH and 158 control cases with a variety of differential diagnosis,from Pontchaillou Hospital, Rennes. Ground Truth was assigned based on the integrative diagnosis of the clinician. Biopsies were reviewed according to the IAIHG updated criteria, and the 2008 Simplified scoring system was computed. We trained a multiple-instance DLM from histology Whole Slide Images alone in order to design an interpretable classifier for the primo-diagnosis of AIH. The model was then tested on an external dataset of 61 AIH from Mondor Hospital, Paris.

Results: Our DLM "Artificial Intelligence On Liver Immunity (AIOLI)", evaluated with a stratified 5-fold cross-validation, achieved Sensitivity of 0.965 ± 0.038, Specificity of 0.861 ± 0.068, F1-score of 0.939 ± 0.035 and AUC of 0.911 ± 0.035 on the training dataset. Additionally, AIOLI achieved Sensitivity of 0.902 ± 0.29 on the external dataset. Retrieval of the five most and least predictive tiles allowed to identify morphological patterns used by the model for prediction.

Conclusion: We choose to tackle AIH diagnosis in a "real-life" setting, with an interpretable DLM able to segregate AIH from a wide variety of control cases with good performance. We plan to enhance our model's performance in future iterations by enriching our dataset, especially in metabolic- and toxic-diseases control cases, and to validate this approach with external datasets.

OFP-08-003

Histopathology, morphomolecular classification and clinical outcomes in hepatocellular carcinoma treated with immune-combined therapy: a prospective study on needle liver biopsies

I. Vlachos[1], S. Pantzios[2], I.M. Grypari[1], D. Myoteri[1], A. Syricha[2], O. Sidiropoulos[2], G. Zogas[2], V. Saltagianni[1], D. Karandrea[1], I. Elefsiniotis[2], D. Tiniakos[1]

[1]Aretaieion Hospital, Medical School, National and Kapodistrian University of Athens, Department of Pathology, Athens, Greece, [2]General Oncology Hospital of Kifissia, National and Kapodistrian University of Athens, Academic Department of Internal Medicine-Hepatogastroenterology Unit, Athens, Greece

Background & Objectives: Hepatocellular carcinoma (HCC) histological subtypes (WHO 2019) are associated with prognosis, treatment response and a recently proposed morphomolecular classification. Our aim was to study histopathological features and morphomolecular subgroups in HCC treated with immune-combined therapy.

Methods: We prospectively evaluated 48 liver biopsies from 48 HCC patients [38 male, median age 69 years, BCLC stage A 3(6.2%), B 20(41.7%), C 25(52.1%)] treated with immune-combined therapy and followed-up 3-41(mean 11) months. Morphological examination and immunohistochemistry (IHC) for beta-catenin(B-CTNN), glutamine synthetase, TP53 and keratin 19 were applied to reflect HCC molecular classification based on Nault JC,J Hepatol 2018.

Results: Histological grade (WHO 2019) was 1 in 4(8.3%), 2 in 37(77.1%) and 3 in 7(14.6%) HCC. There were 30(62.5%) NOS, 9(18.8%) macrotrabecular-massive (MTM), 7(14.6%) steatohepatitic, 1(2.1%) clear-cell and 1(2.1%) scirrhous HCC. Morphomolecular subgrouping (n=41) highlighted 18(44%) proliferative and 23(56.0%) non-proliferative HCC. Morphomolecular class (n=27) was G1 in 2(7.4%), G2-G3 in 5(18.5%), G4 in 5(18.5%) and G5-G6 in 15(55.5%). MTM subtype positively correlated with mutated TP53 (p=0.012) and negatively with mutated B-CTNN (p=0.002) IHC pattern. Mean progression-free survival (PFS) was 7.7 months (2-34 months). At the end of follow-up, 31(64.5%) patients had progressed and 20(41.6%) patients were alive. Objective response-OR was observed in 6/48(12.5%) patients and was significantly related with overall survival-OS (p=0.009). Disease progression correlated with histological grade (p=0.036), mutated B-CTNN (p=0.027) and morphomolecular class (p=0.048). PFS correlated with morphomolecular class (p=0.035) and mutated TP53 (p=0.09). There was no significant correlation between histological subtypes and morphomolecular subgroups with OR, PFS or OS.

Conclusion: In HCC treated with immune-combined therapy, morphomolecular class can predict disease progression and PFS, while histological grade and mutated B-CTNN correlate with disease progression. Histological subtypes and morphomolecular proliferative/non-proliferative subgrouping do not have prognostic or predictive significance. Studies in a larger cohort are ongoing to validate these results.

OFP-08-004

Unraveling immune composition in pancreatic cancer for personalized immunotherapy

J. Shi[1], S. Zhang[1], E. Daniels[1], J. McGue[1], S. Krishnan[1], H. Kim[1], D. Thomas[1], T. Frankel[1], A. Rao[1]

[1]University of Michigan, Ann Arbor, USA

Background & Objectives: Limited progress has been made towards effective immunotherapies for pancreatic ductal adenocarcinoma (PDA) patients. Treatment resistance remains a major roadblock toward improving survival. We have identified a subset of PDAs that carry alterations in a group of epigenetic genes named Complex Proteins Associated with Set1 (COMPASS)-like complex genes (CLCG). Approximately one-quarter of PDAs harbour CLCG alterations which commonly occur concomitantly with established driver mutations like KRAS and TP53 and are associated with high-grade histology, squamous or basal-like features, and poor patient survival compared with CLCG-wild type PDAs.

This study aims to dissect the complex immune composition of CLCG-mutated PDAs by single-cell spatial analysis and compare them with matched CLCG-wild type PDAs. Our goal is to identify vulnerabilities in this subset of PDAs for personalized immunotherapy.

Methods: We identified 15 PDA cases (CLCG mutation=8, wild type=7). The groups were matched for age, sex, and concomitant driver mutations. H&E slides and blocks were selected for single-cell spatial multiplex fluorescent immunohistochemistry (mfIHC) analyses. Ninety-seven stamped areas were analysed using Inform 2.6 software to assign identities to each cell based on IHC markers. R program was used to calculate cell count, percentage, and engagement.

Results: CLCG-mutated PDAs had a significantly lower number of antigen-presenting cells (APCs) and CD4 T cells with increased expression of immune checkpoint (IC) and exhaustion marker, TIGIT, on APCs (p=0.0031) and CD4 T cells (p=0.0053), supporting immunosuppression. There was no difference in the expressions of PD-L1 or another IC, TIM3. Interestingly, more CD4 T cells expressed TIGIT near tumour cells and APCs in CLCG-mutated PDAs. Furthermore, there was a loss of engagement between CD4 and CD8 T cells, and CD8 T cells and tumour cells in CLCG-mutated PDAs.
Conclusion: CLCG-mutated PDAs have a unique mechanism of immunosuppression that can guide personalized IC therapy.

Funding: Dr. Jiaqi Shi is supported in part by the National Cancer Institute of the National Institutes of Health under award number R37CA262209. This project is also funded by the Department of Pathology & Clinical Labs at the University of Michigan

OFP-08-005

Hepatocellular carcinoma demonstrates greater variance in nuclear morphometrics when compared to hepatocellular adenoma

A. Greenberg[1], S. Tsuriel[1], A. Bloomberg[1], D. Hershkovitz[1,2]
[1]Institute of Pathology, Tel-Aviv Sourasky Medical Centre, Pathology, Tel-Aviv, Israel, [2]Sackler Faculty of Medicine, Tel-Aviv University, Medicine, Tel-Aviv, Israel

Background & Objectives: The differential diagnosis between hepatocellular adenoma and well-differentiated hepatocellular carcinoma (in non-cirrhotic liver) can be challenging, especially in a small biopsy with limited diagnostic material. Histological features and use of stains (reticulin in particular) are crucial, yet not always sufficient to differentiate between adenoma and carcinoma. In the current study we examined the nuclear morphometrical features of hepatocellular adenoma and carcinoma to identify any significant differences and assess whether they may be used to better differentiated between adenoma and carcinoma.
Methods: Full slide images from twenty four cases of well-differentiated hepatocellular adenoma and nineteen cases of hepatocellular adenoma were reviewed by a pathologist who captured fifty patches of either adenoma or carcinoma areas per case. An algorithm for nuclear segmentation and extraction morphometric features was used on each patch and provided parameters of size, shape, texture and stain intensity for each nucleus. A second cohort of nine adenomas and seven carcinomas was used for validation.
Results: The hepatocellular carcinoma nuclei were larger in size when compared to the adenoma nuclei and also showed a greater variance in size. Specifically, area and perimeter both showed a higher variance within the hepatocellular carcinoma group, in both cohorts ($p<.0001$). The hepatocellular carcinoma group also showed a larger area (microns), 26.321 ± 14.455 vs 23.899 ± 11.722 ($p<.0001$) and a larger perimeter length (microns), 18.915 ± 6.167 vs 17.839 ± 4.980 ($p<.0001$). Examination of the validation cohort highlighted similar trends for area (28.729 ± 14.449 vs 23.039 ± 10.671, $p<.0001$), perimeter (19.806 ± 6.119 vs 17.460 ± 4.676, $p<.0001$).
Conclusion: The results of this study suggest that hepatocellular carcinoma cells are larger in size and show a greater variance in size and texture when compared to hepatocellular adenoma. Further research may utilize these differences to better differentiate between well-differentiated hepatocellular carcinoma and hepatocellular adenoma.

Background & Objectives: Pancreatic ductal adenocarcinoma (PDAC) is characterized by its immunosuppressive tumour microenvironment. Emerging evidence suggests that the immune landscape of PDAC precursor lesions plays a pivotal role in early tumorigenesis. Genetically engineered mouse models (GEMMs) are essential in studying these precursor stages, as they enable temporal resolution of disease progression. This study aims to characterize the immune microenvironment of both human and murine PDAC precursor lesions using deep-learning approaches.
Methods: We analysed 140 murine tissue samples from 6 KC and 34 KPC mice using tissue microarrays. Samples included normal pancreas, acinar-to-ductal metaplasia (ADM), pancreatic intraepithelial neoplasia (PanIN), and invasive PDAC (central and peripheral regions), along with their respective microenvironments. OPAL 7-colour multiplex immunofluorescence staining was employed using two antibody panels: Panel 1 (anti-CD19, -CD3, -Tryptase, -F4/80, -CD163) and Panel 2 (anti-CD3, -CD4, -CD8α, -Granzyme B, -FoxP3, -PD-1). A total of 944 images (Panel 1) and 918 images (Panel 2) were acquired and analysed using convolutional neural networks (CNNs) including ResNet18, ResNet34, ResNet50, ResNet101, and ResNet152. Training utilized stochastic gradient descent with momentum and the Adam optimizer, employing transfer learning and 10-fold cross-validation.
Results: CNNs reached 91.8% accuracy with Panel 1 in distinguishing normal pancreas vs. precursors vs. PDAC, with F1-scores of 0.920 (normal tissue), 0.945 (ADM/PanIN), 0.913 (central PDAC), and 0.884 (peripheral PDAC). With Panel 2, a 92.2% accuracy was achieved, with F1-scores of 0.874 (normal pancreas), 0.934 (ADM/PanIN), 0.919 (central PDAC), and 0.922 (peripheral PDAC), respectively.
Conclusion: Despite a limited dataset, CNNs demonstrated solid accuracy in classifying the immune microenvironment of PDAC and its precursor lesions in GEMMs. Overlapping regions in multiplex immunofluorescence images present a limitation; however, the use of 10-fold cross-validation enhances reliability. We have already demonstrated similarly robust results in human pancreatic tissue samples. Currently, we are extending our analyses to encompass additional tasks, including spatial profiling of the immuno-infiltrate.

OFP-08-007

Primary mesenchymal tumours of the pancreas: a systematic literature review and outlook on machine-assisted diagnostics

J. Todorovic[1], M. Zielke[1], P. Ströbel[1]
[1]Institute of Pathology, University Medical Centre Göttingen, Göttingen, Germany

Background & Objectives: Primary mesenchymal tumours of the pancreas comprise less than 1% of pancreatic neoplasms and present a unique diagnostic challenge. Despite an increased number of published cases over the past decade, the data remains fragmented. We aimed to systematically review reported cases from the last 10 years to clarify the diagnostic spectrum, highlight age distribution, localization, outcome and common pitfalls. Furthermore, we aim to provide a data platform that could inform future machine-assisted diagnostic tools.
Methods: A systematic literature search was performed in Pubmed, Cochrane Library and Web of Science databases for English- language case reports and case series published between 2015 and 2025. Standardized evidence tables were used for the extraction of data. Studies with a confirmed diagnosis of a primary mesenchymal tumour originating from the pancreas with extractable data on histology, immunohistochemistry, molecular testings, clinical presentation and outcome were included. Mixed epithelial (e.g., carcinosarcomas) and metastatic mesenchymal tumours were excluded.
Results: We retrieved 332 unique records and included 98 studies that met our inclusion criteria. Histologic subtypes ranged from extraskeletal Ewing sarcoma and solitary fibrous tumour (SFT) to even less common entities such as leiomyosarcoma, liposarcoma, perivascular epithelioid cell

tumour (PEComa), angiosarcoma and undifferentiated pleomorphic sarcoma of the pancreas. Morphological features and key diagnostic markers (e.g., SMA, CD117, HMB-45, STAT6, CD34, EWSR1 rearrangements) helped establish definitive diagnoses. Clinical outcomes varied markedly, with some benign tumours being completely resectable and high-grade sarcomas exhibiting aggressive behaviour and early metastasis.
Conclusion: This comprehensive literature-based overview highlights the complexity of primary pancreatic mesenchymal tumours, underscoring the importance of thorough histopathological workup and ancillary testing. By uniting scattered case-level data, our collection offers pathologists and clinicians a valuable reference for recognizing these rare entities. In addition, these data also lay the groundwork for future development of machine-assisted diagnostic approaches, ultimately aiming to improve the diagnostic accuracy.

OFP-08-008
The incidence and prognostic significance of alternative telomere lengthening in hepatocellular carcinomas
A. Aysal[1], O. Erdogan[1], C. Agalar[2], T. Egeli[2], M. Ozbilgin[2], T. Unek[3], T. Unek[2], O. Sagol[1]
[1]Dokuz Eylul University, Pathology, Izmir, Turkey, [2]Dokuz Eylul University, General Surgery, Izmir, Turkey, [3]Dokuz Eylul University, Medical Oncology, Izmir, Turkey

Background & Objectives: The mechanism involved in the maintenance of telomere length, apart from telomerase activation, is alternative telomere lengthening (ALT). ALT is defined in approximately 6-10% of hepatocellular carcinomas (HCC). The prognostic effect of ALT phenotype still remains unclear. This study aims to determine the incidence of ALT in hepatocellular carcinomas using the telomere-specific FISH method and the prognostic impact of ALT, and to contribute to the clinical management and potential treatment approaches of HCC.
Methods: In our study, ALT status was investigated by FISH method in 121 cases of HCC and the association between ALT positivity and clinicopathological features was evaluated statistically. In addition, for the first time in the literature, the presence of ALT in metastatic tumour tissues of the cases, when present, was investigated and whether there was a difference in frequency in primary or metastatic HCC tissues was evaluated.
Results: ALT positivity was observed in 11 cases (9%) including 8 conventional, 2 chromophobe and 1 clear cell HCCs. The rate of ALT positivity among metastatic HCCs was determined as 33.3%. ALT positivity showed strong statistical association with the presence of bizarre nuclei (9/11, 91.8%) ($p<0.001$), rather than morphological subtype (chromophobe subtype) association shown previously in the literature. The presence of ALT was found to be statistically associated with the risk of recurrence, presence and percentage of bizarre nuclei. Although the overall survival time was significantly lower in cases with ALT phenotype compared to those without (74,16/128,9 months), no statistically significance was detected.
Conclusion: In conclusion, our study which is the first to investigate the prognostic importance of ALT phenotype in HCCs and its frequency in metastatic HCCs, has shown that ALT has a potential negative prognostic impact and is observed more frequently in metastases than in primary HCCs.

OFP-08-009
Malignant solid pseudopapillary neoplasms: histological features, molecular alterations and survival outcomes
E. Comut[1], A. Celik[2], A. Uguz[3], O. Ergun[2], S. Erbil[4], A. Argon[4], D. Nart[5], N. Calli Demirkan[1], F. Yilmaz[5]
[1]Pamukkale University Faculty of Medicine, Pathology, Denizli, Turkey, [2]Ege University Faculty of Medicine, Paediatric Surgery, Izmir, Turkey, [3]Ege University Faculty of Medicine, Surgery, Izmir, Turkey, [4]Izmir Bayrakli City Hospital, Pathology, Izmir, Turkey, [5]Ege University Faculty of Medicine, Pathology, Izmir, Turkey

Background & Objectives: Solid pseudopapillary neoplasms (SPNs) typically follow an indolent course with favourable outcomes after resection. Nevertheless, a small subset demonstrates malignant potential, characterized by lymphovascular invasion (LVI), increased mitotic activity, and metastasis –features associated with increased mortality. This study aims to evaluate the clinicopathological characteristics of malignant SPNs, assess relevant histological and immunohistochemical markers, and explore possible related molecular alterations.
Methods: We retrospectively analysed 61 SPN cases diagnosed between 2000 and 2025 at two academic pathology centres. Histopathological features including LVI, perineural invasion, mitotic activity, and capsular/parenchymal invasion were evaluated. Immunohistochemistry was performed for BAP1, β-catenin, CD10, progesterone receptor (PR), androgen receptor(AR), chromogranin, synaptophysin, and Ki-67. Next-generation sequencing (NGS) was performed on selected metastatic and histologically low-risk cases. Statistical analysis was conducted using SPSS version 30.
Results: Median age was 26 years (range: 8–71), and median tumour size was 6.5 cm (range: 1.5–22 cm). Of the patients, 86.9% were female (n=53) and 13.1% male (n=8). LVI was detected in 1.8%. Nuclear β-catenin expression was present in all cases. PR, AR, and BAP1 were positive in 84.1%, 77.5%, and 77.5%, respectively. BAP1 loss was more common in adults than in children ($p<0.05$). Median follow-up was 98.9 months. Metastasis occurred in four cases (liver, lung, and lymph nodes), with two deaths. Ki-67 ≥4% and increased mitotic activity were associated with higher mortality ($p<0.05$). Kaplan-Meier analysis revealed significantly worse overall survival in patients with high Ki-67 expression (≥4%,p=0.03), larger tumour size (≥5 cm,p=0.04), and presence of LVI (p=0.01). NGS revealed concurrent *CTNNB1* and *BRCA2* mutations in one metastatic case.
Conclusion: Although malignant SPNs are rare, recognition of histological risk factors and molecular alterations is essential for risk stratification and personalized management. Integration of immunohistochemical profiling and targeted sequencing may aid in identifying patients who could benefit from closer follow-up or novel therapeutic strategies.

Porto-sinusoidal vascular disease in metabolic-dysfunction associated steatotic liver disease
J. Verheij[1], D.J. van Doorn[2], L. Schoenmakers[3], S. de Jager[2], M.A. Lantinga[4], A.G. Holleboom[5], J.P. Drenth[6], S. Francque[3], R.B. Takkenberg[4], A. Driessen[7]
[1]Amsterdam UMC, University of Amsterdam, Amsterdam Gastroenterology Endocrinology Metabolism, Pathology, Amsterdam, The Netherlands, [2]Amsterdam UMC, University of Amsterdam, Department of Gastroenterology and Hepatology, Amsterdam, The Netherlands, [3]UZ Antwerpen, University of Antwerp, Department of Gastroenterology and Hepatology, Antwerpen, Belgium, [4]Amsterdam UMC, University of Amsterdam, Amsterdam Gastroenterology Endocrinology Metabolism, Department of Gastroenterology and Hepatology, Amsterdam, The Netherlands, [5]Amsterdam UMC, University of Amsterdam, Amsterdam Gastroenterology Endocrinology Metabolism, Department of Vascular Medicine, Internal Medicine, Amsterdam, The Netherlands, [6]Amsterdam UMC, University of Amsterdam, Amsterdam Gastroenterology Endocrinology Metabolism, Amsterdam UMC, University of Amsterdam, Amsterdam, The Netherlands, [7]UZ Antwerpen, University of Antwerp, Department of Pathology, Antwerpen, Belgium

Background & Objectives: The prognosis of metabolic dysfunction-associated steatotic liver disease (MASLD) largely depends on the presence of liver fibrosis. Non-invasive tests to assess fibrotic stage

are being developed, but are lacking diagnostic accuracy. This might be explained by fibrotic features not assessed in the currently used Brunt staging system and/or features of portosinusoidal vascular disease (PSVD) in liver histology.
Methods: We conducted a retrospective cohort study in patients with MASLD who underwent biopsy between 2015 and 2022. All biopsies with early stage disease, defined as Brunt F0-F2, were screened for eligibility and revised by two expert liver pathologists. In addition to the VALDIG criteria for PSVD, we subclassified the number of portal tracts showing obliterative portal venopathy (0, <50% or >= 50%). Perisinusoidal fibrosis was scored as 0, grade 1 (< 1/3), grade 2 (1/3-2/3) and grade 2 (> 2/3). Secondary endpoint was the correlation of histology with liver stiffness measurement (LSM).
Results: We included 136 patients [60% male, median age 50] with a median BMI of 30 kg/m^2, 15% having F1 fibrosis and 85% F2 fibrosis. The median LSM was 8.2 kPa. Obliterative portal venopathy was the most relevant finding in our cohort, occurring in 74% of biopsies, of which 35% had >= 50% of portal fields affected. Perisinusoidal fibrosis was present in 97% of biopsies, with 62% grade 1, 32% grade 2 and 3% grade 3 perisinusoidal fibrosis. We found a positive correlation between LSM and perisinusoidal fibrosis (r= .30, p=0.01). Obliterative portal venopathy did not correlate with LSM.
Conclusion: Obliterative portal venopathy is a frequent finding in patients with MASLD, together with various amounts of perisinusoidal fibrosis, potentially explaining the heterogeneity of LSM as measured with the Fibroscan. The extent of perisinusoidal fibrosis is not adequately taken into account in the current staging systems and correlates significantly with LSM.

OFP-08-011
Intratumoral bacterial abundance confers poor response to adjuvant gemcitabine in resected pancreatic cancer patients which is mitigated by postoperative antibiotics
M. Günther[1,2,3], S.A. Surendran[2], N. Hauer[2], F. Fahrenschon[2], M.D. Arslan[2], S. Ormanns[1,2,3]
[1]Innpath Institute of Pathology, Tirol Kliniken, Innsbruck, Austria, [2]Institute of Pathology, Faculty of Medicine, Ludwig-Maximilians-University, Munich, Germany, [3]Institute of General Pathology, Medical University Innsbruck, Innsbruck, Austria

Background & Objectives: Adjuvant gemcitabine (aGC) is still a therapeutic mainstay after resection of pancreatic ductal adenocarcinoma (PDAC), but its efficacy is impaired by gram-negative intratumoral bacteria, suggesting a potential therapeutic implication of additive antibiotics. PDAC however contains several other bacterial strains capable of gemcitabine degradation.
Methods: Using immunohistochemistry and fluorescence-in-situ-hybridization on the samples of a large cohort of resected PDAC patients (n=342), we examined how the intratumoral bacterial abundance affected patient outcomes with respect to aGC therapy and whether the use of pre- or postoperative antibiotics (ABT) improved the prognosis. We confirmed the findings in several independent external cohorts (total n=297).
Results: High intratumoral bacterial abundance impaired aGC efficacy (disease free survival (DFS) 9.4 vs 19.1 months, p<0.001; overall survival (OS) 19.4 vs 34.0 months, p<0.001), which was mitigated by postoperative ABT application (DFS 7.9 vs 12.4 months, p<0.001, OS 15.2 vs 29.6 months, p<0.001). Postoperative ABT improved outcome of patients with low bacterial abundance in their tumours (DFS 15.1 vs 34.8 months, p<0.001, OS 28.5 vs 56.00 months, p<0.001).
Conclusion: High intratumoral bacterial abundance may predict poor response to adjuvant gemcitabine treatment, whereas postoperative ABT improves it. We propose postoperative ABT as potential additive treatment before or during aGC therapy after PDAC resection.

OFP-08-012
Deep proteogenomic characterization of solid pseudopapillary neoplasm (SPN) of the pancreas reveals specific protein markers, metabolic adaptation, immune microenvironment, and therapeutic targets
M. Roehrl[1]
[1]Beth Israel Deaconess Medical Centre, Harvard Medical School, Pathology, Boston, USA

Background & Objectives: Solid pseudopapillary neoplasm (SPN) is a rare neoplasm of the pancreas of unclear histogenesis. SPN accounts for 1-2% of pancreatic tumours and has a female predominance. The biology of SPN remains poorly understood, especially at proteome level. We report the first comprehensive integrated proteogenomic characterization of SPN and investigate differences to other pancreatic neoplasms.
Methods: We collected tissues from SPNs, pancreatic ductal adenocarcinomas, acinar cell carcinomas, pancreatoblastomas, well-differentiated pancreatic neuroendocrine tumours, and benign exocrine pancreatic tissues. Samples were exome-sequenced. LC-MS was performed on a Q Exactive Plus mass spectrometer. Metascape was used to conduct pathway enrichment analyses. Gene Set Enrichment Analysis was performed by projectingprotein expression onto GO, Hallmark, KEGG, and Reactome pathway sets. We calculated immune scores from the protein expression matrix of all samples. We inferred immune cell abundance using the xCell tool.
Results: We discovered that the SPN proteome is clearly distinct from that of other pancreatic entities, and that lysosome-related proteins were enriched in SPN, suggesting a possible link to metabolic adaptation mechanisms in low-nutrient environments since lysosomal degradation products are biological energy sources.
We also discovered that MITF, one of lysosomal process regulators, was highly specific for SPN and superior to TFE3. Furthermore, our proteome analysis found that SPN was an immune-cold tumour with low MHC class I molecule expression compared to pancreatic ductal adenocarcinoma. To expand possible treatment options for SPN, we conducted drug repositioning searches and identified 21 protein targets that could be targeted with already approved drugs.
Conclusion: We present the first mass-spectrometry-based, comprehensive, unbiased deep proteogenomic characterization of SPN. Our results contribute to a deeper understanding of the biology of SPN and the distinction of SPN from other pancreatic neoplasms such as PDAC, ACC, PBL, or PNET. Our discoveries of new SPN-specific protein biomarkers have direct implications for the development of novel therapeutic targets.

OFP-09-001
Age, gender and skin site are associated with spatial distribution of mitoses in melanoma
S. Tsuriel[1], B. Gabay[1], V. Hannes[1], R. Hagege[1], D. Hershkovitz[1,2]
[1]Tel Aviv Sourasky Medical Centre, Institute of Pathology, Tel Aviv, Israel, [2]Tel Aviv University, Pathology, Tel Aviv, Israel

Background & Objectives: Melanomas can be sub-grouped into those arising in sun-exposed and non-sun-exposed skin regions. Numerous differences have been documented between these groups regarding their origin, microenvironment, mutational landscape, and prognosis. However, limited data exists on the spatial arrangement of melanoma. We developed a deep learning algorithm for mitosis

segmentation on whole H&E slides and used it to evaluate the spatial arrangement of mitosis in melanoma.
Methods: H&E slides from 27 melanoma cases were digitized. Demographic and clinical data were extracted from the pathology reports. The spatial organization of the mitosis on the tumours was analysed using the mitosis segmentation algorithm to identify the location of each mitosis. In 33 slides from 17 cases, the epidermis and the invasive front were annotated, and the relative locations of the mitoses were calculated.
Results: The mitosis algorithm detected 34,363 mitotic figures that underwent spatial analysis for each slide. Our analysis revealed significant differences in the spatial distribution and clustering patterns between patients younger than 70 and those older, as well as between sun-exposed and covered areas, and between tumours in males and females. In a second cohort of 9,176 mitosis, we annotate the epidermis and the invasive front, and found that in exposed areas, mitosis tended to be significantly closer to the invasive front than in covered areas.
Conclusion: Our algorithm enables mass segmentation and spatial analysis of mitosis in melanoma, revealing differences not typically noted in standard pathological examinations. Combining this with spatial analysis of other elements in melanoma, such as blood vessels and immune cells, and correlating results with clinical follow-up may lead to better understanding of the disease.

OFP-09-002
Deep learning-enhanced detection of invasive breast carcinoma in extensive ductal carcinoma in situ: a clinically validated human-AI approach
C. Jiang[1], X. Chao[1], M. Li[1], X. Cai[1], C. Zheng[1], K. Chen[1], S. Xu[2], P. Sun[1]
[1]Sun Yat-sen University Cancer Centre, Pathology, Guangzhou, China, [2]Bio-totem Pte Ltd, Suzhou, China

Background & Objectives: Extensive intraductal carcinoma (EIC), a clinically significant DCIS subtype, presents diagnostic challenges particularly in detecting concurrent invasive components crucial for patient management. We developed a deep learning-based segmentation model for invasive carcinoma detection in EIC and evaluated a human-AI collaborative approach under real-world diagnostic conditions.
Methods: Using an expanded TiGER Challenge dataset, we addressed class imbalance through weakly-supervised pseudo-labelling, achieving ten-fold dataset expansion with minimal manual effort. Clinical validation involved 576 WSIs from 44 EIC patients (with/without invasion), comparing manual (4 pathologists), AI-standalone, and human-AI modes via two-round cross-validation, assessing sensitivity, specificity, NPV, IHC use, and diagnostic time.
Results: The AI segmentation model demonstrated consistent performance across all datasets, achieving weighted DICE scores of 0.8772 (training), 0.8531 (validation), and 0.8468 (test). The model maintained high segmentation accuracy for all critical tissue classes: invasive carcinoma, DCIS, and normal glandular tissue. In diagnostic performance comparisons, manual diagnosis by pathologists showed 82.7% sensitivity, 96.0% specificity, and 89.6% negative predictive value (NPV). Standalone AI analysis significantly increased sensitivity to 95.6% and NPV to 96.4%, though with reduced specificity (76.6%). The human-AI collaborative approach optimally balanced these metrics, achieving 95.1% sensitivity, 91.7% specificity, and 96.7% NPV. Significant clinical workflow improvements were observed in the human-AI collaborative mode, including reduced mean diagnostic time per slide by 41.4% (from 102.6s to 60.1s; $P<0.001$), decreased unnecessary IHC testing by 40.4% (from 52 to 31 cases in 226 WSIs with invasive components; $P=0.011$). Receiver operating characteristic (ROC) analysis revealed superior diagnostic performance in the human-AI collaborative mode (AUC 0.904 vs 0.847 for manual diagnosis; $P=0.0124$).
Conclusion: This human-AI system demonstrates clinically meaningful improvements in EIC diagnosis, showing strong potential for routine implementation to enhance precision and workflow efficiency.

OFP-09-003
Predicting response to neoadjuvant therapy using artificial intelligence on digitized pathology slides: a systematic review
S. Shin[1], K. Kwakkenbos[1], D. Hilling[2,3,4], A. Stubbs[1], K. Verhoef[2,3], C. van Deurzen[1], J. von der Thüsen[1], F. Akram[1]
[1]Erasmus University Medical Centre, Pathology and Clinical Bioinformatics, Rotterdam, The Netherlands, [2]Erasmus University Medical Centre, Surgical Oncology and Gastrointestinal Surgery, Rotterdam, The Netherlands, [3]Erasmus MC Cancer Institute, Rotterdam, The Netherlands, [4]Erasmus MC Datahub, Rotterdam, The Netherlands

Background & Objectives: Neoadjuvant therapy (NAT) is an important treatment strategy in oncology. However, not all patients benefit equally from NAT, and a personalized prediction of response to NAT is needed to improve treatment decision-making and patient survival. Artificial intelligence (AI)-driven approaches have shown potential in predicting treatment response. Despite increasing research in this domain, a systematic review of AI applications in NAT assessment with pathology features is lacking. Therefore, we present a comprehensive overview of studies that applied AI-based methods to Haematoxylin and Eosin (H&E) stained histopathology slides for NAT response prediction.
Methods: A systematic search was conducted in Medline, Embase, Web of Science, Cochrane Central Register of Controlled Trials, and Google Scholar. Two reviewers independently screened the identified studies, following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines.
Results: After removal of duplicates, 235 studies were screened for eligibility based on the exclusion criteria. 26 relevant studies that predicted NAT response using H&E-stained pathologic slides were included and reviewed. 11 studies presented an end-to-end deep learning approach, directly predicting NAT response from H&E slides, while 14 studies used AI to extract biomarkers, after which a second model predicted NAT response. To extract features, 12 studies used a supervised machine learning approach. 6 studies demonstrated that multimodal approaches, especially combining H&E slides with radiomics features, improved the performance of AI in predicting pathological complete response.
Conclusion: The current literature demonstrates that pathological features hold the potential to predict NAT response. Promising biomarkers have recently emerged such as HER2 for breast cancer; however, further investigation is needed for other cancer types. Moreover, to develop reliable, robust, and accurate models, larger datasets are essential. Additionally, these models should be interpretable to gain the trust of clinicians who will use them in the future, necessitating future research into their clinical applicability.

OFP-09-004
Granulomatous inflammation in a cohort of 188,880 lower endoscopy biopsy specimens
F. Wang[1], E. Ho[1], A. Naqvi[2], I. Kak[2], M. Bonert[2]
[1]McMaster University, Department of Medicine, Hamilton, Canada, [2]McMaster University, Department of Pathology & Molecular Medicine, Hamilton, Canada

Background & Objectives: Granulomatous inflammation is an uncommon pathologic finding; however, it is clinically significant. Its prevalence and call rate are not routinely assessed. This work sought to assess the call rate of granulomatous inflammation, by anatomical site, pathologist, submitting MD and polyp status.

Methods: A Hugging Face/Pytorch multilayer perceptron (MLP)-large language model (BERT) was used in conjunction with transfer learning to interpret lower endoscopy biopsy specimens (LEBS). Pre-processing was done with string matching which selected reports with "granuloma" and extracted text fragments with "granuloma". Specimens with the word "granuloma" were randomly audited to assess accuracy of the approach.
Results: The cohort had 188,880 LEBS out of which 1,290 specimens were labelled by two individuals and used to train a MLP-BERT model. Pre-processing identified 173,053 LEBS without the term "granuloma". A partial string matching found two instances where "granuloma" was misspelled. The remaining 15,827 of 188,880 LEBS were classified by MLP-BERT and 1,344 were positive. Accuracy was assessed in a random subset of the 15,827 and was correct in 1494 of 1500 LEBS. Non-polyp specimens (NPS) (108,734/188,880) had 1,307 granulomas present. In logistic regression of NPS, pathologist and submitting MD predicted granulomas (both $P<0.0001$) and anatomical location did not ($P>0.1$). Among pathologists reading >600 NPS LEBS the mean/std/median/max/min granuloma rate was 1.2%/1.6%/0.6%/6.7%/0.03%. 8/30 pathologists reading >1000 NPS LEBS were 99.9% confidence interval outliers on a funnel plot centred on the group median rate (0.6%). "Negative for granuloma" (and text variants) rate median/max/min was 4%/62%/0%.
Conclusion: Granulomatous inflammation does not appear to vary by anatomical location in LEBS. Granuloma call rates were similar for 22/30 pathologists suggesting moderate concordance. Reporting of the negative finding has very high variability. There appears to be room for diagnostic rate optimization; however, the accuracy of individual pathologist rates should be confirmed with targeted reviews, as reporting style may impact MLP-BERT classification.

OFP-09-005
H&E analysis of tumour microenvironment features with prognostic implications in lung adenocarcinoma
W. Ahmad[1], F. Kreten[1], A. Rasokat[2], S. Michels[2], J. Wolf[2], M. Bauer[3], L. Glamann[3], C. Wickenhauser[3], A. Bychkov[4], J. Fukuoka[5], R. Büttner[1], Y. Tolkach[1]
[1]Institute of Pathology, University Hospital Cologne, Cologne, Germany, [2]Lung Cancer Group Cologne, University Hospital Cologne, Department I for Internal Medicine, Cologne, Germany, [3]Institute of Pathology, University Hospital Halle, Halle, Germany, [4]Department of Pathology, Kameda Medical Hospital, Kamogawa, Japan, [5]Department of Pathology Informatics, Nagasaki University, Nagasaki, Japan

Background & Objectives: Lung adenocarcinoma is the most common subtype of lung cancer and a leading cause of cancer related mortality. Digital pathology and AI algorithms allow for the automatic extraction of quantitative morphological and spatial information from H&E stained whole-slide images (WSIs). We establish a fully automated pipeline that segments tumour tissue compartments and classifies individual tumour, immune, and stromal cells, resulting in useful parameters for the assessment of the tumour microenvironment and aggressivity. We study the prognostic relevance of these parameters across several international patient cohorts and survival endpoints.
Methods: The pipeline includes preanalytical modules (tissue detection and rigorous quality control), tissue segmentation algorithm (all tumour-relevant classes), and a previously validated single cell segmentation and classification algorithm allowing detection of tumour cells, lymphocytes, plasma cells, eosinophils, neutrophils, and connective tissue cells. The parameters include overall stromal cellularity assessment, abundance of single cell types in different compartments and spatial parameters deciphering different patterns in cellular neighbourhoods. We extensively analyse intratumoral heterogeneity in the context of these parameters. We utilize one exploratory cohort (n = 431) and four independent validation cohorts (total n = 912) with available follow-up data.
Results: We show independent prognostic value of multiple parameters such as overall stroma cellularity, intraepithelial and stromal lymphocyte quantities, and stroma composition with regard to connective tissue cells and granulocytes. We define 10 types of local cellular neighbourhoods, 7 of them associated with prognosis in validation studies. We show that the patterns of organization of connective tissue cells in the stroma are of significant importance for tumour aggressivity.
Conclusion: We establish a computational pipeline for lung adenocarcinoma that allows for the extraction of fully explainable prognostic parameters directly from routine H&E stained histological slides. These parameters have independent value and can be a foundation for advanced grading systems, fine-grained patient risk stratification, and personalization of oncological therapy.

OFP-09-006
Multimodal whole slide foundation model for pathology
S. Wagner[1,2,3], T. Ding[1,4,5], A.H. Song[1,4,5], R.J. Chen[1,4,5], M.Y. Lu[1,4,5], A. Zhang[1,4,5], A.J. Vaidya[1,4,5], G. Jaume[1,4,5], M. Shaban[1,4,5], A. Kim[1,6], D.F.K. Williamson[7], B. Chen[1,4,5], C. Almagro-Perez[1,4,5], P. Doucet[1,4,5], S. Sahai[1,4,5], C. Chen[1,4,5], D. Komura[8], A. Kawabe[8], S. Ishikawa[8], G. Gerber[1], T. Peng[2,3], L.P. Le[1,9], F. Mahmood[9,4,5]
[1]Mass General Brigham, Harvard Medical School, Department of Pathology, Boston, USA, [2]Helmholtz Munich, Helmholtz AI, Munich, Germany, [3]Technical University of Munich, School of Computation, Information and Technology, Munich, Germany, [4]Dana-Farber Cancer Institute, Data Science Program, Boston, USA, [5]Broad Institute of Harvard and MIT, Cancer Program, Cambridge, USA, [6]Pusan National University, Department of Pathology, Busan, Republic of Korea, [7]Emory University School of Medicine, Department of Pathology and Laboratory Medicine, Atlanta, USA, [8]The University of Tokyo, Department of Preventive Medicine, Tokyo, Japan, [9]Massachusetts Institute of Technology, Harvard-MIT Division of Health Sciences and Technology, Cambridge, USA

Background & Objectives: The field of computational pathology has been transformed with recent advances in foundation models that encode histopathology region-of-interests (ROIs) into versatile and transferable feature representations via self-supervised learning (SSL). However, translating these advancements to address complex clinical challenges at the patient and slide level remains constrained by limited clinical data in disease-specific cohorts, especially for rare clinical conditions.
Methods: We propose the Transformer-based pathology Image and Text Alignment Network (TITAN), a multimodal whole-slide vision-language model for general-purpose slide representation learning in histopathology. Building on the success of knowledge distillation and masked-image modelling for patch encoder pretraining, TITAN introduces a novel paradigm that leverages millions of high-resolution regions-of-interest ($8{,}192 \times 8{,}192$ pixels) for large-scale, resolution-agnostic pretraining and scalable WSI encoding.
Results: Trained using 336K WSIs across 20 organ types, vision-only TITAN produces general-purpose slide representations that can readily be applied to slide-level tasks such as cancer subtyping, biomarker prediction, outcome prognosis, and slide retrieval tasks, outperforming supervised baselines and existing multimodal slide foundation models. To augment TITAN with language capabilities, we further finetune by contrasting with 423K synthetic fine-grained ROI-captions generated with PathChat, a multimodal generative AI copilot for pathology, and with 183K pathology reports at slide level. Through comprehensive evaluation across a large range of clinical tasks, including the first application to rare cancer retrieval across 43 rare cancer types, we demonstrate the efficacy of our vision-language

pretraining approach, showcasing the general-purpose capability of our slide foundation model.
Conclusion: We introduce a multimodal whole-slide foundation model for pathology, TITAN, that combines and elevates successful recipes of self-supervised learning from the patch level to the slide level. Without any finetuning or requiring clinical labels, TITAN can extract general-purpose slide representations and generate pathology reports that generalize to resource-limited clinical scenarios such as rare disease retrieval, few-shot, and zero-shot classification.

OFP-09-007

Evaluation of tumour budding in lung adenocarcinomas a retrospective study about patients received sublobar resection

Z.E. Széll[1], N. Zombori-Tóth[2], F. Hegedűs[1], J. Furák[3], T. Zombori[1]
[1]University of Szeged, Department of Pathology, Szeged, Hungary, [2]University of Szeged, Department of Pulmonology, Szeged, Hungary, [3]University of Szeged, Department of Surgery, Szeged, Hungary

Background & Objectives: The presence and prognostic significance of tumour budding are less investigated particularly in patients diagnosed with pulmonary adenocarcinoma who underwent sublobar resection. We aimed to examine the extent of tumour budding semi-quantitatively and evaluate its prognostic impact on overall survival (OS) and recurrence-free survival (RFS).
Methods: In our retrospective cohort investigation, the number of stromal tumour buds in a hot spot and in 10 medium power fields were recorded on histological slides. Other clinicopathological data were obtained from clinical charts. As statistics, Kaplan-Meier analyses and Cox regressions were applied.
Results: Altogether 61 patients were included. The presence of tumour budding was more frequent in high-grade adenocarcinomas ($p<0.001$) with vascular- ($p=0.025$) lymphovascular spread ($p<0.001$), lymph node metastasis ($p=0.002$) and pleural invasion ($p=0.02$). The results of tumour budding assessment in hot spot and in 10 medium power fields were statistically similar. Concerning OS and RFS data, in univariate models, stage, lymphovascular and pleural invasion, spread through air spaces (STAS), and tumour budding were significant prognostic markers, respectively. In multivariate analysis, higher stage (HR: 7.9; 95%CI: 2.44-12.07; $p=0.007$), lymphovascular spread (HR: 4.62; 95%CI: 1.31-16.4; $p=0.018$) and tumour budding (HR: 3.03; 95%CI: 1.04-10.43; $p=0.019$) were found to have impact on OS data. Regarding RFS estimates, STAS (HR: 5.01; 95%CI: 1.61-15.62; $p=0.005$) and tumour budding (HR: 3.20; 95%CI: 1.24-8.27; $p=0.016$) were independent prognostic markers.
Conclusion: Tumour budding is a less investigated unfavourable prognostic factor among pulmonary adenocarcinomas. However, lobar resection is the gold standard treatment for primary pulmonary neoplasms; sublobar resection is an alternative therapeutic modality for patients with decreased respiratory capabilities. The intraoperative demonstration of presence of tumour budding may be an argument for the escalation of the sublobar resection into a lobar surgery along lymphadenectomy.

p53 immunohistochemistry as a surrogate biomarker for TP53 mutational status in lung cancer

J.L. Hernandez Alfonso[1], A. Benito Berlinches[1], N.I. Torres Calcines[1], S. Aso Manso[1], A. Santon Roldan[1], T. Caniego Casas[1], V.A. Jacome Gaibor[1], M.G. Rosas Hernandez[1], G. Bonilla Hernandez[1], M. Pedrera Rubio[1]
[1]Hospital Ramon y Cajal, Pathology, Madrid, Spain

Background & Objectives: TP53 is a pivotal tumour suppressor gene in humans. In lung cancer, it has been established as both a prognostic and predictive biomarker. Immunohistochemical analysis of p53 (p53 IHC) as a surrogate marker of TP53 mutational status is well established in endometrial, ovarian, and colorectal carcinomas. However, its applicability in lung cancer remains uncertain. This study aimed to evaluate the utility of p53 IHC as a surrogate biomarker for TP53 mutational status in lung cancer.
Methods: A total of 112 lung cancer cases with both p53 IHC and next-generation sequencing (NGS) data were analysed. p53 expression patterns were categorised into three groups: wild-type, overexpression and null. For analytical purposes, p53 IHC results were classified as either wild-type or aberrant (including overexpression and null patterns). TP53 mutational status was determined using four different commercial NGS panels. Statistical analyses were performed using IBM® SPSS® Statistics 25.
Results: Most samples were obtained from biopsies (42%), surgical specimens (38%) and cytology (20%). Adenocarcinoma was the predominant histological subtype (80 cases, 71%), followed by squamous cell carcinoma (8 cases, 7%). Aberrant p53 expression was observed in 65 cases (58%), with overexpression being the most prevalent pattern (91%). TP53 mutations were detected in 58 cases (52%) via NGS. The correlation between p53 IHC and TP53 mutational status yielded a sensitivity of 96.6%, a specificity of 83.3%, a positive predictive value of 86.2%, and a negative predictive value of 95.7%. A "substantial agreement" was observed between both methods ($\kappa = 0.802$).
Conclusion: These findings support the use of p53 immunohistochemistry (IHC) as a surrogate biomarker for evaluating TP53 mutational status in lung cancer. p53 IHC is advocated as a reliable diagnostic and prognostic tool, particularly in settings where next-generation sequencing (NGS) is unavailable.

OFP-09-010

Artificial intelligence-assessed LKB1 immunohistochemical expression better differentiates LKB1-*impaired* and LKB1-*proficient* non-small cell lung cancers rather than NGS analysis

M. Barella[1], C. Borzi[2], V. Lagano[3], B. Bodini[1], M. Gentili[2], A. Fabbri[4], D. Lorenzini[4], R. Mortarini[3], G. Sozzi[2], G. Pruneri[4], M. Moro[2], M. Milione[1]
[1]Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Diagnostic Innovation, Pathology Unit 1, Milan, Italy, [2]Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Experimental Oncology, Epigenomics and Biomarkers of Solid Tumours, Milan, Italy, [3]Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Experimental Oncology, Translational Immunology Group, Milan, Italy, [4]Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Diagnostic Innovation, Pathology Unit 2, Milan, Italy

Background & Objectives: LKB1-mutated non-small cell lung cancers (NSCLCs) display an aggressive phenotype, with unique tumour microenvironment features. However, the correlation between *LKB1* mutational status and protein expression is poor. We recently identified IL-6 stromal expression as a feature of LKB1-*impaired* NSCLCs. Our aim is to compare the efficacy of *LKB1* mutational status and immunohistochemical expression in discriminating IL-6 expressing LKB1-*impaired* NSCLCs.
Methods: We retrieved 36 cases of KRAS-mutated lung adenocarcinoma. Immunohistochemistry for LKB1 (Ley37D/G6, Santa Cruz Biotechnology) and IL-6 (10C12, Leica Biosystems) was performed. A machine learning (ML) algorithm was created to distinguish tumour and stroma for both IHC-staining; IL-6 was evaluated as positive cells/mm2, LKB1 with a modified H-score (mH-score), accounting absolute cell number. *LKB1* mutational status was assessed by Ion-Torrent NGS.

Results: NGS analysis showed 7 cases (19%) with *LKB1* pathogenic or likely-pathogenic variants (MUT), 4 cases (11%) with *LKB1* VUS and 25 *LKB1* wild-type cases (70%) (WT). We calculated the ratio between IL-6 expression in stromal and tumour cells and we found no difference in MUT+VUS versus WT, but an almost statically significant (p=0,05) difference between MUT (mean IL-6 S/T = 3,84) and VUS+WT (mean IL-6 S/T = 1,30 and 1,06). We distinguished LKB1 high-expressor (17 cases) and low-expressor (17 cases), based on the median LKB1 pathologist-assessed H-score (30), but no difference was established in IL-6 expression. Exploiting our ML algorithm, we chose a cutoff of mH-score = 0,2 to distinguish high- and low-expressor, and we identified a higher stromal IL-6 expression in LKB1 low-expressor compared to LKB1 high-expressor (p=0,0452), and no difference in tumour cell IL-6 expression (p=0,362).
Conclusion: An increased stromal cell IL-6 production was guessed in pathogenic *LKB1*-mutated NSLCs and endorsed in LKB1 low-expressor. Artificial intelligence-assessed LKB1 immunohistochemical expression overperforms mutational status and pathologist-assessed H-score in identifying LKB1-*impaired* NSCLCs. Further analyses are needed to better characterize LKB1-*impaired* tumours.

OFP-09-011
Integrated molecular analysis depicts molecular signatures associated with response to tyrosine kinase inhibitors in advanced NSCLC
F. Napoli[1], V. Zambelli[1], P. Bironzo[1], S. Cappia[1], G. Farinea[1], E. Garbo[1], A. Merlini[1], S. Poletto[1], I. Rapa[2], L. Righi[1], G.V. Scagliotti[1], M. Volante[1], S. Novello[1]
[1]University of Turin, Department of Oncology, Turin, Italy, [2]San Luigi Hospital, Pathology Unit, Turin, Italy

Background & Objectives: Tyrosine kinase inhibitors (TKI) are the mainstay of treatment in oncogene addicted non-small cell lung cancer (NSCLC). However, resistance to TKI invariably occurs during treatment course but data on drug resistance-related mechanisms are largely missing. Therefore, we designed a study to deeply characterize the genomic and epigenetic signatures associated with TKI response in oncogene-addicted NSCLC patients.
Methods: Sixty samples from advanced NSCLC patients treated with TKI at first line were analysed for genomic profiling using the Oncomine Comprehensive Assay Plus (ThermoFisher Scientific) panel, including 44 EGFR-mutated and 16 ALK-fused cases. Additionally, 52 cases (46 in overlap with NGS testing, 36 EGFR-mutated and 16 ALK-fused cases) were analysed using a PCR-based global miRNome assay (miRCURY LNA miRNA PCR kit, Quiagen). Potential targets of significantly deregulated microRNA and their biological functions were predicted by STRING and MirDIP softwares.
Results: In EGFR-mutated cases, progressive disease during therapy was associated with lower tumour mutational burden, presence of TP53 co-mutations and gains in Chr1q. Shorter time to progression was observed in cases harbouring TP53 co-mutations and gains in Chr5p and Chr7p. In ALK-fused cases, no molecular characteristic was significantly associated with type of response. However, shorter time to progression was observed in cases with HLA A gene loss. MicroRNA profiling clustered both EGFR and ALK-altered cases into 3 main clusters not significantly associated with specific profiles of responsiveness. However, good and bad responders showed significant deregulation of a set of microRNA. In EGFR-mutated, the most differentially regulated miRNAs were miR-423-3p, miR-744-5p and miR-455-3p, with a main predicted interference of the transforming growth factor-β pathway, whereas in ALK-fused cases immune-related chemokine pathway was deregulated through the modulation of miR-135a-5p, miR-331-3p and miR-196a-5p.
Conclusion: The present data claim the role of extended molecular testing to predict response to TKI in oncogene addicted NSCLC and identify novel potential predictive biomarkers.

OFP-09-012
Loss of Claudin-18 in immunohistochemistry: a potential specific biomarker to differentiate lung adenocarcinoma from lung cancer mimickers
S. Lucà[1], M. Montella[1], S. Campione[2], M. Ali[1], F. Napoli[3], M.G. Disanto[4], R. Monti[5], C.M. Della Corte[6], F. Morgillo[6], A. Fiorelli[7], L. Righi[3], M. Barbareschi[4], R. Franco[1]
[1]University of Campania "Luigi Vanvitelli", Pathology Unit, Department of Mental and Physical Health and Preventive Medicine, Naples, Italy, [2]A. Cardarelli Hospital, Department of Advanced Diagnostic-Therapeutic Technologies and Health Services Section of Anatomic Pathology, Naples, Italy, [3]San Luigi Hospital, University of Torino, Pathology Unit, Department of Oncology, Turin, Italy, [4]Santa Chiara Hospital-APSS, Operative Unit of Anatomy Pathology, Trento, Italy, [5]University of Campania "Luigi Vanvitelli", Department of Precision Medicine, Naples, Italy, [6]University of Campania "Luigi Vanvitelli", Department of Precision Medicine, Medical Oncology, Naples, Italy, [7]University of Campania "Luigi Vanvitelli", Division of Thoracic Surgery, Naples, Italy

Background & Objectives: Lung cancer (LC), particularly lung adenocarcinoma (LUAD), is often diagnosed at an advanced stage, with limited biopsy samples available for molecular testing. Claudins, especially *Cldn18.1*, play a crucial role in lung epithelial barrier function and may impact LUAD progression. Reduced *Cldn18.1* expression in LUAD has been linked to increased YAP activity, promoting cell proliferation. This study aims to evaluate *Cldn18.1* expression in LUAD using immunohistochemistry, exploring its potential as a diagnostic tool.
Methods: We analysed 164 lung surgical resection samples and 51 diagnostic biopsy samples from patients with clinically suspected pulmonary neoplasms, including CT-guided core needle biopsy (CNBs), transbronchial biopsy (TBBs), and cell block (CBs). Immunohistochemical staining for *Cldn18.1* was performed on 4 µm sections using the Ventana platform, with AT1 and AT2 cells as internal controls. *Cldn18.1* expression was evaluated semi quantitatively, stratifying cases by the percentage of tumour-positive cells in 10% intervals.
Results: *Cldn18.1* expression was observed in normal alveolar cells in all cases. Conversely, *Cldn18.1* was absent in all lung cancer histotypes except for LUAD. In invasive Non-Mucinous LUAD (NM-LUAD), 68% of cases showed no expression, 27.8% exhibited 1-49% positivity, and only 4.2% displayed expression in more than 50% of tumour cells. Conversely, all Invasive Mucinous LUAD (IM-LUAD) cases showed positive staining in at least 50% of tumour cells. Mixed IM/NM-LUAD and Colloid-LUAD exhibited either variable or no protein expression. In small biopsy samples, most LUAD (79.3%) showed a lack of *Cldn18.1* expression. LUAD with mucinous features demonstrated widespread *Cldn18.1* staining, while LUAD with colloid features and NSCLC-NOS were negative.
Conclusion: *Cldn18.1* demonstrates a trend of reduced IHC expression in LUAD, except for IM-LUAD. This loss of expression may serve as a useful marker for diagnosing LUAD in small tissue samples, particularly in cases with limited material and in diagnostically challenging cases.

OFP-09-013
Current approaches, barriers, and future directions in mesothelioma diagnostics: results from an Italian national survey
F. Pezzuto[1], G. Lopez[2], F. Barbisan[3], L.P.A. Rosso[2], G. Pelosi[2], L. Righi[4], F. Calabrese[1]

[1]University of Padova, Padova, Italy, [2]University of Milan, Milan, Italy, [3]AOU delle Marche, Ancona, Italy, [4]University of Turin, Turin, Italy

Background & Objectives: This nationwide survey aimed to evaluate current diagnostic practices, adherence to international guidelines, and key challenges faced by Italian pathologists in diagnosing pleural mesothelioma (PM), an aggressive malignancy with rising therapeutic complexity.
Methods: A 38-item questionnaire was distributed electronically to Italian pathologists involved in PM diagnostics. The survey explored demographics, biopsy procedures, immunohistochemical and molecular practices, educational needs, and barriers to research collaboration.
Results: Fifty-five pathologists with diverse experience levels and institutional affiliations participated, predominantly from academic medical centres. Marked variability emerged in tissue sampling and biobanking practices. Diagnostic challenges included accurate recognition of sarcomatoid/desmoplastic features, limited adipose tissue in biopsies, and difficulties in histotype subclassification. Most pathologists employed multidisciplinary discussions and molecular analyses (e.g., BAP1, MTAP) for inconclusive cases. While immunohistochemistry was routinely used, especially calretinin, WT1, and BAP1, standardized reporting protocols and molecular tools like p16 FISH and MTAP IHC were inconsistently adopted. Research-oriented practices, such as biobanking, were limited by institutional infrastructure and the absence of standardized protocols. Although digital pathology infrastructure was not broadly identified as a limiting factor, case-sharing logistics (e.g., paraffin block transport) posed challenges. Participants expressed a strong need for enhanced access to molecular diagnostics, national case repositories, and training on novel biomarkers.
Conclusion: This survey underscores diagnostic variability and resource gaps in PM pathology across Italy. Standardizing histopathological protocols, expanding access to molecular tools, and fostering structured national collaboration are key steps toward improving diagnostic precision. Targeted training initiatives and support for biobanking and multicentre research efforts will be critical for advancing both diagnostic and therapeutic outcomes in PM.

OFP-09-015
Pneumoconiosis, a retrospective study
H. Requena Cabello[1], M. Zabaleta[2], J.J. Gómez Román[1]
[1]Marqués de Valdecilla Universitary Hospital, Pathology, Santander, Spain, [2]Cantabria University, Santander, Spain

Background & Objectives: Exposure-related lung diseases constitute a group of occupational, preventable diseases caused by the inhalation of organic and inorganic dust. The number of affected patients remains high, although it is likely underestimated. Currently, treatment is very limited once the fibrotic stage is reached. Our role as pathologists is crucial, as our diagnoses must clearly establish the presence of foreign elements and the body's response to them.
Methods: A descriptive and retrospective study consisting of 64 patients incidentally diagnosed with pneumoconiosis through biopsy or analysis of surgical specimens from patients without an initial clinical suspicion. Cases were collected between January 9, 2020, and September 25, 2023. Data regarding occupational activity or environmental exposure were gathered as recorded in electronic medical records and corresponding clinical reports.
Results: The majority of patients were diagnosed with mixed pneumoconiosis from coal dust and silicates, with a predominance of male patients and a mean age of 69 years. Information was available in 62.5% of medical records, revealing that these patients worked in the construction industry. A total of 54.6% of patients presented respiratory symptoms, which were generally attributed to COPD. In 25% of cases, neither the patient's occupation nor any environmental or occupational exposure was documented in the medical records.
Regarding disease staging, 78% of patients were diagnosed in the macular or nodular stage, while 22% had progressive massive fibrosis.
Conclusion: It is essential to raise awareness among healthcare professionals about the importance of conducting a thorough medical history, including the patient's occupational and environmental background. The goal of identifying pneumoconiosis at early stages depends on awareness of the disease, as it is often underdiagnosed by pulmonologists, primary care specialists, and even pathologists.
Examining non-neoplastic areas in patients undergoing lung resection for cancer is crucial, as there are numerous lesions that must be properly diagnosed.

OFP-10-001
Deep-learning based recognition of reticulin stain distinguishes germline mutated from sporadic paragangliomas
E. Duregon[1], G. Orlando[1], C. Lopez[2], D. Kumar[3], A. Luchian[3], M. Volante[1], M. Parasiliti-Caprino[2], M. Papotti[1]
[1]University of Turin, Department of Oncology, Turin, Italy, [2]University of Turin, Department of Medical Sciences, Turin, Italy, [3]Aiforia, Helsinki, Finland

Background & Objectives: Grounded on digital pathology, computational pathology exploits the power of artificial intelligence to develop algorithms, which can learn to recognize patterns and anomalies that may elude the human eye on whole slide images (WSI). We recently observed a structural heterogeneity of reticulin framework patterns in pheochromocytomas-paragangliomas (PPGL), possibly genetically-linked. This study aims to develop a deep learning algorithm which predicts PPGL genetic profile from reticulin stained WSI.
Methods: A total of 104 PPGL (90 pheochromocytomas, 14 paragangliomas) were retrieved from the University of Turin pathology files from 2000 to 2023. All clinical, pathological and NGS genetic data were available. Two genetic outcome categories (Sporadic vs Germline mutated) were trained on 39 reticulin stained WSI by means of weakly supervised labels with 2785/10000 iterations, in an extra complex modality and a field of view of 150 μm. The analysis was performed on an untrained dataset of 24 WSI. The performance of the algorithm was considered correct if >70% WSI area was assigned to a single label. Validations on the rest of the dataset and on an external dataset are ongoing. The latest version of Aiforia Create (Version 6.2) was used.
Results: In 19/24 WSI, the algorithm correctly identified the profile (10 germline and 9 sporadic cases). As a weakly supervised model, the algorithm identified WSI regions contributing the outcome prediction. Strikingly, a reticulin framework made of a repertoire of nests from very small to large size (1-2 cells to 10-15) was the feature of germline cases, while wide areas of disrupted reticulin fibres were commonly found in sporadic cases. The cases with discrepant prediction had mixed patterns, possibly intratumor heterogeneity-related.
Conclusion: This novel deep learning model offers solid promises to standardize reticulin framework assessment and to offer pathologists and clinicians a practical tool for identifying patients who should be prioritized for genetic testing.

OFP-10-002
Hormone-associated subtypes of pulmonary neuroendocrine tumours: correlation with clinicopathological, transcriptional signatures, therapy targets and outcome
A. Ura[1], K. Evert[2], M. Evert[3], B. Märkl[4], K. Steiger[1], C. Mogler[1], H. Hoffmann[5], A. von Werder[6], D. Kaemmerer[7], G. Klöppel[1], A. Kasajima[1]

[1]TUM School of Medicine and Health, Pathology, Munich, Germany, [2]University of Regensburg, Pathology, Regensburg, Germany, [3]University of Regensburg, Institute of Pathology, Regensburg, Germany, [4]University Augsburg, Pathology, Medical Faculty, Augsburg, Germany, [5]TUM School of Medicine and Health, Thoracic Surgery, Munich, Germany, [6]TUM School of Medicine and Health, Internal Medicine II, Munich, Germany, [7]Zentralklinik Bad Berka, General and Visceral Surgery, Bad Berka, Germany

Background & Objectives: Recently pulmonary neuroendocrine tumours (NETs) were subgrouped by immunohistochemical expression of transcription factors (TFs) such as OTP, ASCL1, TTF1. The signatures correlated with clinical characteristics. However, the role of hormone expression remained unexplored. This study aimed to identify hormone-associated NET subgroups and clarify their correlation with TF signatures and clinicopathological characteristics.
Methods: We immunostained 111 resected NETs from multiple institutions (2000–2024) for the hormones GRP, ACTH, calcitonin, serotonin, the TFs OTP, ASCL1, TTF1, treatment relevant markers such as SSTR2 and DLL3, and SOX10 to identify sustentacular cells. The results were correlated with clinicopathological features as well as outcome (progression free survival).
Results: Cluster analysis based on hormone expression identified three groups: The largest group expressed GRP (63/111, 57%) with or without other hormone expression and was statistically associated with female sex (79%), non-smoking (67%), peripheral location (36%), spindle cell morphology (60%), ASCL1/OTP expression (67/78%), DLL3 positivity (71%), and presence of sustentacular cells (all $p<0.05$). The second group that expressed no hormones (29/111, 26%) and the third group with serotonin expression (19/111, 17%) shared following features: male sex (59-47%), smoker (69-50%), central location (86-88%), trabecular pattern (48-37%), absence of ASCL1/OTP expression, and sustentacular cells but differed in SSTR2 and DLL3 expression (all $p<0.05$). In addition, within the GRP group, an ACTH subgroup (28/63, 25%) could be distinguished from a calcitonin-subgroup (16/63, 14%). The ACTH-subgroup was associated with older age (median 71), neuroendocrine cell hyperplasia, high DLL3, TTF1 expression, but was negative for SSTR2 (all $p<0.05$). The calcitonin subgroup showed better outcome than the others ($p=0.03$).
Conclusion: Hormonal profiling identifies three clusters closely related to TFs signatures, clinicopathological features, therapy related molecule expression and prognosis and refines pulmonary NET-subclassification by stratifying patients and guide therapeutic strategies.

OFP-10-003

Investigation of the diagnostic and prognostic significance of IGF-2 And FGFR-4 in adrenocortical neoplasms by immunohistochemistry and real-time PCR

H. Yanar[1], M.B. Yılmaz[2], M. Deger[3], G. Akkuş[4], Ş. Erdogan[5]
[1]Gebze Fatih Government Hospital, Pathology, Kocaeli, Turkey, [2]Cukurova University, Medical Biology, Adana, Turkey, [3]Cukurova University, Urology, Adana, Turkey, [4]Cukurova University, Internal Medicine, Endocrinology, Adana, Turkey, [5]Cukurova University, Pathology, Adana, Turkey

Background & Objectives: Adrenocortical carcinomas are rare tumours diagnosed by various multifactorial algorithms. It is relatively easy to distinguish carcinomas with metastatic or periadrenal tissue invasion from adenomas, but there are difficulties in the diagnosis of organ-limited carcinomas. In addition to histopathological findings, biomarkers are needed for these tumours. In our study, we aimed to investigate the importance of IGF-2 and FGFR-4 in adenoma-carcinoma differentiation and prognostically in these tumours.
Methods: A total of 74 patients diagnosed with adrenocortical neoplasia and 19 adrenal gland for control were included in the study. IGF-2 and FGFR- 4 were studied by immunohistochemical method and real-time(RT) PCR from formalin-fixed paraffin-embedded blocks. Histopathologic, clinical findings and ki67 proliferation index and results were evaluated together.
Results: Patients with a Helsinki score of >17 and/or a ki67 proliferation index of > 9% had a statistically significant relationship with poor prognosis (mortality). IGF-2 is a significant biomarker for adenoma-carcinoma differentiation when administered by immunohistochemical and RT-PCR methods. We found a strong and significant positive correlation between IGF-2 immunohistochemistry and PCR. There is a significant correlation between IGF-2 immunohistochemical (protein) values and recurrence, metastasis, mortality and between IGF-2 mRNA (RT-PCR) values and metastasis in carcinomas. FGFR-4 isn't a useful biomarker in adrenocortical tumours in terms of diagnosis and prognostics when administered by immunohistochemical and/or RT-PCR.
Conclusion: Adrenocortical tumours, especially organ-confined carcinomas, are challenging lesions for pathologists. We have shown that when histopathological criteria, reticular framework, ki67 proliferation index and IGF-2 are evaluated together, carcinomas can be distinguished more easily and the rate of misdiagnosis can be reduced. In addition, we found that Helsinki score, ki67 index and IGF-2 are prognostically important in these tumours. We have shown that FGFR-4 isn't useful in distinguishing between adenomas and carcinomas, nor is it prognostically helpful. Therefore further studies are needed to evaulete FGFR-4 expression in adrenocortical tumours.

Autophagy as a mechanism involved in Radioiodine-Refractoriness in papillary thyroid carcinoma

R. Sparavelli[1], R. Giannini[1], S. Moretti[2], E. Macerola[1], P. Vignali[1], F. Basolo[1], E. Puxeddu[2], C. Ugolini[1]
[1]University of Pisa, Department of Surgical, Medical, Molecular Pathology and Critical Area, Pisa, Italy, [2]University of Perugia, Department of Medicine and Surgery, Perugia, Italy

Background & Objectives: Papillary thyroid carcinoma (PTC) is the most common endocrine malignancy. Despite its excellent prognosis, some PTC's variants are associated with an increased risk of recurrence. One of the major causes of local recurrence and distant metastasis is the resistance to Radioiodine (RAI) therapy.
Methods: In this study, we evaluated the expression of >700 immune-related genes in tumour microenvironment (TME) of patients affected by PTC, stratified according to RAI treatment response. In detail, 25 PTCs were subdivided into two categories: RAI resistant (R), RAI sensitive (T); while 6 patients were classified as normal patients (with normal tissue). Normal patients were considered as a reference category. To predict specific interactions between proteins, translated from the identified genes, a specific *in silico* analysis was performed to construct protein networks for R and T categories.
Results: For the R network, among the 49 differential expressed genes, 14 genes resulted as the most relevant interaction nodes, including IL-6, ITGAM, CASP3, RELA, RELB, CASP8, ITGB2, C3, JAK3, PPARG, CLEC7A, TNFRSF10B, CDH5, BCL2. At variance, for the T network, among the 31 differential expressed genes, 11 genes resulted as the most important interaction nodes, including HMGB1, IKBKB, IRAK4, MAVS, TLR7, NOD2, ITGB3, CD28, IFNAR1, CD19, CD7. Interestingly, in regards of autophagy, in the R group the pro-autophagic gene IL-6 resulted upregulated, while the anti-autophagic gene BCL2 resulted downregulated. Conversely, in the T group the key pro-autophagic gene HMGB1 resulted down-regulated.

Conclusion: RAI resistance remains a significant obstacle in the treatment of PTC. Our study suggests that in PTC RAI resistance may be driven by the capacity to activate autophagy. The investigation of process of autophagy, and the involved pathways, in the TME could be an important step for the modulation of RAI refractoriness to improve therapeutic strategies and patients' management.

OFP-10-005

Tumour microenvironment of anaplastic thyroid carcinoma: implications for patient survival

C. Rana[1], P. Ramakant[2], K. Singh[2], A. Mishra[2], I. Makkar[1]
[1]King George's Medical University, Department of Pathology, Lucknow, India, [2]King George's Medical University, Department of Endocrine Surgery, Lucknow, India

Background & Objectives: Anaplastic thyroid carcinoma (ATC) is a highly aggressive malignancy with nearly 100% mortality and limited treatment options. The tumour microenvironment (TME) plays a critical role in ATC progression, particularly immune checkpoint molecules, tumour-associated macrophages (TAMs), and adhesion molecules like E-cadherin.
This study investigates the expression of PD-L1, PD-1, TAM infiltration, and E-cadherin loss in ATC and evaluates their impact on patient survival.
Methods: A retrospective cohort of 22 ATC patients treated at King George's Medical University, Lucknow, India, between January 2017 and August 2022, was analysed. Immunohistochemical staining assessed PD-L1 and PD-1 expression, TAM density, and E-cadherin loss. Statistical correlations between these markers and overall survival were examined.
Results: Immunohistochemical evaluation revealed PD-L1 expression in 68.2% of cases, with a median tumour proportion score (TPS) of 50. PD-1 expression was limited to inflammatory cells. E-cadherin loss was observed in over 69% of cases, suggesting disrupted cell adhesion. TAM infiltration was elevated in 58.8% of patients and correlated significantly with PD-L1 expression ($p = 0.02$). Survival analysis demonstrated a mean overall survival of 3 months, with high PD-L1 expression, elevated TAM density, and increased PD-1 expression associated with shorter survival ($p < 0.001$). Patients expressing PD-L1 had a mean survival of 2.4 months compared to 4.1 months for those without PD-L1 expression ($p < 0.05$). Similarly, high PD-1 expression in inflammatory cells correlated with poorer outcomes (mean survival of 2.5 months versus 4.5 months for low expression; $p = 0.03$).
Conclusion: The findings highlight the critical role of immune markers within the TME in ATC prognosis. The association of PD-L1, PD-1, and TAM density with poor survival underscores the potential of immunotherapeutic strategies. Further research is needed to validate these biomarkers for guiding treatment approaches in ATC.

OFP-10-006

The effect of tumour microenvironment on prognosis and lymph node metastasis in oral squamous cell carcinoma

N. Arı[1], M.F. Tekin[1], B. Atasoy[2], Y. Gündoğdu[3], E.G. Özgür[4], L. Cinel[1]
[1]Marmara University School of Medicine, Department of Pathology, Istanbul, Turkey, [2]Marmara University School of Medicine, Department of Radiation Oncology, Istanbul, Turkey, [3]Marmara University School of Medicine, Department of Otorhinolaryngology, Istanbul, Turkey, [4]Marmara University School of Medicine, Department of Biostatistics, Istanbul, Turkey

Background & Objectives: Oral squamous cell carcinoma (OSCC) constitutes 90% of oral cavity cancers. Low survival rates show that current staging and grading systems are not sufficient for prognostication. Tumour microenvironment (TME) is shown to play a crucial role in cancer biology. This study aims to investigate the impact of TME components such as cancer-associated fibroblasts (CAF), tumour-infiltrating lymphocytes (TILs), tumour budding (TB), desmoplastic reaction (DR), tumour-stroma ratio (TSR) on prognosis and lymph node metastasis (LNM) as well as their potential effect on tumour progression in OSCC.
Methods: H&E slides of 129 OSCC cases diagnosed between 2017-2023 in Marmara University Hospital were histomorphologically evaluated for TSR, TB, DR and TILs. CAF density was assessed using α-SMA immunohistochemistry. Effect of each parameter on survival and their association with LNM, stage and other adverse histologic features were investigated statistically.
Results: Cases with high TB showed more aggressive features including higher depth of invasion (DOI), perineural-lymphovascular invasion, worst pattern of invasion, higher T stage and higher rates of LNM. Higher CAF density, immature stroma and low TSR were associated with higher TB, higher rates of LNM and other mentioned adverse features. High TIL density was associated with antitumoral activity, as they were linked to lower TB, lower DOI and lower rates of LNM. In univariate analysis, high TB, high CAF density, immature stroma, low TIL density and low TSR were associated with poor overall survival. In multivariate analysis, high TIL density in total tumour area and high TSR were associated with better overall survival. High CAF density and low TIL density were associated with worse progression-free survival in univariate analysis, while in multivariate analysis, these parameters did not show independent effects.
Conclusion: This study demonstrates that TME has a significant impact on prognosis, LNM and tumour progression in OSCC. Further research is needed to explore the prognostic value of related parameters and their role in tumour progression.

OFP-10-007

Histomolecular profiling of benign oncocytic neoplasms in the parotid gland

N. Benzerdjeb[1,2], Z. Alsugair[1,3], D. Pissaloux[4,5], F. Descotes[6], S. Paindavoine[4,5], J. Lopez[6,7], A. Houlier[4,5], F. Tirode[5], E. Alix[1], C. Champin[1], S. Phelinas[1], P. Céruse[8], P. Philouze[8], E. Uro-Coste[9], A. Siegfried[9], C. Castain[10]
[1]CHU Lyon Sud, Pathology, Lyon, France, [2]Université Lyon 1, CICLY, Lyon, France, [3]King Abdalaziz Specialist Hospital, Taif Health Cluster, Pathology, Taif, Saudi Arabia, [4]Centre Léon Bérard, Biopathology Department, Lyon, France, [5]Centre de Recherche en Cancérologie de Lyon, Team Genetics, Epigenetics and Biology of Sarcomas, INSERM U 1052 - CNRS UMR 5286, Lyon, France, [6]CHU Lyon Sud, Biochemistry and Molecular Biology Department, Groupement Hospitalier Sud, Lyon, France, [7]Université Lyon 1, Lyon, France, [8]Hôpital La Croix Rousse, Oto-Rhino-Laryngology and Cervico-Faciale Surgery, Lyon, France, [9]Institut Universitaire du Cancer-Oncopole, Pathology, Toulouse, France, [10]University Hospital of Bordeaux, Pathology, Bordeaux, France

Background & Objectives: Oncocytic neoplasms of the salivary gland are rare and include oncocytomas (O) and nodular oncocytic hyperplasia (NOH). While these proliferations have traditionally been considered benign, their molecular characteristics and classification remain debated. This study aimed to characterize the histomolecular features of oncocytic proliferations and investigate their potential as a distinct pathological entity using transcriptomic analysis and immunohistochemical (IHC) markers.
Methods: A cohort of 23 cases of oncocytic proliferations, including O, NOH, oncocytic neoplasms of uncertain malignant potential (ONUMP), and NOH/O hybrid cases, was analysed. Immunohistochemistry was performed for various markers, including CK7, p40, p63, SOX10, PLAG1, HMGA2, PTGER3, and GLUL. Whole Exome RNA sequencing and targeted transcriptomic profiling were conducted to assess gene expression patterns and clustering among oncocytic

lesions and other salivary gland tumours. Statistical analyses included clustering methods and differential gene expression comparisons.
Results: Transcriptomic clustering revealed that oncocytic proliferations, including O, NOH, NOH/O, and ONUMP, formed a distinct molecular group, separate from conventional salivary gland tumours. Notably, *GLUL* (*Glutamine Synthetase*) was significantly underexpressed in oncocytic proliferations in comparison to conventional salivary gland tumours. These findings suggest a shared molecular signature among these lesions, distinct from other benign and malignant oncocytic tumours.
Conclusion: This stu.dy identifies oncocytic proliferations as a unique molecular entity, which we propose to name Low-Grade Oncocytic Tumours (LGOT). The consistent low expression of *GLUL* provides robust IHC markers to differentiate LGOT from other salivary gland neoplasms. These findings support a refined classification of oncocytic salivary gland lesions and have potential diagnostic implication. Further validation in larger cohorts is required.

The hidden threat: how occupational exposures drive inverted sinonasal papilloma and may contribute to its malignant transformation

G. Querzoli[1], A. Camagni[2], A.C. Leucci[3], M. Marzadori[2], P. Farneti[4], A. Ambrosini-Spaltro[5], P. Galli[2], L. Amorosa[6], E. D'angelo[7], E. Donini[7], A. Tosoni[8], S. Venturoli[9], L. Gabrielli[9], E. Pasquini[6], M.P. Foschini[3]
[1]IRCCS Sant'Orsola, Pathology, Bologna, Italy, [2]AUSL Bologna, Sinonasal Cancer Registry of Emilia Romagna, Bologna, Italy, [3]AUSL Bologna, University of Bologna, Biomedical and Neuromotor Sciences (DIBINEM), Alma Mater Studiorum, Bologna, Italy, [4]Ospedale Bellaria, ENT Unit, Bologna, Italy, [5]Morgagni-Pierantoni Hospital, Pathology Unit, Forlì, Italy, [6]AUSL Bologna, ENT Unit, Bologna, Italy, [7]AUSL Bologna, Radiation Oncology, Bologna, Italy, [8]AUSL Bologna, Nervous System Medical Oncology, Bologna, Italy, [9]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Microbiology, Bologna, Italy

Background & Objectives: Inverted sinonasal papillomas (ISPs) are benign epithelial tumours with a recognized potential for malignant transformation into squamous cell carcinoma (ISP-SCC), occurring in 2–7% of cases. While the mechanisms underlying this progression remain unclear, occupational exposure to carcinogens has been proposed as a contributing factor. This study investigates the association between occupational exposure and both the development and malignant transformation of ISPs using a multidimensional approach.
Methods: We conducted a retrospective analysis of 32 patients (22 with ISP and 10 with ISP-SCC), based on a standardized questionnaire from the Italian Register of Sino-Nasal Tumours. All samples were analysed for p53 and p16 via immunohistochemistry, and for high-risk and low-risk HPV using reverse-transcriptase real-time PCR. Focus was placed on exposure to IARC Group 1 and 2A carcinogens. Hierarchical clustering (HC) using Gower distance and complete linkage was performed, incorporating variables such as smoking, gender, allergic rhinitis, septal deviation, turbinate hypertrophy, nasal spray use, and occupational/extra-occupational exposures. HPV data were excluded from clustering due to the limited sample size and low positivity rate. Malignant transformation was evaluated in relation to cluster composition.
Results: In the ISP group (n=22), 68.2% were male, mean age 61.1 years, with lesions mainly in the nasal cavity and maxillary sinus. Occupational exposure was present in 41%. The ISP-SCC group (n=10) was 50% male, mean age 64.4 years, with 40% reporting occupational exposure. HC identified three clusters. Cluster 1 (n=18) had high smoking prevalence; Cluster 2 (n=7), composed entirely of ISP-SCC cases, showed the highest occupational exposure and lowest smoking rates; Cluster 3 (n=7) had low exposure and high nasal spray use.
Conclusion: All ISP-SCC cases grouped into the cluster with predominant occupational exposure, supporting a possible role of occupational carcinogens in malignant transformation. Larger studies integrating HPV data are warranted.

OFP-10-009

Comparative analysis of the WHO reporting system for head and neck cytopathology and the Milan System for Reporting Salivary Gland Cytopathology

A. Kowalewski[1,2,3], J. Borowczak[4], H. Brisse[5], O. Choussy[6], J. Klijanienko[1]
[1]Institut Curie, Department of Pathology and Theranostics, Paris, France, [2]Oncology Centre Prof. Franciszek Łukaszczyk Memorial Hospital, Department of Tumour Pathology, Bydgoszcz, Poland, [3]Bydgoszcz University of Science and Technology, Faculty of Medicine, Bydgoszcz, Poland, [4]Oncology Centre Prof. Franciszek Łukaszczyk Memorial Hospital, Clinical Department of Oncology, Bydgoszcz, Poland, [5]Institut Curie, PSL University, Department of Radiology, Paris, France, [6]Institut Curie, PSL University, Department of Head and Neck Surgery, Paris, France

Background & Objectives: The Milan System for Reporting Salivary Gland Cytopathology (MSRSGC) standardizes the classification of salivary gland fine-needle aspiration (FNA) samples. The newly introduced WHO Reporting System for Head and Neck Cytopathology consolidates categories to improve diagnostic utility, notably merging Non-Neoplastic (NN) and Benign Neoplasm (BN) into a single "Benign" category. This study compares the risk of malignancy (ROM) across categories in both systems using a large cohort of FNA samples.
Methods: We evaluated 2,218 salivary gland FNA samples collected at the Institute Curie, Paris (1954–2022), with 1,356 having histological follow-up. Samples were classified according to the MSRSGC (Non-Diagnostic [ND], NN, Atypia of Undetermined Significance [AUS], BN, Salivary Gland Neoplasm of Uncertain Malignant Potential [SUMP], Suspicious for Malignancy [SM], Malignant [M]) and the WHO system (Insufficient/Inadequate/Non-Diagnostic, Benign, Atypical, Neoplasm of Uncertain Malignant Potential [NUMP], SM, M). ROM was calculated for each category, and diagnostic performance metrics were assessed.
Results: In the MSRSGC, ROM was: ND 50% (n=2), NN 16.8% (n=149), AUS 0% (no cases), BN 4.3% (n=514), SUMP 50% (n=2), SM 56.1% (n=66), and M 98.2% (n=623). In the WHO system, ROM was: Insufficient/Inadequate/Non-Diagnostic 50% (n=2), Benign 7.1% (n=663), Atypical 0% (no cases), NUMP 50% (n=2), SM 56.1% (n=66), and M 98.2% (n=623). The WHO's "Benign" category, combining NN and BN, balanced the NN's higher ROM (16.8%) and BN's lower ROM (4.3%) into 7.1%. In conclusive categories (MSRSGC II, IVa, V, VI), the diagnostic metrics for both systems were: sensitivity 93.3%, specificity 93.9%, positive predictive value (PPV) 94.2%, and negative predictive value (NPV) 92.9%.
Conclusion: Both systems effectively identify malignancy. The WHO system's merger of NN and BN into "Benign" streamlines reporting and reduces variability, though it may mask clinically significant differences between non-neoplastic and benign neoplastic lesions.

OFP-10-010

Multiplex *in situ* expression profiling of lung-cancer-associated genes in the development of squamous cell carcinoma of the larynx and hypopharynx

A. Vombergar[1], E. Bostjancic[1], N. Zidar[1]
[1]Institute of Pathology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia

Background & Objectives: Previous studies suggest similar gene expression patterns in lung carcinoma and squamous cell carcinoma of the larynx and hypopharynx (LHSCC); however, the role of lung-cancer-associated genes in the development of LHSCC from precancerous lesions remains poorly understood.
Methods: We performed multiplex *in situ* hybridization, using Human multi-tissue and cancer gene panel (Xenium, 10X Genomics) consisting of 377 genes, including 63 lung-cancer-associated genes. We first compared *in situ* expression of lung-cancer-associated genes between normal mucosa and invasive carcinoma. We further compared expression between different stages of LHSCC development. We included biopsy samples from three patients with normal mucosa, four patients with low-grade dysplasia, one patient with high-grade dysplasia, one patient with carcinoma *in situ* and two patients with invasive carcinoma.
Results: Totally, we observed 127 differentially expressed genes between normal mucosa, dysplasia and LHSCC. Among them, 28 differentially expressed genes were lung-cancer-associated, including well-known oncogenes (e.g. *MDM2* and *MET*), transcription factors (e.g. *EHF*), cytokeratins (e.g. *KRT7*), glycoproteins (e.g. *LAMP3, PDPN*), enzymes (e.g. *PLCG2, CYP4B1*), cytokines (e.g. *CCL5, CXCL2*) and other immune response-related genes (e.g. *MALL*). Interestingly, some of the genes have been described to be related to nasopharyngeal carcinoma (e.g. *SNTN, TSPAN19, UPK3B*), but not to other head and neck carcinomas. Two of the genes have not yet been reported in head and neck carcinomas (*SFTA2, EDN1*).
Conclusion: Almost half of the analysed lung-cancer-associated genes were differentially expressed in various stages of LHSCC development. Our study confirms similarities in gene expression profiles between lung carcinoma and LHSCC, suggesting similar pathogenesis between the two cancer types.

OFP-10-011

Re-evaluation of difficult salivary gland tumour cases among 125 consultation cases: according to 5th WHO Blue Book

K. Kusafuka[1]
[1]Shizuoka General Hospital, Department of Pathology, Shizuoka, Japan

Background & Objectives: The classification of salivary gland tumours (SGTs) was changed in 5th WHO blue book published in 2024, mainly based on their molecular characteristics. I have received 125 consultation cases of SGTs, and sometimes experienced difficult cases. My aim is re-evaluation and re-diagnose of such cases, based on recent evidence, according to 5th WHO blue book.
Methods: During 1998-2021, I experienced 125 consultation cases of SGTs. Among such cases, I selected especially difficult or rare 8 cases and re-diagnosed them using additional immunostainings.
Results: Case 1 (53y/o. F. Parotid) was re-diagnosed cystic epithelial-myoepithelial carcinoma (EMC) ex pleomorphic adenoma (PA) from combined congenital dystrophic cyst and PA. Case 2 (81 y/o. M. Oral floor) was re-diagnosed sialadenoma papilliferum from intraductal carcinoma. Case 3 (59 y/o. M. Parotid) was re-diagnosed mucoacinar carcinoma ex PA with bone formation and tumour-associated lymphoid proliferation (TALP) from mucoepidermoid carcinoma with TALP. Case 4 (33 y/o. F. Parotid) was re-diagnosed cystic EMC with bizarre cells from basal cell adenoma. Case 5 (74 y/o. M. Parotid) was re-diagnosed striated duct adenoma from so-called monomorphic adenoma, due to diffuse S-100 protein immunostaining. Case 6 (77 y/o. F. Sublingual) was mucinous adenocarcinoma showing signet-ring cell feature. Case 7 (82 y/o. M. Parotid & Lymph nodes) was re-diagnosed secretory carcinoma with high-grade transformation (HGT) from acinic cell carcinoma with HGT, due to S-100 protein, mammaglobin and MIB-1 immunostaining. Case 8 (76 y/o. F. Upper Lip) was re-diagnosed mucinous adenocarcinoma (previously termed as "papillary cystadenocarcinoma") from non-intestinal-type adenocarcinoma.
Conclusion: The diagnosis of SGTs is sometimes very difficult. Some cases could be re-diagnosed using adequate surrogate markers against their molecular characteristics, whereas others need the molecular examinations for the exact diagnosis. As low-grade carcinomas were especially misdiagnosed as benign tumours, careful observation and exact examination are essential.

OFP-10-012

Trem2-expressing multinucleated giant macrophages are a biomarker of good prognosis in head and neck squamous cell carcinoma

G. Gessain[1], A.-A. Anzali[2], M. Lerousseau[3], K. Mulder[2], M. Bied[2], A. Auperin[4], D. Stockholm[5], N. Signolle[6], F. Sassi[1], I. Breuskin[7], P. Gorphe[7], M. Classe[8], J.-Y. Scoazec[8], C. Blériot[2], F. Ginhoux[2]
[1]Gustave Roussy, Pathology Department and Florent Ginhoux Laboratory, Villejuif, France, [2]Gustave Roussy, Florent Ginhoux Laboratory, Villejuif, France, [3]Institut Curie, Paris, France, [4]Gustave Roussy, Biostatistics and Epidemiology Office, Oncostat, Villejuif, France, [5]PSL Research University, Paris, France, [6]Gustave Roussy, Experimental and Translationnal Pathology, Villejuif, France, [7]Gustave Roussy, Head and Neck Department, Villejuif, France, [8]Gustave Roussy, Pathology Department, Villejuif, France

Background & Objectives: Patients with head and neck squamous cell carcinomas (HNSCC) often have poor outcomes; yet integrating novel prognostic biomarkers into clinical practice is challenging. Alongside conventional tumour-associated macrophages (TAM), a proportion of HNSCC patients contains large macrophages termed multinucleated giant cells (MGC). These MGC are performing a foreign body reaction against extracellular keratin produced by carcinomatous cells. While MGC presence is well documented in keratinizing SCC, their biology is not well understood and studies suggest varying impact of MGC on patient survival. Thus, we investigated their potential pronostic impact in HNSCC. Additionally, we designed a deep-learning method to automate MGC quantification and we employed spatial transcriptomic and proteomic approaches to explore their related tumour-microenvironment.
Methods: We had access to two cohorts of HNSCC patients from The Cancer Genome Atlas (TCGA, n=110 patients) and Gustave Roussy (GR, n=284 patients). We quantified the number of MGC per mm^2 of tumour creating an MGC density biomarker. Then, we developed a deep-learning algorithm to automatically quantify the number of MGC and the number of tumour cells, and computed the automatic MGC biomarker as the MGC-to-tumour-cells ratio. The model was trained on TCGA and validated on GR cohort. Finally, we performed spatial transcriptomic (Visium) and proteomic (CosMx) analyses on tumour slides.
Results: Here, we report that the presence of MGC in HNSCC, associates with longer Overall Survival (OS) and Progression Free Interval (PFI). The automatic biomarker was also associated with longer OS and PFI. With spatial-omics approaches we observed an increase in central memory CD4 T cells and a decreased in regulatory T cells. We identified an MGC-specific RNA signature resembling to TREM2-expressing mononuclear TAM, which cluster in keratin-induced granulomas.
Conclusion: Herein, we observed that MGC density associates with a good prognosis in HNSCC patients and we described their related tumour-microenvironment, paving the way for more personalized therapies.

OFP-10-013

Pathological predictors of recurrence in oral squamous cell carcinoma: analysis of 1,365 cases from a high-prevalence region

M. Shah[1], A. Patil[1], N. Mittal[1], S. Rane[1], K. Rabade[1], M. Bal[1]
[1]Tata Memorial Hospital, Mumbai, Department of Pathology, Mumbai, India

Background & Objectives: This study aims to evaluate the pathological factors predicting recurrence in oral squamous cell carcinoma (OSCC) and to propose a practical scoring system for risk stratification based on key clinicopathological parameters.
Methods: A retrospective cohort analysis was performed on 1,365 consecutive OSCC patients who underwent surgical resection at our tertiary-care oncology centre from January to December 2019. Clinicopathologic parameters were correlated with recurrence and survival outcomes. The statistical analysis included 836 treatment-naive patients who completed therapy and had either adverse events or a minimum follow-up of one year. Survival analysis utilized Kaplan-Meier and log-rank tests, while multivariate predictors were assessed via multiple logistic regression. Optimal cut-offs for tumour size, tumour thickness, and depth of invasion (DOI) were determined through Receiver Operating Characteristic analysis.
Results: The cohort had a mean age of 53 years, with a male-to-female ratio of 5.7:1. Buccal mucosa (45.8%) was the most common tumour site. The mean tumour size was 3.29 cm, and mean DOI was 10.6 mm. Perineural and lymphovascular invasions were noted in 28.3% and 3% of cases, respectively. The most frequent worst pattern of invasion (WPOI) was pattern 4 (73.7%). Lymph node metastases occurred in 52.9% of patients, with extranodal extension present in 60.3% of these cases. Recurrences occurred locoregionally in 18.6% of cases, and distant metastases developed in 6.1%. Multivariate analysis identified lymph node metastasis (HR=1.8, $p<0.001$), WPOI 5 (HR=1.7, $p=0.004$), and DOI >10 mm (HR=1.69, $p<0.001$) as significant independent predictors of recurrence. A scoring system derived from hazard ratios (scores ranging from 0 to 4) effectively categorized patients into low, intermediate, and high-risk groups.
Conclusion: Lymph node metastasis, DOI >10 mm, and WPOI 5 significantly predict OSCC recurrence. This risk stratification scoring system can guide oncologists in patient management and follow-up.

OFP-10-014

A comparison of molecular genetic features of primary and recurrent sinonasal intestinal type adenocarcinoma

C. Taverna[1,2], M.C. Cubides-Córdoba[3], M. Hermsen[4], I. Dallan[5], A. Franchi[6], J.L. Llorente[3]
[1]Local Hospital San Giacomo, Pathology Unit, Novi Ligure, Italy, [2]University of Eastern Piedmont "Amedeo Avogadro" UNIUPO, Department of Health Sciences, Novara, Italy, [3]Hospital Universitario Central de Asturias, Otolaryngology, Oviedo, Spain, [4]Health Research Institute of the Principality of Asturias, Head and Neck Oncology, Oviedo, Spain, [5]University Hospital of Pisa, Skull Base Surgery Unit, Pisa, Italy, [6]University of Pisa, Translational Research, Pisa, Italy

Background & Objectives: Intestinal-type sinonasal adenocarcinoma (ITAC) arises predominantly in the ethmoid sinus of male patients with occupational exposure to wood and leather dust. ITACs carry a poor prognosis with local recurrences as the main cause of death. Recurrent tumours can arise several years after primary treatment and with a different histological subtype. We performed whole exome sequencing (WES) on pairs of primary and recurrent tumours to investigate if the recurrences are clonal with primary tumours or if they could in fact be second primary tumours.
Methods: Paraffin embedded primary and recurrent tumour samples of 16 cases were collected and DNA was successfully extracted in 15 cases. Relapse time between primary and first recurrence ranged from 1 to 13 years.
Results: WES was successful in 12 primary and all 15 recurrent tumours. Pairwise comparison showed clonal gene mutations in all 12 pairs. Shared mutations included TP53 (4 cases), APC (3 cases), MAPK pathway genes NF1 and KRAS (each 1 case) and PI3K pathway gene MTOR (1 case) and have been described previously in ITAC. In addition, we found tumour pairs with not yet reported mutations in DNA repair pathway gene FANCD2 (2 cases) and DNMT3B (1 case), and SWI/SNF pathway genes SMARCD1, ARID1A and EZH1 (each 1 case). We also found TP53 and ARID1A mutations unique to the recurrence in 2 instances. Two mutations occurred in the primary tumour only, affecting TP53 and NF1 (each 1 case).
Conclusion: Recurrent ITACs are clonal with corresponding primary tumours, also in cases with a long relapse-free time, and should not be considered second primary tumours. In this relatively small series, two-thirds of ITAC harboured actionable mutations in primary tumour that were retained in recurrences. This indicates that personalized treatment of recurrent ITAC may be based on actionable mutations observed in the primary tumour.

OFP-10-015

Molecular characterization of epithelial-myoepithelial carcinoma: insights from mutation and transcriptomic profiling

Z. Alsugair[1,2], A. Champagnac[2], F. Descotes[1], J. Lopez[1], M. Fieux[1], P. Philouse[3], P. Ceruse[3], B. Thamphya[2], D. Pissaloux[2], F. Tirode[2], N. Benzerdjeb[1]
[1]Groupment Hospitalier Lyon Sud, Lyon, France, [2]Centre Leon Berard, Lyon, France, [3]Hopital Croix Russe, Lyon, France

Background & Objectives: Epithelial-myoepithelial carcinoma (EMC) is a rare malignancy of the salivary glands, representing less than 1% of all epithelial salivary gland tumours. It is characterized by a biphasic arrangement of inner ductal epithelial cells and outer clear myoepithelial cells. Advances in molecular pathology have identified specific genetic alterations in salivary gland tumours, with HRAS hotspot mutations being frequently associated with EMC. This study aimed to analyse the molecular characteristics of EMC and compare its genetic profile to other head and neck tumours with RAS mutations.
Methods: A retrospective analysis of EMC cases was conducted using histological, immunohistochemical, and transcriptomic approaches. Cases were selected from the archives of Lyon Sud University Hospital and Centre Léon Bérard. Whole-exome RNA sequencing was performed on 14 EMC cases and a comparative cohort of various salivary gland neoplasms. Immunohistochemistry was conducted to assess epithelial and myoepithelial markers. Statistical analyses included differential gene expression and clustering methodologies to establish molecular relationships among tumours.
Results: The study included 14 EMC cases, with a mean patient age of 74.5 years. The majority were located in the parotid gland. *HRAS* mutations were identified in 8 cases, predominantly *HRAS* Q61R. Other genetic alterations included *STAT5B*, *NOTCH1*, and *PIK3CA* mutations. Gene fusions, such as *HMGA2*::*WIF1*, were detected in two cases. Transcriptomic analysis showed EMC clustering closely with basal cell adenoma and separated to pleomorphic adenoma.
Conclusion: EMC exhibits a distinct molecular profile with frequent *HRAS* mutations and transcriptomic similarities to basal cell adenoma. The findings suggest that EMC shares genetic pathways with other salivary gland neoplasms, highlighting *HRAS* as a potential diagnostic marker. Further research is warranted to explore the clinical implications of these molecular alterations.

OFP-11 Oral Free Paper Session Uropathology & Nephropathology

OFP-11-001

Large language model–expert concordance in IgA nephropathy scoring using Oxford classification

S. Çolak[1], K. Yılmaz[1], E.A. Sağlam[1], M. Üner[1]
[1]Hacettepe University Faculty of Medicine, Department of Pathology, Ankara, Turkey

Background & Objectives: Large language models (LLMs) are increasingly used to support histopathological evaluation. However, the degree to which LLM-derived scores align with human assessments in complex pathological conditions remains uncertain. In this study, we used ChatGPT-4o, an LLM developed by OpenAI, to generate lesion scores for cases of IgA nephropathy. Given the clinical importance of consistent and accurate lesion scoring, evaluating the concordance between LLM output and expert interpretation is essential. This study aimed to assess the agreement between LLM-generated scores, expert-revised scores, and original pathology reports based on Oxford classification parameters.
Methods: A total of 127 kidney biopsy reports were scored by ChatGPT-4o, a revising expert pathologist, and according to the original report. Each case was assessed using five Oxford parameters: M, E, and S (scored as 0 or 1), and T and C (scored as 0 to 2). Cases with complete scores across all three sources (n = 105) were included in the final analysis. Agreement between sources was evaluated using Cohen's Kappa, Spearman correlation, Wilcoxon signed-rank tests, and Friedman's test.
Results: ChatGPT-4o and revised expert scores showed near-perfect agreement (Cohen's Kappa = 0.970; Spearman Rho = 1.000; Wilcoxon p = 0.7855). Agreement between ChatGPT-4o and original reports was lower (Kappa = 0.799), as was agreement between revised and original scores (Kappa = 0.819). Friedman's test indicated a statistically significant difference across the three sources ($\chi^2 = 6.71$, p = 0.035).
Conclusion: ChatGPT-4o demonstrated high concordance with expert-reviewed scoring, suggesting that LLMs may aid in identifying inconsistencies in original pathology reports. These findings highlight the potential of LLMs as tools for quality control and decision support in renal pathology. While not a replacement for human judgment, LLMs show promise as reliable adjuncts to improve scoring consistency. Further validation in broader diagnostic workflows is needed.

OFP-.11-002

Two classifications, one disease: Oxford and Banff reveal distinct IgA nephropathy profiles in children and adults

M. Životić[1], D. Milivojević[1], M. Pecić[1], G. Nikolić[1], A. Mioljević[1], J. Filipović[1], V. Brković[2], M. Baralić[2], M. Radović[2], S. Radojević Škodrić[1]
[1]Institute of Pathology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia, [2]Clinic for Nephrology, University Clinical Centre of Serbia, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background & Objectives: IgA nephropathy is the most common primary glomerulonephritis, diagnosed through kidney biopsy. The Oxford classification describes histological lesions in native kidneys, while the Banff classification is used in transplant pathology but provides additional insight into inflammatory and vascular changes. The aim was to compare Oxford and Banff classification parameters in paediatric and adult patients, in light of differing therapeutic strategies.
Methods: This retrospective study included 253 patients with biopsy-proven IgA nephropathy: 105 paediatric and 148 adult. Clinical data (haematuria, proteinuria, renal function, comorbidities) and histological parameters (glomerular, tubulointerstitial, vascular changes) assessed by Oxford and Banff classifications were compared across age groups.
Results: Paediatric patients more frequently had macroscopic haematuria and IgA vasculitis symptoms ($p<0.001$), while adults had significantly worse renal function (higher urea/creatinine, lower GFR) and frequently suffered from hypertension and diabetes. According to the Oxford classification, adults had more chronic glomerular ($p=0.005$) and tubulointerstitial lesions ($p<0.001$). The Banff classification revealed a higher frequency of both acute inflammatory (t, i, i-IFTA, ti) and chronic (ct, ci) interstitial lesions, as well as vascular changes (cv, ah, aah) in adults ($p<0.05$).
Conclusion: Oxford and Banff classifications reveal significantly more chronic and inflammatory changes in adults. The combined use of both scoring systems can enhance diagnostic precision and guide individualized management in IgA nephropathy. These findings highlight the need for age-tailored therapeutic strategies. The Banff classification adds value in detecting acute inflammation in native kidneys and may improve risk stratification and long-term prognosis.

OFP-11-003

MicroRNA-371~373 cluster is released in testicular germ cell tumours via extracellular vesicles

J. Lobo[1], N.T. Tavares[2], C. Lourenço[2], V. Constâncio[2], F. Fernandes-Pontes[2], R. Silva-Santos[1], I. Braga[3], J. Maurício[4], R. Henrique[1], A. Bagrodia[5], C. Jerónimo[2]
[1]Portuguese Oncology Institute of Porto (IPO Porto), Pathology, Porto, Portugal, [2]Portuguese Oncology Institute of Porto (IPO Porto), Cancer Biology and Epigenetics Group, Porto, Portugal, [3]Portuguese Oncology Institute of Porto (IPO Porto), Urology, Porto, Portugal, [4]Portuguese Oncology Institute of Porto (IPO Porto), Medical Oncology, Porto, Portugal, [5]University of California San Diego, Urology, San Diego, California, USA

Background & Objectives: Extracellular vesicles (EVs) are membrane-derived particles with important roles in cell communication. EV-derived microRNAs (miRNAs) have been considered potential cancer biomarkers. The miR-371~373 cluster has been proposed as a biomarker of testicular germ cell tumours (TGCTs), but to date it is unknown if they are carried in EVs. We aimed to isolate EVs from different TGCT sample types (cell lines, tissue and plasma), and assess the presence of the miR-371~373 cluster.
Methods: A total of 9 TGCT cell lines, 12 patient-derived tissue explants (tumour and normal testicular parenchyma), and matched plasma samples were used. Healthy blood donor plasma samples were used as controls. Conditioned media were retrieved after cells and tissues were cultured in medium. EVs were isolated by a differential ultracentrifugation protocol, divided into two populations (large EVs (lEV) and small EVs (sEV)), and characterized according to MISEV guidelines, including western blot, nanoparticle tracking assay and electron microscopy. EV-RNA was extracted and miR-371a-3p, 372-3p and 373-3p were tested by RT-qPCR for all sample types.
Results: EV-miRNA levels derived from cell lines paralleled the cells inner total RNA, corroborating our hypothesis that these miRNAs are secreted into EVs. We successfully isolated and characterized EVs from conditioned media in culture with TGCT fresh tissue (tumour and normal parenchyma) and from matched plasma samples. Tumour tissues released significantly higher number of particles into the medium when compared to normal tissue, both for lEV and sEV. MiR-371a-3p levels for tumour-derived EVs were significantly higher than in normal tissue/healthy blood donors-derived EVs, both in tissue and plasma. Upon differentiation of NT2 cells with ATRA, both cellular and EV-derived miR-371~373 cluster were downregulated, recapitulating the observations in teratoma tissues.
Conclusion: A significant part of the circulating miR-371~373 cluster is transported in EVs. This protected secretion mechanism highlights the relevance of this miRNA cluster in TGCTs biology.

Funding: NTT holds a PhD fellowship from Fundação para a Ciência e Tecnologia (FCT) - 2022.09566.BD. The authors would like to acknowledge the funding from miREpiTestis – 'Unveiling miR-371-373 cluster epigenetic reprogramming and downstream targets in testicular germ cell tumours' (PI190-CI-IPOP-23-2023)

The clinical utility of immunohistochemistry for GPNMB and SOX9 in the differential diagnosis of renal neoplasia with oncocytic features

S. Gupta[1], J. Cheville[1]
[1]Mayo Clinic, Department of Laboratory Medicine and Pathology, Rochester, USA

Background & Objectives: In addition to oncocytoma (Onc) and chromophobe renal cell carcinoma (chRCC), the current WHO classification includes a category of other oncocytic tumours of the kidney. Many of these entities have overlapping morphologic and immunophenotypic features. Herein, we evaluated the clinical utility of immunohistochemistry (IHC)-based markers, including GPNMB and SOX9, to reliably separate these tumours.
Methods: IHC was performed on whole slide sections of representative cases of Onc (n=14), chRCC (n=14), (*MTOR/TSC1/2*-mutated) low grade oncocytic tumour (LOT; n=13) and eosinophilic vacuolated tumour (EVT; n=5), and *FLCN*-mutated tumours (FMT; n=39). The IHC panel included CD117, CK7, L1CAM, GPNMB, and SOX9. In addition, IHC for cathepsin K was performed in a subset of cases (EVT, n=5; FMT, n=38). IHC results were quantified using H-scores (product of intensity of staining and percentage of positive cells, range: 0-300).
Results: IHC for CD117 and CK7 had expected results: CD117+/CK7- for all ONC and EVT, CD117+/CK7+ for all chRCC, and a CD117-/CK7+ immunophenotype for all LOT. In contrast, FMT showed low expression of CD117 and scattered positivity for CK7 (H-scores of 17 and 65, respectively). With regards to other traditional markers, L1CAM lacked expression in Onc, chRCC and EVT in contrast to LOT and FMT (mean H-scores of 257 and 184, respectively). With regards to newer markers, GPNMB showed absence of staining in Onc, and higher expression in the rest (mean H-scores, chRCC: 171, LOT: 130, EVT: 230, FMT: 265), while SOX9 showed absence of staining in Onc, LOT and EVT, variable positivity in chRCC (mean H-score: 80), and frequent positivity in FMT (mean H-score: 211).
Conclusion: Our results suggest that IHC for markers such as GPNMB (negative in Onc) and SOX9 (variable and diffuse positivity in chRCC and FMT) may complement traditional markers such as CD117, CK7, L1CAM and cathepsin K in the differential diagnosis of oncocytic renal neoplasia.

OFP-11-005

Nested urothelial carcinoma: a rare subtype needs an optimized treatment approach - a multicentre retrospective study

Di Marco[4], R. Contieri[7], G. Musi[5], D. D'Andrea[9], S. Mancon[7], S. Nazzani[10], M. Catanzaro[10], G. Procopio[3], R. Miceli[2], N. Nicolai[3], B. Paolini[1], P. Giannatempo[3], M. Milione[1]
[1]Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Diagnostic Innovation, Pathology Unit 1, Milan, Italy, [2]Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Bioinformatics and Biostatistics, Milan, Italy, [3]Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Genito-Urology Oncology, Milan, Italy, [4]Istituto Oncologico Veneto (IOV), Department of Oncology, Padua, Italy, [5]Istituto Europeo di Oncologia (IEO), Department of Urology, Milan, Italy, [6]AUO Città della Salute e della Scienza, Ospedale Molinette, Department of Urology, Turin, Italy, [7]Istituto Clinico Humanitas, Department of Urology, Milan, Italy, [8]ASST Papa Giovanni XXIII Hospital, Urology Department, Bergamo, Italy, [9]Medical University, Department of Urology, Vienna, Austria, [10]Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Urology, Milan, Italy

Background & Objectives: Nested urothelial carcinoma (N-UC) is a challenge for diagnosis and optimal treatment strategy. This multicentre study aims at evaluating prognostic endpoints according to disease extent [non-muscle invasive (NMIBC) and muscle invasive (MIBC)], presentation and treatment [Bacillus Calmette-Guérin (BCG), radical cystectomy (RC) and chemotherapy (CT)].
Methods: Data were collected from 61 patients with N-UC across 5 centres over a 10-year period (2013–2023). Patients were stratified according to time of nested-subtype diagnosis (onset vs recurrence), disease extent (NMIBC vs MIBC) and initial treatment (BCG±RC vs RC only vs RC+CT). Kaplan-Meier analysis was used to assess median progression free survival (mPFS) and median overall survival (mOS).
Results: 15 NMIBC and 26 MIBC were identified, with a median follow-up of 30.6 months. Of the 15 NMIBC, 80% received initial BCG. Patients with N-UC at onset had worse mPFS and mOS [99.6 months (95% CI: 55.2-NR) and 107.3 months (95% CI: 71.6-NR) respectively], than those with N-UC at recurrence [mPFS of NR (95% CI: 42.1-NR) and mOS of 138.4 (95% CI: 51.7-NR)]. According to treatment, the best mPFS and mOS were recorded among patients receiving RC+CT [mPFS = 99.6 months (95% CI: 55.2-NR) and mOS = 107.3 months (95% CI: 107.3-NR)]. Those receiving BCG followed by RC had a mPFS of 84.2 months (95% CI: 68.1-NR) and mOS of 85.9 months (95% CI: 71.6-NR), while those undergoing RC alone apparently had the worse mPFS (42.1 months, 95% CI: 42.1-NR) and mOS (51.7 months, 95% CI: 14.7.1-NR). None of these differences were statistically significant.
Conclusion: This study represents the largest case series of nested urothelial carcinoma. It suggests limited benefit from BCG treatment and most of NMIBC lastly need CT. Diagnosis at recurrence and combination of RC and CT tend to better survivals. Further analyses are ongoing to expand case number and evaluate pathologic features.

OFP-11-006

An audit of correlation between tumour size and renal sinus invasion in renal cell carcinoma

A. McMullin[1], T. Crotty[1], N. Swan[1]
[1]St. Vincent's University Hospital, Department of Pathology, Dublin, Ireland

Background & Objectives: Renal sinus invasion (RSI) is an important prognostic indicator in renal cell carcinoma (RCC), which upstages a tumour to pT3a and influences treatment decisions, including eligibility for immunotherapy. RCCs measuring >7cm have RSI in >90% of cases. This audit aimed to assess the correlation between tumour size, presence of RSI, and sinus sampling in RCC specimens at our centre.
Methods: A retrospective search of the laboratory information system for nephrectomy specimens containing carcinoma examined over a 58-month period was performed. Pathological data collected included histological subtype, tumour size, ISUP grade, and pTNM stage including RSI status (macroscopic and microscopic).
We used the 'Invasive Carcinoma of Renal Tubular Origin Histopathology Reporting Guide, 1st edition (2017). International Collaboration on Cancer Reporting; Sydney, Australia' as our standard.
Results: • 130 cases were identified, with 43% of tumours measuring >7cm and RSI present in 62%.
• 69% of clear cell RCCs >7cm had RSI.
• 63% of tumours were pT3a or higher, with RSI present in 63.4% of these.
• 48% of high-grade RCCs (ISUP 3/4) had RSI versus 29% in low-grade RCCs (ISUP 1/2).

• Macroscopic and microscopic assessment of RSI was discordant in 16% of cases.
• 31% of specimens did not have any blocks labelled as renal sinus, with the terms renal hilum or
pelvis used in 73% of these cases.
• The median number of blocks of renal sinus taken was 1.
Conclusion: The detection of RSI in our audit was 21% lower than the expected standard, with undersampling of the renal sinus and underestimation of macroscopic features likely significant factors. Our results highlight several key areas for improvement, including meticulous macroscopic examination and appropriate renal sinus sampling in tumours >7cm.
Frequent mislabelling of blocks demonstrates the need for differentiation of these terms in guidelines.
Inconsistency in the macroscopic assessment of RSI underscores the need for experienced macroscopic examiners.

OFP-11-007

B-cell antitumor immunity: prognostic role in penile squamous cell carcinoma

J. Hrudka[1], N. Zavillová[1], M. Kendall Bártů[2], Z. Prouzová[1], D. Čapka[3], P. Waldauf[4], R. Matěj[5]
[1]University Hospital Královské Vinohrady, 3rd Faculty of Medicine, Charles University, Department of Pathology, Prague, Czech Republic, [2]General University Hospital, 1st Faculty of Medicine, Charles University, Department of Pathology, Prague, Czech Republic, [3]University Hospital Královské Vinohrady, 3rd Faculty of Medicine, Charles University, Department of Urology, Prague, Czech Republic, [4]University Hospital Královské Vinohrady, 3rd Faculty of Medicine, Charles University, Department of Anaesthesia and Intensive Care Medicine, Prague, Czech Republic, [5]Thomayer University Hospital, 3rd Faculty of Medicine, Charles University, Department of Pathology and Molecular Medicine, Prague, Czech Republic

Background & Objectives: Penile squamous cell carcinoma (pSCC) displays the worst prognosis among male genital tumours, and is characterized by slowly increasing incidence and stagnant mortality. Several prognostic markers have been recently identified, including tumour infiltrating lymphocytes (TILs), mostly focusing on T-cells. The prognostic role of B-cells has not yet been sufficiently described in pSCC.
Methods: 152 cases of invasive pSCC with available FFPE tumour tissue were analysed. Whole tissue sections have been examined immunohistochemically for p53, CD20, CD138. The cohort was classified into p53 mutated (overexpression+negative) vs. wild type. B-cell immunoscore (B-IS) divided the cohort based on the expression of the two B-cell/plasma cell markers (CD20 and CD138) counted separately in tumour centre and tumour invasion front per mm2; into the high/low status using the median value of each of the four categories. The B-IS distinguishes five groups: the cases with high status in all four categories belong to B-IS 4, the cases with low status in all belong to B-IS 0. Cox regression and Pearson's chi squared test were used.
Results: The patients with pSCC displaying low B-IS (0-1, n=51) showed significantly worse overall survival (OS) compared to those with high B-IS (2-4, n=101): HR=1.89, 95%CIs 1.18-3.03, p=0.009). Similarly, shorter OS was found in tumours with low CD20+cells in tumour centre (HR=1.67, 95%CIs 1.04-2.7, p=0.033) and low CD20+cells in tumour invasion front (HR=1.69, 95%CIs 1.05-2.7, p=0.029). Of note, high B-IS was strongly associated with a mutated p53 profile (OR=4.76, 95%CIs 1.32-25, p=0.011). High CD20+ cells in invasion front were associated with histological grade 3 (OR=2.44, 95%CIs 1.15-5.26, p=0.015).
Conclusion: High number of tumour infiltrating B-cells is a favourable prognostic marker in pSCC, but displayed unexpected association with mutated p53, which is known as a key detrimental prognosticator. Deeper discussion and research to elucidate the role of p53 in B-cell mediated antitumor immunity are warranted.

BK polyomavirus (BKPyV)-associated urothelial carcinoma in renal and non-renal transplant recipients: a clinicopathological and molecular study

J. Schmitz[1], A. Schwarz[2], S. Silling[3], V. di Cristanziano[3], U. Lehmann[4], R. Schmitt[5], F. Keller[6], H. Haller[2], K. Schmidt-Ott[2], J.H. Bräsen[1]
[1]Institute of Pathology, Unit Nephropathology, Hannover Medical School (MHH), Hannover, Germany, [2]Hannover Medical School (MHH), Nephrology and Hypertension, Hannover, Germany, [3]Institute of Virology, University Hospital and University of Cologne, Cologne, Germany, [4]Institute of Pathology, Molecular Pathology, Hannover Medical School (MHH), Hannover, Germany, [5]University Hospital Schleswig-Holstein, Nephrology and Hypertension, Kiel, Germany, [6]Institute of Experimental and Clinical Pharmacology, Toxicology and Pharmacology of Natural Products, University Hospital Ulm, Ulm, Germany

Background & Objectives: Urothelial carcinoma expressing BK polyomavirus (BKPyV) Large-T antigen (LTag) may represent a distinct tumour entity in transplant recipients. We aimed to identify yet unknown cases and to assess how patients with BK virus nephropathy (BKVN) after non-renal organ transplantation and those with BKPyV-positive urothelial carcinoma differ from renal transplant patients with BKVN.
Methods: We searched the pathology archives of Hannover Medical School over a 20-year period for cases of BKVN and BKPyV-associated urothelial tumours, including patients after solid organ and stem cell transplantation. Identified cases were morphologically re-evaluated and underwent SV40-LTag immunohistochemistry. The clinical course of BKVN patients was analysed retrospectively. Viral isolates from tumour samples were genotyped and sequenced.
Results: 14 of 42 urothelial carcinomas in transplant recipients were SV40-LTag positive by immunohistochemistry. These occurred equally in renal and non-renal transplant patients. SV40-LTag-positive cases were significantly associated with previous BKV infection (p=0.021), tacrolimus-based immunosuppression (p=0.001), and the micropapillary variant (p=0.0002). All 10 successfully amplified isolates belonged to the predominant European genotype Ib-2. Sequencing of BKPyV genomes isolated from tumours showed rearrangements in regulatory elements, including duplications and deletions, particularly in the non-coding control region (NCCR).
Conclusion: BKPyV-associated urothelial carcinoma affects both renal and non-renal transplant recipients. Previous BKVN and tacrolimus therapy are potential risk factors. Early post-transplant BKPyV replication may represent a necessary prerequisite for later tumorigenesis. The observed restructuring of the NCCR may be associated with increased pathogenicity.

OFP-11-009

Comparison of the two urinary markers Bladder EpiCheck and Xpert BC Monitor in the follow-up of 648 patients with non-muscle invasive bladder cancer

B. Barioglio[1], M. Brunelli[2], E. Trenti[3], S. Gobbo[2], A. Eccher[4], E. Hanspeter[1], C. Mian[1]
[1]Hospital of Bozen, Department of Pathology, Bozen, Italy, [2]University of Verona, Department of Pathology, Verona, Italy, [3]Hospital of Bozen, Department of Urology, Bozen, Italy, [4]University of Modena and Reggio Emilia, Department of Pathology, Modena, Italy

Background & Objectives: The surveillance of patients diagnosed with non-muscle invasive bladder cancer (NMIBC) relies mainly on cystoscopy and cytology. At the Hospital of Bozen two urinary markers based on real-time polymerase chain reaction (PCR) are routinely analysed alongside: Bladder EpiCheck Test, based on DNA methylation alterations associated with bladder carcinoma (BC), and Xpert BC Monitor,

which measures the levels of five target mRNAs. The aim of this study is to confirm the diagnostic accuracy of these urinary markers and to compare them with each other and with urinary cytology and/or histology in the same cohort of patients undergoing follow-up for NMIBC.
Methods: The 648 patients enrolled in this prospective study (for a total of 1900 samples) were tested with urinary cytology, cystoscopy, Bladder EpiCheck and Xpert BC Monitor. Suspicious lesions were biopsied or removed transurethrally, and the samples were reported according to the TNM classification of bladder cancer.
Results: 200 samples were excluded due to invalid values. Of the remaining 1700, 158 showed a recurrence of NMIBC, specifically 106 LG NMIBC and 52 HG NMIBC. The other 1542 cases were negative on cystoscopy and/or histology. The overall sensitivity of cytology was 25.3%. Based on tumour grade, it was 8.4% for LG tumours and 59.6% for HG tumours. Running both tests and considering a result positive if either test was positive, Bladder EpiCheck and Xpert BC Monitor together identified 78.4% of tumours (124/158), 71.6% of LG tumours, and 92.3% of HG tumours.
Conclusion: Xpert BC Monitor and Bladder EpiCheck achieved excellent results. The negative predictive value (NPV) was higher than that of cytology, especially when used together (97%). Their sensitivity was significantly higher than that of cytology in both tumour groups, LG and HG. Together they identified 92.3% of HG tumours. Their specificity was high, but it did not reach the one of cytology.

OFP-11-010
ADAR2, Androgen Receptor (AR), and PD-L1 expression in papillary urothelial carcinoma: implications for prognosis and therapy
L. Pepe[1], V. Fiorentino[1], V. Zuccalà[1], C. Pizzimenti[2], M. Franchina[1], E. Germanà[1], G. Ricciardi[1], P. Tralongo[1], F. Pierconti[3], A. Ieni[1], G. Fadda[1], G. Tuccari[1], M. Martini[1]
[1]University of Messina, Messina, Italy, [2]Papardo Hospital, Messina, Italy, [3]Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy

Background & Objectives: Bacillus Calmette-Guérin (BCG) is standard therapy for urothelial carcinoma in situ. Emerging evidence suggests roles for Androgen Receptor (AR), Adenosine Deaminase Acting on RNA 2 (ADAR2), and Programmed Death Ligand 1 (PD-L1) in urothelial carcinoma, with modulation of the tumour microenvironment. This study aimed to investigate these markers in papillary urothelial carcinoma, correlating their expression with clinicopathological features and patient outcomes.
Methods: A retrospective, multi-institutional study was done analysing 128 patients with papillary urothelial carcinoma. Seventy-seven had low-grade papillary urothelial carcinomas (all Ta), and 51 high-grade papillary urothelial carcinomas (11 Ta and 40 T1). Immunohistochemistry was performed on tissue sections to assess AR, ADAR2, PD-L1 expression, and tumour-infiltrating lymphocytes (TILs, CD4/CD8 ratio). Receiver operating characteristic (ROC) curve analysis determined optimal cutoffs for high and low expression. Statistical analyses examined associations between marker expression, clinicopathological parameters, and recurrence-free survival (RFS).
Results: All 77 low grade papillary urothelial carcinomas presented low AR/high ADAR2 levels. Of the 51 high-grade papillary carcinomas, 25/40 T1 cases and 1/11 Ta cases showed high AR/low ADAR2 levels. High AR expression correlated with lower ADAR2 expression ($P < .0001$), higher PD-L1 expression ($P < .0001$) and higher CD4/CD8 ratio ($P < .0001$). Patients with low AR, high ADAR2, and low PD-L1 expression, had better RFS ($P < 0.0001$). Additionally, miR-200a-3p and INF-γ were significantly higher in tumours with low AR/high ADAR2 expression.
Conclusion: This study shows that AR, ADAR2, and PD-L1 expression are significantly associated and are prognostic indicators in papillary urothelial carcinoma.

OFP-11-011
Stroma AReactive Invasion Front Areas (SARIFA) - a promising prognostic biomarker in muscle-invasive urothelial bladder cancer
S. Bertz-Kalinka[1], N. Reitsam[2], B. Grosser[2], A. Hartmann[1], B. Märkl[2], M. Eckstein[1]
[1]Institute of Pathology, University Hospital Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Erlangen, Germany, [2]Pathology, Faculty of Medicine, University of Augsburg, Augsburg, Germany

Background & Objectives: SARIFA (Stroma AReactive Invasion Front Areas) describes an entity-independent histopathological biomarker with prognostic and possibly predictive relevance. It is assumed that direct contact between tumour cells and adipocytes leads to activation of the tumour's lipid metabolism, providing the tumour cell with significant survival advantages. The prognostic relevance of SARIFA has previously been described in gastrointestinal and prostatic adenocarcinomas. This study investigates the relevance of SARIFA in muscle-invasive urothelial carcinomas (miUC) of the urinary bladder.
Methods: SARIFA is defined as ≥5 tumour cells in direct contact with at least one adipocyte. A single focus is sufficient for classification as SARIFA-positive. The total cohort included samples from 559 miUC patients who underwent radical surgery with curative intent. Cases with poor scan quality or unclear results despite discussion between three pathologists were excluded (n=33).
Results: The prevalence of SARIFA was 56% (296/526). In pT2 carcinomas, the prevalence rate was 31% (SARIFA of submucosal or intramuscular adipose tissue). The prevalence rates of SARIFA were 48% for conventional urothelial carcinomas (UC), 58% for UCs with divergent differentiation (>95% squamoid), 61% for UC with subtype histology, 77% for UC with sarcomatoid dedifferentiation, and 83% for small-/large-cell neuroendocrine UCs (Chi-square $P<0.001$). Median disease-specific survival was 22.9 months in the SARIFA group and 89.7 months in the non-SARIFA group (Log-Rank $P<0.001$). Multivariable Cox regression analysis (adjusted for pT, pN, histology, L, V, biological sex, age, grading), revealed a 1.40-fold higher risk of disease-specific mortality (HR=1.40, 95% CI 1.02–1.93, P=0.033) in SARIFA-positive patients.
Conclusion: After investigations in the gastrointestinal tract, we now present SARIFA as a prognostic marker in the urogenital tract. Following recently published data on prostate carcinomas, we demonstrate the prognostic significance of SARIFA in miUC of the bladder as well. Detailed analyses with additional data from independent validation cohorts will be presented at the conference.

OFP-11-012
AI-assisted prostate cancer grading: validation study on diagnostic accuracy and efficiency
B. Altrabulsi[1,2], A. Abbas[3], W.P.K. Teng[4], K. Taghipour[4], Y.P. Singh[4], A. Nahal[2,1]
[1]Cleveland Clinic Abu Dhabi, Pathology and Laboratory Medicine Institute, Abu Dhabi, United Arab Emirates, [2]National Reference Laboratory, Pathology, Abu Dhabi, United Arab Emirates, [3]Qritive Pte. Ltd, Medical Affairs, Singapore, Singapore, [4]Qritive Pte. Ltd, Product, Singapore, Singapore

Background & Objectives: Prostate cancer (PC) is the fourth most common cancer and a leading cause of cancer-related death globally. Accurate grading is essential, as the Gleason score is a crucial predictor of biochemical recurrence and prostate cancer-specific mortality. AI-based solutions have significant potential for enhancing diagnostic accuracy in PC. This study aims to evaluate the performance of an AI algorithm in detecting and grading prostate carcinoma at a tertiary care centre.
Methods: This retrospective analysis included 254 prostate biopsy slides, with 2-3 slides selected per case to enhance dataset diversity.

AI-generated results were compared to the ground truth established by two senior genitourinary (GU) pathologists. The algorithm classified cases as benign, malignant (with Gleason patterns 3, 4, or 5), or benign with ambiguous foci (AMF) needing further review. Key performance metrics included sensitivity, specificity, and ISUP grade concordance (identical grade, 1 or 2 grade differences).
Results: The AI algorithm correctly identified 149 slides as benign (true negatives) and 77 as malignant (true positives), with 17 false positives. Two slides were excluded due to rare atypical acini. Nine slides were flagged for AMF, later confirmed as malignant by pathologists. The AI algorithm demonstrated high sensitivity (100% considering AMF as malignant and 89.5% excluding AMF) and specificity (89.7%). Complete ISUP grade concordance was achieved in 38 of 86 malignant slides, with only 2 showing a 2-grade difference.
Conclusion: The AI algorithm has proven to be a reliable and efficient clinical decision support tool, demonstrating high accuracy in prostate cancer detection and grading. While AI serves as an auxiliary resource, pathologist review remains essential for all cases. This validation underscores AI's potential to enhance pathology processes and improve diagnostic efficiency.

Anti-oxidants protect Nucleic Acids integrity during paraffin embedding of glyoxal and formaldehyde-fixed tissues

E. Berrino[1,2], S.E. Bellomo[1], P. Detillo[3], A. Chesta[1], C. Murzio[3], A. Sapino[1,4], B. Bussolati[5], C. Marchiò[1,6], G. Bussolati[2]
[1]Candiolo Cancer Institute, FPO-IRCCS, Candiolo, Italy, [2]University of Turin, Department of Medical Sciences, Turin, Italy, [3]ADDAX Biosciences srl, Turin, Italy, [4]University of Turin, Department of Medical Sciencesitaitalit, Turin, Italy, [5]University of Turin, Department of Molecular Biotechnology and Health Sciences, Turin, Italy, [6]University of Turin, Department of Medical Sciences, Turinita, Italy

Background & Objectives: Nucleic Acids (NA) integrity purified from Formalin Fixed Paraffin Embedded (FFPE) tissues represents a pivotal checkpoint in the era of Precision Medicine. Although it is known that most of the NA quality issues are related to the cross-linking between nucleotides and nearby proteins and to the fragmentation induced by formaldehyde, we also reasoned that oxidative events during tissue processing might affect the NA chains. Pursuing improvements in NA preservation, we focused on the two main steps of tissue handling: fixatives and paraffin embedding.
Methods: We envisioned four parallel fixation protocols *per* sample: we compared the standard of care method with neutral buffered formalin (NBF) to the Glyoxal Acid-Free (GAF), a di-aldehyde that only forms unstable links with guanine. Moreover, antioxidants (AO) were added to paraffin for both NBF (NBF-AO), and GAF (GAF-AO) processing. We applied all fixations and embedding workflows on 16 human cancer specimens. A cohort of 100 retrospective, NBF-fixed colorectal cancers (CRCs) were used as external control. We assessed DNA quality using the DNA Integrity Number (DIN) obtained by the TapeStation Assay.
Results: Starting from the different fixatives, GAF ($median_{DIN}$:6) better preserved DNA compared to the matched NBF tissues ($median_{DIN}$:3.75). The retrospective FFPE-CRCs confirmed a superimposable, strong fragmentation induced by NBF ($median_{DIN}$:3.1). The addiction of the AOs to paraffin improved the fragment size for the NBF fixation ($median_{DIN}$:4.85), with the most preserved DNA purified from GAF-AO processed tissues ($median_{DIN}$:7.3). Considering the standard of care (NBF) and the best performing protocol (GAF-AO), we induced a 2-fold increase for DIN, implying a shift from a median size of 2.1 Kbp to 11.2 Kbp.
Conclusion: We prospect a novel, paradigm shifting protocol for DNA preservation in paraffin embedded tissues, based on the reduction of the oxidation during the tissue processing, opening the way to more reliable and reproducible genetic analyses..

OFP-12-002
Spatiotemporal organisation of residual disease in mouse and human BRCA1-deficient mammary tumours and breast cancer

S. Rottenberg[1,2], D.P. Turos[1,2], M. Decollogny[1,2], J.-C. Tille[3], O. Tredan[4,5], I. Labidi-Galy[6,7], A. Valdeolivas[8]
[1]Institute of Animal Pathology, Vetsuisse Faculty, University of Bern, Bern, Switzerland, [2]Bern Centre for Precision Medicine (BCPM), Department for BioMedical Research, University of Bern, Bern, Switzerland, [3]Hôpitaux Universitaires de Genève, Division of Clinical Pathology, Department of Diagnostics, Geneva, Switzerland, [4]Centre Leon Berard, Department of Medical Oncology, Lyon, France, [5]CRCL UMR INSERM, Lyon, France, [6]Center of Translational Research in Onco-Haematology, Faculty of Medicine, University of Geneva, Geneva, Switzerland, [7]Hôpitaux Universitaires de Genève, Department of Oncology, Switzerland, [8]F. Hoffmann-La Roche Ltd, Roche Pharma Research and Early Development, Roche Innovation Centre Basel, Basel, Switzerland

Background & Objectives: Breast cancer remains one of the prominent causes of death worldwide. Although chemo- and immunotherapeutic agents often result in substantial reduction of primary or metastatic tumours, remaining drug-tolerant tumour cell populations, known as minimal residual disease (MRD), pose a significant risk of recurrence and therapy resistance. Here, we aimed to characterize the spatiotemporal organisation of therapy response and MRD in BRCA1;p53-deficient mouse mammary tumours and human clinical samples using a multimodal approach.
Methods: By focusing on our genetically engineered mouse model for *BRCA1*-mutated breast cancer, we integrating single-cell RNA sequencing (scRNA-seq), spatial transcriptomics (ST), and imaging mass cytometry (IMC) across multiple treatment time points, and characterized dynamic interactions between tumour cell subpopulations and their surrounding microenvironment. Our dataset includes more than 30 individual ST samples spanning multiple timepoints and chemotherapy treatments, complemented by pathological annotations, cell type abundances, and several gene set signatures. This is further supplemented with scRNA-seq data and integrated with IMC for a direct assessment of drug uptake and the associated transcriptional changes. To translate our findings from the mouse model into human disease, we analysed 5 human BRCA1-deficient breast cancer ST samples, characterizing intratumoural heterogeneity and molecular features across species.
Results: Our analysis identifies a distinct, drug-tolerant epithelial-mesenchymal transition (EMT) cancer cell population, which exhibits a conserved expression program in human BRCA1-deficient tumours and significantly correlates with adverse clinical outcomes. We further reveal the spatial distribution of residual EMT-like tumour cells within specific anatomical niches, providing a framework for understanding the persistence of MRD and potential therapeutic vulnerabilities.
Conclusion: Our data yield a comprehensive molecular roadmap of MRD that may open new avenues for therapeutic strategies targeting EMT-driven drug tolerance and tumour relapse.

OFP-12-003
Sestrin3 links aromatic amino acid sensing to proteasome dynamics and tumour progression

I. Livneh[1,2], V. Cohen-Kaplan[2], B. Fabre[3], P. Stein[1], A. Dahan[1], Y. Zohar[1], A. Ciechanover[2]
[1]Rambam Health Care Campus, Institute of Pathology and Cytology, Haifa, Israel, [2]Technion - Israel Institute of Technology, Faculty of

Medicine, Haifa, Israel, [3]Université de Toulouse, CNRS, Auzeville-Tolosane, France

Background & Objectives: The aromatic amino acids (AAAs)—tyrosine, tryptophan, and phenylalanine—have been shown to regulate proteolysis by governing the subcellular distribution of the proteasome between the nucleus and cytoplasm. This dynamic plays a critical role in cancer cell adaptation to stress, and proteasome recruitment was demonstrated to serve as an essential survival mechanism. While mTOR was shown to mediate this response, the upstream sensors through which AAAs influence proteasome localization and cell fate remain unclear. This study aimed to identify the molecular mediator of AAA sensing and its potential role in cancer biology.
Methods: We performed a CRISPR-Cas9 knockout screen, targeting 20 candidate proteins implied in mTOR signalling, to uncover regulators of AAA-induced proteasome translocation. Hits were validated using confocal microscopy, co-immunoprecipitation, mass-spectrometry, and functional rescue assays. The role of the identified mediator was further tested in animal tumour models, and its expression patterns were evaluated in human cancer datasets.
Results: We identified Sestrin3 (SESN3) as a critical mediator of AAA-driven proteasome translocation. SESN3 knockout abrogated nuclear-to-cytosolic proteasome translocation in response to nutrient stress, while ectopic re-expression rescued this function. Mechanistically, AAAs disrupted SESN3's interaction with the GATOR2 complex, particularly with WDR59 and MIOS, thereby relieving its inhibitory effect on mTOR. SESN3-deficient cells showed constitutive mTOR lysosomal localization, independent of amino acid availability. In vivo, SESN3-deficient tumours were significantly smaller (94.1% reduction, $p = 4.5\times10^{-11}$) and exhibited nuclear-restricted proteasome distribution without any intervention. Analysis of human datasets revealed consistent SESN3 overexpression in multiple aggressive tumour types.
Conclusion: Our findings uncover a previously unrecognized signalling axis in which SESN3 serves as a sensor of AAAs, linking nutrient cues to proteasome localization and mTOR activation. SESN3 appears to be a tumour-promoting factor and a candidate oncogene, whose expression may serve both as a biomarker and a potential therapeutic target across cancer types.

OFP-12-004
Spatial tissue proteomics of non-small cell lung cancer (NSCLC)
N. Deigendesch[1,2], S. Kallabis[1], L. Bubendorf[2], F. Meissner[1]
[1]Institute of Innate Immunity, Department of Systems Immunology & Proteomics, Bonn, Germany, [2]Institute of Pathology, University Hospital Basel, Basel, Switzerland

Background & Objectives: Lung adenocarcinoma, the predominant subtype of non-small cell lung cancer (NSCLC), exhibits significant molecular heterogeneity, characterized by oncogenic driver mutations, gene rearrangements, and amplifications. Despite advances in targeted therapies and immune checkpoint inhibitors, a substantial proportion of NSCLC cases lack identifiable driver alterations and limiting treatment options. Additionally, resistance mechanisms to therapy remain poorly understood. This study aims to utilize spatial tissue ultrasensitive mass spectrometry (MS)-based proteomics to explore tumour heterogeneity, signalling pathways, and metabolic states beyond genetic alterations, with the goal of identifying novel predictive biomarkers and mechanisms of therapy resistance.
Methods: Retrospective NSCLC samples from formalin-fixed and paraffin-embedded (FFPE) tissues were analysed with deep visual proteomics. Wer employed histology-guided laser-capture microdissection (Leica LMD7) followed by ultrasensitive LC-MS/MS proteomics. Samples were measured with the EvoSep One LC system, coupled to a timsTOF pro 2 (Bruker) mass spectrometer in dia-PASEF scan mode. Additionally, we use patient-derived tumour samples obtained from fine-needle aspirates and cytological smear preparations.
Results: With our approach, we quantified over 5,000 protein groups per sample from approximately 30,000 µm² of FFPE tissue, corresponding to 200–300 tumour cells. Spatially resolved tissue proteomics reveal tumour-specific protein signatures and alterations in signalling pathways in NSCLC depending on the histomorphological subtype, grading and presence or absence of known driver mutations. Notably, this approach also uncovers intratumoral heterogeneity and characteristics of the tumour microenvironment, which may influence immune evasion and variability in therapeutic response.
Conclusion: Morphology-guided ultrasensitive spatial MS-based proteomics is an emerging and powerful approach to study pathophysiology at an unbiased (i.e. untargeted), quantitative and system-wide level. By uncovering tumour-specific proteomic signatures of a few hundred tumour cells with spatial resolution, MS-based tissue proteomics enhances our understanding of tumour heterogeneity and the interaction with its microenvironment, and paves the way for more precise, individualized treatments in NSCLC.

A crucial role of DUSP8 in glioblastoma by endothelial transdifferentiation inhibition of Glioblastoma Stem-like Cells
G. Ricciardi[1,2], E. Germanà[1], M. Buccarelli[3], G. Castellani[3], C. Pizzimenti[4], G. Fadda[5], L. Ricci-Vitiani[3], M. Martini[5]
[1]University of Messina, Department of Biomedical, Dental, Morphological and Functional Imaging Sciences, Messina, Italy, [2]Istituto Clinico Polispecialistico C.O.T. Cure Ortopediche Traumatologiche s.p.a, Messina, Italy, [3]Istituto Superiore di Sanità, Department of Oncology and Molecular Medicine, Rome, Italy, [4]Papardo Hospital, Pathology Unit, Messina, Italy, [5]University of Messina, Department of Human Pathology in Adult and Developmental Age "Gaetano Barresi", Messina, Italy

Background & Objectives: Glioblastoma is the most common malignant brain tumour in adults, characterized by increased VEGF levels, leading to abnormal angiogenesis. While patients respond to VEGF inhibitors, resistance develops over time. Recent studies suggest that glioblastoma stem-like cells (GSCs) can transdifferentiate into endothelial-like cells (GdECs), contributing to resistance to anti-VEGF therapies.
Methods: GSCs were isolated from GBM surgical samples and transdifferentiated into GdECs. Endothelial markers expression was confirmed by flow cytometry, while gene and miRNAs expression was assessed through RNA extraction, qRT-PCR and RNA-seq. Protein analysis was performed with WES technology. Combined ISH/IHC was performed directly on patient tissue to visualize the localization and co-expression of DUSP8 and miR-1825. Drug cytotoxicity experiments were carried out to evaluate selective inhibitors effects on GSC viability. In vivo, xenograft mice were used to evaluate tumour growth, microvessel density and DUSP8/miR-1825 interaction.
Results: We identified a signature of three miRNAs (miR-4516, miR-1281, and miR-1825) that distinguishes GSCs from GdECs. Gene Set Enrichment Analysis (GSEA) revealed the involvement of these miRNAs in angiogenesis, hypoxia, and reactive oxygen species (ROS) metabolism. Specifically, high miR-1825 levels negatively regulate DUSP8 expression. Molecular analysis showed that low DUSP8 levels activate the MAPK signalling pathway leading to high microvascular density ($p=0.041$) and poor overall survival ($p=0.0062$) in GBM patients. Furthermore, DUSP8-overespressing xenograft displayed reduced tumour spread, while those with silenced DUSP8 exhibited increased invasion ($p<0.001$). Pharmacological inhibition of MAPK signalling with ralimetinib impaired GdEC viability and reduced tube

formation ability (p<0.001), highlighting its potential therapeutic relevance.
Conclusion: These findings suggest that regulating the miR-1825/DUSP8 pathway could be a therapeutic strategy to inhibit tumour vascularization in GBM.

OFP-12-006
Enhancing *BRCA* mutation detection in metastatic prostate cancer: the critical role of early testing and sample quality
M. Vescovo[1], M.R. Raspollini[2], L. Nibid[1], F. Castiglione[2], E. Nardi[2], D. de Biase[3], F. Massari[2], F. Giunchi[3], F. Pepe[4], G. Troncone[4], U. Malapelle[4], M. Carosi[5], B. Casini[5], E. Mellucci[5], M. Fassan[6], L. Toffolatti[7], E. Guerini-Rocco[8], F. Conversano[8], A. Rappa[5], S. Tommasi[9], C.A. Coppola[9], A. Caputo[10], S. Gaeta[10], P. Zeppa[10], F. Pagni[11], D. Seminati[11], A. Vecchione[12], S. Scarpino[12], D. Righi[1], C. Taffon[1], F. Prata[1], G. Perrone[1]
[1]Fondazione Policlinico Universitario Campus Bio-Medico, Roma, Italy, [2]University Hospital Careggi, Florence, Italy, [3]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, [4]University Federico II of Naples, Naples, Italy, [5]Regina Elena National Cancer Institute, Rome, Italy, [6]University of Padua, Padova, Italy, [7]Ca' Foncello General Hospital, ULSS2 Marca Trevigiana, Treviso, Italy, [8]European Institute of Oncology, IRCCS, Milan, Milano, Italy, [9]IRCCS Istituto Tumori Giovanni Paolo II, Bari, Italy, [10]University of Salerno, Salerno, Italy, [11]University Milan Bicocca and Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy, [12]Sant'Andrea Hospital, Sapienza University, Roma, Italy

Background & Objectives: Metastatic prostate cancer frequently harbours DNA damage repair (DDR) mutations, particularly in *BRCA1 and BRCA2* genes, which are actionable targets for poly(ADP-ribose) polymerase (PARP) inhibitors. Early detection of these mutations is crucial for optimizing therapeutic strategies. However, pre-analytical factors such as tissue storage duration and DNA degradation significantly impact next-generation sequencing (NGS) success rates, potentially affecting patient eligibility for targeted therapies.
Methods: This multicentre study retrospectively analysed 954 formalin-fixed paraffin-embedded (FFPE) tissue samples (559 biopsies and 395 surgical specimens) from 11 italian institutions. The impact of storage duration (categorized into seven intervals: 0–12 months, 13–24 months, 25–36 months, 37–48 months, 49–60 months, 61–72 months, and >72 months), DNA concentration, and DNA fragmentation on NGS success rate was evaluated. Logistic regression and Cox proportional hazards models were used to assess correlations between these variables and sequencing outcomes.
Results: NGS success rate declined progressively across all participating centres over the seven storage intervals, with the highest success rate observed in samples stored for 0–12 months (87.8%) and a significant decrease beyond 72 months, where the success rate dropped to approximately 50% (p<0.001). This sharp decline highlights the detrimental impact of prolonged storage on DNA integrity. Higher DNA concentrations and fragmentation indices were associated with improved sequencing success (p<0.001). Surgical specimens demonstrated superior success rate (83.3%) compared to biopsies (72.8%), likely due to better DNA preservation.
Conclusion: Timely *BRCA1/2* mutation testing is essential to maximize the identification of metastatic prostate cancer patients eligible for PARP inhibitors. Surgical specimens are more reliable than biopsies for *BRCA1/2* detection. Early *BRCA* testing should be proposed in high-risk and very high-risk prostate cancer patients. Standardization of formalin fixation time, DNA extraction, and sequencing protocols across diagnostic centres is crucial for improving patient access to personalized therapies.

OFP-12-007
SPOP mutations and MMR deficiency are associated with high PD-L1, low TIL and high Gleason Score in prostate cancer
M. Ballato[1], V. Fiorentino[2], E. Germanà[1], G. Ricciardi[1,3], W.G. Giordano[1], G. Giuffrè[2], V. Ficarra[4], F. Pierconti[5], G. Fadda[2], M. Martini[2]
[1]University of Messina, Biomedical, Dental, Morphological and Functional Imaging Sciences, Messina, Italy, [2]University of Messina, Human Pathology of Adults and Developmental Age "Gaetano Barresi", Division of Pathology, Messina, Italy, [3]Istituto Clinico Polispecialistico C.O.T. Cure Ortopediche Traumatologiche s.p.a, Messina, Italy, [4]University of Messina, Clinical and Experimental Medicine, Division of Urology, Messina, Italy, [5]Catholic University of the Sacred Heart, "A. Gemelli", Hospital Foundation, IRCCS, Women, Children and Public Health Sciences, Division of Pathology, Roma, Italy

Background & Objectives: The application of immunotherapy in prostate cancer (PCa) has met with limited success to date, with only a small subgroup of patients experiencing significant clinical benefits. This modest response rate stresses the urgent need to refine patient selection. The aim of this retrospective study was to explore the relationship between SPOP mutations and MMR/MSI status with the expression of AR, PD-L1 and TIL (as CD4/CD8 ratio) in a cohort of PCa cases.
Methods: A total of 153 PCa patients were selected. Immunohistochemistry for CD4, CD8, and PD-L1 was performed, with PD-L1 expression evaluated using the Combined Positive Score (CPS). SPOP mutations were analysed by exon sequencing. MMR/MSI status was assessed by immunohistochemistry and the EasyPGX® ready MSI kit (Diatech, Jesi, Italy), respectively. The expression levels of AR and CD274 were examined with qRT-PCR. The role of SPOP silencing on the expression of CD274 was evaluated using SPOP interfering RNAs on two prostate cancer cell lines (LNCaP, PC3) and western blot analysis.
Results: SPOP mutations, identified in 14 out of the 153 samples (9.15%), were associated with higher PD-L1 expression and lower TIL (both p<0.0001), higher Gleason score and higher PSA level (both p<0.0001). Patients with SPOP mutations had increased mRNA levels of CD274 and AR compared to non-mutated patients (p=0.0006 and p=0.0148, respectively). Silencing SPOP expression with specific siRNA led to a significant up-regulation of PD-L1 expression in both cancer cell lines. MMR/MSI status was significantly correlated with higher PD-L1 expression (p<0.0001), lower TIL (p=0.0004), and higher Gleason score (p=0.001).
Conclusion: Our study supports SPOP mutations and MMR/MSI status as potential biomarkers for better identifying PCa patients who could be more susceptible to immunotherapy. Further research is required to validate these findings and translate them into clinical practice.

OFP-12-008
Exploring the relationship between BRAF V600E and PD-L1 in histiocytic dendritic cell neoplasms: a potential link to immune escape?
C. Utku[1], N. Ozsan[1], B. Tuzun[2], A. Güneş[2], E. Ataseven[3], B. Doganavsargil[1], M. Sezak[1], G. Saydam[2], M. Hekimgil[1], D. Demir[1]
[1]Ege University Faculty of Medicine, Department of Pathology, Izmir, Turkey, [2]Ege University Faculty of Medicine, Department of Haematology, Izmir, Turkey, [3]Ege University Faculty of Medicine, Department of Paediatrics, Izmir, Turkey

Background & Objectives: Histiocytic and dendritic cell neoplasms (HDCNs) are very rare malignancies. Although data are limited, *BRAF* mutations may negatively impact disease progression. In aggressive subtypes like histiocytic sarcoma (HS), treatment

response is generally low, though some patients have shown responses to anti-PD-L1 therapies. This study aimed to investigate the relationship between PD-L1 expression, *BRAFV600E* mutation, histopathological, clinical, and prognostic features of HDCNs.

Methods: We retrospectively analysed 108 patients diagnosed with HDCN between 2006-2025, evaluating histopathological features (necrosis, fibrosis, atypia, immune microenvironment), laboratory and viral data (LDH, CRP, EBV, CMV), risk organ and CNS involvement, treatment response, disease-free survival (DFS), recurrence, and overall survival (OS). PD-L1 expression was assessed by SP263 immunohistochemistry and quantified in tumour and immune cells using 5%, 10%, 20%, and 50% cutoffs. BRAF status was evaluated immunohistochemically.

Results: The mean age was 31.06 years, with 64.2% being male. Subtypes included 65 LCH, 11 BPDCN, 8 HS, 7 RD, 6 JXG, 3 EC, 3 FDHS, 3 IDHS, 1 LCS, and 1 ALK-H. Among 94 evaluable patients, 29 (30.9%) were BRAF-positive. PD-L1 positivity at 5%, 10%, 20%, and 50% cutoffs was 50%, 35%, 26.6%, and 7.4%, respectively. At 5% cutoff, PD-L1 positivity was seen in 83.3% of HS, 80% of RD, 56.1% of LCH, 50% of FDHS and IDHS, 16.7% of JXG, and 100% of LCS and ALK-H, but was absent in EC. PD-L1 positivity was significantly associated with BRAF mutation at 5%, 10%, and 20% thresholds (p=0.014, 0.005, 0.010). Multisystem-involvement was associated with shorter DFS (p=0.001); BRAF and PD-L1 were not directly related. Kaplan-Meier analysis showed 1-year and 5-year OS rates of 90% and 78%, respectively.

Conclusion: Recent study shows *BRAFV600E* promotes immune evasion via PD-L1 in melanoma and papillary thyroid carcinoma. Our findings support this in HDCNs, especially HS with high PD-L1 positivity (83.3%), suggesting anti-PD-L1 therapy as a potential option.

OFP-12-009

Can morphologic features predict TP53 abnormalities in acute myeloid leukaemia post-cytotoxic therapy?

G. Aydogan[1], D. Demir[1], D. Cetin[2], A. Gunes[2], E. Demir[3], N.A. Soyer[2], E. Karaca[4], M.B. Durmaz[4], H. Akin[4], G. Saydam[2], N. Ozsan[1], M. Hekimgil[1]

[1]Ege University Faculty of Medicine, Department of Pathology, Izmir, Turkey, [2]Ege University Faculty of Medicine, Department of Haematology, Izmir, Turkey, [3]Ege University Faculty of Medicine, Department of Medical Biostatistics, Izmir, Turkey, [4]Ege University Faculty of Medicine, Department of Medical Genetics, Izmir, Turkey

Background & Objectives: TP53 mutations frequently occur in acute myeloid leukaemia post-cytotoxic therapy (AML-pCT) and are linked to treatment resistance, complex cytogenetics, and poor prognosis. Identifying morphological characteristics predictive of TP53 abnormalities may enhance diagnostic accuracy and clinical management. This study aimed to evaluate the impact of TP53 abnormalities in AML-pCT.

Methods: This study evaluated 50 AML-pCT patients diagnosed between 2010-2025. Bone marrow (BM) morphology was reviewed, and p53 immunohistochemistry (IHC) was performed in 48 patients, with cytogenetic data available for 26 patients. TP53 abnormality was defined as either ≥5% nuclear p53 expression in blasts or deletion of chromosome-17p. Blast cells were graded (G1–G3) based on nucleolar prominence, particularly eosinophilic nucleoli.

Results: The median age of patients was 63 years, with females comprising 52%. The most frequent primary malignancies included hematolymphoid (24%), breast (18%), gastrointestinal (16%) cancers. The median time from primary cancer to AML diagnosis was 39 months. TP53 abnormalities were detected in 54%. Nucleolar grading revealed G1 in 12 (24%), G2 in 14 (28%), and G3 in 21 (42%) patients. Grade 3 blasts (prominent eosinophilic nucleoli) were significantly more common in TP53-abnormal patients (73.1%,p< 0.001). BM-hypercellularity was also more frequent in the TP53-abnormal group (70%,p=0.01). Dysplastic changes were common in all patients.TP53-abnormal patients showed less mature granulocytic lineage cells, though not statistically significant. Notably, one cytogenetically TP53-mutant case lacked detectable p53 protein expression by IHC but had G3 blasts. Median overall survival was identical (3 months) in both groups; however, mean survival was shorter in the TP53-abnormal group (5.20 vs 15.14 months), without statistical significance(p=0.468).

Conclusion: In conclusion, specific morphologic features such as prominent eosinophilic nucleoli and hypercellularity in BM morphology are indicative of TP53 abnormalities in AML-pCT, potentially aiding early detection and diagnostic precision. While p53 IHC provides valuable insights, confirmation through molecular or cytogenetic methods remains indispensable for definitive diagnosis.

OFP-12-010

Genomic profiling of primary cutaneous follicle centre lymphoma reveals major differences from systemic follicular lymphoma with cutaneous involvement and identifies two distinct PCFCL clinicopathological subgroups

R. Albero[1], A. Combalia[2], N. Vidal[2], F. Nadeu[1], C. Lopez[2], N. Garcia[1], P. Mozas[2], I. Salaverria[1], T. Estrach[2], E. Campo[1], A. Garcia[2]

[1]FCRB-IDIBAPS, Barcelona, Spain, [2]Hospital Clinic, Barcelona, Spain

Background & Objectives: Primary cutaneous follicle centre lymphoma (PCFCL) is a rare, indolent cutaneous lymphoma that responds well to local treatment. Differentiating it from systemic follicular lymphoma with cutaneous involvement (FL-CI), which requires systemic treatment and has a worse prognosis, remains challenging. While genetic alterations in systemic follicular lymphoma are well understood, mutations in PCFCL remain unclear. Molecular characterization could aid in diagnosis, reveal different mechanisms driving oncogenesis, and identify distinct patient subgroups.

Methods: We analysed the clinicopathological characteristics and mutational profile using an NGS panel including 120 genes involved in follicular lymphoma pathogenesis. The cohort consisted of 27 PCFCL samples (24 patients), 13 FL-CI samples (10 patients), and the reanalysis of 50 systemic FL samples. The study included two synchronous tumours in one patient (PCFCL) and sequential samples from four patients (2 PCFCL, 2 FL-CI). BCL2 rearrangement analysis was performed using FISH, and clonality was assessed by NGS.

Results: PCFCL showed lower CD10 positivity, with an absence of BCL2 rearrangement (one case), compared to FL-CI. FL-CI exhibited recurrent mutations in chromatin-regulating genes (CREBBP (90%), KMT2D (90%), EP300 (30%)) and overlapped with the mutational profile of systemic FL. We also describe two groups of PCFCL cases: 55% harboured mutations in immuno-scape genes (IRF8, FAS, CIITA, B2M), which were mutually exclusive with 20% of PCFCL cases showing mutations in STAT6 DNA-binding or SH2 domains. These cases showed increased CD23 (5/5) and CD10 positivity (4/5), as well as CREBBP mutations (4/5).

NGS-based B-cell clonality analysis in synchronous and sequential tumours from the same precursor B-cell revealed significant mutational and pathological diversity in PCFCL recurrences. In contrast, FL-CI relapses showed greater genetic and histological stability.

Conclusion: We present the largest cohort of PCFCL, including genomic and clinicopathological data, identifying recurring genetic and pathological features to improve clinical management, differential diagnosis, and characterization of novel subgroups in this rare disease.

Transcriptional reprogramming of splenic endothelial cells in myelofibrosis

C. Tripodo[1], E. Savino[1], F. Lazzaroni[2], G. Cicio[1], V. Cancila[3], G. Bertolazzi[4], M. Ponzoni[5]

[1]The AIRC Institute of Molecular Oncology - IFOM - ETS, Advanced Pathology Laboratory, Milan, Italy, [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Haematology Unit, Milan, Italy, [3]University of Palermo, Department of Health Sciences, Palermo, Italy, [4]Kore University of Enna, Enna, Italy, [5]San Raffaele Hospital (IRCCS), Unit of Pathology, Milan, Italy

Background & Objectives: The spleen plays a central role in blood filtration and immune regulation, supporting both steady-state and stress-induced haematopoiesis. Littoral endothelial cells (ECs) are a unique subset of splenic ECs, yet their transcriptional identity remains largely undefined. This vascular niche is particularly relevant in myelofibrosis (MF), where the spleen becomes a major site of extramedullary haematopoiesis (EMH). We aimed to define the native transcriptional profile of human splenic littoral ECs and characterize their molecular reprogramming upon EMH establishment in MF.

Methods: We performed whole-transcriptome digital spatial profiling on 48 regions of interest (ROIs) of FFPE splenic tissue sections from two healthy donors and two MF patients (one Primary MF, one Polycythemia Vera-associated MF). CD8A and CD3E were used as markers to identify splenic littoral ECs (CD8+CD3−) and distinguish them from non-endothelial compartments (CD3+; CD8−CD3−).

Results: In healthy spleen, differential gene expression analysis identified a unique littoral EC signature, consisting of 417 genes upregulated in EC ROIs (adj-p < 0.01, logFC > 0.58). This included NR5A1, a key regulator of splenic vasculature development, along with hallmark genes BLNK, NR0B2, SIGLEC11, STAB2 and IL34. The signature was validated against two reference single-cell atlases of human vascular cells, confirming its specificity for splenic ECs. In MF, the expression of splenic EC signature genes was dampened, indicating a global attenuation of littoral EC identity in favour of genes involved in EC stress response and potentially supporting EMH, including NOS2, NOX4, FOXC1, CX3CL1, PDGFB, and CSF3. Additionally, inflammatory pathways were upregulated, with increased expression of class-I IFN genes, IL6, and complement factors C3 and C5, suggesting a shift toward a pro-inflammatory endothelial state.

Conclusion: Our study delineates the transcriptional landscape of native littoral ECs and uncovers their reprogramming in MF, marked by a transition from intrinsic endothelial identity to a stress-adaptive state.

Funding: This study was supported by the Italian Foundation for Cancer Research (AIRC)

OFP-12-012

Megakaryocytic activation (M-ACT): a novel morphological predictor of fibrotic progression in philadelphia-negative myeloproliferative neoplasms

V. Fiorentino[1], V. Zuccalà[1], C. Pizzimenti[2], L. Pepe[1], M. Franchina[1], M. Ballato[1], W. Giordano[1], A. Allegra[1], P. Tralongo[1], A. Ieni[1], G. Fadda[1], G. Tuccari[1], L.M. Larocca[3], M. Martini[1]

[1]University of Messina, Messina, Italy, [2]Papardo Hospital, Messina, Italy, [3]Unicamillus, Saint Camillus International University of Health Sciences, International Medical University in Rome, Rome, Italy

Background & Objectives: Philadelphia-negative myeloproliferative neoplasms (MPNs) exhibit variable clinical courses, including progression to myelofibrosis (MF). Current prognostic models lack morphological features associated with fibrotic evolution. This study evaluates Megakaryocytic Activation (M-ACT), a novel morphological parameter, as a predictor of fibrotic progression in MPNs and explores underlying mechanisms.

Methods: We analysed bone marrow biopsies from 450 MPN patients [150 polycythemia vera (PV), 250 early/prefibrotic primary myelofibrosis (PMF), 50 essential thrombocythemia (ET)] at diagnosis. M-ACT was defined by coexisting: 1) megakaryocytic (MK) emperipolesis; 2) MK clustering; and 3) peri-MK fibrosis. Progression-free survival (PFS; progression to overt MF) was assessed. An in vitro model was also developed. CD34+ stem cells were isolated from bone marrow aspirates of patients with Philadelphia-negative MPNs exhibiting M-ACT (n=20), not exhibiting M-ACT (n=20), and healthy controls (n=10). Megakaryocyte differentiation was induced, with CD42+ cell quantification after 15 days. Soluble mediators in culture medium were analysed.

Results: M-ACT was present in 65% PV patients and in 55% early/prefibrotic PMF ones, but absent in ET. M-ACT correlated with splenomegaly, elevated white blood cell count, lactate dehydrogenase, platelet count, JAK2V617F allele burden (PV), and CALR mutations (PMF). M-ACT patients had significantly worse PFS (P<0.0001). Multivariate analysis confirmed M-ACT as an independent predictor of fibrotic progression. In vitro studies showed increased CD42+ cells in cultures from M-ACT-positive patients. Megakaryocytes from M-ACT-positive patients showed higher pro-fibrotic cytokine levels (TGF-β, PDGF) in the culture medium.

Conclusion: M-ACT is a readily assessable morphological parameter that independently predicts fibrotic progression in PV and early/prefibrotic PMF, potentially aiding in differentiating ET from early/prefibrotic PMF. The in vitro model shows that M-ACT megakaryocytes present pro-fibrotic features.

SY-02 Quantitative morphology in electron microscopy - methods old and new

SY-02-004

Electron microscopy in renal pathology. A hospital's experience with an outsourced electron microscope

F. Leiva-Cepas[1], J. Osuna Soto[2], A. Sanz Zorrilla[2], M. Jurado Rivera[2], J. Sawas Abuamin[3], R. Sánchez Sánchez[2]

[1]University of Cordoba/Universitary Hospital Reina Sofia, Department of Morphological and Socio-Health Sciences/Pathology Unit, Cordoba, Spain, [2]Universitary Hospital Reina Sofia, Pathology Unit, Cordoba, Spain, [3]Universitary Hospital Juan Ramon Jimenez, Pathology Unit, Huelva, Spain

Background & Objectives: Electron microscopy (EM) remains vital to the diagnostic repertoire of pathologies; however, in the case of renal pathology, it is essential for certain morphological entities. Fewer and fewer hospitals have an electron microscope and rely on their nearest university or a private company. Our study analyzes turnaround times since our institution's electron microscope ceased to operate in 2020.

Methods: We analysed the response times for sample submission and the ability to view the sample by our centre's pathology team. We analysed the referred cases, nonviable samples (without glomeruli), and the agreement between the paraffin-embedded and ultrastructural diagnoses.

Results: During the period 2020-2024, a total of 326 electron microscopy studies were requested. 318 samples corresponded to renal pathology, the rest to cardiac, nerve, or skeletal muscle pathology. Twelve samples were not representative because they lacked glomeruli or were poorly processed. The mean response time for image viewing, including tissue processing, was 27 days. The level of agreement between the paraffin-embedded and ultrastructural diagnoses was 83%.

Conclusion: Access to EM services remains vital, but is increasingly being outsourced to external centres. Pathologists depend on accurate images and ultrastructural reports to inform the diagnosis. It is

necessary to create hospital referral units to centralize cases, reducing dependence on external centres and increasing quality and efficiency.

Leveraging AI for medical laboratories ISO 15189:2022 accreditation and compliance: a histopathology proof-of-concept on documentation and workflow efficiency

F. Pereira[1,2,3], T. Osadolor[1], I. Sharp[2], S. Di Palma[1], P. Ruwona[1], D. Cook[1], N. Newman[1], BESSIE
[1]Berkshire and Surrey Pathology Services, Cellular Pathology, Surrey, United Kingdom, [2]School of Engineering and Science of the Greenwich University, Biomed, London, United Kingdom, [3]School of Medicine and Biomedical Sciences, Institute for Research and Innovation in Health of the University of Porto, Porto, Portugal

Background & Objectives: As pathology services adopt increasingly complex regulatory frameworks, the demand for scalable digital solutions to manage accreditation workflows has never been greater.
Berkshire and Surrey Pathology Services (BSPS), an ISO 15189:2022 accredited pathology service within the United Kingdom, leverages the iPassport platform to manage its extensive document archive, exceeding 15,000 items, encompassing standard operating procedures (SOPs), work instructions, and quality records. BSPS launched a proof-of-concept using Large Language Models (LLMs) to audit and refine SOPs for potential noncompliance, streamline updates, and reinforce operational excellence.
Methods: We leveraged pre-trained cloud-based models (OpenAI and Mistral), in conjunction with locally deployed quantized models on Msty (Q4 DeepSeek R1 and Mistral Small). Standardised instructions ensured consistency across models. Execution times were documented, and staff contributed by reviewing standard operating procedures to provide practical compliance feedback. This allowed efficient document review and supported ongoing quality improvement initiatives.
Results: LLM-based analysis significantly outperformed manual review. Each model required approximately two minutes per document, compared to twenty minutes for human evaluators. While all models generated relevant suggestions and logical reconstructions, performance varied. Locally deployed models, while faster than human review, occasionally produced nonfactual outputs. Staff engagement was limited, further highlighting the value of automation.
Conclusion: This study shows that LLMs can effectively detect noncompliance issues, identifying up to three times more findings than manual reviewers. Both cloud-based and locally deployed AI models showed strong performance. Human oversight was retained as a critical final validation step, ensuring compliance accuracy and mitigating risks associated with model hallucinations. This initiative informs the development of Project BESSIE (Baseline Enhanced Semantic System for Intelligent Embeddings), a targeted governance AI designed to support ISO-aligned clinical workflows. Our findings position LLMs as a transformative force for accreditation-readiness, quality improvement, and operational efficiency in digital pathology services.

CP-01-005

Analysis of histopathology data drift in a real-world data set over an 8-year period reveals laboratory- and instrumentation-induced variability

M. Zarella[1], M. Francis[1], W. Han[1], C. Garcia[1]
[1]Mayo Clinic, Division of Computational Pathology and Informatics, Department of Laboratory Medicine and Pathology, Rochester, MN, USA

Background & Objectives: AI solutions in histopathology are susceptible to data drift arising from changes in laboratory preparation, slide scanner variability, and other factors. Continuous monitoring after deployment can help combat this problem, which is often performed indirectly by analysing how AI model responses may change over time. Methods to *directly* monitor complex histopathology data, on the other hand, are not well established. We developed a method to directly evaluate data drift in whole-slide images (WSIs) which we applied to slides scanned over an eight-year period to mimic a real-world AI deployment with sample sizes supporting fine-scale time resolution.
Methods: We analysed 5,781 WSIs of Ki-67 breast slides acquired between 2016-2023 at the time of diagnosis (and therefore not contaminated with artifacts associated with retrospective slide scanning). We trained an autoencoder on WSIs from 2016 (reference set) and, using a novel computational paradigm, evaluated data from 2017-2023 to detect deviations from the reference. As a negative control, we held out 50% of the 2016 samples for analysis. As positive controls, we analysed 52 Ki-67 WSIs using a different slide scanner and a set of ER/PR-stained slides scanned alongside the reference data.
Results: Positive control images were strongly separable from reference data, confirming that the model was capable of detecting scanner-induced and even subtle stain differences. In contrast, data drift was of much lower magnitude with occasional deviations that quickly returned to baseline.
Conclusion: This study addresses the unmet need to directly monitor data drift in histopathology for quality assurance after an AI model is put into production. We discovered that scanner-induced differences are far more dominant than laboratory-induced variability at our site. These results not only demonstrate a novel method for AI monitoring but also underscore that best practices in local site validation may be a bigger priority than histology laboratory standardization for ensuring AI safety.

CP-01-006

Enhancing pathologist accuracy and agreement in reporting for prostate cancer: a clinical validation study

F. Maclean[1], C. Petrucco[2], A. De Souza[2], M. Peratikos[3]
[1]Douglass Hanly Moir Pathology, Anatomical Pathology, Sydney, Australia, [2]Franklin.ai, Sydney, Australia, [3]Biostatistics and Data Science, LLC, Nashville, USA

Background & Objectives: International bodies, including ICCR, ISUP and GUPS have provided recommendations regarding minimum data sets for reporting prostate core biopsy (PCB) and Transurethral resections of the prostate (TURP). The use of artificial intelligence (AI) is a potential solution for discrepancies in diagnostic agreement among pathologists. We sought to demonstrate how our model enhanced agreement between pathologists in classifying key clinical findings when assessing whole slide images (WSI).
Methods: The diagnostic accuracy and overall agreement of 29 pathologists were evaluated by classifying PCB and TURP WSIs (n = 1735). Accuracy was evaluated by the per-subject Area Under the Curve (AUC) and overall agreement by the Interclass Correlation Coefficient (ICC).
Results: Analysis of pathologist performance revealed that when assisted with AI, pathologists demonstrated improved diagnostic accuracy and overall agreement in identification of Gleason patterns for both PCB and TURP specimens. When assisted with AI, pathologists' accuracy of acinar adenocarcinoma in PCBs improved from an AUC of 0.84 to 088 for Gleason pattern 3, 0.93 to 0.94 for Gleason pattern 4, and from 0.91 to 0.89 for Gleason pattern 5. Similarly, in TURP specimens, AI-assisted pathologists reported AUC improvements from 0.83 to 0.84 in Gleason pattern 3, 0.91 to 0.91 in Gleason pattern 4, and 0.87 to 0.92 in Gleason pattern 5. Further on this, interobserver classification of Gleason patterns of AI

assisted pathologists was overall in 'Good' agreement (0.75 > ICC > 0.90) for Gleason Patterns 3, 4 and 5 compared to unassisted with 'Moderate' to 'Poor' agreement (0 > ICC >0.75).
Conclusion: The diagnostic assistance provided by the AI algorithm improves pathologist accuracy and overall agreement. AI applications have the potential to enhance patient care by increasing pathologist diagnostic agreement in Gleason grading accuracy, as well as reducing interobserver variability.

CP-01-007
Deepath-SCC: a deep learning model for accurate tissue origin identification in squamous cell carcinoma
Q. Wang[1,2,3], S. Lu[1,2,3], Y. Sun[2,4,5], H. Wen[4,6], Y. Pang[1,2,3], J. Liu[1,2,3], X. Yang[4], S. Huang[2,5], Q. Xu[4]
[1]Fudan University Shanghai Cancer Centre, Pathology, Shanghai, China, [2]Fudan University, Oncology, Shanghai Medical College, Shanghai, China, [3]Fudan University, Institute of Pathology, Shanghai, China, [4]Canhelp Genomics Co., Ltd., Canhelp Genomics Research Centre, Hangzhou, China, [5]Fudan University, Shanghai Key Laboratory of Medical Epigenetics, International Co-laboratory of Medical Epigenetics and Metabolism, Institutes of Biomedical Sciences, Shanghai Medical College, Shanghai, China, [6]Tongji University, College of Computer Science and Technology, Shanghai, China

Background & Objectives: Squamous cell carcinoma (SCC) is a common malignancy that arises in various organs. Despite differences in anatomical location, SCCs and urothelial carcinoma (UC) often exhibit similar histomorphological features and immunophenotypes, making it challenging for conventional pathological methods to determine their origin accurately. To address this challenge, we developed and validated Deepath-SCC, a deep learning model designed to improve the accuracy and interpretability of SCC tissue origin identification.
Methods: In this retrospective multicentre study, we assembled a dataset of H&E-stained whole-slide images (WSIs) encompassing nasopharyngeal carcinoma (NPC), head and neck/oesophageal SCC (HNE), lung SCC (LUSCC), cervical SCC (CSCC), and UC. We trained Deepath-SCC, a deep learning-based classifier designed to identify the tissue of origin of pan-SCC directly from H&E-stained slides, without requiring manual tumour region annotation. Model performance was evaluated using the area under the receiver operating characteristic curve (AUROC) and accuracy metrics for tissue origin classification.
Results: Our analysis included 2,144 patients with confirmed diagnoses. In the validation cohort of 865 specimens, Deepath-SCC demonstrated exceptional performance, achieving accuracy of 93.3% (807/865) and AUROCs ranging from 0.975 for UC to 0.995 for NPC. Among 803 high-confidence predictions (similarity score >0.51), the model achieved an overall accuracy of 96.1% (772/803). For primary SCCs, Deepath-SCC attained an overall accuracy of 96.9% (659/680), with subtype-specific accuracies ranging from 94.7% for NPC to 98.5% for LUSCC. For metastatic SCCs, the model achieved an overall accuracy of 91.9% (113/123), with subtype-specific accuracies ranging from 78.6% for LUSCC to 100% for NPC.
Conclusion: The Deepath-SCC model offers a promising, efficient, and cost-effective solution for identifying the tissue origin of SCC, particularly for cases with unknown primary or multiple primary SCC.

CP-01-008
Prospective evaluation of deepath-MSI for microsatellite instability assessment in colorectal cancer: a novel whole slide image-based approach versus promega MSI assay
Q. Wang[1,2,3], Y. Sun[2,4,5], H. Wen[4,6], Q. Xu[4], X. Zhou[1,2,3]
[1]Fudan University Shanghai Cancer Centre, Department of Pathology, Shanghai, China, [2]Fudan University, Department of Oncology, Shanghai Medical College, Shanghai, China, [3]Fudan University, Institute of Pathology, Shanghai, China, [4]Canhelp Genomics Co., Ltd, Research Centre, Hangzhou, China, [5]Fudan University, Shanghai Key Laboratory of Medical Epigenetics, International Co-laboratory of Medical Epigenetics and Metabolism, Institutes of Biomedical Sciences, Shanghai Medical College, Shanghai, China, [6]Tongji University, College of Computer Science and Technology, Shanghai, China

Background & Objectives: Microsatellite instability (MSI) plays a critical role in colorectal cancer (CRC) diagnosis and treatment, particularly for guiding immunotherapy decisions. The Promega MSI assay is widely used but has limitations in terms of cost, time, and tissue requirements. This study aimed to compare the consistency of Deepath-MSI, a whole slide image (WSI)-based approach, with the traditional Promega MSI assay in assessing MSI status in CRC.
Methods: A total of 728 primary CRC specimens were prospectively enrolled, all of which underwent Promega MSI assay testing. Samples with fewer than 100 tiles or unclear diagnoses were excluded, leaving 636 samples for analysis. Among these, 490 surgical specimens (24 MSI-H and 466 MSI-L or MSS) and 146 biopsy specimens (11 MSI-H and 135 MSI-L or MSS) were included. The Promega MSI assay served as the gold standard, and performance metrics including sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy were evaluated for Deepath-MSI.
Results: In the 490 surgical specimens, the overall AUROC was 0.982, with an accuracy of 91.84% (450/490). Using a 0.4 threshold, Deepath-MSI showed sensitivity of 95.83% (23/24), specificity of 91.63% (427/466), PPV of 37.1% (23/62), and NPV of 99.77% (427/428). In the 146 biopsy specimens, the overall AUROC was 0.924, with an accuracy of 88.36% (129/146). Using a 0.2 threshold, sensitivity was 81.82% (9/11), specificity was 88.89% (120/135), PPV was 37.5% (9/24), and NPV was 98.36% (120/122). Overall, Deepath-MSI reduced the need for traditional PCR testing by 87% in surgical specimens and 82% in biopsy samples.
Conclusion: Deepath-MSI provides a highly accurate and efficient alternative to traditional MSI detection methods in CRC. It significantly reduces reliance on costly and time-consuming PCR-based assays, making MSI detection more accessible and less resource-intensive. The integration of Deepath-MSI into clinical practice has the potential to streamline diagnostic workflows and improve patient care.

CP-02 Sustainability & interoperability

CP-02-003
Commercial artificial intelligence solutions in histopathology: a 2025 market landscape from a european perspective
K. Faryna[1], K. van Leeuwen[2], M. Horton[2], L. Tessier[1], F. Meeuwsen[1], J. van der Laak[1], S.-F. Kammerer-Jacquet[3], G. Litjens[1]
[1]RadboudUMC, Nijmegen, The Netherlands, [2]Romion Health, Utrecht, The Netherlands, [3]The Rennes University Hospital, Rennes, France

Background & Objectives: Artificial intelligence (AI) is increasingly becoming a component of digital pathology workflows. Amidst the transition to the In Vitro Diagnostic Regulation (IVDR) across Europe, there is increasing interest in understanding the current landscape of regulatory-cleared AI-based tools in histopathology. This study aims to provide a comprehensive overview of CE-marked and FDA-cleared AI software for diagnostic histopathology, focusing on clinical applications, regulatory trends, and market dynamics relevant to the European setting.
Methods: A structured review was conducted across regulatory databases (FDA, EUDAMED), vendor documentation, press releases, and curated AI repositories. Inclusion criteria encompassed AI tools approved for diagnostic use on whole-slide images (WSIs) in histopathology or cytopathology, bearing CE marking (under IVDD or IVDR) and/or FDA clearance. Key data points included pathology subdomain, stain type, subspecialty, use case, regulatory status, approval

specifications (e.g., scanner regulatory applicability), and integration capabilities.
Results: As of March 2025, 60 CE-marked AI tools were identified from 23 vendors (14 headquartered in Europe). Of the 60 tools, 87% are still operating under the legacy IVDD framework, and 13% of tools are certified under IVDR (i.e., Class C). To date, only three solutions have received FDA clearance. The most common clinical applications include prostate cancer detection, quantification, and grading (n=12), biomarker quantification in breast cancer (ER, PR, HER2, Ki-67) (n=16), and lymph node metastasis detection (n=5). Most tools analyse WSIs from H&E- (n=30) or IHC-stained (n=27) slides. Public resources widely lack detailed information regarding regulatory approval conditions, intended use, system integration, and evidence-substantiated claims of clinical-grade AI-based algorithms in pathology, therefore, the complete dataset will be made available at https://pathology.healthairegister.com.
Conclusion: CE-marked AI solutions in pathology are expanding across various subspecialties, primarily addressing high-throughput diagnostic tasks. For safe clinical adoption and to support purchase decision-making, ongoing efforts towards AI-based pathology market transparency are critical.

CP-02-004
Building a database of tumour immunohistochemical profiles from PubMed abstracts using large language models
Y. Kim[1], M.W.S. Ong[2], D.W. Rogalsky[3], M. Rodriguez-Justo[2,4], H. Wu[1,5], A.P. Levine[2,4]
[1]University College London, Institute of Health Informatics, London, United Kingdom, [2]University College London, Research Department of Pathology, London, United Kingdom, [3]Hadassah-Hebrew University Medical Centre, Department of Pathology, Jerusalem, Israel, [4]University College London Hospitals NHS Foundation Trust, Department of Cellular Pathology, London, United Kingdom, [5]University of Glasgow, School of Health & Wellbeing, Glasgow, United Kingdom

Background & Objectives: Immunohistochemistry (IHC) is essential in diagnostic pathology for tumour classification, prognostication, and treatment decisions. Whilst many IHC markers are well established, others lack consistent evidence with IHC-tumour data often fragmented, outdated, or restricted by subscription. To address this, we leveraged large language models (LLMs) to extract structured IHC-tumour profiles from PubMed abstracts at scale. Our objective was to develop an automated pipeline for building a comprehensive IHC-tumour database.
Methods: A two-stage LLM-based pipeline was developed. First, PubMed abstracts were classified for relevance using a fine-tuned LLM (Gemma2) trained on 1,000 examples. Second, IHC-tumour profiles (tumour type/site, marker name, positive counts) were extracted in structured format using a prompt-based method trained on 462 examples. Marker and tumour names were normalised to Unified Medical Language System (UMLS) concepts to ensure consistency using a SapBERT model. Extracted data were compared against ground truth and reference data (PathologyOutlines) to assess concordance and added value.
Results: Abstract classification was achieved with 91.5% accuracy. From 107,759 abstracts identified for 50 common IHC markers, 30,481 were classified by the model as relevant. IHC-tumour profiles were extracted with a correct output rate of 63.3% (n=98). Across all markers, the total cohort size was over 5 million with an average of 854 per marker. Examining 50 IHC-tumour profiles, 10 lacked reference data, 18 only had qualitative data and 22 had quantitative data all but one within 5% of the calculated. For example, TTF1 showed 79% positivity (3410/4315) in lung adenocarcinoma, within the reference range (65–93%).
Conclusion: This study demonstrates the potential of LLMs to systematically extract and structure IHC-tumour data from biomedical literature. With further refinement, this pipeline will enable the creation of a scalable, prospectively updated open-access granular IHC-tumour database to support diagnostic accuracy, efficiency and research in pathology.

CP-02-005
Artificial intelligence program to engage a broad segment of an academic pathology department
T. Flotte[1], K. Reed[1], S. Derauf[1], D. Bell[1], M. Zarella[1]
[1]Mayo Clinic, Laboratory Medicine and Pathology, Rochester, USA

Background & Objectives: Artificial intelligence (AI) is transforming anatomic pathology. Currently, only limited algorithms are available for clinical application. The algorithm development effort is predominantly in industry. However, pathologists have the domain expertise in pathology with knowledge of the problems that will benefit from AI. The objective of this program is to engage a broad segment of an academic pathology community in AI algorithm development.
Methods: The program is in its sixth year. The platform was developed over the first two years. The platform requirements included an intuitive user interface, diverse algorithmic modelling options, seamless mechanism for discovery to clinical deployment transition, and scalable over time. A vended product was selected. To engage pathologists without prior AI experience, a support system was created that included lectures, open office hours, one-on-one tutorials, short videos for specific topics, ticketing system for questions/problems, data science and project management guidance.
Results: In the first two years of algorithm development (years 3 and 4 of the program), there was an emphasis on project management with at least monthly meetings with a project manager to help resolve problems and allow the investigators to meet their milestones. The first two cohorts included 114 unique users working on 57 projects. Nearly all of the projects progressed to algorithm development and approximately 50% resulted in USCAP abstracts. For the next two years, the same resources are available, but the intense project management was no longer needed. The program continues to have an average of 89 unique users/year working on 25 projects of which twelve are new projects.
Conclusion: Engagement of the pathology community in algorithm development has benefited the pathology staff and trainees with enhanced understanding of AI, interest in developing algorithms, collaborating with vendors, as well as extending their efforts to other AI methods such as foundation models.

CP-02-006
Optimization of large-scale digital scanning operations at a tertiary cancer centre
O. Ardon[1], A. Manzo[1], P. Ntiamoah[1], I. Ahmed[1], E. Stamelos[1], M. Hanna[1], V. Reuter[1], M. Hameed[1]
[1]Memorial Sloan Kettering Cancer Centre, New York, USA

Background & Objectives: Memorial Sloan Kettering Cancer Centre in New York is an early adopter of digital pathology. After 17 years of increased digital scanning growth in several hospital locations, the clinical digital pathology operations were consolidated to one central, dedicated, newly built laboratory adjacent to the histology laboratory. The design and build of the new laboratory infrastructure was completed in December 2023, with full clinical operations that started in

January 2024. The resulting quality and productivity gains of the 2024 operations were studied and analysed.
Methods: The planning process for the infrastructure needs was summarized from planning records. The operational data that was collected in the 2024 scanning of >1.4 million slides was compared to the 2023 records. Scan data, turnaround times, rescan rates, instrument failures and downtime data were analysed based on observational and scan team dashboard data. Staffing data were obtained from departmental records.
Results: An increase in digital scanning productivity and a decrease in turnaround times was observed for the 2024 year in comparison to the 2023 operation. This also included a decrease in instrument failures and rescan needs. There were changes in our 24 hours/day staffing needs and training needs not just for the digital scan team but also for the histology laboratory, pathologists, office assistants, slide file room clerks and administration. New digital workflows allowed the digital scanning operation to reach the milestone of prospectively scanning all the departmental in-house cases by the end of 2024. Lessons learned from the new laboratory transformation will be shared in this presentation.
Conclusion: A centralized dedicated digital pathology laboratory adjacent to the histology laboratory allowed the quality expansion of the clinical digital scanning at our institution. This improved lean digital pathology operation is a step towards sustainable digital pathology workflows in a high volume, large pathology department.

CP-02-007
Deep learning for lymph node metastases detection: toward a unified and accurate pan-cancer diagnostic model
R. Bourgade[1], C. Lépine[1], M. Denis Musquer[1], A. Nebout[1], C. Sagan[1], C. Toquet[1], D. Loussouarn[1]
[1]University Hospital of Nantes, Department of Pathology, Nantes, France

Background & Objectives: Lymph node metastasis is a key prognostic factor in many malignancies and can be particularly challenging, especially in micrometastases. While they have been extensively explored in specific cancers (e.g., breast or gastric), fewer studies have addressed this issue in a comprehensive pan-cancer context. By leveraging state-of-the-art deep learning methodology, this study introduces a unified framework for detecting and classifying both macroscopic and micrometastatic lymph node involvement across various tumour types.
Methods: A total of 1,030 lymph node whole-slide images were retrospectively collected from patients diagnosed with skin, head and neck, colon, lung, kidney, pancreas, breast, endometrial, and prostate cancers. This in-house dataset was organized into four classes: normal (n=570), melanoma (n=243), squamous cell carcinoma (n=114), and adenocarcinoma (n=103). Each whole-slide image underwent processing with the Trident toolbox and feature extraction using UNIv2. An attention-based multiple-instance learning framework was then employed for the final classification.
Results: Across all tumour types, the proposed model achieved an AUC of 0.976 and a balanced accuracy (BAC) of 0.928. When considering all metastatic lesions as a single class, performance improved to an AUC of 0.984 and a BAC of 0.967. Subgroup analyses demonstrated robust detection of micrometastases, highlighting the model's ability to identify even small or early-stage lesions.
Conclusion: These preliminary findings suggest that this AI-driven approach can reliably detect both macroscopic and micrometastatic spread across multiple cancer types. Future work will focus on external validation to confirm its clinical utility and applicability for large-scale screening. Additionally, evaluating the algorithm's performance in more complex clinical cases and refining the integration process into standard diagnostic workflows will be crucial for maximizing its real-world impact.

Clinicopathological features of breast carcinoma with Ultra-Low Risk MammaPrint® result: a comparative analysis with low-risk cases
C. Ariño-Palao[1,2], I. Carretero-Barrio[3,2,4], R. Meléndez-Gispert[5], N. Cadavid-Fernández[3], A. Tenelanda-Santillán[3], S. Molés-Caparrós[3], A. Veliz-Dominguez[3], J. Palacios[3,2,4], B. Pérez-Mies[3,2,4]
[1]Severo Ochoa University Hospital, Pathology, Madrid, Spain, [2]Alcalá University, Madrid, Spain, [3]Ramón y Cajal University Hospital, Pathology, Madrid, Spain, [4]Centre for Biomedical Research in Cancer Networks, Madrid, Spain, [5]Infanta Leonor Hospital, Pathology, Madrid, Spain

Background & Objectives: MammaPrint® is a 70-gene expression signature that stratifies early-stage breast carcinoma into Low-Risk (LR) and High-Risk groups, supporting personalized treatment decisions. Within the LR, it further identifies an Ultra-Low Risk (U-LR) subset with an exceptionally low probability of distant metastasis. Patients in this group may safely forgo adjuvant chemotherapy and potentially reduce endocrine therapy without compromising long-term outcomes. While the clinical implications of U-LR are gaining recognition, its associated histopathological characteristics remain underexplored.
Methods: We retrospectively analysed patients diagnosed with early-stage luminal breast cancer between 2012 to 2023 who had an available MammaPrint® result. Patients classified as LR and U-LR were selected. Clinicopathological variables—including histological type and grade, tumour size, lymph node status, lymphovascular and perineural invasion, tumour-infiltrating lymphocytes (TILs), progesterone receptor expression (Allred score), Ki-67 index, and recurrence were collected. Statistical analysis was performed using Chi-square/Fisher's exact test or Student's t-test, as appropriate.
Results: Among 470 patients in the MammaPrint® cohort, 215 (46%) were classified as LR and 53 (11%) as U-LR, separately. Significant differences were observed: no U-LR tumours were grade 3 ($p = 0{,}042$), and U-LR tumours showed lower nuclear grade ($p = 0.012$). U-LR tumours were also smaller (1.5 vs 1.7cm, $p = 0{,}022$) and had a lower Ki-67 index (8% vs 13%, $p < 0{,}001$). No other histopathological differences were found. Although not significant, there were no U-LR recurrences, compared to 12 in LR ($p = 0{,}080$).
Conclusion: Our findings offer valuable insight into the histopathological profile of U-LR tumours identified by MammaPrint®. These tumours are characterized by favourable features, including lower grade, smaller size, and reduced proliferation (Ki-67 index). The absence of recurrences in the U-LR group supports its potential role in identifying patients who may safely reduce endocrine treatment while maintaining excellent outcomes. Further studies on long-term follow-up are necessary.

PS-01-002
Clinicopathologic characteristics and tumour-infiltrating lymphocyte patterns in HER2-low vs. HER2-0 triple-negative breast cancer
A. Syrnioti[1], G. Kalliopitsas[1], V. Papadopoulos[2], E. Timotheadou[3], T. Koletsa[1]
[1]Department of Pathology, School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece, [2]First Department of Surgery, Papageorgiou University General Hospital, School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece, [3]Department of

Medical Oncology, Papageorgiou University General Hospital, School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background & Objectives: Triple-negative breast cancer (TNBC) comprises a heterogeneous group of tumours with distinct clinicopathologic, and molecular characteristics. HER2-low, a subset of TNBC, is gaining therapeutic relevance. This study evaluates differences in clinicopathologic features and immune microenvironment between HER2-low and HER2-0 TNBC.
Methods: A retrospective analysis was conducted on surgically resected specimens from 60 newly diagnosed, treatment-naive TNBC patients. HER2 status was determined by immunohistochemistry (IHC), with interobserver agreement among three independent reviewers evaluated using Fleiss' Kappa ($p<0.05$). Clinicopathologic features, along with tumour-infiltrating lymphocytes (TILs), distribution patterns (fully-inflamed, immune-desert, stroma-restricted, margin-restricted), and heterogeneity (>10% variation across tumour areas) were compared between HER2-low and HER2-0 TNBC.
Results: HER2-low TNBC comprised 63% (38/60) of cases. Median age was 63 (IQR: 42–75) for HER2-low and 62 years (IQR: 48–76) for HER2-0. No significant differences were observed in tumour size, grade, lymph node status, or TILs density (all p-values >0.05). TILs distribution patterns were similar across both groups, with immune-desert being the most common phenotype, although these patterns were not properly applicable in all cases. TILs heterogeneity was more frequent in HER2-0 TNBC (45% vs. 27%, p=0.2). Tertiary lymphoid structures were rare (2/60). Invasive breast carcinoma of no special type (IBC, NST) was more common in HER2-low (82% vs. 59%), while metaplastic (23% vs. 2.6%) and medullary (14% vs. 2.6%) carcinomas were more frequent in HER2-0 cases. Substantial HER2 evaluation interobserver agreement (0.707) was noted, with 8.6% clinical critical disagreement rate.
Conclusion: Our findings suggest that HER2-low and HER2-0 TNBC exhibit comparable clinicopathologic features, except for a higher prevalence of IBC, NST, in HER2-low cases, while medullary and metaplastic carcinomas were primarily HER2-0. TILs density and distribution patterns were similar, with greater TILs heterogeneity in HER2-0 TNBC. Disagreements among expert pathologists with similar training background underscore the need for enhanced standardization and ongoing training for HER2-low expression.

PS-01-003

Extracellular matrix remodelling in breast cancer: the role of BMP-1, LTBP-1, and Fibulin-4 in tumour invasiveness and liver metastases

A. Boduroglu[1], G.Ö. Elpek[2], G. Erdogan[3], N. Erin[4]
[1]Dokuz Eylül University, Departmen of Pathology, Izmir, Turkey, [2]Akdeniz University, Department of Pathology, Antalya, Turkey, [3]Akdeniz University, Departmen of Pathology, Antalya, Turkey, [4]Akdeniz University, Departmen of Medical Pharmacology, Antalya, Turkey

Background & Objectives: Breast cancer is one of the most common malignancies in women, with a high propensity for liver metastasis. This study evaluates BMP-1, LTBP-1, and Fibulin-4 expression across breast cancer subtypes and liver metastases to clarify their roles in tumour invasion and metastasis. As regulators of extracellular matrix (ECM) remodelling and latent TGF-β activation, these proteins may contribute to tumour–stroma interactions and metastatic progression.
Methods: Immunohistochemical staining for BMP-1, LTBP-1, and Fibulin-4 was performed on 69 samples, including 8 intraductal carcinomas, 24 invasive ductal carcinomas, 22 invasive lobular carcinomas, and 15 breast cancer liver metastases. Staining extent and intensity were each scored from 0 to 3, and their product was used to calculate a final immunohistochemistry (IHC) score. Marker expression levels were compared among tumour groups to evaluate their role in invasion and metastasis.
Results: BMP-1 tumour cell expression was elevated in liver metastases compared to invasive ductal carcinomas ($p = 0.020$). Fibulin-4 and LTBP-1 expression in tumour cells was significantly higher in intraductal carcinomas than in invasive ductal carcinomas ($p = 0.00004$ and $p = 0.0147$, respectively). Fibulin-4 peritumoral stromal expression was markedly higher in metastases than in all primary tumours ($p < 0.001$). LTBP-1 expression was also increased in metastatic tumour cells and intratumoral stroma compared to invasive ductal and lobular carcinomas ($p < 0.01$, and $p < 0.01$, respectively).
Conclusion: The elevated expression of Fibulin-4 and LTBP-1 in tumour cells of intraductal carcinomas compared to invasive ductal carcinomas suggests their potential role in maintaining the non-invasive phenotype, possibly linked to intracellular ECM accumulation before stromal release in early tumour progression. In contrast, increased Fibulin-4 and LTBP-1 stromal expression along with the upregulation of BMP-1 in metastatic tumour cells in liver metastases supports their involvement in TGF-β–mediated ECM remodelling and tumour–stroma interaction that facilitates invasion and distant spread.

PS-01-004

Comparison of clinicopathological characteristics between HER2-ultralow and HER2-null in triple-negative breast cancer

T. Tran Trung[1,2], A. Duong Thi Ngoc[2], T. Nguyen Van[2], H. Bui Thi My[1,2], T. Ta Van[1,2]
[1]Hanoi Medical University, Hanoi, Vietnam, [2]Vietnam National Cancer Hospital, Pathology and Molecular Biology Centre, Hanoi, Vietnam

Background & Objectives: Triple-negative breast cancer (TNBC) is a breast carcinoma subtype that has been shown to have poorer outcomes, mainly owing to the limited treatment options available. In the current context, low human epidermal growth factor receptor 2 (HER2) expression is of interest as a useful biomarker for the treatment of breast cancer with new anti-HER2 drugs. Beyond the evaluation of HER2-low, the inclusion of HER2-ultralow in the DESTINY-Breast 06 trial has further complicated HER2 detection and classification. This study aims to analyse potential clinicopathological differences between the HER2-ultralow and HER2-null groups in TNBC.
Methods: A cross-sectional descriptive study was conducted on a cohort of 146 TNBC patients with HER2-0 (IHC score 0 according to ASCO/CAP 2018 guidelines) diagnosed at our hospital between October 2021 and February 2024. Immunohistochemical expression was assessed using the anti-HER2 antibody (clone 4B5, Ventana). HER2 status was further classified into HER2-null (no staining) and HER2-ultralow (incomplete and faint/barely perceptible staining in ≤10% of tumour cells). Clinicopathological features were compared between the HER2-ultralow and HER2-null groups.
Results: Of 146 TNBC patients with HER2-0, the mean age was 53.6 years (range: 29-90 years). The histologic types in this study were invasive carcinoma no special type (NST) 89.7%; metaplastic carcinoma 8.2%; other special types 2.1%. Histological grade 3 accounts for the highest proportion (83.6%). There were 94 (64.4%) HER2-null patients, 52 (35.6%) HER2 ultra-low patients. There were no significant differences in age, histologic type, grade, lymphovascular invasion, and stromal tumour infiltrating lymphocyte (sTIL) between HER2-ultralow and HER2-null patients. Additionally, no significant differences were found in Ki67 index, AR expression, CK5/6 expression, or EGFR expression (all p> 0.05).
Conclusion: Approximately one-third of TNBC cases with HER2-0 in this study were classified as HER2-ultralow. No significant

clinicopathological differences were observed between HER2-ultralow and HER2-null patients.

PS-01-005

Decision making in breast pathology reporting: the effect of clinical relevant thresholds

Z.E. Kain[1], C.H. van Deurzen[1]
[1]Erasmus MC, Pathology, Rotterdam, The Netherlands

Background & Objectives: In breast cancer (BC) pathology reports, small differences around cut-off values can impact staging and consequently, clinical decision making. Several pathology variables are not very exact, leaving room for interepretation by the pathologist. Therefore, the aim of this study was to investigate pathologists' decision-making around clinically relevant cut-off values.
Methods: We performed a retrospective, nationwide analysis of primary invasive BC specimens in the Netherlands using real-world data from the National Pathology Registry. Data collection included tumour diameter and ER/PR status from patients diagnosed between 2014 and 2022.
Results: Overall, 64.099 BCs were analysed for tumour diameter. For larger tumours (>2 cm), rounding was observed to the nearest half- or whole centimeter. For smaller tumours, rounding occurred only to half-centimeters, while there was an avoidance of the 1.0 cm and 2.0 cm threshold. For ER/PR assessment, 74.502 BCs were analysed. In cases with low ER expression, rounding was observed at multiples of 5. However, around the clinically relevant cut-off value of 10% in the Netherlands, pathologists tend to semiquantify the percentage of ER and/or PR expression, by also using 9% and 11%, with a trend to classify a case as just positive (10% or 11%).
Conclusion: Pathologists take clinical cut-off values into account in their decision making process. For tumour size, they tend to avoid the 1.0 cm and 2.0 cm thresholds. For ER/PR, they tend to categorize the tumour as positive around the threshold. Futher research is needed to determine the implication of this for treatment decisions.

PS-01-006

The landscape of HER2-low breast cancer: a retrospective study

I.-A. Petraru[1,2], D. Anderco[2], C.D. Lăzureanu[1,2], A.M. Mureșan[1,2], C.S. Suciu[3,2], A. Dema[1,2]
[1]ANAPATMOL Research Centre, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania, [2]Department of Pathology, Pius Brinzeu County Clinical Emergency Hospital, Timisoara, Romania, [3]Angiogenesis Research Centre, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania

Background & Objectives: HER2-low breast cancer, defined as IHC 1+ or 2+ with an ISH-negative result, represents a newly recognized category of breast tumours. Precise classification of HER2-low tumours is crucial for both prognosis and treatment decisions. Emerging antibody-drug conjugates provide promising therapeutic options for this patient subgroup.
Methods: From the database of the Emergency County Hospital of Timișoara, all cases of breast cancer evaluated by immunohistochemistry (IHC) for ER, PR, HER2, and Ki67, were identified. Among these, cases of HER2 1+ and HER2 2+ ISH-negative (non-amplified) tumours were selected, for which the following information was collected: patient age, the presence or absence of neoadjuvant treatment, type of specimen (core-needle biopsy, partial or radical mastectomy), histologic tumour type, hormonal receptor status (ER and PR), and Ki67 proliferation index.
Results: A total of 348 cases were collected, comprising 263 surgical resections and 85 biopsies. HER2-low tumours accounted for approximately 35.63% of all cases, with similar distributions in both specimen types. Most HER2-low tumours were diagnosed in patients over 50 years old, particularly in the 61–70 age group. Among 50 cases with a HER2 2+ score, FISH analysis revealed HER2 gene amplification in 7 cases, no amplification in 39 cases, and no available data in 4 cases, resulting in a 22% HER2 amplification rate. Within the HER2-low group, 41.41% were classified as Luminal A, 62.99% as Luminal B (HER2-negative), and 12.60% as triple-negative. Of the HER2-low cases from surgical specimens, 65.45% of patients received neoadjuvant therapy.
Conclusion: HER2-low cancers accounted for just over one-third of all breast carcinomas, a lower prevalence than that reported in the literature, predominantly affecting patients over 50 years old. Most tumours were Luminal A or B, with a minority classified as triple-negative.The prevalence of HER2-low cases in the group of tumours treated with neoadjuvant therapy was 65.45%.

SUPERB – AI SUPported Evaluation of immunotherapy Response in early triple negative Breast cancer

R. Erber[1,2], A. Kochanke[3], D. Calvopina[3], M. Päpper[3], A. Youssef[2], A. Hamzeh[2], C. Eck[2], P. Wagner[2], A. Hartmann[2], C. Kolberg-Liedtke[4], H.-C. Kolberg[5], P. Räth[6], M. Evert[1], M. Braun[7], P.A. Fasching[8], E.-M. Grischke[9], A. Hartkopf[9], T. Lang[3], T. Köhler[3]
[1]University Regensburg, Institute of Pathology, Regensburg, Germany, [2]University Hospital Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg, CCC Erlangen-EMN, Institute of Pathology, Erlangen, Germany, [3]Mindpeak GmbH, Hamburg, Germany, [4]Bochum University of Applied Sciences, Gesundheitscampus, Bochum, Germany, [5]Marienhospital Bottrop, Department of Obstetrics and Gynaecology, Bottrop, Germany, [6]palleos healthcare GmbH, Wiesbaden, Germany, [7]Rotkreuzklinikum München gGmbH, Frauenklinik, München, Germany, [8]University Hospital Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg, CCC Erlangen-EMN, Department of Gynaecology and Obstetrics, Erlangen, Germany, [9]Universitätsklinikum Tübingen, Department für Frauengesundheit, Tübingen, Germany

Background & Objectives: Triple-negative breast cancer (TNBC) is an aggressive subtype of breast cancer, where immunotherapies are gaining increasing importance. Despite promising results, not all patients respond to these treatments. The collaborative project SUPERB aims to develop an AI-supported predictive biomarker that accurately forecasts the response to immunotherapy based on (sub-) visual and spatial tissue features. This will enable optimized patient stratification for personalized therapy and improve treatment efficiency.
Methods: We utilized a unique dataset of 328 digitized breast cancer core biopsy slides from the clinical neoMono trial, which investigated an innovative immunotherapy approach for TNBC patients. We developed deep-learning algorithms to analyse histopathological images and to identify predictive tissue and cell patterns. These patterns were then combined to develop the novel "AI Therapy Predictor," which can detect specific cell types, the tumour-associated immune microenvironment, and sub-visual tissue properties before therapy. The AI Therapy Predictor is then, based on these image-based biomarkers, aimed to predict neoadjuvant treatment response (i.e. pathological complete response yes/no).
Results: We completed 292,104 expert-level manual annotations for granular tissue structures and cells on 221 images for multiple tissue classes, including invasive carcinoma, in-situ and immune tissue. These were used in combination with other broader data to build deep learning algorithms for image-based biomarker detection for TNBC patients. On a holdout dataset, the accuracy for the fine-grained delineation of invasive carcinoma tissue structures within tissue images was 93.2% (specificity 99.9%, sensitivity 86.5%). Correlation of the AI Therapy Predictor with treatment response is ongoing.
Conclusion: It is expected that the AI Therapy Predictor will achieve high-precision predictions of therapy response, contributing to

improved care for TNBC patients and advancing the development of AI-assisted diagnostics in oncology.

PS-01-010

The relationship between PIK3CA mutation and tumour immune microenvironment in hormone receptor positive (HR+)/HER2 negative breast cancer and their prognostic value

E. Babarovic[1,2], F.J. Linhart[1], D. Lopac[3], M. Pfeiler[1], J. Hagen[1], P. Madžar[2], D. Fučkar Čupić[1,2], M. Avirović[1,2], I. Hadžisejdić[2,1]
[1]Faculty of Medicine, University of Rijeka, Department of General Pathology and Pathological Anatomy, Rijeka, Croatia, [2]Clinical Hospital Centre Rijeka, Clinical Department of Pathology and Cytology, Rijeka, Croatia, [3]Clinic for Orthopedic Surgery, Lovran, Croatia

Background & Objectives: The prognostic value of tumour-infiltrating lymphocytes (TILs) in HR+/HER2-breast cancer (BC) remains unclear. Studies have shown that genetic alterations in cancer cells can influence the tumour immune microenvironment (TME). PIK3CA gene mutations are the most common genetic alterations in HR+/HER2- BC with unknown impact on the composition of the TME.
Methods: To address this question, we enrolled 123 patients with HR+/HER2- BC with long term follow-up available. Surgical specimens were reviewed for evaluation of TILs in intratumoral (iTIL) and stromal compartments (sTIL) and for presence of stromal plasma cells (PCs). FOXP3+ cells in tumoral and stromal compartments were evaluated by immunohistochemistry on tissue microarrays. Real-time PCR was used for detection of hotspot mutations of the PIK3CA gene.
Results: BCs were luminal A (N=65) or luminal B (N=58). Genotyping PIK3CA was successful in 112 samples, and patients were divided into three groups: wild-type (N=59), exon 9 (N=20) and exon 20 mutation (N=33). Analyzed components of TME did not differ significantly between groups of patients regarding PIK3CA mutational status. Higher iFOXP3+ and sFOXP3+ were associated with lower clinical stage (P=0.039 and P=0.012) and negative nodal status (P=0.029 and P=0.047). Negative PCs were associated with luminal B phenotype (P=0.007), higher recurrence (P=0.019) and metastatic disease at diagnosis (P=0.033). Overall survival was significantly longer for patients with iTIL (P=0.039), higher iFOXP3 and sFOXP3 (P=0.021 and P=0.009) and with positive PCs (p=0.004). Disease-free survival (DFS) was significantly longer for patients with PIK3CA mutation (p=0.041), higher sTIL (p=0.019) and positive PCs (p=0.041). In multivariate analyses PCs showed prognostic value with regard to better overall (HR=0.30; 95%CI 0.11-0.81; P=0.002) and DFS (HR=0.38, 95%CI 0.19-0.78; P=0.008).
Conclusion: Our study demonstrated that FOXP3 and PCs infiltrates were associated with important clinicopathological variables and better prognosis, and also that immune TME of HR+/HER2- BCs don't differ regarding the PIK3CA mutational status.

PS-01-011

Analysis of serum immune profiles in breast carcinoma: association with clinicopathological factors and survival in a retrospective cohort

Y.G. Montoyo-Pujol[1], P. Martínez-Peinado[2], S. Pascual-García[2], A.B. López-Jaén[2], J. Ponce[1], I. Lozano[1], E. Castellón-Molla[3], S. Delgado[4], T. Martin-Bayón[4], H. Ballester[4], A. Ramos[4], J.M. Sempere-Ortells[2], G. Peiró[3]
[1]Dr Balmis University General Hospital and Alicante Institute for Health and Biomedical Research (ISABIAL), Medical Oncology Department, Alicanrte, Spain, [2]University of Alicante, Biotechnology Department, Immunology Division, Alicanrte, Spain, [3]Dr Balmis University General Hospital and Alicante Institute for Health and Biomedical Research (ISABIAL), Pathology Department, Alicanrte, Spain, [4]Dr Balmis University General Hospital and Alicante Institute for Health and Biomedical Research (ISABIAL), Gynaecology and Obstetrics Department, Alicanrte, Spain

Background & Objectives: Recent research has highlighted the crucial role of inflammation in breast cancer (BC). Consequently, recent efforts have focused on identifying biomarkers through liquid biopsies. Cytokines, chemokines, growth factors, and immune checkpoints are among the most relevant, but their serum patterns remain unclear. We aim to analyse different serum factors among BC subtypes and evaluate their association with clinicopathological features and survival.
Methods: We included a retrospective cohort of 229 invasive BC patients and 50 healthy donors. A total of 10 serum factors were measured using LEGENDplex™ panels by flow cytometry. The results were correlated with clinicopathological factors and patient survival. Statistical analysis was performed using the SPSS v.23.
Results: BC patients exhibited higher MIP-3α, IFN-γ, M-CSF, IL-9, and IL-10 and lower IL-2RA, B7.2, IL-27, IL-1β, and PD-1 (all p≤0.047). Younger patients had increased IL-9, IL-10, IFN-γ, M-CSF, and reduced IL-2RA and B7.2 (p≤0.043). IL-9 and IFN-γ were elevated in grade I (p≤0.046) and, alongside IL-10, M-CSF, B7.2, IL-27, and IL-1β, in low-proliferative tumours (p≤0.05). M-CSF correlated with lymphnode involvement and low sTILs (p≤0.029). MIP-3α and IL-27 were elevated in highly proliferative and smaller tumours (p≤0.043) respectively. Furthermore, IL-9, IFN-γ, and M-CSF were predominant in luminal tumours, while MIP-3α was higher in non-luminal subtypes (p≤0.049). Notably, elevated IL-2RA and B7.2 levels correlated with shorter overall survival -OS- (p≤0.009), while high PD-1 was linked to poor disease-free survival -DFS- (p=0.008). However, only IL-2RA and PD-1 (p≤0.013) emerged as independent factors for worse OS and DFS, respectively.
Conclusion: Our results showed that BC patients had specific serum profiles. IL-9, IL-10, IL27, and IFN-γ correlated with favourable clinicopathological features, while M-CSF and MIP-3α with aggressiveness. Moreover, IL-2RA and PD-1 emerged as independent factors for a worse prognosis.

PS-01-012

p53 status and its impact on the response to perioperative hormonal therapy in luminal breast cancer

Y.G. Montoyo-Pujol[1], L. Martínez-Gauffin[2], S. Delgado-García[3], H. Ballester[3], T.A. Martin-Bayón[3], J. Ponce-Lorenzo[1], E. Castellón-Molla[2], G. Peiró[2]
[1]Dr Balmis University General Hospital and Alicante Institute for Health and Biomedical Research (ISABIAL), Medical Oncology, Alicante, Spain, [2]Dr Balmis University General Hospital and Alicante Institute for Health and Biomedical Research (ISABIAL), Pathology, Alicante, Spain, [3]Dr Balmis University General Hospital and Alicante Institute for Health and Biomedical Research (ISABIAL), Gynaecology and Obstetrics, Alicante, Spain

Background & Objectives: Perioperative hormonal therapy (pHT) is a common strategy in luminal breast cancer (BC). However, 30-40% of patients develop resistance to this therapeutic modality, leading to higher recurrence rates and worse prognosis. Alterations in p53, present

in up to 55% of luminal B tumours, may influence this response, but its role remains unclear. This study examines the relationship between p53 status and changes in oestrogen receptor (ER), progesterone receptor (PR), and Ki67 expression after pHT, aiming to assess its prognostic and therapeutic implications.
Methods: A retrospective study (January 2020 through July 2024) was conducted on 237 luminal A and B BC patients treated with pHT. Immunohistochemical ER, PR, and Ki67 expression were evaluated in core needle biopsies (CNB) and surgical specimens. p53 status was classified as wild-type (p53-wt) (1-75% positive nuclei/3+) or mutated (p53-mut) (0% or >75% positive nuclei/3+). Associations were analysed using χ^2 or Fisher's exact test.
Results: Medium/high expression of ER (98%), PR (62%), and 15% for Ki67 was found in CNB. In the surgical specimen, we observed medium/high expression of ER (92%), PR (26%), and 6% for Ki67. Among p53-wt BC, ER remained highly expressed (94%), PR was predominantly negative (39%), and Ki67 expression was reduced to <15% (69%) after pHT (all p<0.0001). Similarly, in p53-mut BC, ER was maintained (81%) (p=ns), PR was negative in 55%, and the Ki67 index dropped by 64% after treatment. However, no significant differences were found.
Conclusion: In our clinical series, we observed that p53-wt BC showed a significant reduction in the expression of PR and Ki67. However, these changes were not significant in p53-mut BC. Thus, our data suggest that p53-positive status could predict poor response to pHT and is postulated as a potential predictive biomarker.

PS-01-013
Correlation of HER2 2+ usual and unusual immunohistochemistry staining patterns with FISH results in breast carcinomas
I. Arun[1], P. Mane[1], M. Parihar[2]

[1]Tata Medical Centre, Histopathology, Kolkata, India, [2]Tata Medical Centre, Cytogenetics, Kolkata, India

Background & Objectives: Apart from the usual HER2 2+ immunohistochemistry (IHC) staining patterns defined by ASCO/CAP guidelines, there are patterns that do not exactly fulfil their criteria and the guidelines are silent on whether these would merit inclusion into the HER2 2 + category. The objective of our study is to evaluate the proportion of different HER2 2+ IHC staining patterns and their correlation with FISH results.
Methods: 210 breast carcinoma core biopsies reported as HER2 2+ over a period of 1 year were studied. All cases reported as HER2 2+ were subjected to FISH analysis. HER2 2+ cytoplasmic membrane staining patterns were classified into described usual pattern and unusual staining patterns as all nondescript cases were also included in HER2 2+ category in our institute. Unusual patterns include 1) complete intense in ≤10% cells, 2) incomplete, weak to moderate in >10% cells 3) complete, weak to moderate in 10% cells 3) basolateral or basal 4) cytoplasmic granular staining. The proportion of FISH positivity was compared between the usual and unusual IHC patterns.
Results: HER2 gene amplification was seen in 34/210 (16%) cases of which 18/34 (53%) cases showed usual (complete moderate >10%) pattern and 16/34 (47%) cases showed unusual patterns (intense complete <10% - n=2 (6%), complete moderate 10% n= 8 (23%), incomplete moderate n= 6 (18%) while cases with cytoplasmic granular or basolateral staining were negative for FISH.
Conclusion: In addition to the described usual HER-2 2+ staining patterns, our study showed 4 unusual patterns. Few cases with incomplete moderate intensity and complete moderate intensity staining in 10% cells which may not be have been subjected to FISH testing if strict guidelines were followed, showed FISH positivity. Our study shows that these rare IHC pattens should be recognized and reflexed to FISH testing to avoid missing HER-2 targeted therapy in possible HER-2 amplified tumours.

PS-01-014
Exploring the transcriptomic landscape of non-metastatic axillary lymph nodes as a prognostic factor in breast cancer
E. Sauras Colón[1], J. Badia-Cabré[2], N. Gallardo-Borràs[1], A. Fischer-Carles[1,3], A. Fiorin[1,4], T. Sánchez-Alcántara[1], J. Casanova-Ribes[1], M.A. Fábrega-Marcos[1], D. Mata-Cano[1], L. Adalid-Llansa[1,5], E. Goyda[1,5], A. Masip-Bonet[5], R. Bosch-Príncep[1], M. Lejeune[1], C. López-Pablo[1]
[1]Oncological Pathology and Bioinformatics Research Group, Hospital Verge de la Cinta, Institut d'Investigació Sanitària Pere Virgili, Universitat Rovira i Virgili, Tortosa, Spain, [2]Southern Catalonia Institute of Oncology, Hospital Universitari Sant Joan de Reus, IISPV-URV-CERCA, Reus, Spain, [3]BCN MedTech, Department of Engineering, Universitat Pompeu Fabra, Barcelona, Spain, [4]Department of Computer Engineering and Mathematics, Universitat Rovira i Virgili, Tarragona, Spain, [5]Department of Pathology, Hospital Joan XXIII, Tarragona, Spain

Background & Objectives: The intratumoral immune response plays an important role in breast cancer (BC) prognosis. However, limited research has explored the potential impact of the immune response within axillary lymph nodes (ALNs). Studies evaluating the immune composition of non-metastatic ALNs (ALNs-) using immunohistochemistry suggest that ALN- immune cellularity may be a prognostic factor for patient survival and relapse. Given the observed differences at the protein level, this study aims to analyse whether transcriptomic differences in ALNs- are also associated with prognosis in BC patients.
Methods: This retrospective cohort study included 18 patients diagnosed with invasive ductal BC between 2006 and 2015. Clinicopathological data were collected, and patients were followed for 10 years from diagnosis. Formalin-fixed paraffin-embedded ALN- samples were selected for RNA extraction and gene expression analysis using Human Clariom S microarrays to identify differentially expressed genes between patient groups. Bioinformatics analysis was conducted using Bioconductor in R.
Results: This study included three patient groups: Relapse (n=6), Exitus (n=6), and Alive (n=6). Bioinformatics analysis identified Butyrophilin Subfamily 3 Member A2 (*BTN3A2*) as the only gene found across all comparisons, specifically in the Relapse vs. Exitus comparison, with a log fold change (logFC) greater than 2 (logFC=2.15). Biological significance analysis revealed that *BTN3A2* is involved in over-represented biological processes related to immune response regulation (normalized enriched score (NES)=1.53) and activation (NES=1.62). However, no differentially expressed genes or biological processes were found using an adjusted p-value threshold of 0.05. Higher *BTN3A2* expression was significantly associated with a lower histological grade (p=0.013) and improved overall (p=0.042) and cancer-specific survival (p=0.017).
Conclusion: *BTN3A2* plays a role in T-cell responses in the adaptive immune response. Therefore, these findings underscore the importance of further investigating the ALN microenvironment, as immune responses within ALNs may also play an important role in BC prognosis.

Long term follow-up of B3 lesions

M.E. Maracci[1], G. Randazzo[2], A. Marcatelli[2], L. Santilli[2], M.C. Cucchi[3], V. Galluzzo[3], A. Baldissera[4], E. D'angelo[4], S. Ciabatti[4], A. Mura[5], A. Maestri[5], A. Tafà[2], M.P. Foschini[1]

[1]Ospedale Bellaria, Department of Biomedical and Neuromotor Sciences, University of Bologna, Unit of Anatomic Pathology, Bologna, Italy, [2]Ospedale Bellaria, Unit of Senology, Bologna, Italy, [3]Ospedale Bellaria, Unit of Breast Surgery, Bologna, Italy, [4]Ospedale Bellaria, Unit of Radiotherapy, Bologna, Italy, [5]Ospedale Bellaria, Unit of Oncology, Bologna, Italy

Background & Objectives: The B3-category encompasses a group of lesions with low potential of malignant transformation. The aim of the present study is to evaluate the evolution of B3-lesions in long term follow-up, comparing cases treated with open surgery and cases that did not undergo surgery.

Methods: A revision of 256 B3 lesions, including flat epithelial atypia (FEA), atypical ductal hyperplasia (ADH) and classical lobular neoplasia (LIN), diagnosed between January 2008 and December 2015, by VAB was performed.

Cases were subdivided as follows: "Open surgery" group (OS, 168 cases in which surgical excision followed the B3 diagnosis) and "VAB only" group (88 cases in which no further surgery was performed).

Results: Open Surgery: 25% (42/168) were upgraded to in situ/invasive carcinoma. The upgrade rate was the highest in ADH (35.71%) and in mixed lesions (23,6%).

VAB only: 9% (8/88) developed in situ/invasive carcinoma during the follow-up period (mean 12.5 years). No further events were recorded in 80/88 cases (91%).

FEA, both pure and mixed, was the most frequently occurring lesion in both groups.

Conclusion: Open Surgery: upgrade rates corresponded to the average upgrade rates reported in literature. However, the scientific literature reports a wide range of upgrade with marked inter-institutional differences, leaving the question of the optimal approach for the treatment of these lesions open for debate.

VAB only: A strict follow-up was shown to be a sufficient measure to avoid disease progression in 91% of cases; the 9% of patients that have presented with disease upgrade are currently alive and in follow-up. The results of this study suggest that open surgery can be avoided in patients with B3 lesions, and that a strict follow-up regime is sufficient in order to maintain control over the disease.

PS-01-017

Agreement analysis between manual and computational scoring of Ki-67 in breast cancer

E. Petcu[1], W.J. Senarathne[2], J. Krausz[3], W. Saliba[3], H. Belhanes Peled[3], N. David[3], Y. Sufrin[2], C. Steele[2], Y. Glickman[2]

[1]New York Institute of Technology, Histology Core Facility, Old Westbury, NY, USA, [2]Applied Spectral Imaging, Carlsbad, USA, [3]Emek Medical Centre, Pathology, Afula, Israel

Background & Objectives: Pathologists traditionally assess Ki-67 through visual estimation, a method prone to variability, especially when the proliferation index is not clearly high or low. This subjectivity increases the likelihood of discrepancies in borderline cases. The gold standard for Ki-67 evaluation remains manual counting of positive and negative tumour cells, expressed as a percentage. However, this approach is time-consuming and impractical for routine clinical use. With advancements in digital pathology and AI-driven algorithms, automated quantification has become a feasible solution.

Methods: Ki-67 specimens stained with clone MIB-1 (Agilent) using the BenchMark Ultra (Roche) were selected from a slide repository to cover a clinically relevant range. Both Ki-67 and corresponding H&E slides were scanned at 20x on GenASIs HiPathPro (Applied Spectral Imaging). Three regions of interest (ROIs) per slide were digitally marked within the tumour area on the H&E images and automatically transferred to the Ki-67 images following tissue matching. Marked regions were scored by the computational algorithm to determine the Ki-67 score. Three pathologists independently assessed the same ROIs and results were statistically compared.

Results: Core biopsies from 23 breast cancer patients (age 53±13) were included, 22 with IDC and one with mucinous carcinoma. A total of 69 ROIs were analysed. The Intraclass Correlation Coefficients (ICC) between pathologist's Ki-67 assessments were 0.899, 0.902 and 0.913, comparable to the ICC between each pathologist and the computational algorithm (0.929, 0.911 and 0.929). When applying a cutoff of 30%, high agreement was observed for all data pairs with a Cohen's Kappa measure higher than 0.85 (0.87, 0.91 and 0.91 between pathologists and 0.87, 0.91 and 1.00 between pathologist and computational score).

Conclusion: Our analysis evaluates the agreement between manual and automated scoring, highlighting the potential of computational algorithm to enhance accuracy and reproducibility in Ki-67 assessment.

PS-01-018

HER2 APP, breast cancer based algorithm for precise scoring of HER2-null, ultra-low, and low expression as an alternative to ASCO/CAP visual scoring: an analysis of 422 cases

X.X. Lim[1], D.F. Sanchez[2,3], T.W. Ramsing[4], A.B. Jensen[4], J. Thagaard[4], A. Cramer[1], P. Oliveira[1]

[1]The Christie NHS Foundation Trust, Manchester, United Kingdom, [2]Cancer Research UK - Manchester Institute, Manchester, United Kingdom, [3]Manchester Cancer Research Centre, Manchesterunited, United Kingdom, [4]Visiopharm A/S, Hoersholm, Denmark

Background & Objectives: ASCO/CAP updated breast HER2 guidance to include HER2-null [HN], HER2-Ultra-Low [HUL], and HER2-Low [HL]. Reporting HUL and HL is challenging because it requires extensive examination of specimens that are time intensive and imprecise. Artificial Intelligence [A.I.] advancements have enabled membrane staining quantification, though real-world use is unclear. This study assesses A.I.-based membrane scoring as a complement or alternative to visual scoring [VS].

Methods: 422 core biopsies of real-world, invasive breast type NOS, HER2 0 (n=225) and HER2 1+ (n=197) cases, were retrieved from 2023-2024. Original slides were anonymised, scanned at x40, and analysed with an advanced version of Visiopharm's HER2-APP, Breast Cancer algorithm [APP]. APP scored cases were stratified with updated ASCO/CAP criteria using APP derived cell membrane positivity (MP) percentages. Cases were reclassified as HN: MP=0%, HUL: MP=1–10%, and HL: MP>10%. VS was not re-evaluated.

Results: APP scores reclassified original cases into HN (n=40; 9.5%), HUL (n=122; 29%), and HL (n=260; 61.5%). From the diagnosed VS HER2 0 group (n=225), 38 (17%) persisted as HN, while the remaining were reclassified as HUL (n=116; 52%), and HL (n=71; 31%). 187 (83%) previously HER2 0 cases were reclassified as positive. In the VS HER2 1+ group,189 (96%) cases were classified as HL, 6 as HUL, and 2 as HN. The majority of HUL cases contained a MP of ≤ 5% (n=80).

Conclusion: APP precisely quantified MP, distinguishing HN, HUL, and HL. Potentially 52% of previously "negative" cases fit the HUL category, greatly increasing Trastuzumab Deruxtecan [T-DXd] eligibility. Most HUL cases had ≤ 5% MP, which is challenging for VS detection.

APP shows a promising approach for identifying these groups according to updated ASCO/CAP guidelines. Precise, unbiased MP scores may also enhance T-DXd dosing for lower toxicity and better patient outcomes. Agreement and process time analysis vs VS are needed to reassure clinical utility.

PS-01-019

Pathological characteristics of male breast cancer: a study of 81 cases in Southern Tunisia

M. Zghal[1], W. Ghribi[1], O. Belhadj[1], S. Graja[1], C. Chaari[1], R. Kallel[1], T. Boudawara[1], S. Makni[1]
[1]Habib Bourguiba University Hospital, Pathology, Sfax, Tunisia

Background & Objectives: Male breast cancer (MBC) is a rare condition representing less than 1% of all male neoplasms. Despite the morphological resemblance to female breast cancer (FBC), MBC has different pathological characteristics. We aimed to investigate the clinico-pathological features of MBC.
Methods: This is a retrospective study of 81 cases of MBC, registered at the department of pathology of the university hospital of Sfax in Tunisia, during a period of 19 years (2006-2024).
Results: The mean age was 68 years (29-90 years). The mean tumour size was 3.4 cm (0.5-13 cm). The tumours were bifocal in 6 cases and bilateral in 2 cases. One patient had gynecomastia. Invasive carcinoma of non-specific type (ICNST) was the most common histological subtype, accounting for 87.6% of cases (n=71). The other tumours were invasive lobular carcinoma (ILC) in 3 cases, ductal carcinoma in situ in 3 cases, encapsulated papillary carcinoma in 2 cases, invasive micropapillary carcinoma in one case and angiosarcoma in another. The most common histological grade was II in 68% of cases. Node involvement was observed in 65% of cases. Paget disease was associated in 7.4% (n=6). Estrogen receptors (ER), progesterone receptors (PR) and Her2 status were positive respectively in 82.8%, 81% and 23.8%. The most frequent molecular subtype was Luminal A in 70.7%, followed by luminal B (22%), Her2 overexpressing (4.8%) and triple negative (2.5%).
Conclusion: Less than 1% of breast cancer patients are male. For MBC, The mean age at diagnosis is around 60 years, 10 years later than in women. ICNST is the predominant histological type. ILC is exceptional. Compared to the FBC, MBC is more hormonosensitive with less frequency of Her2 overexpressing. Triple negative tumours in MBC are rare. MBC seems to be more aggressive than FBC due to its discovery at an advanced stage with larger tumour size and frequent node metastases.

PS-01-020

HER2 scoring agreement for HER2-low and overexpression in breast carcinomas: comparison of HER2 status in breast carcinomas tested by four different HER2 IHC assays scored manually by pathologists and AI

S. Nielsen[1], N.M. Villena Salinas[1], V. Montalvo Calero[2], D. Wang[2], A. Saxena[2], J. LaMar[2], R. Decamillis[2], M. Cossutta[3], F. Soussaline[3], A. Papine[3], M. Korsdal Stensballe[1], S. Huus Pedersen[1]
[1]Aalborg University Hospital, Department of Pathology, Aalborg, Denmark, [2]Sakura Finetek, Torrance, USA, [3]IMSTAR Dx, Paris, France

Background & Objectives: Artificial Intelligence (AI) enhances accuracy, efficiency, and consistency of HER2 IHC scoring. This study compares the interobserver accuracy of four HER2 IHC assays in breast carcinomas (BCs) between AI and pathologist assessments focusing on HER2-low and HER2 classical overexpression.
Methods: 98 human FFPE BCs from two microarrays were analysed by FISH and four different IHC assays: (1) HercepTest SK001, Agilent, (2) HercepTest GE001, Agilent, (3) PATHWAY 4B5, Roche, and (4) HER2 EP3, Sakura Finetek using 2023 ASCO/CAP guidelines. Consensus IHC results were determined by four reviewers serving as ground truth and then compared to AI from IMSTAR Dx.
Results: Initial clinical agreement from the reviewers for the HER2 IHC assays GE001, SK001, 4B5, and EP3 were 92.9%, 92.9%, 88.8%, and 87.8%, respectively, and a final clinical agreement was consolidated as ground truth. Final clinical agreement between reviewers and AI for HER2 IHC assays 4B5, GE001, EP3 and SK001 were 93.9%, 83.7%, 80.6% and 70.4%, respectively. The clinical disagreement usually occurred for HER2-low BCs. The negative predictive agreement (NPA) between reviewers and AI for HER2 IHC assays EP3, 4B5, SK001 and GE001 were 100%, 91.9%, 89.3%, and 73.1% respectively. The positive predictive agreement (PPA) for 4B5, GE001, EP3, SK001 were 97.2%, 95.7%, 73.6%, and 62.9%.
Conclusion: There is a strong NPA for EP3 and a strong PPA for 4B5 when comparing AI to the ground truth. Similarly, interobserver variability in HER2 IHC scoring across the four IHC assays was observed, with greater disagreement for the EP3 assay. The discrepancy between reviewers and AI likely stemmed from the fact that both observers and AI were primarily trained on the 4B5 assay with its specific staining profile rather than all assays. To ensure diagnostic and clinical accuracy, alternative IHC assays should be integrated into training and validation of HER2 IHC scoring algorithms, including AI.

PS-01-022

Diagnostic utility of TRPS1 immunohistochemistry in identifying breast origin: a two-year retrospective analysis

F.G. Salman[1], M. Oktay[1], F. Aktepe[1], S. Balci[1], İ. Türkmen[1]
[1]Memorial Hospitals Group, Pathology, Istanbul, Turkey

Background & Objectives: TRPS1 has been proposed as a potential immunohistochemical marker for determining the breast origin of metastatic tumours. Accurate identification of the primary site is critical for guiding treatment strategies, making TRPS1 a valuable diagnostic tool. In this study, we aimed to share our two-year experience in evaluating the utility of the TRPS1 antibody in identifying breast origin.
Methods: Between 2022 and 2024, cases examined with the TRPS1 antibody were retrospectively reviewed. The expression of TRPS1 was assessed in various primary tumour origins, including breast, lung, gastrointestinal, gynaecological, and other malignancies. Statistical analyses were performed to determine the sensitivity, specificity, and predictive values of TRPS1 for identifying breast origin.
Results: A total of 250 cases were included in the study, of which 95% (n=238) were female and 5% (n=12) were male. The primary tumour site was the breast in 68% (n=171) of cases, while 27% (n=67) had other primary sites and, in 5% (n=12) of cases, the origin of the tumour could not be determined due to poorly differentiated tumours or insufficient tumour tissue. TRPS1 expression was positive in 66% (n=165) of cases and negative in 34% (n=85). Of the TRPS1-positive cases, 96.4% were breast cancer. Interestingly, most TRPS-1 positive non-breast cancers (83.3%, n:5) were gynaecological.
TRPS1 demonstrated a sensitivity of 93% (95% CI: 88.1%-96.3%) and a specificity of 91% (95% CI: 81.5%-96.6%) in detecting breast carcinoma. The positive and negative predictive values were 96.4% (95% CI: 92.3%-98.7%) and 83.6% (95% CI: 73.0%-91.2%), respectively.
Conclusion: TRPS1 immunohistochemistry is a highly sensitive and specific marker for differentiating breast cancer from other malignancies. Its high positive predictive value suggests that TRPS1 expression in metastatic tumours is strongly indicative of breast origin. However, it should be noted that TRPS1 positivity can also be observed in other tumours, particularly gynaecological malignancies.

PS-01-023

Aberrant expression of p53 in HR+/HER2- early breast cancer – association with luminal B/non-luminal subtypes and higher risk category in the Prosigna Assay

N. Böhme[1], E. Weisser[1], S. Jürges[1], C. Entenmann[1], I. Götting[1], J. Milla[1], S. Matovina[2], L.-L. Volmer[2], H. Armbruster[1], T. Engler[2], D. Dannehl[2], A. Koch[2], M. Overkamp[1], V. Bahlinger[1], I. Montes Mojarro[1], R. Rottscholl[1], I. Bonzheim[1], S. Brucker[2], A. Hartkopf[2], F. Fend[1], A. Staebler[1]

[1]University Hospital of Tuebingen, Institute of Pathology and Neuropathology, General and Molecular Pathology, Tuebingen, Germany, [2]University Hospital of Tuebingen, Department of Women's Health, Tuebingen, Germany

Background & Objectives: Pathogenic *TP53* mutations have been associated with endocrine resistance in hormone-receptor-positive, HER2-negative early breast cancer (HR+/HER2-BC). We have validated aberrant patterns for p53 (p53abn) in immunohistochemistry (IHC) known from gynaecologic cancers as surrogate markers for mutations in BC (*Armbruster et al, Virchows Arch 2024*). The present study delineates the results of the Prosigna gene expression profile (Veracyte) in this selected group of potentially high-risk patients.

Methods: We included 199 consecutive cases of early HR+/HER2-BC from the University Women's Hospital Tuebingen from 2023-2024 analysed with the Prosigna assay (including NST and ILC, pT1 and pT2, pN0 and pN1a). p53-IHC pattern was classified into four categories: variable nuclear expression (wild-type, wt), and the aberrant patterns (p53abn) defined as overexpression, complete absence and cytoplasmic.

Results: p53abn was observed in 24 of 199 cases (12.1%) of HR+/HER2- BC. p53abn cases were distributed differently across molecular subtypes (LumA 29.2%, LumB 58.3%, HER2-enriched 4.2%, Basal-like 8.3%) compared to p53wt pattern (LumA 53.1%, LumB 45.1%, HER2-enriched 1.1%, Basal-like 1.1%) (p=0.01, Pearson-Chi-Square). A tendency towards higher risk categories for distant metastasis was computed for the p53abn group, with low/intermediate/high risk were 16.7/29.2/54.2% for p53abn vs. 33.1/30.9/36.0% for p53wt pattern.

Conclusion: p53abn was found in a significant number of HR+/HER2-early BCs and was associated with gene expression profiles enriched for LumB/non-luminal cases. The weak association with Prosigna risk categories might indicate p53 as an independent prognostic parameter. Further clinical investigations are required to show whether the systematic application of *TP53* mutational profiling or its validated surrogate marker, p53 IHC staining patterns, is able to identify patient subpopulations potentially at risk of suboptimal therapeutic efficacy from adjuvant endocrine therapy alone.

PS-01-024

Tumour-infiltrating lymphocytes in triple-negative breast cancer: What is their correlation with molecular subtypes, tumour grade, and stage?

D. Hellal[1,2], S. Merouche[3,1], R. Saad Bouzid[4], N. Boutahir[1], I. Houichi[1], H. Khadraoui[1,2], K. Boulmezair[5], O. Mekentichi[5]

[1]Anti-Cancer Centre of Batna, Department of Pathology, Batna, Algeria, [2]University of Batna 2, Department of Medical Sciences, Batna, Algeria, [3]Anti-Cancer Centre of Batna, Department of Oncology, Batna, Algeria, [4]University of Batna 2, Laboratory of Acquired and Constitutional Genetic Diseases (MAGECA), Batna, Algeria, [5]Anti-Cancer Centre of Batna, Pathology, Batna, Algeria

Background & Objectives: Tumour-infiltrating lymphocytes (TILs) are key components of the tumour microenvironment and play a crucial role in the immune response against cancer. In triple-negative breast cancer (TNBC), TILs are particularly relevant as prognostic markers. This study aims to evaluate the presence and distribution of TILs in TNBC and examine their correlation with tumour grade, tumour size, and disease stage.

Methods: This retrospective study examined 64 consecutive cases of triple-negative breast cancer (TNBC) treated surgically at CAC Batna Hospital in 2023. TNBC was defined by the absence of oestrogen receptor, progesterone receptor, and HER2 expression on immunohistochemistry. Tumour-infiltrating lymphocytes (TILs) and their volume (TILV) were assessed on haematoxylin and eosin (H&E)-stained slides according to International TILs Working Group (ITILWG) guidelines. Stromal TIL density was quantified by estimating the percentage of tumour stroma occupied by lymphocytes, excluding necrotic areas. Cases were classified into low (<10%), moderate (10–30%), and high (≥30%) TIL infiltration groups. To ensure reliability, two senior pathologists independently and blindly reviewed all evaluations.

Results: TIL analysis revealed distinct stromal (sTIL) and intratumoral (iTIL) infiltration patterns. High sTIL correlated with larger tumours (r=0.45, p=0.003) and elevated grade (35% vs. 15%, p=0.002), while iTIL increased with metastases (25% vs. 10%, p=0.005) and advanced stage (p=0.008). The strong sTIL-iTIL correlation (r=0.52, p<0.001) suggests coordinated anti-tumour immunity. Notably, iTILs showed stronger association with poor prognosis markers, potentially serving as biomarkers for metastatic risk and treatment resistance. These findings highlight the need for standardized TIL assessment protocols in clinical practice. Future studies should explore how TIL spatial distribution influences immunotherapy response and patient outcomes, particularly in aggressive tumour subtypes.

Conclusion: The evaluation of TILs in triple-negative breast cancer provides valuable insights into the antitumor immune response. This analysis is a quick, cost-effective method that can enhance clinical management by refining therapeutic strategies and optimizing treatment decisions.

PS-01-025

Phyllodes tumours of the breast: Pathologic characteristics of 81 cases, with a highlight of the diagnostic challenges

P. Kousidis[1], I. Sidiropoulos[1], G. Panselinas[1], R. Iosifidou[2], F. Pavlidou[2], C.C. Kontos[2], N. Salveridis[2], S. Parpoudi[2], E. Triantafillidou[1], A. Nikolaidou[1]

[1]"Theageneio" Anticancer Hospital, Pathology, Thessaloniki, Greece, [2]"Theageneio" Anticancer Hospital, Breast Surgical Oncology, Thessaloniki, Greece

Background & Objectives: Phyllodes tumours of the breast are neoplasms of fibroepithelial origin and are rare, with an estimated incidence rate of 2.1 per million female patients per year. They can be categorized, using their histological features, into benign, borderline or malignant. We present an analysis of 81 cases, examined in our Pathology Department over a 20-year period.

Methods: A comprehensive search was performed in our Department's database. Patients with pathology reports compatible with biopsies and excision specimens of phyllodes tumours of the breast, over the prior 20 years, were included. Reports and tissue slides were separately reviewed by a different than the initial diagnosing pathologist. For patients with a probable or definite diagnosis of phyllodes tumour of the breast, patient records were accessed to determine patient characteristics. A thorough and complete assessment of each patient's histopathologic reports followed.

Results: We identified 81 total patients. Regarding patient characteristics, all 81 (100%) were female. Mean age at diagnosis was 50.7 years (SD 14.93 years). The type of specimen was core needle biopsy for 4 patients (4.9%) and excision specimen for 77 patients (95.1%). Median tumour size was 4.4 cm (IQR 2.85 cm). Among the 71 excised, unequivocally categorized phyllodes tumours, 46 (64.8%) were classified as benign, 12 (16.9%) as borderline and 13 (18.3%) as malignant. Diagnostic challenges occurred in 6 (7.7%) cases of excision specimens. Recurrence occurred in 6 (7.7%) patients having undergone

excision. The heterogeneity in mitotic activity accounted for most of the diagnostically challenging cases.
Conclusion: Phyllodes tumours of the breast present rare, yet not uncommonly encountered tumours in surgical centres with high volume of Breast Pathology specimens. Accurate histologic categorization is important for subsequent appropriate management. Special attention is required in the categorization of cases with overlapping features.

PS-01-027
Insulin-like growth factor receptor 1: expression and prognostic significance in diabetic and non-diabetic women with breast cancer
D. Batinić Škipina[1], N. Lalović[2], L. Ljiljana[3], M. Ćuk[1], S. Kulić[1], N. Dukić[4], J. Vladičić Mašić[5]
[1]University Hospital Foča, Department of Pathology and Cytology, Foča, Bosnia and Herzegovina, [2]University Hospital Foča, Department of Surgery, Foča, Bosnia and Herzegovina, [3]University Clinical Centre of the Republic of Srpska, Department of Pathology and Cytology, Banjaluka, Bosnia and Herzegovina, [4]University Hospital Foča, Department of oncology, Foča, Bosnia and Herzegovina, [5]University Hospital Foča, Department of Oncology, Foča, Bosnia and Herzegovina

Background & Objectives: Aim was to investigate the correlation between expression of IGF1R and basic histopathological and immunohistochemical prognostic breast cancer parameters and to investigate the difference between diabetic and non-diabetic women. Patients with type 2 diabetes mellitus (T2DM) may have a poor prognosis due to the increased number and activity of the insulin-like growth factor receptor 1 (IGF1R) in a physiological environment of hyperglycemia
Methods: A 129 women with invasive breast cancer (stage I-III) have been diagnosed in University hospital Foča; prior surgery T2DM was diagnosed in 14 (10.8%) women. Formalin-fixed paraffin-embedded tumour samples we used for immunohistochemically staining for visualization: IGF1R, oestrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor receptor (HER-2). Statistical analyse of the obtained data was performed using the SPSS version 17.0; two-sample t-test was performed. The relapse-free survival (RFS) was examined using *Kaplan-Meier* curves, and the difference between parameters was assessed by the *Log-Rank test.*
Results: Women with T2DM had significant higher tumour stage (P=0.038), number of metastatic lymph node (P=0.019), diameter (P=0.039) of breast cancer, ER expression (P=0.001) and IGF1R expression (P=0.039), as well as significant higher rate of multifocality/multicentricity (P=0.036) of breast cancer. Log-Rank test showed that T2DM (P=0.023), tumour stage (P=0.039) and HER-2 (P=0.033) were independent prognostic factors for RFS
Conclusion: Type 2 diabetes mellitus was associated with adverse outcomes because of early recurrence of breast cancer and advanced tumour and lymph node involvement stage. T2DM can induce the higher expression and increased binding capacity of IGF1R and ER, as well as preoperative multicentric or multifocal tumour growth.

PS-01-028
Assessing tumour-infiltrating lymphocytes in breast cancer: depth variability across sections, observer agreement, and prognostic implications
N. Gallardo-Borràs[1], L. Adalid-Llansa[1,2], E. Sauras-Colón[1], D. Mata-Cano[1], E. Goyda[1,2], A. Fiorin[1,3], A. Fischer-Carles[1,4], T. Sánchez-Alcántara[1], A. Masip-Bonet[2], M. Ballester-Navarro[1], M. Salvadó-Piñol[1], R. Bosch-Príncep[1], M. Lejeune[1], C. López-Pablo[1]
[1]Oncological Pathology and Bioinformatics Research Group, Pathology Department, Hospital de Tortosa Verge de la Cinta, Institut d'Investigació Sanitària Pere Virgili, Universitat Rovira i Virgili, Tortosa, Spain, [2]Pathology Department, Hospital Universitari Joan XXIII de Tarragona, Tarragona, Spain, [3]Department of Computer Engineering and Mathematics, Universitat Rovira i Virgili, Tarragona, Spain, [4]Simulation, Imaging and Modelling for Biomedical Systems Research Group, Department of Engineering, BCN MedTech, Universitat Pompeu Fabra, Barcelona, Spain

Background & Objectives: Tumour-infiltrating lymphocytes (TILs) are valuable prognostic biomarkers in breast cancer (BC), particularly in triple-negative and HER2-positive subtypes. However, assessing TILs in H&E-stained slides remains challenging due to tumour heterogeneity, interobserver variability, and lack of standardized evaluation criteria. This study aimed to evaluate TILs variability between two distinct BC tumour depths, assess interobserver agreement among pathologists, and determine whether TILs variability across tumour depths influences patient outcomes.
Methods: Two pathologists independently scored stromal TILs in two sections obtained from 12 consecutive 2-µm sections, specifically selecting the 1st and 12th (24 µm apart) from 104 invasive ductal carcinoma biopsies. Both pathologists were blinded to clinical data and section order and assessed TILs (%) following International TILs Working Group guidelines. Variability in TILs percentage across depths and interobserver agreement were evaluated using the intraclass correlation coefficient (ICC). TILs percentage was categorized with a 10% cutoff for the analysis of kappa, Cox regression, and Kaplan-Meier statistics. The relation between TILs scores and survival outcomes was analysed using Cox regression and Kaplan-Meier curves for disease-free survival (DFS).
Results: The ICC for TIL differences between sections 1 and 12 was 0.950, with a kappa of 0.913, indicating excellent agreement. Interobserver variability showed an ICC of 0.878 and a kappa of 0.748, demonstrating strong agreement. For one pathologist, Cox regression showed significantly better DFS for patients with >10% TILs compared to <10% in section 1 ($p = 0.007$) and section 12 ($p = 0.039$). Kaplan-Meier analysis further confirmed this prognostic value in DFS at both depths ($p = 0.004$, $p = 0.033$). For the other pathologist, although TILs were not significantly prognostic, their value remained consistent across depths.
Conclusion: TIL assessment showed high consistency across tumour depths and between pathologists. Despite minor variability, TILs remained a reliable DFS prognostic biomarker, maintaining their prognostic value among both sections.

Funding: This work was supported by BosomShield, a project that has received funding from Marie Skłodowska-Curie Doctoral Networks Actions (HORIZON-MSCA-2021-DN-01-01) under grant agreement 101073222. Background & Objectives: Data on low HER2 expression in early luminal breast cancer and its influence on survival is scarce. We investigated the impact of low HER2 expression on prognosis in postmenopausal patients with early luminal breast cancer treated within the prospective randomized ABCSG 8 trial.
Methods: HER2 immunoreactivity was assessed centrally on 2132 whole tumour slides using current ESMO guidelines. Univariable Cox regression was used to estimate a group difference for disease-free (DFS), distant recurrence-free (DRFS) and overall survival (OS). Differences of baseline clinicopathological parameters (age, grade, tumour size, lymph node status, hormone receptor status, Ki67 labelling index) between HER2 negative, ultra-low and low, respectively, were estimated by Fisher`s exact test or Wilcoxon test.
Results: 1756 (82.4%) tumours were scored as HER2 negative (score 0), 87 (4.1%) as HER2 ultra-low (score 0), 222 (10.4%) as HER2 low (score 1+), 28 (1.3%) as HER2 equivocal (score 2+) and 39 (1.8%) as HER2 positive (score 3+). Negative, ultra-low and low HER2 expression did not show a significant association with any of the above mentioned clinicopathological parameters. The median follow-up time was 10.1 years. Outcome between HER2 low and ultra-low did not show statistically significant differences (e.g., 10-year DFS = 71.9% vs. 72.8%). HER2 score 3+ was associated with a significantly worse DFS (p=0.003) and DRFS (p=0.02), but not for OS (p=0.16).
Conclusion: Within the prospective randomized ABCSG 8 trial, the rate of ultra-low and low HER2 expression was considerably lower than described in previous studies. There was no difference in the baseline characteristics between HER2 negative, HER2 ultra-low and HER2 low invasive breast carcinomas. The HER2 score was prognostic for DFS and DRFS with similar outcomes for HER2 low and HER2 ultra-low expression.

PS-01-030
Mixed breast carcinomas: collision tumour or clonal progression? An immunohistochemical and molecular study of 20 cases
R. Rodriguez[1], L. Leon[1], M.J. Viso Soriano[1], B. Eizaguirre Zarza[1], B. Roche Latasa[1]
[1]Hospital Universitario Miguel Servet, Department of Pathology, Zaragoza, Spain

Background & Objectives: Mixed carcinomas of the breast are rare, accounting for approximately 5% of cases according to the WHO classification. The relationship between the ductal and lobular components remains poorly understood. Some authors suggest these tumours may represent a collision of two distinct neoplasms, while others propose a single tumour in which one component arises from the other.
Methods: We analysed 20 cases of mixed breast carcinomas diagnosed at our hospital over a three-year period. Each case was evaluated not only by morphological criteria but also by assessing E-cadherin expression. Immunohistochemical analysis included oestrogen receptor (ER), progesterone receptor (PR), E-cadherin, Ki-67, HER2, and p53. Additionally, PIK3CA mutations were analysed using PCR.
Results: We did not observe significant differences between the ductal and lobular components regarding ER, PR, p53, or PIK3CA status. These findings support the hypothesis that the lobular component may originate from the ductal component following specific genetic alterations, particularly the loss of E-cadherin.
Conclusion: • Our findings suggest an immunohistochemical relationship between ductal and lobular carcinoma.

- Lobular carcinoma should be diagnosed based on its characteristic morphology and complete loss of E-cadherin.
- In most cases, the lobular component appeared to arise from the ductal component following loss of E-cadherin.
- PIK3CA was the most frequently observed molecular alteration.
- p53 mutations were not identified in any case, in either component.

PS-01-031
Invasive papillary breast cancer. Approaching morphology and molecular profiling
A. Canino[1], D. Fanni[1], T. Congiu[1], A. Mateddu[1], D. Accalai[1], M. Vincis[1], R. Ambu[1], L. Pilloni[1], A.P. Urru[1], C. Gerosa[1]
[1]University of Cagliari, Cagliari, Italy

Background & Objectives: Invasive Papillary Carcinoma (IPC) is a rare breast cancer subtype marked by an invasive papillary structure, with fibrovascular cores covered by high epithelial cells. Since limited data are available, this study aims to investigate the molecular features of IPC.
Methods: We analysed three of five IPC cases from our archives using paraffin-embedded samples. Immunohistochemistry was performed alongside next-generation sequencing (NGS) with the Myriapod NGS Cancer Panel on an Illumina iSeq100 platform, targeting 17 genes. The largest tumour, a mass about 11 cm diameter, underwent additional analysis using scanning electron microscopy (SEM) with a Zeiss 600.
Results: SEM observation of the papillary structures, which are already well visualised by light miscroscopy, allows us to better understand the three-dimensional architecture and the connections between the vascular connective axis and the epithelial component, as well as the connective tissue with the vessel wall. In this tumour molecular analysis identified PIK3CA mutations, including a pathogenic missense variant in exon 5 (c.1035T>A, p.Asn345Lys) with an allelic frequency of 42.5%. Additionally, a PIK3CA c.1252G>A mutation in exon 8 was detected, resulting in p.Glu418Lys, classified as a missense and splice region variant with conflicting pathogenicity assessments (allelic frequency: 42.0%). No mutations were found in the other two IPC cases.
Conclusion: SEM osservation of IPCs'papillae bring us a different point of view. The depth of field emphasises the connections between epithelial and connective structures and the included blood vessels t. PIK3CA mutations, which are commonly found in various human cancers, are present in up to 40% of breast cancers and are paradoxically associated with a better prognosis (2). Although PIK3CA promotes cell proliferation and transformation in vitro (3), its presence in the large tumour is consistent with a favourable prognosis for IPCs.

PS-01-032
Is it TIME for the clinical stratification of HR+/HER2- breast cancer?
C. Scatena[1,2], F. Di Cocco[1], E. Belcastro[1], A. Fontana[2], A. Szumera-Cieckiewicz[3,4], M. Loda[5], A.G. Naccarato[1,2], G.N. Fanelli[1,2,5]
[1]University of Pisa, Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy, [2]Azienda Ospedaliero-Universitaria Pisana, Department of Oncology, Pisa, Italy, [3]Maria Sklodowska-Curie National Research Institute of Oncology, Biobank, Warsaw, Poland, [4]Maria Sklodowska-Curie National Research Institute of Oncology, Department of Pathology,

Warsaw, Poland, [5]Weill Cornell Medicine, Department of Pathology and Laboratory Medicine, New York, USA

Background & Objectives: Tumour immune microenvironment (TIME) plays a pivotal role in the prognosis and therapeutic response in triple-negative and HER2+ breast cancer (BC). Our study aimed to characterize TIME cellular composition of HR+/HER2- BC to gain insight into tumour biology.
Methods: Tissue Microarrays from 70 HR+/HER2- BC patients have been created. Imaging analysis (HALO®) was used to assess the immunohistochemical expression of immune markers (CD3, CD20, CD4, CD8, FOXP3, CD68/KP1, CD163, iNOS). Statistical analysis was performed using GraphPad Prism Software. The study was approved by the local Ethical Committee and was partially funded by Gilead Fellowship Program 2023.
Results: Both CD4+ and CD8+ tumour-infiltrating lymphocytes (TILs) were higher in tumour stroma than in the normal counterpart (P=0.0087 and P=0.0014, respectively). This was particularly significant for the FOXP3+ subpopulation, which include regulatory T cells (Treg, CD4+/FOXP3+) and activated CD8+ T cells (CD8+/FOXP3+) (P=0.0007). Interestingly, the tumour stroma was also enriched in Th1 TILs (CD4+/FOXP3-) (P=0.0096). In terms of prognosis, the metastatic tumours had less CD4+/FOXP3- TILs than the non-metastatic ones (P=0.0045). Together, tumour associated macrophages (TAMs) were polarized into M1 (pro-tumoral) and M2 (anti-tumoral) phenotypes.
Conclusion: These data suggest a complex interplay between immune cells in HR+/HER2- BC: while the presence of CD4+ and CD8+ TILs may indicate an active immune response, the enrichment of Tregs, activated CD8+ T cells and TAMs suggests a potentially dysfunctional immune response. Intriguingly, the lower levels of Th1 TILs in metastatic tumours imply that the immune environment may be less capable of mounting an effective response, and their depletion could be a marker of poor prognosis.

Funding: The study was partially funded by Gilead Fellowship Program 2023

PS-01-033
Ex-vivo confocal microscopy: a novel approach for evaluating needle breast biopsies
A. Castillo[1,2], D. Humaran[3], L. Pons[1,2], J. García-Gómez[1], K. Matute-Molina[1], S. Hochman[1], I. Pascual[3], L. Blay[3], J.F. Julián[3], P.L. Fernández[1,2]
[1]Hospital Universitari Germans Trias i Pujol, Pathology, Barcelona, Spain, [2]Germans Trias i Pujol Research Institute, Molecular and Translational Pathology, Barcelona, Spain, [3]Hospital Universitari Germans Trias i Pujol, General Surgery, Barcelona, Spain

Background & Objectives: Breast cancer diagnosis relies on histopathological evaluation of core needle biopsies, but conventional processing with fixation and paraffin embedding delays results. Confocal microscopy (CM) offers a rapid, non-destructive alternative for immediate tissue evaluation.
Methods: We analysed 47 ex-vivo core needle biopsies from 41 lumpectomy patients, assessing both benign and malignant tissues. Biopsies were assessed using fusion CM (Vivascope, Germany), which provides H&E-like images, and the results were compared to the gold-standard histopathological analysis.
A rapid staining protocol was applied, consisting of 30 seconds of Acridine Orange followed by 20 seconds of Fast Green, repeated twice, with intermittent saline washes, preserving sample integrity for routine processing.
One pathologist with experience in confocal imaging evaluated confocal H&E-like images for invasive carcinoma presence, histological type, percentage involvement, and in situ carcinoma. H&E stained histological sections of the biopsies were then obtained after fixation and routine processing.
Results: CM produced good-quality images allowing to identify key histological features.
The correlation between preliminary findings from confocal imaging and the final diagnosis based from H&E-stained histological sections was 89%. Five biopsies remained inconclusive under confocal imaging. The pathologist correctly identified three lobular invasive carcinomas (LIC) and one ductal carcinoma (DIC) with mucinous differentiation but misclassified two DICs as LICs. In four cases, confocal imaging raised uncertainty between inflammation and tumour, highlighting a diagnostic challenge in certain scenarios.
Of the core needle biopsies, 24 were carcinoma-positive, with 84% concordance in tumour involvement ($\geq$50% vs. <50% of the tissue), reflected by a Cohen's kappa coefficient of 0.60, indicating moderate agreement between confocal imaging and histopathology.
Conclusion: While paraffin-embedded histopathology remains the definitive diagnostic method, the use of CM offers a potential new tool for early diagnostic information. This approach could improve biopsy quality by avoiding non-representative samples and accelerate the diagnostic process, enhancing the clinical workflow without compromising accuracy.

PS-01-034
Evaluation of P63 positivity in breast carcinomas as a prognostic value
B. Alay[1], N.S. Şeker[1], B. Ercan[1]
[1]Eskisehir Osmangazi University, Department of Pathology, Eskisehir, Turkey

Background & Objectives: Breast carcinoma is the most commonly diagnosed malignancy in women worldwide with a high mortality rate. P63 is an immunostain used as a myoepithelial marker in breast tumours. P63 is a transcription factor from the P53 protein family and expressed by the TP63 gene located at the chromosome 3q28. P63 positivity is reported in breast carcinomas, not otherwise specified (NOS) subtype. The pattern of P63 staining is reported as focal and weak staining. This staining pattern can be explained with possible mechanisms such as tumour progression, tumour cell transdifferentiation or early phase differentiation. Recent studies showed correlation between P63 positivity and worse prognostic outcome in HER2-positive breast carcinomas. In this study, we aim to evaluate possible correlations between P63 positivity and biomarker status/tumour grade in breast carcinomas.
Methods: This study included 118 cases of breast carcinoma diagnosed at our centre between 2020 and 2025. The relationship between P63 positivity and demographic, histopathological and biological markers was evaluated in this study. IBM SPSS 21.0 was used for statistical analysis.
Results: P63 expression was significantly associated with higher Ki-67 proliferation indices (p=0.009), with p63-positive cases showing Ki-67 values predominantly above 40%. A statistically significant correlation was observed between p63 and HER2 (CerbB2) positivity (p=0.006), and HER2 score 3 was more common in p63-positive cases (p=0.029). Additionally, p63 positivity correlated with ER negativity (p=0.044). No significant associations were found between p63 and PR status (p=0.536) or tumour grade (p=0.098).
Conclusion: Findings of this study show that p63-positive breast cancer cases are more likely to exhibit HER2 overexpression, ER negativity, and high proliferative activity (Ki-67 > %40) — all of which are associated with poor prognosis. This supports the potential role of p63 as a marker of biologically aggressive tumour behaviour.

PS-01-035

Her2/neu protein expression in primary tumour and local metastases of breast cancer

K. Konyshev[1,2], S. Sazonov[1,2]
[1]Institute of Medical Cell Technologies, Pathology, Yekaterinburg, Russia, [2]Ural State Medical University, Histology, Yekaterinburg, Russia

Background & Objectives: Prognostic and predictive significance of heterogeneity of Her2/neu in primary and metastatic tumour in breast cancer stays unclear. Objective: to assess discordance rate of Her2/neu protein expression in breast cancer local metastasis compared with primary tumour.
Methods: Surgical specimens of the primary tumour and local metastases of 104 patients with breast cancer were studied. Immunohistochemistry (antibodies to Her2/neu, Ventana) was used to determine Her2/neu expression level in primary tumour and metastases. ASCO/CAP 2013 scoring system was used. Groups were formed according to the primary tumour Her2/neu expression level: group 1: 0 (61 patients), group 2: 1+ (12 patients), group 3: 2+ (19 patients), group 4: 3+ (12 patients). Frequency of Her2/neu expression changes in metastases was analysed in groups using Fisher exact probability test.
Results: In group 1 Her2/neu expression level in local metastasis and primary tumour was discordant in 19 cases of 61 (31,2%, 95% CI 20,3-44,4%), increased only. In group 2 – in 10 cases of 12 (83,3%, 95% CI 51,6-97,9%), increased in 2 of 12 (16,7%, 95% CI 2,1-48,4%), decreased in 8 of 12 (66,7%, 95% CI 34,9-90,1%), p=0,036. In group 3 – in 17 cases of 19 (89,5%, 95% CI 65,5-98,2%), increased in 1 (5,3%, 95% CI 0,3-28,1%), decreased in 16 (84,2%, 95% CI 59,5-95,8%), p<0,05. In group 4 – in 6 cases of 12 (50,0%, 95% CI 22,3-77,7%), decreased only.
Conclusion: Her2/neu expression may be discordant when breast cancer primary tumour and local metastases are compared. Discordance rate depends on the Her2/neu primary tumour expression and is highest in cases with 2+ Her2/neu level and lowest in cases without (0) expression. Among cases with discordant Her2/neu expression cases with decrease of Her2/neu level predominate.

PS-01-036

Leptomeningeal carcinomatosis is more likely to have an earlier onset in patients with an initial metastatic breast cancer

O. Boudaouara[1], S. Makni[1], S. Khmiri[2], W. Ghribi[1], T. Sellami-Boudawara[1], M. Triki[1]
[1]Habib Bourguiba Hospital, Pathology Department, Sfax, Tunisia, [2]Habib Bourguiba Hospital, Carcinology Department, Sfax, Tunisia

Background & Objectives: Leptomeningeal carcinomatosis (LC) is a devastating late-stage complication occurring in few patients with breast cancer (BC). We aimed through this study to determine whether clinico-pathological features of BC at diagnosis influence the time to develop LC.
Methods: Data analysis of our cerebral-spinal-fluid (CSF) cytology database was performed in the period between 2005 and 2021, identifying 34 patients who have undergone at least one CSF-cytology-sampling in the context of suspicion of BC-LC. Amongst them, 20 patients met diagnostic criteria for LC diagnosis (positive CSF cytology and/or neuroimaging in the presence of suggestive neurological symptoms). We used Student's and Anova tests for comparisons of means.
Results: The median age of patients at the time of initial BC diagnosis was 46,5 years. The majority of patients were assigned a stage III-IV at baseline (65%) with distant metastases in 30% of cases. Fifteen patients (75%) underwent a breast surgery. Primary breast tumours were predominantly HR-positive (75%) and HER2-negative (65%). All patients developed a LC within a median interval of 37 months (≈ 3 years). Patients with a metastatic disease at baseline experienced shorter time between diagnosis of BC and LC (p<0,001) compared with non-metastatic ones. In contrast, time taken for LM to develop was much longer for patients initially treated by breast surgery, especially those having experienced a radical mastectomy (p=0,002).
Conclusion: LC represents a late complication of BC, occurring within an interval counted in years from the date of initial BC diagnosis. According to this study, patients with an initial metastatic status as well as those who were not eligible for a breast surgery showed an earlier onset of LC in comparison with their non-metastatic and operated-on counterparts, respectively.

PS-01-037

Morphological and immunohistochemical variability between high vs low-grade encapsulated papillary carcinomas

J. Yang[1], A. Bane[1]
[1]University of Toronto, University Health Network (UHN), Toronto, Canada

Background & Objectives: Encapsulated papillary carcinoma (EPC) is a distinct type of breast carcinoma currently classified as an in-situ carcinoma of low to intermediate grade due to indolent nature despite lacking myoepithelial cells around the tumour periphery. However, evidence suggests there is a subset of pure EPCs that have high-grade features and should be considered invasive carcinomas with an expansile growth pattern. This study aims to define morphologic and immunohistochemical features that can distinguish high-grade EPC with potential impact on patient management.
In this retrospective study, our aim was to identify morphologic and immunohistochemical features that may be associated with histologically high grade EPCs with potential clinical implication in patient care and prognosis.
Methods: Resection specimens of pure EPCs diagnosed from 2014-24 at Toronto General Hospital were selected and their clinicopathologic features were reviewed: including patient age, tumour size, nuclear grade, Nottingham histologic grade, mitotic count, presence or absence of necrosis, presence or absence of lymphovascular space invasion and the expression of ER, PR and HER2.
Results: 31 cases of pure EPC were reviewed. The high-grade cohort (n=6) had a mean size of 2.92 cm (SD=0.93), mean mitotic count of 16.83 (SD=10.96), 33% with necrosis. 67% had strong ER expression while 20% had strong PR expression. The intermediate-grade cohort (n=25) had a mean size of 1.21 cm (SD=0.73) and mean mitotic count of 4.96 (SD=4.49), 5% with necrosis. 95% of specimens showed strong ER expression while 50% showed strong PR expression. In summary, when compared to the intermediate group, the high-grade specimens had a significantly larger overall size (p<0.05), higher rate of necrosis (p<0.05), higher mitotic count (p<0.05), and less ER expression (p<0.05).
Conclusion: Possible associated indicators of high grade EPCs include: Larger size at time of grossing, presence of necrosis, higher mitotic count and lack of ER expression.

PS-01-038

Observational study comparing current pathology practices with utilization of computational pathology algorithms for primary breast cancer diagnosis

M. Vecsler[1], S. Ambrogio[2], S. Jindal[3], J. Parry[3], T. Blackmur[4], P. Nagi[4], D. Mevorach[1], D. Ignatov[2], G. Mallel[1], P. Channathodiyil[5], E.-A. Raiber-Moreau[5], S. McCutcheon[6]
[1]Ibex Medical Analytics, Tel Aviv, Israel, [2]Ibex Medical Analytics, London, United Kingdom, [3]Healius Limited, Western Diagnostic Pathology, Perth, Australia, [4]Healius Limited, Brisbane, Australia, [5]AstraZeneca, Cambridge, United Kingdom, [6]AstraZeneca, Baar, Switzerland

Background & Objectives: The increasing global burden of breast cancer, along with rising diagnostic demands and a shortage of pathologists, requires innovative solutions to improve histopathological workflows while ensuring high diagnostic accuracy. This study evaluated an AI-powered decision-support solution (Ibex Breast®) to assess its impact on workflow efficiency, diagnostic performance, and AI standalone accuracy in detecting breast cancer, invasive carcinoma, and ductal carcinoma in situ (DCIS).
Methods: The study included a cohort of 200 retrospective breast biopsies with H&E slides evaluating different subtypes (IDC, ILC, DCIS) from a pathology lab in Western Australia. The two-arm crossover study design evaluated two diagnostic workflows: a standard digital pathology workflow (Arm A) and an AI-assisted workflow (Arm B). Efficiency metrics, including pathologists' reporting time, were measured, and patient turnaround time (TAT) was assessed. Diagnostic performance, including sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV), were compared between workflows. Standalone AI accuracy was also evaluated.
Results: The integration of AI significantly improved efficiency, reducing pathologist review times by an average of 43.5% (from 71.0 ± 47.8s/case in Arm A to 40.2 ± 28.4s in Arm B; $p < 2.2 \times 10^{-16}$). AI-assisted workflow showed high diagnostic performance compared to standard workflows, achieving 100% sensitivity and specificity for cancer and invasive carcinoma detection. The standalone AI demonstrated 100% sensitivity and specificity for cancer and invasive carcinoma, and 92.9% sensitivity for DCIS. AI integration could reduce TAT by 1.7 days for cases requiring immunohistochemistry (IHC) tests through preordering based on AI findings.
Conclusion: The AI-assisted workflow significantly enhances diagnostic efficiency and reduces patient TAT for primary diagnosis of breast cancer without compromising accuracy. By streamlining workflows, reducing pathologist workloads, and expediting case reporting, AI has the potential to address critical challenges in modern pathology, including rising workloads and pathologist shortages, ultimately improving patient outcomes.

PS-01-039
Multimodal discovery of cellular and microanatomical determinants in breast cancer metastasis
Y. Zheng[1], A. Rendeiro[1], J. Winkler[2]
[1]CeMM, Vienna, Austria, [2]Medical University of Vienna, Centre for Cancer Research, Vienna, Austria

Background & Objectives: Cancer metastasis remains one of the leading causes of cancer-related mortality following ineffective treatment. While genomic alterations and tumour-intrinsic factors are well-established drivers of metastasis, recent evidence suggests that tissue architecture and organ-specific microenvironments play an active role in shaping the metastatic process. Despite the recognition of the tumour microenvironment as a key driver of metastasis, the specific contributions of the microanatomical composition and arrangement of the metastatic site to the metastatic process remain poorly characterized.
Methods: We conducted a comprehensive analysis comprising 22 patient-derived xenografts comprising of paired primary and metastatic cancer samples across molecular subtypes. Our approach integrated 420 H&E whole slide images and 120 multiplexed imaging datasets incorporating 50 distinct markers. Following manual annotation of 120 slides, we developed a deep-learning semantic segmentation model capable of identifying vascular structures, airways, and tumour lesions in H&E slides of metastatic lung tissue. We further employed advanced spatial analysis techniques to interrogate cellular arrangements within multiplexed images to elucidate their association with metastatic potential.
Results: Our model successfully identified all microanatomical structures (vessels, airways) and tumour lesions across the entire H&E slide collection. Subsequent analyses revealed how morphological features, and spatial arrangements of microanatomical structures and tumour lesions correlate with metastatic potential and molecular subtypes. Multiplexed imaging data enabled the identification of specific molecular markers that are microanatomically dependent, and further specification of cellular heterogeneity during the process of cancer colonization in breast cancer metastasis to the lung.
Conclusion: Investigating the role of microanatomical structures in early-stage breast cancer metastasis in PDX models reveals the intricate, multi-scale nature of factors conditioning the metastatic process. The fundamental principle studied in this work, once validated in human datasets such as TCGA and METABRIC, has the potential to enable better disease prognosis and other clinical applications that would ultimately improve patient outcomes.

PS-01-040
Real-world experience with the 70 gene assay for treatment decisions in ER+/HER2- invasive breast cancer
S. Lax[1,2], K. Markowski[1], V.A. Martinez Manzo[1], S. Bracic Tomazic[1], C. Suppan[3], G. Pristauz-Telsnigg[4], C. Siebenhofer[5], O. Scheiber[1], G. Rinnerthaler[6]
[1]Hospital Graz II, Anatomic and Molecular Pathology, Graz, Austria, [2]Johannes Kepler University Linz, School of Medicine, Anatomic and Molecular Pathology, Linz, Austria, [3]University Clinic for Internal Medicine, Medical University Graz, Medical Oncology, Graz, Austria, [4]Hospital Oststeiermark, Gynaecology and Obstetrics, Feldbach, Austria, [5]Hospital of Charity, Gynaecology, Graz, Austria, [6]University Clinic for Internal Medicine, Medical University of Graz, Medical Oncology, Graz, Austria

Background & Objectives: Multigene classifiers have been established for treatment decisions in ER+/HER2- invasive breast carcinoma but these tests are expensive, in part centrally performed and have been only partially tested in prospective trials. In our certified breast units we used the EndoPredict® but recently switched to MammaPrint® (70-gene assay). Our aim is to report our first experience with the 70-gene assay with respect to prognostic groups and clinicopathological parameters.
Methods: Patients for testing are determined in tumour boards. The pathologist as ordering physician selects a representative tumour block from the surgical specimen; 10 consecutive sections are cut according to the instructions by the manufacturer and submitted within the provided kit box to central lab. Each case is registered online. The report is immediately available online after analysis (email alert). The 70-gene assay considers low-risk and high-risk carcinomas with 2 further subgroups each.
Results: During the last 14 weeks we have submitted 20 cases. Median analysis time was 7.5 days. 15 (75%) cases were classified as high-risk, 5 (25%) as low risk. Low risk cases were younger compared to high-risk cases (median age 54 versus 68 years), showed lower Ki67 labelling index (median 12.5% versus 30%) and were less frequently HER2 low (1/5 versus 13/15). No differences were found with respect to PR, tumour size and nodal status. Due to the small number of cases, we omitted the subgroup analysis. All EndoPredict® analyses were classified as high risk.
Conclusion: In real world the use of the 70-gene assay is feasible despite central analysis and recognizes a low-risk group. Low-risk carcinomas seem to be distinct from high-risk carcinomas with respect to

age, Ki67 labelling index and HER2 low frequency. In this prospective setting we will be able to report a larger cohort at the congress.

PS-01-041

Evolution the testing of the human epidermal growth factor receptor 2 (HER2) in breast cancer in Spain over the last 10 years

V. Peg[1], O. Burgués[2], I. Ruiz[3], D. Carcedo[4], J.F. García[5], M.A. Monzón[6], I. Tonic[5], B. Pérez-Mies[7]
[1]Vall d'Hebron University Hospital, Pathology, Barcelona, Spain, [2]Hospital Clínico Universitario de Valencia, Pathology, Valencia, Spain, [3]Hospital Universitario Donostia, Pathology, San Sebastian, Spain, [4]Health economics. Hygeia Consulting S.L, Madrid, Spain, [5]Roche Farma, Medical Department, Madrid, Spain, [6]Health economics. Hygeia Consulting S.L., Madrid, Spain, [7]Hospital Ramón y Cajal, Pathology, Madrid, Spain

Background & Objectives: Human epidermal growth factor receptor 2 (HER2) is assessed by immunohistochemistry (IHC) and in-situ hybridization (ISH). CONFIRMA-HER2 is the largest registry in Spain with information on the HER2 biomarker testing in breast cancer (BC). The aim of this study was to analyse the evolution of HER2 status over a decade within the CONFIRMA-HER2 registry.
Methods: A retrospective analysis of HER2 determinations recorded in the CONFIRMA HER2 registry of BC samples diagnosed between 2013 and 2023 in 160 hospitals across Spain. The evolution over time of the technique used to determine HER2 (IHC and ISH) and the result of the determination (HER-negative or HER-positive) was analysed.
Results: A total of 199,934 HER2 determinations recorded in the CONFIRMA-HER2 registry were analysed. The use of IHC for HER2 testing has increased over the 10 years of analysis (lowest value 93.0% in 2014 to 99.8% in 2023) while hybridizations have decreased (highest value 33.2% in 2015 to 19.5% in 2023). Overall IHC results were 35.5% IHC 0, 27.8% IHC 1+, 22.7% IHC 2+, 11.2% IHC 3+ and 2.9% invalid/non-evaluable, with the proportion of IHC 0 increasing most over time. Of the total hybridizations performed, 17.9% were amplified and 82.1% were non-amplified, with this distribution remaining fairly constant over time. After excluding invalid/non-evaluable results, 15.3% determinations were HER2-positive and 84.7% were HER2-negative over the period 2013-2023. The highest percentage of HER-positives was recorded in 2015 (18.8%) and the lowest in 2022 (16.6%). Of all determinations, 46.5% were HER2-low (IHC 1+ or IHC 2+/non-amplified ISH) with the highest percentage in 2020 (48.6%).
Conclusion: CONFIRMA-HER2 registry provides key information on the evolution of HER2 testing in Spain, a critical element in the treatment and prognosis of BC, especially in recent years with advances in HER2-targeted therapy.

PS-01-042

***CDH1* somatic mutation analysis in advanced breast cancer: correlation with clinicopathologic and molecular features**

H. Chen[1], R. Krasniqi[1], A. Alrohaibani[1], K. Sweeney[1], Q. Ding[1], Y. Wu[1], C. Albarracin[1]
[1]The University of Texas MD Anderson Cancer Centre, Pathology, Houston, USA

Background & Objectives: *CDH1* inactivation is typically correlated with loss of E-cadherin expression and often associated with lobular breast carcinomas and rarely seen in ductal carcinomas. The loss of expression of E-cadherin, a cell adhesion molecule, has been proposed to correlate with higher risk of metastasis and therefore poor prognosis. In this study, we aimed to compare *CDH1* mutated and non-mutated breast cancer with their associated clinicopathologic and genetic characteristics.
Methods: We evaluated 304 patients with metastatic/recurrent breast cancer who underwent next generation sequencing performed on an institutional custom-built hybrid capture 610-gene panel between 2021-2024. *CDH1* somatic mutation status was examined with respect to clinical, pathologic, and molecular profile including tumour mutational burden (TMB).
Results: *CDH1* somatic mutations were detected in 43 of 304 patients (14%): 40 truncation mutations (93%), 2 missense (5%) and 1 in-frame deletion (2%). *CDH1* mutated cases were all females (100%), predominately HR positive (93%), and all HER2 negative (100%). *CDH1* mutated cases were mostly lobular carcinomas (72%) and mixed ductal and lobular (IDLC) (23%), and rarely ductal (5%), as compared to *CDH1* non-mutated cases (4% lobular, 5% IDLC, and 91% ductal, $p<0.001$). Of 10 IDLC with *CDH1* mutations, 5 (50%) were multifocal, 1 (10%) bilateral, 1 (10%) stage IV with lung metastasis. TMB-high was higher in *CDH1* mutated cases (21%) than *CDH1* non-mutated (7%, $p=0.02$). Co-existing *PIK3CA* mutation was frequent in *CDH1* mutated cases (60%) as compared to *CDH1* non-mutated cases (32%, $p<0.001$). In contrast, *TP53* mutation was less frequent in *CDH1* mutated cases than those without (9% vs 49%, $p<0.001$).
Conclusion: *CDH1* mutated breast cancers were mostly ER positive, HER2 negative, lobular or IDLC, and notably predictive of multifocality. They were likely TMB-high, with co-existing *PIK3CA* mutation, and less likely *TP53* mutation. These enhanced knowledge enables strategic multidisciplinary planning in identifying targeted and immunotherapy beyond conventional treatment.

Aging of AI caused by scanner drift can be rescued by colour calibration

R. Salmon[1], X. Ji[2], A. Blilie[3], L. Collins[1], K. Kartasalo[2]
[1]PathQA Ltd, London, United Kingdom, [2]Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden, [3]Stavanger University Hospital, Department of Pathology, Stavanger, Norway

Background & Objectives: The full potential of artificial intelligence (AI) in digital pathology is limited by technical inconsistencies in scanning of whole slide images (WSIs), posing a challenge for widespread clinical application as fine-tuning algorithms for each new site is impractical. A recent study comprehensively demonstrated that standardizing intra- and inter-vendor WSI colour by calibration increases AI robustness and reliability. Further concerns exist over 'AI aging' as scanners change in colour reproduction fidelity over time, impacting AI post-validation performance and potentially compromising safety.
Methods: We employed a colour calibration technology that corrects WSIs to ground truth colour of real glass slides using ICC profiles. To assess impacts of temporal colour variation, 119 prostate cores with balanced ISUP grade distribution were scanned alongside the colour calibration slide on one scanner every 14 days for one year. The tissue colour was measured for change. Scanner-induced temporal variance on pathologist concordance and AI model performance was evaluated on a deep learning model trained on over 46,000 WSI for prostate cancer diagnosis.
Results: The RGB colour stability of the scanner degraded over even short timepoints, discernable by humans and revealing traceable events needing quality assurance that caused sudden changes. Timepoint ICC profiles recovered to stable, accurate colour resulting in better AI concordance with pathologist ISUP grading, and actual tissue did not change colour. With only scanner colour left uncontrolled, AI performance linearly regressed which ICC colour calibration rescued to intended consistency.
Conclusion: Frequent colour calibration provides a universal solution to the variation introduced by scanners drifting, making AI-based

cancer diagnostics more reliable in the real world. In future studies introducing more scanners will investigate impacting AI reliability exponentially and grade-specific rescuing of AI-aging for ISUP 2-4 is expected to have significant diagnostic impact. This study pioneers real-time quality assurance for stable and scalable performance of scanners and AI over time.

PS-02-002

Development of an automated tumour region segmentation model of prostate cancer using weak labels and in-silico data generated with a diffusion model

N. Triltsch[1], M. Azqueta Gavaldon[1], Y. Popov[1], A. Race[1], N. Brieu[1], D. Winter[1]
[1]AstraZeneca, Computational Pathology, Munich, Germany

Background & Objectives: Accurate segmentation of tumour regions in histopathological images using deep learning models relies heavily on training with precisely labeled datasets. However, crafting these annotations is costly and time intensive. Our work addresses this challenge by showcasing how weak labels and *in-silico* data can be used to minimize the dependency on extensive pathologist input while maintaining model accuracy.
Methods: To train a tumour epithelium segmentation model for prostate immunohistochemical (IHC) slides, we implemented a weak labelling workflow that reclassified predictions from an epithelium segmentation model into *tumour* and *normal* epithelium based on coarse tumour centre annotations from a pathologist. Thereby we generated pixel-precise weak labels. Utilizing a diffusion model, we augmented these weakly labelled images with in-silico data. For training, we generated 7,080 weak labelled patches of size 512x512pxl at 0.5µm/pxl and 4.0µm/pxl resolution from 57 whole slide images (WSIs) and evaluated the models on 86 annotated Fields-Of-View of size 500x500µm from 20 WSIs. Experiments involved training with random subsets (5%, 10%, 25%) of the original patch dataset and systematically increased in-silico data through augmentations (1x-15x). Using the H-Optimus-0 foundation model as a feature extractor, we investigated the overlap of real and in-silico data distributions in UMAPs.
Results: Our baseline tumour epithelium segmentation model achieved a Dice score of 0.91 using 100% of weakly labelled data. While accuracy remained stable using 25% of data, it decreased to 0.90 for 5% and 10% subsets. Adding 1x and 10x folds of in-silico data restored the performance to 0.91. An optimal number of augmentation rounds was identified beyond which model accuracy decreases again. UMAPs showed in-silico images reproduce real appearances while enriching training data diversity.
Conclusion: The study demonstrates the feasibility of developing highly accurate segmentation models with minimal pathology annotations (5-10% of original dataset) using weak labels and in-silico data.

PS-02-003

AI-based morphological characterization of Small Cell Lung Cancer subtyped by molecular transcriptional pattern

D. Karaoglu[1], A. Ura[2,3], C. Mogler[2], G. Klöppel[2], T. Hayashi[3], P. Schüffler[2], A. Kasajima[2]
[1]Technical University of Munich, School of Computation, Information and Technology, Munich, Germany, [2]Technical University of Munich, Institute of Pathology, Munich, Germany, [3]Juntendo University Graduate School of Medicine, Department of Human Pathology, Tokyo, Japan

Background & Objectives: Small cell lung cancer (SCLC) has recently been classified into four subtypes by their molecular transcriptional signature based on four specific proteins: ASCL1, NEUROD1, POU2F3, and YAP1. However, the possible morphological differences of these subtypes have not been examined. Hence, we aim to investigate the morphology of these subtypes by providing AI-based strategies. To the best of our knowledge, this is the first study to explore the morphological characteristics of SCLC subtypes from the computational point of view.
Methods: Here, we first perform single-cell classification to analyse the morphological features by detecting each cell and measuring their colour- and shape-related features in the regions of interest. Second, we conduct whole-slide image (WSI) classification to investigate whether these subtypes can be identified based on the visual, morphological, and spatial features of image patches. We use a weakly supervised state-of-the-art pathological image classification method, CLAM (Clustering-constrained Attention Multiple Instance Learning). Additionally, we generated heatmaps with the help of the attention mechanism to visualize the model's focus in the prediction process.
Results: The single-cell analysis shows that the geometrical features of ASCL1-positive and POU2F3-positive cases are very similar, with only small differences compared to NEUROD1-positive cases. However, the colour-related features play a more significant role than the geometric features. Furthermore, the WSI classification framework proves that the morphological differences across subtypes are distinct enough for accurate classification. The generated heatmaps highlight regions of interest to better understand the importance of specific regions within a slide. Importantly, these highlighted regions correspond well with the rough annotations provided by our pathologist, supporting the model's reliability.
Conclusion: Overall, we showcase that SCLC subtypes based on the expression of different transcription factors exhibit distinct morphological characterization.

PS-02-004

Computer-aided scoring as an objective method in the assessment of HER2 immunostaining in breast cancer with high intratumoral heterogeneity

E. Petcu[1], J. Krausz[2], W. Saliba[2], W.J. Senarathne[3], H. Belhanes Peled[2], N. David[2], Y. Sufrin[3], C. Steele[3], Y. Glickman[3]
[1]New York Institute of Technology, Histology Core Facility, Old Westbury, USA, [2]Emek Medical Centre, Pathology, Afula, Israel, [3]Applied Spectral Imaging, Carlsbad, USA

Background & Objectives: The interpretation of HER2 IHC in cases with elevated intra-tumoral heterogeneity may be challenging, sometimes resulting in high interobserver variability. The aim of this evaluation was to assess the usefulness of a computer-aided method for the scoring of HER2 immunostaining, particularly in specimens with high intra-tumoral heterogeneity.
Methods: Specimens stained with HER2 clone 4B5 using the BenchMark Ultra (Roche) were selected from a slide repository to include various HER2 expression levels. Both HER2 and corresponding H&E slides were scanned at 20x on GenASIs HiPathPro (Applied Spectral Imaging). Three distinct regions were digitally marked within the tumour on the H&E images and automatically transferred to the HER2 specimens following tissue matching. Three independent pathologists provided one integrative HER2 score of 0, 1+, 2+ or 3+ for the 3 marked regions analysed together. A score for the three regions and per individual region were also obtained using a computational algorithm.
Results: Core biopsies from 23 breast cancer patients (age 53±13) were included, 22 with IDC and one with mucinous carcinoma. 20 out of the 23 HER2 specimens (87%) were scored identically by the 3 pathologists and the computational algorithm (10 negative 0 or 1+, 7 equivocal 2+, and 3 positive 3+). The 3 discrepant cases were scored either 1+ or 2+ by the pathologists. In these cases, high heterogeneity

was observed across the 3 marked regions, with individual computational score per region varying between 0 and 2+. For note, the proliferation index Ki-67 for these discrepant cases was >20% while the integrative computational score across the 3 regions was 2+.
Conclusion: Manual HER2 assessment may be hampered in cases of high intra-tumoral heterogeneity, particularly when assessing HER2 low. In such cases, computational analysis emerges as a useful integrative method providing objective and reproducible scoring across heterogeneous tissue.

PS-02-005
Convolutional neural networks improve metastatic risk prediction beyond staging in early-stage melanoma using histopathological images from the population-based Dutch Early-Stage Melanoma Study (D-ESMEL)
J. Ouwerkerk[1], F. Akram[1], L. Hollestein[2], C. Zhou[2], T. Kerkour[2], A. Stubbs[1], A. Moyaart[1], Y. Li[1]
[1]Erasmus Medical Centre, Department of Pathology and Clinical Bioinformatics, Rotterdam, The Netherlands, [2]Erasmus Medical Centre, Department of Dermatology, Rotterdam, The Netherlands

Background & Objectives: Current melanoma staging is insufficient to identify high risk patients of distant metastasis among stage I/II melanoma (i.e. no metastasis at diagnosis), as 41% of melanoma deaths occur among patients who were initially diagnosed at stage I/II. We aimed to develop a convolutional neural network (CNN) model using whole slide images (WSIs) from primary early-stage melanomas to improve the prediction of future distant metastasis for possible adjuvant treatment or increased surveillance.
Methods: To identify novel histopathological predictors beyond known staging predictors, we used the Dutch Early-Stage Melanoma (D-ESMEL). This study includes a discovery set with 224 matched case-control sets and a validation cohort consisting of a population-based nested case control study, including 5,558 patients with 154 unmatched case-control sets. In the discovery set each metastatic case is matched to a control on date of diagnosis, age, sex, Breslow thickness, and ulceration to identify novel prognostic factors. An end-to-end workflow was developed on the discovery set which automatically extracts relevant patches from WSIs, performs filtering, classifies patches into low and high-risk, and outputs patient-level risk predictions. The workflow is applied on the validation cohort and the CNN predictions were used to perform a weighted Cox proportional hazards (CoxPH) regression and a log likelihood test to assess the added value on top of staging in a population-based cohort.
Results: Our CNN model reached 83% sensitivity and 100% specificity in a holdout test set of the discovery set. In the validation cohort, staging alone reached a weighted C-index of 0.82. Adding our CNN's predictions on top of staging contributed significantly to the prognosis of metastasis (hazard ratio=1.24, 95% confidence interval: 1.03-1.48, $p<0.05$) and significantly improved the weighted C-index to 0.84 ($p<0.01$).
Conclusion: To our knowledge, this is the first histopathological model that adds prognostic value on top of staging for predicting distant metastasis in early-stage melanomas.

PS-02-006
Evaluating the performance and generalisability of a clinical-grade AI-based approach for determining MSI/dMMR status in colorectal cancer: A blinded multi-regional study
S. Arslan[1], S. Wolf[1], F. Ntelemis[1], A. Geraldes[1], J. Schmidt[1], D. Mehrotra[1], S. Singhal[1], N. Kumar[1], J. Blackwood[1], N. Bennett[2], M. Hyde[2], G. Rogerson[2], E. Walsh[2], R. Clarkson[3], M. Salto-Tellez[4], M. Loughrey[4], D.J. Harrison[5], N.M. Orsi[2], J.N. Kather[6], P. Pandya[1], C. Bass[1]
[1]Panakeia Technologies Limited, Cambridge, United Kingdom, [2]Women's Health Research Group, Leeds Institute of Cancer & Pathology, St James's University Hospital, University of Leeds, Leedsunituni, United Kingdom, [3]Wales Cancer Biobank, Cardiff University, Cardiff, United Kingdom, [4]Queen's University Belfast, School of Medicine, Dentistry and Biomedical Sciences, Patrick G Johnston Centre for Cancer Research, Belfast, United Kingdom, [5]University of St Andrews, School of Medicine, St Andrews, United Kingdom, [6]Else Kröner Fresenius Centre for Digital Health, Faculty of Medicine, TU Dresden, Dresden, Germany

Background & Objectives: Microsatellite instability (MSI) and mismatch repair deficiency (dMMR) testing are essential for colorectal cancer (CRC) management. Despite guidelines recommending routine testing, high costs, long turnaround times, and pathology workforce shortages limit widespread implementation. PANProfiler Colorectal (PPC) is an artificial intelligence (AI)-driven approach that determines MSI/dMMR status in minutes using only H&E-stained whole slide images (WSIs), offering a cost-effective and scalable alternative. This study evaluates PPC's performance and generalisability across diverse UK subpopulations using real-world retrospective CRC cases.
Methods: A blinded validation study was conducted using 3,576 WSIs of H&E-stained primary CRC tumours from three sites, with results compared against traditional testing methods. WSIs were sourced from St James's University Hospital (n=3,124), Wales Cancer Biobank (n=54), and Northern Ireland (NI) Biobank (n=398), with the cohorts representing England, Wales, and NI, respectively. MSI-high/dMMR prevalence across cohorts (12.5% - 20.6%) was consistent with reported UK rates. PPC provided results as *Stable* (proficient MMR or non-MSI-High), *Unstable* (dMMR or MSI-High), or *Indeterminate* (no definitive result).
Results: PPC provided a definitive result for 86.6% of cases, as measured by the test replacement rate (TRR). Overall percent agreement (OPA) ranged from 84.3% (Wales) to 94.1% (England), with an aggregated OPA of 93.8% (95% CI: 92.9% - 94.7%). Positive percent agreement (PPA) varied between 91.7% (NI) and 100.0% (Wales), with an aggregated PPA of 92.5% (95% CI: 89.5% - 94.9%). Negative percent agreement (NPA) ranged from 80.0% (Wales) to 94.3% (England), with an aggregated NPA of 94.0% (95% CI: 93.1% - 94.9%). TRR varied between 71.4% (NI) and 94.4% (Wales) across regions.
Conclusion: Using real-world retrospective data, PPC demonstrated robustness and accuracy in assessing MSI/dMMR status in CRC tumours. These findings support its wider adoption as a valuable solution for improving CRC management, highlighting its ability to generalise across diverse patient populations.

Funding: This project was (partially) funded by IUK Smart Grant 10054824

PS-02-007
Deep learning-powered scoring of ER, PR and Ki-67 across major WSI scanners using a single, generalizable cell-classification model in breast cancer
V. Valaboju[1], Z. Shanis[1], S. Nofallah[1], J. Hipp[1], N. Agrawal[1], S. Balasubramanian[1], R. Bhargava[1], E. Walk[1]
[1]PathAI, Boston, USA

Background & Objectives: Estrogen receptor (ER), progesterone receptor (PR), and Ki-67 are routinely examined by immunohistochemistry (IHC) to assess hormone receptor status and tumour proliferation in breast cancer. However, IHC scoring in a digital pathology setting can be hindered by variation in staining and scanning, as well as inter- and intra-reader variability, and scanner variability. To

address the aforementioned issues, we developed a deep learning-based tool to provide ER, PR, and Ki-67 scores from whole slide images (WSIs).
Methods: A deep convolutional neural network (DCNN) segmented and classified invasive carcinoma, in-situ carcinoma, cancer stroma, necrosis, and normal stroma in regions of evaluable tissue predicted by an artifact model. Another DCNN identified IHC signal-positive and -negative cancer cells. Both DCNNs were trained and evaluated using sparse annotations (N=111,622) across 14,646 WSIs. Continuous slide-level ER, PR, and Ki-67 scores were calculated using the ratio of positive cancer cells to total cells within invasive carcinoma. For model evaluation, 5-way manual pathologist slide-level scores were collected on held-out WSIs (N=1,115) for ER, PR, and Ki-67, and intra-class coefficient (ICC) values were calculated. Models were considered non-inferior to pathologists if ΔICC (the difference between model and pathologist ICCs) > -0.1.
Results: Model performance was non-inferior to manual pathologist scoring. Model ICC values were 0.91, 0.86, and 0.93, and ΔICC values were -0.05, 0.00, and -0.02 for ER, PR, and Ki-67, respectively. Model performance was generalizable across six whole slide scanners (ICC range: 0.89-0.96).
Conclusion: This tool effectively and accurately scores ER-, PR-, and Ki-67-stained WSI and is non-inferior to pathologists for this task across major digital pathology scanners. Although further evaluation is needed to understand model performance in real-world laboratories, these findings support digital IHC scoring, which has the potential to improve pathologist efficiency.

PS-02-008
The WHO Classification of tumours evidence gap map tool: a software tool supporting evidence-based decision making in tumour pathology
R. Cierco Jimenez[1], C. Giesen[1], H. Wijesinghe[1], I. A Cree[1], D. Lokuhetty[1], B.I. Indave Ruiz[1], WCT EVI MAP
[1]International Agency for Research on Cancer (IARC), World Health Organization, WHO Classification of Tumours, Lyon, France

Background & Objectives: Evidence-based practice improves tumour pathology research and its classification. However, identifying high quality scientific publications and research evidence gaps can be challenging. The WCT EVI MAP project funded by European Commission (HORIZON-HLTH-2021-CARE-05 grant number 101057127) aims to create a decision-making support tool by developing a software that visualises evidence gap maps (EGMs) to facilitate evidence-based decision-making and assisting in its analysis, helping researchers and healthcare professionals to identify knowledge gaps informing future research.
Methods: We developed a web application that visualises EGMs and integrates its outcomes in a searchable database of scientific publications composing the evidence-base of the WHO Classification of Tumours (WCT). Built using open-source technologies, the web application utilizes the R Shiny package (v4.3.3, v1.8.1.1) for the web interface and a MariaDB (v10.4.32), a fork of MySQL, for the database prototype. Both components have been optimized to efficiently handle user queries through a dynamic, responsive approach.
Results: The tool consists of three sections. The first is the EGM Panel, where the maps can be consulted. The second is the Dashboard, which allows users to filter articles by tumour type, tumour characteristics, and based on methodology to analyse specific areas of tumour pathology. To enhance the experience, visual figures complement specific outcomes. Finally, the EGM Creator Panel allows users to select specific findings and build new EGMs from our database based on user needs.
Conclusion: This web application constitutes a powerful tool to facilitate evidence-based decision-making in tumour pathology and its classification, significantly improving future review processes of the WCT. By providing access to EGMs, facilitating their analysis and linking them to relevant publications, this tool simplifies the identification of research gaps and pockets of low-level evidence in tumour pathology. This will promote evidence-based practice in pathology, benefiting pathologists, researchers and clinicians.

PS-02-009
AI-driven microsatellite instability testing in gastric and endometrial cancers: towards reflex testing
M. Lubrano[1], E. Samuelsson[1], A. Filiot[1], J. Klein[1], A. Lyon[1], C. Wiscart[1], A. Fouillet[1], L. van Praet[1], A. Vinçotte[1], C. Genestie[2], J. Hernandez Losa[3], G. Broeckx[4], F. Deman[4], L. Cano Ayestas[1], K. Von Loga[1]
[1]Owkin, Paris, France, [2]Gustave Roussy, Department of Pathology, Paris, France, [3]Vall d'Hebron Institut de Recerca, Department of Pathology, Barcelona, Spain, [4]Ziekenhuis aan de stroom (ZAS), Department of Pathology, Antwerp, Belgium

Background & Objectives: Microsatellite instability (MSI) testing is crucial for managing solid tumour patients, particularly for immune checkpoint inhibitor therapy. Reflex MSI testing is recommended for colorectal cancer (CRC), gastric cancer (GC), and endometrial cancer (EC), but challenges such as workload, cost, and tissue availability result in underdiagnosis. While AI models were developed for MSI testing in CRC, limited work exists for less prevalent cancers like GC and EC. This study aimed to develop AI models for MSI testing in GC and EC with strong validation performance, paving the way for clinical use of these screening methods.
Methods: AI classification models were developed to predict MSI status from digitized H&E slides in GC and EC, using independent multicentre cohorts (4 proprietary, 2 per indication, from 3 countries, N=556 patients; TCGA, N=851 patients). Foundation models (H-optimus-0) were combined with the Chowder architecture. In EC, non-tumour regions were automatically excluded during training. A "leave-one-cohort-out" validation approach was used to ensure generalizability and minimize overfitting.
Results:•**GC**: The model achieved an average AUROC of 0.934 (0.916, 0.935, 0.950) for three left-out cohorts. In cross-validation, AUROC reached 0.938 (95% CI: 0.889-0.988), with 0.909 (95% CI: 0.837-0.981) specificity at 0.800 sensitivity.
•**EC**: The model achieved an average AUROC of 0.830 (0.774, 0.820, 0.895) for three left-out cohorts. In cross-validation, AUROC reached 0.833 (95% CI: 0.755-0.911), with 0.716 (95% CI: 0.575-0.856) specificity at 0.800 sensitivity.
Conclusion: Our AI models for MSI detection in GC and EC demonstrated strong validation performance. The "leave-one-cohort-out" strategy was crucial in ensuring robust generalization for future external validation and clinical use. These models have the promise to deliver faster, cost-effective solutions, advancing toward routine reflex MSI testing for GC and EC.

Enhancing lymph node metastasis detection with AI: diagnostic, efficiency, and cost benefits of DeepPATH–LYDIA
I. Vamvakaris[1], G. Kalykakis[2], I. Tarampoulous[2], K. Gyftodimos[2], G.A. Agrogiannis[3], A. Sepsa[3], M.G. Samaras[4], C. Manolis[5], X. Spyropoulos[5], N. Niotis[5], T. Papathymiopoulos[5], K. Vougas[5]

[1]Sotiria Hospital, Pathology, Athens, Greece, [2]DeepPath, Athens, Greece, [3]National and Kapodistrian University of Athens, 1st Dept of Pathology, Faculty of Medicine, Athens, Greece, [4]Medical School, National and Kapodistrian University of Athens, Attikon University Hospital, Second Dept of Pathology, Athens, Greece, [5]DeepPath PC Papagou, Athens, Greece

Background & Objectives: AI integration in histopathology helps ease diagnostic bottlenecks. DeepPATH-LYDIA, a CE-marked AI tool for breast, colon, lung cancer, and melanoma, highlights suspected tumour areas in lymph-node whole slide images (WSI). This evaluation measures its impact on diagnostic accuracy, workflow efficiency, and cost savings from fewer immunohistochemistry (IHC) requests.
Methods: Four histopathologists with varying experience levels independently reviewed WSIs representing macro-metastases, micro-metastases, isolated tumour cells (ITCs), and negative WSIs. Each completed two assessments—one with AI assistance and one without—separated by four weeks. Slide order and rotation were randomized to reduce bias. Diagnostic labels were compared to ground truth, while review times were recorded to assess efficiency. Time savings, along with Positive Predictive Value (PPV), Sensitivity, and False Positive Rate (FPR), were calculated. IHC savings for breast cancer and melanoma were estimated using Monte Carlo simulation, incorporating relevant diagnostic guidelines and the performance gains observed with AI assistance.
Results: A total of 105 WSIs were evaluated: 30 macro-metastatic, 30 micro-metastatic, 15 ITCs, and 30 negative. DeepPATH–LYDIA assistance improved all performance metrics. PPV increased for macro (95.2% vs. 89.8%), micro (94.3% vs. 87.9%), and ITCs (87.2% vs. 64.9%). Sensitivity also improved: macro (98.3% vs. 95.0%), micro (82.5% vs. 78.3%), and ITC (68.3% vs. 40.0%). FPR was lower with AI assistance (5.0% vs. 10.8%). Review times were reduced across all categories—up to 1.5× for macro, 2.4× for micro, 1.7× for ITC, and 2.2× for negative slides. IHC savings, tailored to breast-cancer and melanoma use-cases, reached up to €11 and €63 per case, respectively.
Conclusion: DeepPATH-LYDIA improves diagnostic accuracy, enhances efficiency, and reduces IHC costs compared to unassisted reviews, supporting its integration for AI-assistance into clinical practice for cancer staging.

3D HnE: optimising nucleic acid dye penetration for 3D histology

N.K.N. Chow[1,2], B.T.Y. Wong[1,2], L. Zhang[1,2], C.N. Yau[1,2], E.P.L. Tsoi[2,1], H.M. Lai[1,2]
[1]The Chinese University of Hong Kong, Department of Chemical Pathology, Faculty of Medicine, Hong Kong, Hong Kong, SAR of China, [2]The Chinese University of Hong Kong, Li Ka Shing Institute of Health Sciences, Faculty of Medicine, Hong Kong, Hong Kong, SAR of China

Background & Objectives: Histology plays a crucial role in elucidating tissue microarchitecture and diagnosing diseases. However, histology has been limited to a 2D tissue section. Recently, a new technology called 3D histology has enabled the visualisation of tissues in 3D, but 3D histology is currently limited by insufficient dye penetration. We aim to develop a staining method called 3D Haematoxylin analogue and Eosin (3D HnE) to increase the penetration depth of a nucleic acid dye.
Methods: Since 3D histology is fluorescence-based, we selected SYTOX orange, a DNA- and RNA-binding dye to mimic haematoxylin staining. The 3D histology protocol consisted of fixation, delipidation, staining and clearing. In the staining step, we used different combinations of supramolecular hosts and organic solvents. To quantify dye penetration depth, we cut the stained tissue in half and imaged the cut-face with a confocal microscope.
Results: We tested 8 supramolecular hosts and 8 organic solvents. SYTOX in water stained only the tissue edge brightly and showed the least penetration depth (70 μm). The addition of sulfobutylether-β-cyclodextrin (SBECD) improved the penetration depth to 130 μm. On top of SBECD, addition of most organic solvents further increased penetration depth, showing a synergistic effect between SBECD and organic solvents. Among organic solvents, the addition of 50% tetrahydrofuran (THF) and 50% 1-methylimidazole (1-MI) achieved the best penetration depths (600 μm, 900 μm). We also tested numerous supramolecular hosts. SBECD achieved the best penetration depth among all supramolecular hosts.
Conclusion: To the best of our knowledge, we are among the first research groups to develop a specific strategy for optimising nucleic acid dye penetration. This allows imaging of a large piece of tissue, overcoming a major limitation in 3D histology. Moreover, 3D HnE does not require trained technicians or specialised equipment, facilitating a wider adoption in biomedical research and clinical histopathology.

PS-02-012

Next generation histopathology: a 3D atlas of normal and cancer tissues

N.K.N. Chow[1,2], B.T.Y. Wong[1,2], L. Zhang[1,2], C.N. Yau[1,2], E.P.L. Tsoi[1,2], H.M. Lai[1,2]
[1]The Chinese University of Hong Kong, Department of Chemical Pathology, Faculty of Medicine, Hong Kong, Hong Kong, SAR of China, [2]The Chinese University of Hong Kong, Li Ka Shing Institute of Health Sciences, Faculty of Medicine, Hong Kong, Hong Kong, SAR of China

Background & Objectives: Histopathology has traditionally been limited to 2D tissue sections, which fail to display the full 3D context of tissue microarchitecture. To overcome this, we have made advances in 3D histology by inventing the 3D Haematoxylin analogue and Eosin (3D HnE) staining method. Here, we apply 3D HnE to normal and cancer tissues to construct a 3D histological atlas.
Methods: The workflow of 3D histology was different from the traditional 2D histology. The tissue was first fixed with 4% formaldehyde. Then, the tissue was delipidated with 66% dichloromethane. The tissue was rehydrated and stained with the 3D HnE staining solutions. The tissue was then dehydrated and cleared with benzyl alcohol-benzyl benzoate. A confocal microscope or light-sheet microscope was used for imaging. ImageJ and Matlab were used for converting fluorescent images into bright-field haematoxylin and eosin (H&E) images.
Results: With the 3D histology workflow, we imaged mouse and human tissues including ileum, pancreas, spleen, lung, colon cancer and breast cancer. Interestingly, in the ileum tissue sample, we could observe the 3D transition from intestinal villi to intestinal crypt, as well as the myenteric ganglion embedded between the inner circular and outer longitudinal smooth muscle layers. In the pancreas and spleen samples, we could view the 3D distribution of tissue components, including pancreatic acini and islets, splenic red and white pulp. In the lung sample, we could visualise the 3D shape of alveoli. In the colon cancer and breast cancer samples, we could view the dysplastic glands with a distorted 3D architecture.
Conclusion: We have constructed a 3D histological atlas of normal and cancer tissues, which could serve as a valuable reference for histopathologists. 3D histology could advance the understanding of 3D tissue microarchitecture, such as the characterisation of 3D glandular morphology.

PS-02-013

Artificial intelligence prediction of clinicopathological factors and LRRC15-immunolabeled Cancer-associated-Fibroblast level in colorectal carcinoma using attention-based multiple instance learning

J. Lee[1], M. Fan[2], S.-M. Hong[3], Y. Kim[4]
[1]Korea University Guro Hospital, Seoul, Republic of Korea, [2]AIVIS Incorporation, Seoul, Republic of Korea, [3]Asan Medical Centre, Seoul,

Republic of Korea, [4]Asan Institute for Life Sciences, Seoul, Republic of Korea

Background & Objectives: Leucine-rich repeat-containing 15 (LRRC15) expression in cancer-associated fibroblasts (CAFs) correlates with poor prognosis across multiple cancer types. Traditional immunohistochemical (IHC) assessment of LRRC15 is labor-intensive, subjective, and requires specialized staining beyond routine H&E. We aimed to develop an innovative AI approach that could predict LRRC15 expression levels and key clinicopathological factors (specifically pT, pN categories) directly from H&E-stained images.
Methods: We developed a novel two-pronged approach: First, for direct LRRC15 quantification in IHC slides to generate ground truth values, we implemented a novel encoder-decoder model incorporating YOLOv8 detection on 2,980 CAF-area patches (512×512 pixels) from LRRC15-immunolabeled TMA slides. Using 50 annotated patches with bounding boxes and staining intensity scores (0-3), we created a linear-weighted H-score system (range 0-5) emphasizing higher staining intensities. Then for H&E-based prediction of pT, pN categories and LRRC15 H-score, we designed an innovative weakly supervised attention-based multiple instance learning (MIL) framework. This model was trained and tested with dataset spilt on 82 colorectal cancer cases to predict LRRC15 expression levels, muscle invasiveness (≥pT2), and nodal metastasis status (pN0 vs. pN+) directly from H&E patches without requiring IHC staining.
Results: Our dual-model system achieved remarkable performance. The encoder-decoder YOLOv8 model provided objective LRRC15 quantification with H-scores ranging from 1.0 to 2.84 (median 1.18), with 80% accuracy. The attention-based MIL model demonstrated high predictive accuracy from H&E slides alone, achieving 80% accuracy in identifying high LRRC15 expression (grade 3), 83.3% accuracy in predicting muscle invasive carcinoma (≥pT2), and 81.82% accuracy in identifying pN0 status.
Conclusion: Our innovative AI approach successfully bridges the gap between routine H&E histology and specialized biomarker assessment. The attention-based MIL framework effectively extracts predictive features from standard H&E images to simultaneously predict LRRC15 expression and critical clinicopathological factors, offering a cost-effective alternative to special staining, with potential in treatment stratification and prognostic assessment.

PS-02-014
Sparkling Science Project "DigiPath Cancer Fight" – reaching pupils through digital pathology
T.M. Godschachner[1], M. Kern[1], I. Speicher[1], M. Plass[1], C. Stumptner[1], M. Köhler[1], N. Bordag[2], H.-M. Stummer[2], E. Schadelbauer[2], A. Pessentheiner[2], I. Brcic[2]
[1]Medical University of Graz, D- &R- Institute of Pathology, Graz, Austria, [2]Medical University of Graz, Department of Dermatology and Venereology, Graz, Austria

Background & Objectives: Cancer remains one of the leading global health challenges, with accurate diagnosis being crucial for effective treatment. Digital pathology, enhanced by artificial intelligence (AI) and machine learning (ML), has revolutionized histopathological analysis, improving diagnostic precision and efficiency. This project aims to engage pupils in digital pathology and cancer research through interactive learning experiences. The pupils actively participate in research by generating their own datasets for training AI tools, which are then cross-evaluated by pathology experts and AI models.
Methods: In collaboration with Medical University of Graz (University Clinic of Dermatology and Venerology, D&R Institute of Pathology, and BBMRI.at), pupils (aged 12-18) from three secondary schools in Graz/Austria participate in workshops and hands-on training sessions where they learn about pathology and biobanking. Furthermore, they explore whole-slide imaging (WSI), actively use digital pathology tools (QuPath) and annotate data. Activities include working with anonymized datasets, analysing tissue samples, and applying AI-assisted diagnostic techniques. The project is funded by the ÖAD (Agency of Education and Internationalisation) and the Federal Ministry of Education, Science, and Research in Austria.
Results: Pupils gain fundamental knowledge in cancer biology and prevention, biobanking, pathology, and digital diagnostics. They actively create annotated datasets for ML algorithms. Comparative analysis between pupil-annotations, expert pathologists, and AI models provides valuable insights into the accuracy of machine-assisted diagnostics. The increased interest in medicine, science, and technology careers among participants highlights the project's educational impact.
Conclusion: This initiative successfully bridges the gap between education, research, and healthcare technology by integrating pupils into the evolving field of digital pathology. By fostering early exposure to biomedical innovation, the project enhances scientific literacy and promotes the development of future professionals in medicine, life sciences, and AI. The findings will be disseminated through scientific conferences, public outreach events, and online platforms to raise awareness of digital innovations in cancer research and diagnostics.

PS-02-015
Utilizing the report structure when extracting information from free text reports via natural language processing and an open large language model
M. Bonert[1], E. Ho[2], F. Wang[2], H. Daneshvar[3], A. Naqvi[1]
[1]McMaster University, Pathology and Molecular Medicine, Hamilton, Canada, [2]McMaster University, Hamilton, Canada, [3]Toronto Metropolitan University, Electrical, Computer & Biomedical Engineering, Toronto, Canada

Background & Objectives: Free text pathology reports are still common and cannot be easily analysed to extract aggregate data. Open multi-lingual large language models (LLM), such as BERT, may be adaptable to healthcare environments, where privacy is paramount.
Methods: A code base on GitHub leveraging Hugging Face, pyTorch and BERT was used to do transfer learning on lower endoscopy biopsy specimens (LEBS). Reports were processed to extract the LEBS and a subset was labelled by two individuals with the help of rule-based string matching (RBSM). A keyword search was used to identify fragments of interest (FOIs) which were then used to train a multilayer perceptron-BERT model (MLP-LLM) and used to help classify all specimens.
Results: The cohort had 188,880 LEBS and 1,290 were labelled. The RBSM suggested that pathology specimens can be classified into three groups: GR1 (positive for X), GR2 (negative for X) and GR3 (X not mentioned), where X (e.g. "granuloma") is a term of interest. The RBSM could separate GR1/GR2 versus GR3; however, it failed on GR1 versus GR2. Thus, the labelled data was used to extract 720 FOIs geared to GR1 (134/720) versus GR2 (586/720). 15,827 of 188,880 cases were GR1+GR2. By MLP-LLM, 1,344 were GR1 and the accuracy of GR1 versus GR2 was 1494/1500 in randomly selected GR1+GR2 LEBS. Five training/validation/testing splits yielded a mean (standard deviation) accuracy of 97.6%(1.5%) in testing and 97.5%(3.1%) in a balanced GR1+GR2 set (n=268). GR1+GR2 had 2,152 unique phrases and 1,374 were singular. The 30 least common accounted for 33.0% of the GR1+GR2 cases.
Conclusion: The analysis demonstrated quantitatively the variation in free text reporting and confirmed that RBSM alone is not viable in LEBS. Understanding the inherent structure of free text reports allow them to be more accurately analysed. Transfer learning uses moderate computational resources and delivers a high accuracy with appropriate pre-processing.

PS-02-016

AI-based estimation of tumour cell percentage in NSCLC: agreement analysis and feature overview from digital pathology algorithms

M. Brevet[1,2], W. Althakfi[3], T. Vidal[1], A. Fonseca[2], J. Adam[4], F. Mege-Lechevallier[2]
[1]BIWAKO, Lyon, France, [2]TECHNIPATH, Dommartin, France, [3]King Saud University, Pathology Department, Riyad, Saudi Arabia, [4]Hôpital Saint-Joseph, Paris, France

Background & Objectives: Estimation of tumour cell percentage (TC%) is a mandatory pre-analytical step before molecular testing in non-small cell lung cancer (NSCLC) yet remains poorly reproducible and imprecise when performed manually by pathologists. While tumour recognition relies on pathologist expertise, TC% quantification is a mathematical task for which the human eye is poorly suited.
Methods: This study presents the application of two artificial intelligence (AI)-based algorithms to 100 NSCLC whole-slide images scanned with a Leica GT450. These tools provide quantitative features such as total tissue area, tumour area, TC%, number of tumour and non-tumour cells, and proportions of necrosis or mucin when available. Manual TC% estimations by two pathologists were collected for comparison but not used as ground truth.
Results: Among the 100 cases, both algorithms provided interpretable results for over 90% of slides. The agreement between algorithms was high, with a mean TC% difference of 1.54% and a standard deviation of 5.71%. In contrast, inter-pathologist variability showed a mean TC% difference of 23.58% with a standard deviation of 16.51%. The average TC% provided by the AI was 24.38% (SD: 17.62%). In contrast, the average TC% estimated by the pathologists was 47.49% (SD: 26.23%), with wider discrepancies observed in samples with low tumour cellularity, potentially leading to overestimation risks.
Conclusion: These findings highlight the improved agreement and objectivity of AI tools for TC% quantification. Their implementation may help reduce variability and support consistent sample triage for molecular analysis. These tools are especially valuable for digital pathology workflows and for molecular biology platforms. A follow-up study is underway to extend this agreement analysis to other tumour types.

PS-02-017

Predicting microsatellite instability in colorectal cancer H&E-stained whole slide images with interpretable deep learning

W. Aswolinskiy[1], C. Aichmüller[1]
[1]PAICON GmbH, Heidelberg, Germany

Background & Objectives: Microsatellite instability (MSI) is a clinically relevant biomarker for colorectal cancer with an increasing number of deep learning approaches using H&E staining for its prediction. We developed an interpretable deep learning model to predict MSI and investigated its performance in combination with tissue type analysis to quantify the amount of tissue required for accurate prediction and improve interpretability.
Methods: We used additive multiple instance learning (Add-MIL), an approach that requires only slide-level labels for training and can assign a probability to each patch (small image tile) of the whole slide image, allowing efficient evaluation of each patch's contribution to the prediction. For the approach, we used the foundational model H-optimus-0 at 1 µm/px with 224x224 px patches. The training set consisted of 1401 colorectal slides (214 MSI) from TCGA and CPTAC databases. Evaluation was performed on two external cohorts with 250 (100 MSI) and 850 (87 MSI) resection slides, respectively. To assess the tissue type, we used a publicly available segmentation model from the tia-toolbox to determine which patches predominantly contained tumour.
Results: The model achieved an area under the receiver operating characteristic (AUC) of 0.951 on the small and 0.909 on the large evaluation dataset. When limited to tumour patches (comprising 24% and 28% in the small and large cohorts, respectively), the AUC decreased slightly to 0.945 and 0.895. Using only the top 100 patches with the highest MSI scores moderately decreased performance to AUCs of 0.937 and 0.886, respectively.
Conclusion: Add-MIL yielded high performance while allowing greater insight into the results, especially when combined with tissue segmentation. Our findings demonstrate that MSI status can be determined accurately even from a limited number of informative tissue regions. Future work includes more fine-grained analyses and extending the evaluation to biopsies, where only a limited amount of material is available.

PS-02-018

Fast tissue origin classification for quality control in digital pathology with deep learning

W. Aswolinskiy[1], J. Wong[1], M. Zapukhlyak[1], C. Aichmüller[1]
[1]PAICON GmbH, Heidelberg, Germany

Background & Objectives: Digitalization of large histopathology archives requires processing and validating millions of scanned whole slide images in a limited amount of time. We aim to automatically classify the tissue origin (organ) of H&E-stained slides within one second to enable efficient quality control in digital pathology. Such rapid classification can support the detection of mislabeled slides early in the workflow.
Methods: We trained a deep learning model using thumbnails (1024×1024 pixels) from 11,579 diagnostic images from TCGA and 5,045 from CPTAC. The images were categorized into 14 classes based on the most common tissue types in TCGA: Bladder, Brain, Breast, Colorectal, Kidney, Liver, Lung, Pancreas, Prostate, Skin, Stomach, Thyroid gland, Uterus and Other (encompassing the remaining tissue types). We used a ConvNeXt-Small architecture, pretrained on ImageNet, and trained it using five-fold cross-validation with early stopping. The resulting model ensemble was evaluated on two independent external cohorts: a smaller cohort with 2,876 slides across five classes (Colorectal, Kidney, Liver, Pancreas, Prostate) and a larger cohort with 7,773 slides across all 14 classes. For evaluation, we extracted the thumbnail of the largest tissue component within each slide, identified via contrast-based thresholding.
Results: The model achieved a balanced accuracy of 93.1% on the 5-class cohort and 78.1% on the full 14-class cohort. Notably, when considering only the predictions with high confidence, 50% of the large cohort could be classified with 90% balanced accuracy. The inference time was approximately 60 milliseconds per slide using an RTX 3090 GPU.
Conclusion: Our deep learning approach demonstrates high classification performance with very low inference time, indicating its potential for real-time and cost-effective quality control in digital pathology. Future work includes expanding to more tissue types and more detailed evaluation on challenging cases such as metastases.

PS-02-019

Implementing an AI-assisted digital system in real-world practice: the IMP diagnostics experience

C. Fleming[1], R. Vieira[1], D. Montezuma[1,2], A. Monteiro[1], A. Furtado[1], I. Macedo-Pinto[1]
[1]IMP Diagnostics, Porto, Portugal, [2]Portuguese Oncology Institute of Porto (IPO Porto), Porto Comprehensive Cancer Centre Raquel Seruca (Porto.CCC), Cancer Biology & Epigenetics Group, Porto, Portugal

Background & Objectives: Digital Pathology (DP) provides a significant opportunity to optimize workflows but its integration into clinical practice requires significant adjustments. We outline a strategic framework for implementing the Genius™ Digital System (Hologic), an AI-driven platform for cervical cancer screening, detailing the strategies employed to address real-world challenges in a high-volume pathology laboratory.
Methods: A redesigned workflow transitioned traditional analog cytology to digital. Training occurred in two stages: an initial hands-on session by Hologic, including case reviews and competency assessment, followed by internal training, to reinforce new diagnostic protocols and ensure staff proficiency (n=1300 cases; 8 participants). Routine roll-out began in May 2024, with continuous monitoring and iterative adjustments. A satisfaction survey (1-5) was conducted and workload capacity was reassessed post-implementation. Descriptive statistical analysis was performed (Microsoft®Excel®2019).
Results: IMP Diagnostics processes ≈90,000 gynaecologic cytology exams annually, scanning 90% (liquid-based). Workflow modifications included batch registration (vs. continuous daily registration), updating staining protocol, and using dedicated workstations. In the internal training set, 22 additional cases of ≥LSIL were identified using the digital system (firstly interpreted as negative in the traditional screening). Early challenges included delays in service distribution due to unexpected increase in exam volume, initial learning curve, limitations from using three workstations, and hardware issues. In response, staff schedules were revised and an extra workstation and second scanner were added. Staff satisfaction surveys showed high ratings for ease of navigation (4.8), diagnostic quality (3.9), and overall system performance (4.1), demonstrating confidence in the system. The digital platform allowed resident cytotechnicians to screen 2-3x more cases daily.
Conclusion: Our experience implementing an AI-assisted digital cytology system offers valuable insights for laboratories transitioning to DP. Our findings show improved efficiency and diagnostic accuracy. By sharing our challenges and solutions, we provide a practical framework for similar initiatives.

PS-02-020

Optimizing deep learning image analysis model training using uncertainty metrics-guided selection of regions of interest in non-small cell lung cancer

A. Shumilov[1], C. Gebbe[1], P. Wortmann[1], M. Rosati[1], Z. Kokaragac[1], H. Hessel[1], S. Haneder[1], N. Triltsch[1], O. Badmos[1], T. Wiestler[1]
[1]AstraZeneca Computational Pathology GmbH, Munich, Germany

Background & Objectives: Supervised deep learning models for analysing immunohistochemically stained histology images require high-quality annotated regions for training. However, manual selection of the regions of interest (ROIs) for annotation on histology slide images is time-consuming and subjective. This study investigates the use of uncertainty metrics to guide ROI selection, aiming to improve model performance while reducing annotation efforts during model development. We hypothesize that concentrating on annotating areas where the model exhibits lower prediction confidence (i.e., regions of high uncertainty) can improve training efficiency and model's accuracy.
Methods: We applied an existing deep learning model (baseline model) to 120 IHC-stained non-small cell lung cancer (NSCLC) slides. Based on the model's prediction errors, a pathologist selected and annotated 457 regions of interest (ROIs). Using Monte Carlo Dropout, we measured the model's uncertainty and categorized these ROIs into four groups (Q1–Q4), with Q1 representing regions of highest uncertainty. New models were trained on different subsets of this training data: all 457 ROIs, only the highest uncertainty ROIs (Q1), only the lowest uncertainty ROIs (Q4), combined high-uncertainty ROIs (Q1 and Q2), and combined low-uncertainty ROI groups (Q3 and Q4). We then compared models' performance on an independent test set of 198 ROIs from 70 slides, annotated by three independent pathologists.
Results: Models trained on high-uncertainty ROIs (baseline model+Q1, 115 ROIs) consistently outperformed those trained on lower-uncertainty regions (baseline+Q4, 113 ROIs), demonstrating a significant 12.1% improvement in predictive accuracy (F1 score 0.805 vs 0.774).
Conclusion: Uncertainty-guided ROI selection provides a promising strategy to optimize computational pathology model training, improving performance and streamlining annotation workflows. Our results suggest that incorporating uncertainty-based ROI selection enhances model learning efficacy, potentially reducing the number of ROIs that pathologists need to annotate for model development. Future work will expand the application to additional datasets and evaluate its utility beyond NSCLC.

PS-02-023

AI-assisted macroscopic assessment of lung resections: a pilot study

R. Marques[1], Y. Zhu[2], A. Alsalemi[2], S. Raza[2], A. Azam[1]
[1]University Hospitals Coventry & Warwickshire, Cellular Pathology, Coventry, United Kingdom, [2]University of Warwick, Tissue Image Analitics Centre, Coventry, United Kingdom

Background & Objectives: The recent implementation of the NHS Lung Cancer Screening Program in the UK has resulted in a rise in early-stage diagnoses, which has subsequently increased the workload for histopathology departments and specimen complexity. Macroscopic assessment is a crucial yet time-consuming step in pathology, that requires specialised expertise to accurately identify and sample tumour areas. This study aims to develop and compare three AI-driven algorithms for analysing macro photographs of lung specimens, providing automated detection, classification, and mapping of lung tumours.
Methods: A total of 184 macro photographs were collect from 117 lung resection specimens, which included both benign and malignant cases. Each image was labelled with segmentation annotations to highlight abnormal areas, such as non-neoplastic changes, benign neoplastic lesions, and malignant neoplastic tumours. We developed, fine-tuned and tested three deep learning segmentation models, including U-Net, ConvNeXt V2 and Segment Anything Model (SAM), to identify abnormal regions, comparing their performance in detecting lung lesions on macro photographs.
Results: The fine-tuned SAM model achieved high accuracy in identifying abnormal lung regions on macro-images (F1: 0.74; Dice: 0.75), outperforming U-Net (F1: 0.17; Dice: 0.23) and ConvNeXt V2 (F1: 0.72; Dice: 0.62), indicating its potential to assist with accurate tumour sampling.
Conclusion: The Segment Anything Model demonstrates promising performance in the segmentation task, utilising data that reflects real-world variability. These findings suggest that this AI tool can streamline macroscopic assessment of lung specimens, improving the consistency in tumour sampling. Additionally, it can support pathologists in managing increasing case volumes and assist in training new junior doctors. Integrating AI into macroscopic analysis, may contribute to faster, standardised specimen processing and improved diagnostic workflows. Further validation on a larger dataset is essential to refine its clinical applicability and integration into routine practice.

PS-02-024

AI-based automatic analysis of sputum smears stained Ziehl-Neelsen used as screening tool for tuberculosis

S. Zurac[1], A.B. Witarto[2], B. Ceachi[3,4], C. Popp[3], F.E. Sari[5], N. Putranto[5], S. Pratama[5], B.P. Octavianus[6], L. Nichita[1], J. Gerald Dcruz[7], C. Mogodici[7], M. Cioplea[3], L. Sticlaru[1], M. Busca[3], O. Stefan[3], I. Tudor[3], C. Dumitru[3], P. Mustatea[8], A. Bastian[1]

[1]University of Medicine and Pharmacy Carol Davila, Colentina University Hospital, Pathology, Bucharest, Romania, [2]Faculty of Medicine and Health Sciences, Indonesia Defense University, Kawasan, Medical Biodefense Research Centre, Sentul, Indonesia, [3]Colentina University Hospital, Pathology, Bucharest, Romania, [4]National University of Science and Technology Politehnica Bucharest, Faculty of Automatic Control and Computer Science, Bucharest, Romania, [5]Faculty of Medicine and Health Sciences, Indonesia Defense University, Medical Biodefense Research Centre, Sentul, Indonesia, [6]Badan Kesira Gerindra, Pasar Minggu, Indonesia, [7]Zaya Artificial Intelligence, Voluntari, Romania, [8]University of Medicine and Pharmacy Carol Davila, Surgery, Bucharest, Romania

Background & Objectives: Tuberculosis is the main cause of death by infectious diseases world-wide. Mycobacterium tuberculosis can be identified in sputum or tissue for positive diagnosis and in screening programs especially in high incidence of tuberculosis regions.
Methods: Microscopic identification of Mycobacterium tuberculosis in Ziehl-Neelsen (ZN)-stained sputum smears is extremely time consuming, thus not entirely suitable for screening on a large number of subjects. We previously presented an algorithm able of automatic detection of Mycobacterium tuberculosis on tissue stained with ZN with very good results (specificity of 100%, sensitivity of 95.65% and accuracy of 98.33%).
We tested the performances of this algorithm on 1059 ZN-stained sputum smears as a possible tool in screening. The slides were scanned with automatic scanners Leica Aperio AT2 and GT450 40× scanning mode in one plane without Z-stacked images. The results of the algorithm were displayed as a heat-map of 32x32pixels patches in batches of different levels of confidence with an increment of 5: (95-100], (90-95], etc. Each patch could include one or more bacilli, either single or in clusters.
Results: The analysis of the positive patches reveals a good specificity (86.84%) and 100% sensitivity for patches with level of confidence over 90; the accuracy remains over 95% for all level of confidence over 80 except the class (95-100]. Problems with specificity (13.16% false positive results) are caused by peculiarities of sputum smear appearance (uneven thickness, dust contamination, lack of coverslip) but this is expected in screening. Further training of the algorithm on sputum smears will be perform to increase the specificity over 95%.
Conclusion: Even in its current form, our algorithm is suitable for screening since its results show no false negative results; in this manner the persons with highest risks to disseminate the infection are identified and further diagnosed and treated

Funding: This research was partially funded by a grant of the Ministry of Research, Innovation and Digitization, CNCS–UEFISCDI, project number PN-III-P4-PCE-2021-0546, within PNCDI III (no. PCE 109/2022)

PS-03 Poster Session Head & Neck Pathology

PS-03-001

Diagnosis of amyloidosis with minor salivary gland biopsy: case series

B. Kaliullayev[1], N. Vicente[1], D. Ayquipa-Arróspide[1], R.M. Penin[1], J. Bosch-Schips[1], F. Gómez[2], A. Pardo[3], A.M. Rau[2], M. Gomà[1]
[1]Bellvitge University Hospital, Anatomic Pathology, Barcelona, Spain, [2]Bellvitge University Hospital, Nephrology, Barcelona, Spain, [3]Hospital Universitario San Pedro, Nephrology, Logroño, Spain

Background & Objectives: The minor salivary gland biopsy (MSGB) is a sensitive and low-invasive method to diagnose amyloidosis. Another advantage of MSGB is related to distinct distribution patterns of amyloid deposits within the salivary gland in case of different types of amyloidosis. The current study describes our experience of diagnosing amyloidosis on the base of MSGB.
Methods: Retrospective study of all MSGB with the clinical suspicion of amyloidosis performed at our centre between 2023-2025. The diagnosis of amyloidosis was based on histologic evaluation of H&E MSGB slides and positivity for Congo red stain with the assessment of amyloid distribution pattern. Immunohistochemical (IHC) subtyping of amyloidosis was performed with antibodies against serum amyloid A protein, transthyretin and kappa and lambda light chains.
Results: The study included MSGB from 32 patients whose median age was 73 years old (range: 50-92). There was female predominance (18/32, 56%). In 18 cases (56%), the diagnosis of amyloidosis was confirmed; in 16 of them the amyloid was subtyped. AL amyloidosis was detected in 8 patients (53%), AA amyloidosis in 6 (40%) and wild-type transthyretin amyloidosis (ATTR) in 1 (7%). Among patients with AL amyloidosis, 6 had been previously diagnosed with monoclonal gammopathies. The underlying pathology in AA amyloidosis was determined in 3 cases and included familial mediterranean fever, chronic osteomyelitis and rheumatoid arthritis. One patient was diagnosed with AL and concurrent ATTR with MSGB and endomyocardial biopsy, respectively. Histologically, both AL and AA amyloidoses had a predominant basement membrane (BM) distribution pattern (94%) with minor vascular and interstitial patterns. In the ATTR case, nodular amyloid deposits were observed.
Conclusion: AL and AA amyloidoses were almost equally prevalent in our series without traditionally described predominance of the former. Histologically, AL and AA amyloidoses were indistinguishable, both demonstrating BM pattern that in our opinion can be overlooked mimicking salivary gland atrophy.

PS-03-002

Evaluating tumour budding in laryngeal squamous cell carcinomas: a comprehensive study of the largest Indian cohort with insights on prognostic implications and clinical outcome

A. Toshniwal[1], S. Mehta[1], R. Shah[1], P. Trivedi[1]
[1]The Gujarat Cancer and Research Institute, Ahmedabad, India

Background & Objectives: Tumour budding(TB) is a promising prognostic predictor in many carcinomas. Yet its utility and importance is underexplored in laryngeal squamous cell carcinoma (LSCC). The objectives of this study were: (1) to assess TB (tumour budding score, maximum tumour budding/hpf, total tumour budding/10 hpf) in LSCCs; (2) to investigate its association with clinical and histopathological parameters; and (3) to determine its prognostic significance.
Methods: This study is the largest Indian study on LSCC, analysing 94 cases from total laryngectomy specimens over five years.
Results: The cohort comprised 85 men and 9 women, aged 38–76 years. Most tumours (63.82%) had transglottic involvement, with 73.4% being moderately differentiated. The majority were in pT4a stage (71.27%). Nodal involvement was present in 45% of cases. Lymphovascular invasion (31.9%) and perineural invasion (38.29%) was recorded. Tumour budding was high (>10 buds/hpf) in 9.5%, moderate (5-9 buds/hpf) in 30.85%, and low (1-4 buds/hpf) in 59.57%. Significant correlations were found with N stage ($p \leq 0.01$), lymphovascular invasion ($p = 0.04$), T stage ($p = 0.02$), perineural invasion ($p = 0.02$), and lymphocytic stromal response ($p = 0.02$). These results suggest that greater tumour budding is linked to more aggressive cancer characteristics and worse prognosis.
Follow-up at six months was available for 66 patients, with 3 showing recurrence within 6 months. Higher tumour budding showed significant association with recurrence($p \leq 0.03$).
Over a period of 8 to 20 months, 10 patients developed recurrence. Of these, 6 had recurrence in the neck nodes, 2 at the operated site, and 2 at both the operated site and in the neck nodes. Additionally, 2 patients later developed lung metastasis.

Conclusion: As the largest Indian study on LSCC, this research highlights that tumour budding is an independent prognostic marker and necessitates the need to standardize the assessment of TB in larynx.

PS-03-003

Gnathic metastases: a 10-year retrospective analysis of rare bone and soft tissue malignant involvement

D. Proca[1], D. Doan[1], M. Jabbar[1], K. Firde[1], A. Tushir[1], R. Kuklani[1]
[1]Temple University, Pathology, Philadelphia, USA

Background & Objectives: Metastases to the bone and soft tissues of the jaws are extraordinarily rare, often signifying advanced-stage cancer and a poor prognosis. This study investigates the clinicopathologic features of 14 metastatic neoplasms involving the oral region and diagnosed at our institution over a decade.
Methods: We searched EPIC and COPATH for all cases signed as metastatic tumours in the past decade at Temple University. Inclusion criteria consisted of the following:
(a) Archived cases from our institution, diagnosed between 2013 and 2023, with available haematoxylin and eosin (H&E) and immunohistochemical slides.
(b) Adequate documentation of clinicopathologic characteristics of jaw metastases, along with a confirmed history of primary malignancy.
(c) Microscopic findings indicative of metastatic disease, regardless of whether the primary site was identified.
Results: A total of 14 cases of oral metastases were identified, comprising 4 cases (29%) in men and 10 cases (71%) in women, with a median age of 69 years (range: 43–89 years).

- **Anatomic location:** 2 cases (14.2%) involved the oral soft tissues, 7 cases (50%) occurred in the posterior mandible, 3 cases (21.4%) in the anterior mandible, and 2 cases (14.2%) in the maxilla.
- **Clinical associations:** 4 cases (28.5%) were linked to extraction sites, and 4 cases were initially misdiagnosed as pyogenic granuloma.
- **Primary sites:** The most common primary site was the breast (n = 5, 35.7%), followed by cases with an unknown primary origin (n = 5, 35.7%). Other identified primary sites included kidney (n = 1, 7.1%), colon (n = 1, 7.1%), lung (n = 1, 7.1%), and thyroid (n = 1, 7.1%).

Conclusion: Metastases in the jaws are exceedingly rare, representing 1% of tumours in this area. Greater awareness in the differential diagnosis is essential, as these lesions often mimic inflammatory, reactive, or benign processes, and, sometimes, may represent the first clinical manifestation of an occult malignancy.

PS-03-004

Mucin-rich salivary duct carcinoma: a distinct subtype or a new entity? Insights from transcriptomic analysis

Z. Alsugair[1], F. Descotes[1], D. Pissaloux[2], S. Paindavoine[2], F. Tirode[2], J. Lopez[1], P. Ceruse[3], P. Philouse[3], A. Champagnac[2], E. Uro-Coste[4], A. Siegfried[4], J. Bishop[5], N. Benzerdjeb[1]
[1]Groupment Hospitalier Lyon Sud, Lyon, France, [2]Centre Leon Berard, Lyon, France, [3]Hopital Croix Russe, Lyon, France, [4]Institut Universitaire du Cancer-Oncopole, Tolouse, France, [5]University of Texas Southwestern Medical Centre, Dallas, USA

Background & Objectives: Mucin-rich salivary duct carcinoma (SDC) is a rare and poorly characterized subtype of SDC. Conventional SDC shares molecular features with breast carcinoma, but the transcriptomic profile of mucin-rich SDC remains unclear. Given its distinct histopathological features, we aimed to explore the molecular characteristics of mucin-rich SDC through transcriptomic analysis and compare it with conventional SDC and pulmonary adenocarcinoma to better understand its classification.
Methods: We analysed three cases of mucin-rich SDC diagnosed in the parotid gland and palate. Immunohistochemistry (IHC) and molecular analysis, including next-generation sequencing (NGS), were performed. Whole Exome RNA sequencing and targeted transcriptomic profiling were conducted to assess gene expression patterns and clustering among mucin-rich SDC in comparison to conventional SDC and pulmonary adenocarcinoma. Hierarchical clustering analysis was performed to determine molecular similarities.
Results: All three cases demonstrated positive expression of CK7 and HER2, with variable expression of additional markers such as EMA and androgen receptors. Mutational analysis identified alterations, including KRAS (G13D) and PIK3CA (H1047R), among others. Transcriptomic profiling revealed that mucin-rich SDC cases clustered with pulmonary adenocarcinomas rather than with conventional SDC of the salivary glands. This molecular distinction suggests a different oncogenic pathway and possible implications for classification.
Conclusion: Mucin-rich SDC exhibits a transcriptomic profile that is more closely related to pulmonary adenocarcinoma than to conventional SDC. These findings suggest that mucin-rich SDC may represent a distinct molecular entity with potential diagnostic implications. Further studies with larger cohorts are needed to validate these observations and refine the classification of mucin-rich SDC.

PS-03-005

Prognostic impact of immune phenotype in oral squamous cell carcinoma

M. Hermanova[1], M. Herman[2], J. Michalek[3], R. Pink[2], K. Kopecka[2], J. Zapletalova[4], S. Hotarkova[1], M. Hendrych[1], Z. Bednarik[1]
[1]Faculty of Medicine, Masaryk University and St. Anne´s University Hospital Brno, First Department of Pathology, Brno, Czech Republic, [2]Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Department of Oral and Maxillofacial Surgery, Olomouc, Czech Republic, [3]Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Department of Clinical and Molecular Pathology, Olomouc, Czech Republic, [4]Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Department of Medical Biophysics, Olomouc, Czech Republic

Background & Objectives: In oral squamous cell carcinoma (OSCC), the current tumour-node-metastasis staging system fails to reliably identify high-risk patients, and potential biomarkers improving the risk, prognostic, and predictive stratification of OSCC are sought. Due to the importance of the tumour immune microenvironment in the development and progression of cancer, here we investigated the prognostic impact of the immune phenotype in OSCC.
Methods: The study included 119 OSCC patients treated by curative surgery. Densities of stromal and intra-tumoral tumour-infiltrating lymphocytes (TILs) were evaluated according to guidelines of the International Immune-Oncology Biomarker Working Group in haematoxylin and eosin-stained slides. Based on the extent and spatial distribution of TILs, the tumours were classified as immune-excluded, immune-inflamed, and immune-desert, immune phenotypes were correlated with clinicopathological parameters, and their prognostic significance was investigated. Survival analyses for disease-free, disease-specific, and overall survival were performed by the Kaplan-Meier method, and the prognostic value of immune phenotypes was assessed by Cox regression models.
Results: Immune-desert and immune-inflamed phenotypes significantly correlated with lymph node metastasis, higher stage and grade, infiltrative pattern of invasion, and perineural invasion. A significantly higher incidence of local recurrence was demonstrated in patients with immune-inflamed phenotype versus excluded-phenotype. In Kaplan-Meier analysis, the most prevalent immune-excluded phenotype displayed significantly better disease-free, disease-specific,

and overall survival, in contrast to shorter survival rates for immune-desert and immune-inflamed OSCC. Cox regression analyses showed an independent negative prognostic impact of both immune-desert and immune-inflamed phenotypes compared to immune-excluded OSCC, in all measured clinical endpoints including disease-free, disease-specific, and overall survival.
Conclusion: Our findings support that the histological evaluation of tumour immune phenotype might provide significant information on OSCC hazard discrimination, prognostication, and treatment decisions. The study identified the immune-desert and immune-inflamed OSCC phenotypes associated with worse prognosis reflecting the lack of pre-existing anti-tumour immunity or immunosuppressive tumour immune microenvironment.

Funding: Supported by the Ministry of Health, Czech Republic – conceptual development of research organization (FNOl, 00098892) and the Internal Grant Agency of Masaryk Univerzity (MUNI/A/1621/2024)

PS-03-006
Liquid biopsy in saliva: MMP-2, MMP-9, and TIMP-2 as potential biomarkers for oral squamous cell carcinoma
P.C. Castro Quiroga[1], S.D. Cruz Romero[1,2], P.A. Baldion[2], M. Baldion[1], J. Hakim[3], P.A. Rodriguez-Urrego[1]
[1]University Hospital Fundacion Santa Fe de Bogota, Pathology Department, Bogotá, Colombia, [2]National University of Colombia, Oral Health Department, Bogotá, Colombia, [3]University Hospital Fundacion Santa Fe de Bogota, Head and Neck Division, Bogotá, Colombia

Background & Objectives: Oral squamous cell carcinoma (OSCC) is a prevalent malignancy with a significant global burden. Early detection remains challenging. Matrix metalloproteinases (MMPs) and their tissue inhibitors (TIMPs) are associated with tumour invasion and metastasis. This study aimed to evaluate the diagnostic utility of salivary MMP-2, MMP-9, and TIMP-2 as potential non-invasive biomarkers for OSCC.
Methods: An observational cross-sectional study was conducted including 60 patients with histologically confirmed OSCC and 30 age- and sex-matched controls from the HEADSpace/Interchange Colombian cohort. Saliva and serum samples were collected to quantify biomarker levels using ELISA. Generic MMP activity in saliva was measured via fluorescence-based assays. Tissue microarrays were constructed from paraffin-embedded tumour blocks, and protein expression was evaluated by immunohistochemistry (IHC).
Results: MMP-9 and MMP-2 concentrations were significantly elevated in saliva from OSCC patients compared to controls (MMP-9: 936.47 ng/ml vs. 13.16 ng/ml; MMP-2: 79.93 ng/ml vs. 2.06 ng/ml; both $p<0.005$). Serum analysis confirmed increased MMP-9 levels (656.92 ng/ml). Salivary MMP activity was higher in the case group (134.86 RFU ±13.19) compared to controls (66.66 RFU ±14.66; $p>0.05$). IHC demonstrated significantly higher expression of MMP-9, MMP-2, and TIMP-2 in tumour tissues than in normal mucosa ($p<0.005$).
Salivary MMP-9 showed strong diagnostic performance (Sensitivity = 0.817, 1-Specificity = 0.133), as did MMP-2 (Sensitivity = 0.717, 1-Specificity = 0.367). Among tissue markers, TIMP-2 demonstrated the best performance (Sensitivity = 1.00, 1-Specificity = 0.00).
Conclusion: Salivary concentrations of MMP-2 and MMP-9 are significantly increased in OSCC patients, supporting their use as potential diagnostic biomarkers. These findings were consistent with serum levels, MMP activity, and IHC expression. Further studies are warranted to assess the prognostic value of these biomarkers in relation to recurrence, metastasis, and patient survival.

PS-03-008
MTAP loss correlates with favourable prognosis in HPV-independent, p16-negative oropharyngeal squamous cell carcinoma
H. Yamamoto[1], H. Hara[1,2], R. Kuga[2], T. Yamamoto[2], M. Taniguchi[2], T. Manako[2], Y. Oda[2]
[1]Okayama University, Pathology and Oncology, Okayama, Japan, [2]Kyushu University, Anatomic Pathology, Fukuoka, Japan

Background & Objectives: HPV-independent oropharyngeal squamous cell carcinoma (OPSCC) is an aggressive cancer, but molecular prognostic stratification has not been established. Deletion of *CDKN2A* (encoding p16) is a common genetic event in HPV-independent OPSCC. Homozygous deletion of *CDKN2A* is recognized as a poor prognostic factor in various tumours such as gliomas, and MTAP immunostaining serves as a surrogate marker for it. In addition, since MTAP is related to the methionine salvage pathway, various cancer cell lines with *MTAP* deletion are reported to exhibit increased sensitivity to the pyrimidine analog 5-fluorouracil (5-FU). In this study, we aimed to clarify the prognostic impact of expressions and homozygous deletions of *CDKN2A* (*p16*) and *MTAP* in OPSCC.
Methods: We examined *CDKN2A* (*p16*) and *MTAP* in 177 cases of OPSCC (106 HPV-positive, 71 HPV-negative), using immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH).
Results: MTAP loss by IHC was observed in 25.3% (16/63) of HPV-negative/p16-negative OPSCCs, and FISH confirmed the homozygous deletions of both *CDKN2A* and *MTAP*. All HPV-negative/p16-positive OPSCCs (n=8) and HPV-positive OPSCCs (n=106) did not show MTAP deficiency. The prognosis of HPV-negative/MTAP loss group (n=16) was significantly better than that of HPV-negative/MTAP-retained group (n=47), and was as favourable as HPV-positive group (n=106). Moreover, a similar trend was confirmed in HPV-negative OPSCC patients treated with pyrimidine-based chemotherapy (n=46).

Conclusion: These findings suggest that MTAP deficiency is closely associated with homozygous deletions of *CDKN2A* and *MTAP* in HPV-negative/p16-negative OPSCC. Furthermore, MTAP loss may be a favourable prognostic factor in HPV-negative OPSCC and this paradoxical phenomenon might be explained by the enhanced treatment efficacy to chemotherapy with pyrimidine analogs.

PS-03-009
Clinicopathological spectrum of salivary gland myoepithelial carcinoma of the head and neck region
A. Hange[1], M. Bal[1], S. Rane[1], N. Mittal[1], U. Sakhadeo[1], A. Patil[1], K. Kante[1]
[1]Tata Memorial Centre, Department of Pathology, Mumbai, India

Background & Objectives: Myoepithelial carcinoma (MECA) is a rare salivary gland tumour accounting for 0.1-0.45% of salivary gland neoplasms. MECA often arises from pleomorphic adenomas and exhibits aggressive behaviour with high recurrence and metastasis rates. Diagnosing MECA is challenging due to its histological overlap with benign and other malignant tumours.
This study aims to evaluate clinical and histological features and immunohistochemical profile of MECA, distinguish de novo cases from those arising in pleomorphic adenomas.
Methods: MECA cases of the head and neck region diagnosed at our institute from January 2014 to December 2023 were retrieved and reviewed. Clinical details were obtained from electronic medical records.
Results: A total of 58 cases (36 males, 22 females; M:F = 1.6:1) were analysed, with age range 14-80 years (mean 52.2 and median 51 years).

Minor salivary glands were more commonly involved as compared to major salivary glands (1.3:1), although the parotid gland was the most frequent site (34.5%). Tumours displayed lobulated and expansile invasion patterns Diverse cell morphologies were noted, predominantly epithelioid, followed by plasmacytoid, clear cell and spindle cell morphology, in a myxoid and/or hyalinised stroma. Architectural patterns included solid, nested, cord-like, and trabecular, with 63.8% showing a combination of these patterns.
Pre-existing pleomorphic adenoma was found in 24.1% of cases (8 in major and 6 in minor salivary glands). Immunohistochemistry confirmed myoepithelial differentiation, with SOX10 (86.4% cases) and S100 (87.8% cases) as reliable markers. Poorer recurrence-free survival (RFS) was linked to presence of necrosis ($p = 0.002$), invasive growth patterns ($p = 0.023$), mitotic index >4/10 HPFs ($p = 0.028$), and Mib1 proliferation index >6% ($p = 0.05$).
Conclusion: This is the largest series of MECA of head and neck region in Indian continent. Our study shows that presence of necrosis, infiltrative invasion, and high Mib1 proliferation are key predictors of poor outcomes in MECA.

PS-03-010
Superselective intra-arterial chemotherapy for p16+ oropharyngeal cancer: long-term outcomes
A. Filin[1], I. Moshurov[2,3], M. Olshansky[2,3], S. Stikina[2,3], V. Shishkina[4], E. Pershin[5], A. Fedortsov[3]

[1]Voronezh State Medical University, Department of Pathological Anatomy, Voronezh, Russia, [2]Voronezh Regional Clinical Oncology Centre, Voronezh, Russia, [3]Voronezh State Medical University, Department of Oncology, Voronezh, Russia, [4]Voronezh State Medical University, Department of Histology, Voronezh, Russia, [5]Voronezh Regional Pathological Bureau, Voronezh, Russia

Background & Objectives: Despite being accessible for visual examination, the incidence of oropharyngeal cancer continues to rise. Improving treatment efficacy for these patients remains a critical challenge. The aim of this study was to analyse long-term outcomes in patients with oropharyngeal cancer p16+ treated selective intra-arterial chemotherapy and chemoembolization in combination 3D conformal radiation therapy (RT).
Methods: The study included patients with stage III (T1-3N0-1M0) and IVa (T2-4N1-3M0) p16+ squamous cell carcinoma. The exclusion criterion was the presence of distant metastases. Patients were divided into two groups: I comprised 28 patients stage III– 9; IVa – 19. Treatment protocol for Group I involved superselective volume-controlled intra-arterial chemotherapy (SIAC) using an original modified PF regimen. Intra-arterial infusion of cisplatin (100 mg/m²) and 5-fluorouracil (250 mg/m²). Supplemented with daily intravenous 5-fluorouracil (750 mg/m²). Infusion duration: 45–60 minutes. Final: intratumoral vessel injection of cisplatin concentrate (10 mL). After SIAC in parallel RT is performed daily (70 Gy/35 fr). SIAC was repeated every 21 days (3–4 cycles). Group II included 28 patients: stage III– 16; IVa– 12. Treatment: PF regimen in parallel RT is performed daily (70 Gy/35 fr).
Results: The technical success - 100%. In Group I positive tumour response was observed 24 hours after SIAC. Overall response rate 100% in Group I (SSIAC + chemoradiotherapy); 72% in Group II (PF + RT) ($p < 0.01$). No statistically significant difference in adverse events was observed between the two groups. Median survival 25 months in Group II; 81% survival rate in I at 25 months ($p < 0.01$). 7-year survival: 58% - Group I; 36% - II.
Conclusion: This study demonstrates a significant improvement in 7-year survival for patients with p16+ oropharyngeal cancer when SIAC is incorporated into the chemoradiotherapy regimen. SIAC technique proved highly effective, with superior long-term outcomes compared to PF.

PS-03-011
Incidental thyroid carcinoma: assessing prevalence and subtype reporting practices at an Irish tertiary hospital
J. Byrne[1,2,3], E. O'Regan[1,2,4], R. O'Connor[1,2,4]
[1]St James's Hospital, Department of Histopathology, Dublin, Ireland, [2]Trinity St James's Cancer Institute, Dublin, Ireland, [3]Trinity College Dublin, School of Medicine, Dublin, Ireland, [4]Dublin Dental University Hospital, Division of Oral & Maxillofacial Surgery, Dublin, Ireland

Background & Objectives: Incidental thyroid carcinoma (ITC) can be diagnosed postoperatively in thyroid specimens removed for benign conditions, where preoperative imaging and cytology are benign or indeterminate. This audit assesses the prevalence, histopathological features, and subtype reporting practices of ITC against the Royal College of Pathologists (RCPath) Thyroid Cancer Reporting Dataset (2023).
Methods: All thyroidectomy specimens (2020-2024) were identified using SNOMED coding. Demographic and histopathological data were collected from electronic patient records and crosschecked with laboratory reporting databases. ITC case data was reviewed, focusing on tumour prevalence, histological subtype reporting, and pathological staging compliance with RCPath (2023) guidelines.
Results: ITC was identified in 7% (n=47) of 666 thyroidectomy specimens. Patients had a mean age of 52.4 years, and 74.5% were female. The predominant indications for surgery were thyroid nodules (45%) and symptomatic goitre (38%). Tumours were predominantly small, with a mean size of 6mm (range 0.2-45mm). AJCC staging revealed the majority of cases were pT1a (85%), followed by pT1b (8%) and pT3a (5%). The most frequent histological subtypes were classic PTC (32%) and follicular PTC (30%). Initially, 32% (n=15) of cases lacked documented PTC subtype. Following introduction of RCPath (2023) guidelines – which recommends replacing the term "papillary microcarcinoma" in favour of PTC and explicit subtyping – only 8% (n=4) did not have subtype documented. High-grade features and lymphovascular invasion were rare, observed in just 2% and 4% of cases respectively.
Conclusion: This audit demonstrates a notable prevalence (7%) of ITC in patients undergoing thyroidectomy for benign conditions. Implementation of RCPath (2023) guidelines significantly improved subtype reporting compliance. Future steps include periodic re-audits, extending the audit timeframe, and assessing ITC prevalence and clinical outcomes in an Irish population through a retrospective cohort study.

PS-03-012
Optimizing intraoperative frozen section diagnosis in laryngeal surgery: navigating the challenge of small specimen size in voice preservation
K. Viswanathan[1], K. Magliocca[1], A. Law[2]
[1]Emory University Hospital Midtown, Pathology and Laboratory Medicine, Atlanta, USA, [2]Emory University Hospital Midtown, Otolaryngology, Atlanta, USA

Background & Objectives: Intraoperative consultation (frozen sections, FS) is essential in guiding surgical management of laryngeal lesions. In voice-preservation surgeries, where biopsies are small, data on FS performance and diagnostic discordance are limited. This study reviews our institutional experience to assess diagnostic accuracy and identify causes of discordance in small biopsy specimens from voice-preserving procedures.
Methods: We reviewed pathology archives for FS specimens obtained by laryngologists between October 2022 and February 2025. Of 83 FS samples from 63 patients, 10 were excluded (7 extralaryngeal, 3

missing slides). Concordance was defined as a perfect FS-to-permanent diagnosis match; any upgrade or downgrade (e.g., dysplasia to carcinoma) was considered discordant. Causes of discordance were categorized as block sampling error, interpretative differences, contextual discordance, or ancillary testing needs. Clinical and demographic data were collected.

Results: Among 76 FS samples, the primary purpose was diagnosis (82.9%) or margin assessment (17.1%). Most biopsies (72.3%) measured ≤0.4 cm, with a median of 0.3 cm and two fragments per sample. Concordance between FS and final diagnoses was 65.8%. Upgrades and downgrades occurred in 25.0% and 5.3% of cases, respectively. Discordance was attributed to combined sampling and contextual issues (30.4%), sampling alone (21.7%), interpretative differences (17.4%), contextual discordance alone (13.0%), ancillary testing (13.0%), and contextual issues with ancillary needs (4.3%). FS sensitivity and specificity for neoplasm or dysplasia were 80%, with positive and negative predictive values of 95.2% and 44.4%.

Conclusion: FS remains a valuable tool in voice-preserving surgery, with high positive predictive value and low interpretative error. However, small biopsy size challenges diagnostic certainty. Block sampling—linked to over half of discordant cases—may reflect efforts to preserve tissue for permanent sections. Improved communication between surgeons and pathologists is key to balancing diagnostic accuracy with voice preservation.

PS-03-013

The role of glucose transporter type 1 expression in the pathogenesis of oral cancer

J. Maffei[1], G. Tonini Peterle[2], I. Bittencourt do Valle[3], B. Castelari Bissoli[4], P. Fernandes Pansini[2], C. Batista Daniel[2], J. Graça Sant'Anna[2], J. Lenzi[5], R. Mai Rocha[5], E. Duccini de Souza[5], J. Roberto Vasconcelos de Podestá[5], S. Ventorin von Zeidler[3]

[1]Federal University of Espírito Santo, Dental Sciences Post-Graduation Program, Vitória, Brazil, [2]Federal University of Espírito Santo, Biotechnology Post-Graduation Program, Vitória, Brazil, [3]Federal University of Espírito Santo, Department of Pathology, Health Science Centre, Vitória, Brazil, [4]Federal University of Espírito Santo, Faculty of Dentistry, Vitória, Brazil, [5]Santa Rita de Cássia Hospital, Head and Neck Surgery Sector, Vitória, Brazil

Background & Objectives: The upregulation of hypoxia-associated genes, such as glucose transporter type 1 (GLUT-1), plays a key role in the pathogenesis of Oral Squamous Cell Carcinoma (OSCC), with increased expression correlating with greater tumour aggressiveness. This study aims to evaluate the gene expression profile of GLUT-1 in OSCC and correlate its expression patterns with the clinical and pathological data of affected individuals.

Methods: Fresh OSCC samples (n=36) and healthy gingival tissue (control samples) were collected from oncology referral hospitals in Espírito Santo, Brazil. Real-time reverse transcription-quantitative polymerase chain reaction (RT-qPCR) was performed to assess GLUT-1 gene expression. Total RNA was extracted, treated, and synthesized into cDNA for RT-qPCR analysis using SYBR green dye. Clinical and pathological data were obtained from histopathological reports and medical records. GLUT-1 expression levels and their correlation with the clinicopathological profile were analysed using Student's t-test. Gene expression was assessed using the comparative method ($2^{-\Delta\Delta CT}$). This study was approved by the Research Ethics Committee of the Integrated Health Care Centre, Vitória-ES (Process No. 318/2011) and by the National Research Ethics Commission (Approval No. 681/2011).

Results: GLUT-1 mRNA expression showed a 38.89% increase in OSCC samples compared to healthy gingival control tissues. Moreover, significantly higher GLUT-1 expression was observed in early-stage OSCC (I/II) compared to advanced stages (III/IV) ($p < 0.05$).

Conclusion: These findings highlight the potential of GLUT-1 as a biomarker for early OSCC lesions, suggesting its possible use for early diagnosis. Further research is urgently needed to validate these findings and explore additional clinical implications.

PS-03-014

Prognostic value of tumour-infiltrating lymphocytes and the expression of PLK1 in oral squamous cell carcinoma

J. Maffei[1], T. Coeli Dias Damasceno[2], C. Batista Daniel[2], I. Bittencourt do Valle[3], P. Marinho de Abreu[2], J.R. Vasconcelos de Podestá[4], S. Ventorin von Zeidler[3]

[1]Federal University of Espírito Santo, Dental Sciences Post-Graduation Program, Vitória, Brazil, [2]Federal University of Espírito Santo, Biotechnology Post-Graduation Program, Vitória, Brazil, [3]Federal University of Espírito Santo, Department of Pathology, Health Science Centre, Vitória, Brazil, [4]Santa Rita de Cássia Hospital, Head and Neck Surgery Sector, Vitória, Brazil

Background & Objectives: Oral squamous cell carcinoma (OSCC) patients display heterogeneous clinical behaviour and are often diagnosed at advanced stages, leading to a worse prognosis. Therefore, analysing the dynamics among immune response through the assessment of tumour-infiltrating lymphocytes (TIL) and tumour progression, evaluated by the biomarker Polo-like kinase 1 (PLK1), can serve as essential tools for aiding in the recurrence and prognosis of the disease. This study aims to evaluate TIL and PLK1 expression profile and their association with the clinical and pathological features of OSCC patients.

Methods: TIL was analysed in haematoxylin and eosin staining according to Marsh et al. (2011). PLK1 expression by immunohistochemistry was evaluated in 109 paraffinized tissue samples representative of adjacent epithelium, dysplasia and OSCC. PLK1 gene expression was analysed by qRT-PCR in frozen tumour fragments (n=21) and serum samples (n=30), being 17, before treatment initiation and 13, after treatment. Clinical and pathological data were obtained from histopathological reports and medical records. The Chi-Square and Fisher's Exact tests were used to establish an association between the clinicopathological profile with TIL density and PLK1 expression.

Results: Low TIL density was associated with larger tumours (T3/T4) ($p = 0.001$) and advanced stages (III/IV) ($p = 0.011$), while high TIL density correlated with smaller tumours (T1/T2) ($p = 0.001$) and early stages (I/II) ($p = 0.01$). The analysis of PLK1 expression in the segments showed a correlation between the adjacent epithelium pairs and the dysplasia and tumour regions ($p<0.001$). High PLK1 expression was associated ($p<0.001$) with the variables T3/4 tumour size, lymph node metastasis and stage III/IV.

Conclusion: These findings suggest that TIL density and PLK1 expression may serve as valuable biomarkers for understanding tumour development and progression in OSCC.

PS-03-016

Parameters associated with lymph node metastasis in papillary thyroid carcinoma

H. Maaroufi[1], F. Khanchel[1], I. Helal[1], D. Chiboub[2], R. Hedhili[1], E. Ben Brahim[1], R. Jouini[1], A. Chadli[1]

[1]Habib Thameur Hospital, Department of Pathology, Tunis, Tunisia, [2]Habib Thameur Hospital, Department of Otorhinolaryngology, Tunis, Tunisia

Background & Objectives: Papillary thyroid carcinoma (PTC) is the most common type of thyroid cancer. Among patients with PTC 30 to 80% develop lymph node metastasis, prompting the routine practice of prophylactic lymph node dissection. Factors associated with the development of lymph node metastases (LNM) remain

poorly understood. The aim of this study was to identify the association between demographic and pathological factors and the occurrence of lymph node metastases in PTC.
Methods: This was a descriptive and retrospective study focused on cases of PTC patients operated in the otolaryngology department of the Habib Thameur hospital and whose resection specimens were analysed in the pathology department of the same hospital between 2020 and 2024. Pathology reports were reviewed for clinical and histological data.
Results: A total of 179 cases were included. The mean age of patients was 48.3 years [12-87], and the sex ratio was 0.22. Tumour size more than 1 cm was seen in 92 patients (51.4%). LNM were identified in 50 cases (27.9%). Male gender, Age<40, bilaterality, multifocality, the presence of vascular invasion and extrathyroidal extension of the tumour were statistically significantly associated with LNM (all $p<0.05$). A tumour size over 1 cm was not statistically significantly associated with LNM. In multiple logistic regression analysis, only the presence of vascular invasion was identified as an independent risk factor for LNM (OR 32, $p=0.02$).
Conclusion: Male gender, age < 40 years, bilaterality, vascular invasion and the existence of extrathyroidal invasion are features associated with a high risk of lymph node metastasis in PTC. Vascular invasion was found to be an independent risk factor for LNM in PTC. Further studies on larger samples are necessary to identify additional factors that may contribute to predicting LNM in these patients.

PS-04 Poster Session Molecular Pathology

A mass spectrometry pipeline for amyloid typing in Belgium

A. Vandendriessche[1,2], D. Van Haver[2], S. Dufour[2], M. Van der Linden[3,1], I. Kaya[3,1], J. Van Dorpe[3,1], F. Impens[2,1], S. Devos[2,1], A. Dendooven[3,1,4]
[1]Ghent University, Ghent, Belgium, [2]VIB-UGent Centre for Medical Biotechnology, Ghent, Belgium, [3]Ghent University Hospital, Ghent, Belgium, [4]Antwerp University, Antwerp, Belgium

Background & Objectives: Accurate typing of amyloidosis deposits is crucial for patient management. Immunohistochemistry remains the standard method but lacks specificity. We present a diagnostic pipeline integrating laser capture microdissection (LCM) of amyloid with liquid chromatography-tandem mass spectrometry (LC-MS/MS). The workflow is being validated by extensive retrospective analysis of amyloid-containing tissue.
Methods: Sixty archived myocardial biopsies, 83 renal biopsies and 100 samples from various other organs were analysed. Amyloid-rich regions were identified on Congo red-stained slides after which LCM was performed. Approximately 60,000 µm² of amyloid was collected per sample into Eppendorf tubes. Protein extraction occurred in a buffer containing 5% sodium dodecyl sulfate (SDS), along with ultrasonication and heat incubation to reverse formaldehyde crosslinks. Proteins were purified using S-trap columns, digested with trypsin, and peptides were analysed using a sensitive timsTOF SCP mass spectrometer using data-independent acquisition (DIA). Proteins were identified from the mass spectral data using DIA-NN software. A custom-built software tool is used to generate reports, integrating protein abundance calculations and visualizations in R.
Results: On samples that could be typed by immunohistochemistry, the concordance rate with MS-based typing was 87%, in line with literature. Importantly, our pipeline allows to type an additional number of patients that could not be typed through immunohistochemistry. Ongoing intra- and inter-run assessments are used to optimize reproducibility. Collaborations across Europe are set up for external validation of the pipeline. Turnaround time is around two months, with ongoing efforts to streamline processing for faster clinical applicability.
Conclusion: Our MS-based pipeline has clear potential for diagnostic use when immunohistochemistry is inconclusive, providing precise amyloid typing via LCM and LC-MS/MS analysis. Further validation and optimization will enhance diagnostic accuracy and reduce turnaround time to meet clinical demands. Our goal is to implement this workflow as a routine diagnostic service in Belgium.

First results of liquid biopsy analysis with OncomineTM Precision Assay GX pan

A. Mályi[1], H. Engi[1], L. Báthory-Fülöp[1], E. Tóth[1]
[1]National Institute of Oncology, Department of Surgical and Molecular Pathology, Budapest, Hungary

Background & Objectives: Tissue biopsy is considered the conventional source for molecular pathological analysis. However, there may be barriers to obtaining a tissue sample, such as inaccessible tissue due to the significant procedural risk associated with biopsy, making it less suitable for continuous monitoring of disease progression. Liquid biopsy, circulating cell free/ tumour nucleic acid, as it contains the tumour-specific mutations, offers a potent solution for detection of resistance mutations and follow up of the patients.
Methods: The Genexus Purification System was used to isolate total cell free nucleic acid from 124 liquid biopsy samples of 122 patients and quantification was completed with the onboard quantitation assay and sequenced on the GenexusTM Integrated Sequencer using OncomineTM Precision Assay GX panel. This panel covers 78 variants across 50 key genes.
Results: Based on histological or clinical data our patient cohort was grouped into 4 categories lung (n=98), colorectal (n=11), breast (n=9) and other (n=2). Six cases had no prior histological diagnosis. In 40% of the samples we did not find any clinically relevant mutation. In 39 samples we found clinically relevant EGFR mutations, in 13 samples KRAS, in 3 samples NRAS and in 8 samples BRAF mutation. In 5 breast cancer samples we found ESR1 resistance mutation and in 2 samples targetable AKT1 mutation. In one sample RET mutation, in one sample HER2 mutation and in one sample BRAF-MKRN1 fusion was detected. In a patient`s two samples, after previous ALK positive lung adenocarcinoma, ALK resistancy mutation was observed.
Conclusion: Liquid biopsyis gaining ground in the routine diagnostics. Compared to standard tissue based examination it's less invasive and easy to repeat. The available settings today based on liquid biopsy are screening for minimal residual disease after surgery, monitoring tumour recurrence and therapy efficacy and based on our results effectively detecting tumour-specific mutations.

PS-04-003
Breast cancer characterization via LA-REIMS: exploring a novel mass spectrometry-based diagnostic approach

Z. Karancsi[1], A.D. Márton[2,3], G.S. Horkovics-Kováts[4], B.A. Deák[1], A.M. Tőkés[1], T. Karancsi[3]
[1]Semmelweis University, Department of Pathology, Forensic and Insurance Medicine, Budapest, Hungary, [2]Budapest University of Technology and Economics, Department of Chemical and Environmental Process Engineering, Budapest, Hungary, [3]Ambimass Kft., Budapest, Hungary, [4]University of Regensburg, Depatment for Multimodal Imaging of Intracellular Communication, Regensburg, Germany

Background & Objectives: This study evaluates the feasibility of Laser-Assisted Rapid Evaporation Ionization Mass Spectrometry (LA-REIMS) for distinguishing breast cancer subtypes and normal tissue based on lipidomic signatures. While mass spectrometry (MS) with chromatography is the gold standard for lipid metabolism analysis,

LA-REIMS enables real-time lipidomic profiling, potentially supporting intraoperative decision-making. By integrating spatial data, LA-REIMS findings can be directly compared with H&E-stained slides, linking molecular signatures to histopathology.
Methods: Frozen tissue from 41 breast cancer cases, 34 normal tissues, and five benign tumours was analysed. All patients underwent primary surgery at Semmelweis University. Histological subtypes included 28 no special type (NST), five invasive lobular carcinoma (ILC), and eight others. Molecular subtypes comprised 10 Luminal A, 15 Luminal B1, 2 Luminal B2, 4 HER2, and 9 TNBC. Tissue slices (10–20 µm) were analysed with LA-REIMS at 75 µm resolution, and data were processed using linear discriminant analysis and cross-validation.
Results: Through multistep optimization, the laser focal length was set at 36.7 mm. Preliminary analysis of 20 cancer cases (25,064 scans) and 16 normal samples (7,312 scans) demonstrated 87.88% accuracy excluding outliers and 87.57% including outliers in distinguishing tumours from normal tissue. To differentiate ER-positive (12 cases) and ER-negative (8 cases) tumours, we analysed 13,663 scans (ER-positive) and 11,401 scans (ER-negative), achieving 75.76% accuracy excluding outliers and 73.93% including outliers. Finally, we differentiated grade 3 tumours (14 cases, 5,976 spectra) from grade 1 and 2 cases (6 cases, 23,563 spectra) with 76.60% accuracy excluding outliers and 68.82% including outliers.
Conclusion: Our preliminary findings show promising results, suggesting that LA-REIMS could aid real-time tumour classification and molecular subtyping. We aim to expand our dataset, improving accuracy across molecular subtypes and identifying key differentiation markers. Final results may contribute to biomarker discovery, enhancing personalized treatment, risk stratification, and intraoperative decision-making in breast cancer management.

PS-04-004
Somatic BRCA1/2 mutation analysis in breast cancer patients
Z. Pálinkás[1], P. Székely[1], A. Simon[1], E. Papp[1], H. Butz[2], E. Tóth[1]
[1]National Institute of Oncology, Department of Surgical and Molecular Pathology, Budapest, Hungary, [2]National Institute of Oncology, Department of Molecular Genetics, Budapest, Hungary

Background & Objectives: BRCA1/2 germline mutations are well-documented in breast cancer, present in approximately 5-10% of cases, and serve as predictive mutation for PARP inhibitor therapy. We performed a large number of somatic BRCA tests at our Institute, which provided valuable information about the distribution of somatic BRCA mutations among different breast tumour subtypes and the ratio of somatic to germline mutations.
Methods: We analysed 805 breast cancer patients from 2019 to 2024 at the National Institute of Oncology. Tumours were classified into intrinsic subtypes based on immunohistochemical studies. DNA extraction was performed using the Maxwell RSC system, tumour cell content was above 10% in every case. Next-generation sequencing (NGS) assays, including the Oncomine BRCA Research Assay and the Oncomine Comprehensive Assay v3 (Thermo Fisher), were used for somatic BRCA mutation analysis. Germline data were obtained from the Department of Molecular Genetics, where genetic analysis was performed using the Illumina TruSeq Hereditary Cancer Panel.
Results: Among the intrinsic subtypes, 36% were triple-negative, 32% Luminal A, 29% Luminal B, and 3% HER2-enriched. Somatic BRCA1/2 testing in 805 patients revealed 115 (14%) pathogenic variants and 8 variants of unknown significance. Mutations comprised 50.4% BRCA1 and 48.7% BRCA2 alterations, with one case exhibiting mutations in both genes. Germline testing was available in 92 patients, within 39 pathogenic variants were identified. Germline mutations were more likely to occur at somatic allele frequencies above 50%. The triple-negative subtype exhibited the highest frequency of both somatic and germline mutations.
Conclusion: Our studies have enabled the identification of patients for whom germline BRCA1/2 mutation analysis is indicated. Ongoing research suggests that patients with somatic BRCA1/2 mutations may soon be eligible for PARP inhibitor treatment. Our data show that somatic BRCA mutations occur 3.5 times more frequently than germline mutations.

PS-04-005
Comparison of molecular alterations in uterine endometrioid carcinomas and serous carcinomas: an *in-silico* study
Z. Sagnak Yilmaz[1,2]
[1]Dokuz Eylül University Institute of Health Sciences, Molecular Pathology, Izmir, Turkey, [2]Karadeniz Technical University Faculty of Medicine, Pathology, Trabzon, Turkey

Background & Objectives: Uterine serous carcinomas exhibited frequent *TP53* mutations, extensive copy number alterations, minimal DNA methylation changes. In contrast, most uterine endometrioid carcinomas exhibited frequent mutations in *PTEN, CTNNB1, PIK3CA, ARID1A* and *KRAS*, minimal copy number alterations or *TP53* mutations.
Methods: Genomic alterations, mRNA expressions, protein expressions and DNA methylation in uterine endometriod carcinoma (n=399) and uterine serous carcinoma (n=109) in the Uterine Corpus Endometrial Carcinoma (TCGA, PanCancer Atlas) data set were compared from Cbioportal, open access, public genomic bioinformatics database (https://www.cbioportal.org). In the comparison, $p<0.05$ and $q<0.05$ were considered statistically significant.
Results: The most common mutations in endometrioid carcinomas were *PTEN* (82%), ARID1A (54.4%), *PIK3CA* (53.6%), *TTN* (43.8%), *PIK3R1* (36.3%), *CTNNB1* (33.5%), *KMT2D* (32%), *CTCF* (31.4%), *MUC16* (31.2%), *RYR2* (28.4%), while *TP53* (88%), *PPP2R1A* (37%), *PIK3CA* (37%), *FBXW7* (24.1%), *TTN* (23.1%), *ARHGAP35* (18.5%), *CHD4* (17.6%), *CSMD3* (13%), *FLG* (13%), *MUC16* (13%) in serous carcinomas. Among these genes, *TP53, PTEN, ARID1A, PIK3R1, CTNNB1, CTCF, PPP2R1A, TTN,* and *RYR2* mutations were significantly different between the two groups ($p<0.05$, $q<0.05$). *SRARP, LINCO2418, ELAPOR1, ERMN, and TFF3* mRNA expressions were the highest significance in endometrioid carcinomas, whereas *WNT7A, L1CAM, SLC6A12, FIGNL2* mRNA expressions were the highest significance in serous carcinomas ($p<0.05$, $q<0.05$). DNA methylation levels of *DOK5, ADARB2, SYT6, KCNB2*, and *PRKCDBP* were the highest significance in endometrioid carcinomas and *BEST3, C1orf64, FM24B, TNFSF18, KRT1* DNA methylation levels were the highest significance in serous carcinomas ($p<0.05$, $q<0.05$). Overall survival and disease free survival were significantly different between the two groups ($p<0.05$, $q<0.05$).
Conclusion: In this *in-silico* study, significant differences were found between the two groups in terms of 2505 genomic alterations, 10757 mRNA expressions, 3350 DNA methylation rates and 85 protein expressions. It was concluded that the epigenetic mechanism was also effective among the molecular changes between uterine endometrioid carcinomas and serous carcinomas.

PS-04-006
Validation of TruSight oncology 500 HRD for homologous recombination deficiency testing in ovarian cancer
S. Kjaer-Frifeldt[1], T. Block Mattesen[1], J. Matthiesen Bojsen[1], D. Schledermann[1]
[1]Vejle Hospital, Clinical Pathology, Vejle, Denmark

Background & Objectives: Homologous Recombination Deficiency (HRD) is a crucial biomarker in oncology, indicating impaired DNA double-strand break repair and serving as a predictive marker for PARP inhibitor therapy in ovarian cancer. The Myriad myChoice® CDx test

determines HRD status by analysing genomic instability markers, classifying a Genomic Instability Score (GIS) ≥42 as HRD-positive. Previously, HRD testing was only available through Myriad. However, a collaboration with Illumina led to the development of TruSight Oncology 500 HRD (TSO500 HRD), integrating comprehensive genomic profiling with HRD assessment.
Methods: This study validated TSO500 HRD against Myriad myChoice® CDx using 20 ovarian cancer patient samples with known GIS scores. Three samples underwent repeated testing to assess repeatability, robustness, sensitivity, and detection limits
Results: Correlation analysis showed $R^2 = 0.97$, Negative Percent Agreement (NPA) = 100%, Positive Predictive Value (PPV) = 87.5%, and Overall Percent Agreement (OPA) = 95%. The test variation ranged from -9 to +7, with 85% of samples fluctuating between -5 to +5, aligning with manufacturer expectations. One sample near the threshold (GIS ≥42) shifted HRD status, consistent with expected variability.
A sample with tumour content below the recommended 32% limit demonstrated sensitivity in a quality control parameter, highlighting the importance of tumour percentage evaluation. The test also showed robustness across varying DNA input levels, with samples near the minimum (40 ng) displaying no increased variation.
Conclusion: These findings confirm TSO500 HRD delivers comparable performance to Myriad myChoice® CDx, supporting its implementation for routine HRD testing, reducing turnaround times, and improving treatment decisions in ovarian cancer.

PS-04-007
NTRK1 gene fusions are frequent in juvenile xanthogranuloma
L. Müllauer[1], E. Schlögl[1], H. Hürner-Unterberger[2], I. Simonitsch-Klupp[1], G. Amann[1], J. Blank-Foltin[1], B. Neudert[1], L. Wozelka-Oltjan[1], C. Haberler[3], G. Ebetsberger-Dachs[2]
[1]Medical University of Vienna, Department of Pathology, Vienna, Austria, [2]Johannes Kepler University Linz, Department of Paediatrics and Adolescent Medicine, Linz, Austria, [3]Medical University of Vienna, Division of Neuropathology and Neurochemistry, Department of Neurology, Vienna, Austria

Background & Objectives: Juvenile xanthogranuloma (JXG) is a rare form of non-Langerhans cell histiocytosis. The most common known gene mutations affect the mitogen-activated protein (MAP) kinase and phosphoinositide 3-kinase (PI3K) signalling pathways. We diagnosed and treated a case of congenital JXG in a premature newborn from a dicygotic twin pregnancy with subdermal infiltrates on the chest, hepatosplenomegaly, ascites, pancytopenia, and petechiae on the abdomen and extremities. Next-generation sequencing of tissue from a subdermal infiltrate revealed a tropomyosin 3::neurotrophic tyrosine kinase receptor (*TPM3*::*NTRK1*) gene fusion. Therefore, a retrospective analysis of 34 additional non-Langerhans cell histiocytoses (16 JXG, 3 adult xanthogranuloma and 1 benign cephalic histiocytosis, both clinical subtypes of JXG, as well as 13 Rosai-Dorfman and 1 Erdheim-Chester disease) for *NTRK*1, 2 and 3 alterations was performed.
Methods: Formalin-fixed, paraffin-embedded (FFPE) non-Langerhans cell histiocytoses (non-LCH) tissues were stained for TRK A, B and C expression using a pan-TRK rabbit monoclonal antibody (clone EPR17341; Ventana Medical Systems). Additionally, fluorescence in situ hybridization (FISH) with NTRK1 and NTRK3 gene probes was performed. Furthermore, DNA and RNA were isolated from non-LCH FFPE tissues and sequenced with a 161 gene panel (Oncomine Comprehensive Assay v3, Thermo Fisher Scientific).
Results: This study revealed an *NTRK1* gene fusion in five JXGs and one adult xanthogranuloma. In conclusion, NTRK1 gene fusions are common in JXG (6/21; 28.6% in our series). This finding places JXG in the category of proliferative diseases with one of the highest frequencies of *NTRK* gene rearrangements.
Conclusion: Therefore, *NTRK* gene fusions should be included in a gene panel test for difficult-to-treat JXG. Given the potential of NTRK gene fusions as a therapeutic target, *NTRK* inhibitors may represent a novel effective treatment for JXG with a challenging clinical course.

PS-04-008
External quality assessment for *FGFR3* testing in urothelial / bladder cancer
V. Williams[1], M. Cheetham[1], S. Patton[1]
[1]EMQN CIC, Manchester, United Kingdom

Background & Objectives: Bladder cancer is the ninth most commonly diagnosed cancer worldwide with both incidence and mortality rates increasing, urothelial carcinoma is the most common sub-type. FGFR Kinase Inhibitors were approved by the European Medicines Agency (EMA) in 2024 for treatment of metastatic urothelial carcinoma patients with susceptible *FGFR3* variants. We have piloted a global external quality assessment (EQA) scheme for urothelial / bladder cancer *FGFR3* testing to assure quality of diagnostic services.
Methods: A survey was sent to over 2000 molecular pathology laboratories and thirty were selected to participate in the pilot EQA. Three formalin fixed paraffin embedded (FFPE) samples with mock clinical referrals were sent for *FGFR3* small variant or fusion testing and laboratories were instructed to use their routine test methodologies. Anonymised clinical reports were returned and assessed for *FGFR3* genotyping accuracy, result interpretation in the context of therapy, and clerical accuracy.
Results: The survey was completed by 67 laboratories from 20 countries, with the highest applications from France and Italy. Of the applicants, 87% (58/67) performed targeted NGS, 7% (5/67) performed RT-PCR and 6% (4/67) used other methods for FGFR analysis.
Of the 30 laboratories selected to participate in the pilot EQA, 27 returned results. Overall, the standard of genotyping was high. Three laboratories reported false positive results (3/27, 11.1%), with an overall error rate of 3.9% (3/77 reports). There was some variation in nomenclature used for reporting of the fusion; 33% (9/27) laboratories did not use internationally recognised nomenclature.
Conclusion: Evidence from EQA shows that the introduction of a new test is usually accompanied by a high diagnostic error rate. This pilot EQA indicated that genotyping accuracy was good but there are improvements to be made for laboratories performing *FGFR3* testing for Urothelial cancer, and that there is a need for harmonisation, particularly in reporting of fusions.

PS-04-009
Clinicopathologic and molecular analysis of brain metastases highlights genomic discordance with primary tumours
S. Kim[1], M. Kim[1], Y. Kim[1], Y.E. Sung[1], S.H. Lee[1], Y.S. Lee[1], C.K. Jung[1,2]
[1]College of Medicine, The Catholic University of Korea, Department of Hospital Pathology, Seoul, Republic of Korea, [2]College of Medicine, The Catholic University of Korea, Cancer Research Institute, Seoul, Republic of Korea

Background & Objectives: Brain metastases are the most common malignant tumours of the central nervous system and exhibit diverse biological behaviours. Molecular heterogeneity between primary tumours and their corresponding brain metastases remains poorly understood. This study aimed to investigate the clinicopathologic features and molecular profiles of brain metastases, focusing on discordance in variant status between primary tumours and matched brain metastases.
Methods: We retrospectively reviewed 394 cases of brain metastases surgically resected at a single university-affiliated hospital. Clinicopathologic data were collected, and molecular analyses, including

Next-Generation Sequencing (NGS), Sanger sequencing, real-time PCR, and fluorescence in situ hybridization, were performed on both primary tumours and corresponding brain metastases.
Results: Of the 394 patients, 203 (51.5%) were male and 191 (48.5%) were female, with a median age of 59 years. The most common primary tumour sites were the lung (47.2%), breast (15.0%), colorectum (8.8%), and kidney (5.8%). In lung cancer cases (n=186), *EGFR* variants were identified in 50.0% of primary tumours and 54.4% of brain metastases, while *ALK* fusions and *KRAS* variants were detected in 9.6% and 15.2% of primaries and in 10.6% and 9.8% of brain metastases, respectively. NGS revealed *EGFR* and *TP53* variants (24.3% each) as the most frequent alterations in primary lung tumours, whereas *EGFR* variants (18.0%), *TP53* variants (16.0%), and *MET* alteration (6.0%) predominated in brain metastases. Among 57 paired lung cancer cases, variant discordance was observed in 30%, mainly due to the emergence of additional *EGFR* T790M variants (39%). In colorectal cancer brain metastases, *KRAS* variants were detected in 57% of primary tumours and 60% of brain metastases.
Conclusion: Our findings demonstrate notable molecular discordance between primary tumours and their matched brain metastases, particularly involving *EGFR* variants. Molecular profiling of brain metastases is essential for accurate therapeutic guidance and may influence clinical outcomes.

PS-04-010

Development and validation of digital PCR TaqMan multiplex assays as a tool for liquid biopsy *ESR1* mutations detection

J. Feenstra[1], X. Jiang[2], S.M. Leow[2], A. Soh[2], Y.P. Tan[2], M. Schumaker[1], J. Wong[2]
[1]Thermo Fisher Scientific, South San Francisco, USA, [2]Thermo Fisher Scientific, Singapore, Singapore

Background & Objectives: *ESR1* mutations are key biomarkers of resistance to endocrine therapies in breast cancer. The development of novel selective oestrogen receptor (ER) degrader treatments for ER+, HER2- advanced or metastatic breast cancer with *ESR1* mutations necessitates highly sensitive detection methods. This is crucial for cancer research focused on detecting emerging therapeutic resistance in liquid biopsy samples. While sequencing can detect *ESR1* mutations, digital PCR (dPCR) offers a more affordable alternative with a simplified workflow and rapid turnaround time, suitable for frequent testing or resistance detection. We designed and assessed three multiplex assays for dPCR analysis of the eight most common *ESR1* mutations, covering over 85% of cases.
Methods: Assays were designed to detect *ESR1* mutations: E380Q, L536H, L536P, L536R, Y537C, Y537N, Y537S, and D538G in three multiplex panels. Performance was evaluated for analytical specificity, analytical sensitivity, limit of blank, and linearity. Testing included contrived liquid biopsy specimens using plasma with synthetic mutant DNA spike-in. Cell-free DNA was isolated using MagMAX™ Cell-Free DNA Isolation Kit. dPCR was performed on Absolute Q™ instrument (Thermo Fisher Scientific).
Results: For all 3 multiplexes the assays demonstrated >99.9% analytical specificity for respective mutations at 5000 copies/µl. Analytical sensitivity reached an allelic frequency of 0.1% with 500-1000 copies/µl of wild type template for all 8 mutations tested. The limit of blank, established using the wild-type template, was below the sensitivity threshold at 0.3 copies/µl. In contrived plasma samples, 10 copies of mutant DNA were detectable per ml of plasma for the 8 *ESR1* mutations included in the panels.
Conclusion: Our newly developed dPCR multiplex assays for research use only on the Absolute Q instrument accurately detect *ESR1* mutations down to an allelic frequency of 0.1%. This rapid detection technique capable of detecting 8 mutations in only 3 PCR reactions is particularly suitable for analysing liquid biopsy material in cancer research.

PS-04-011

Molecular analysis of endometrial carcinoma using next generation sequencing

M. Andújar-Sánchez[1], E. Fraile-Bethencourt[1], S.A. Geleano-Reyes[1], S. Lacerenza[1], I. Domazetovski[1], M. Santana-Verano[1], MC. Camacho-García[1], M. Federico[2], O. Arencibia-Sánchez[3], A. Ramchandani-Vaswani[4], E. Dorca-Duch[5], A. Velasco-Sánchez[6], X. Matias-Guiu[6]
[1]Complejo Hospitalario Universitario Insular Materno-Infantil, Pathology, Las Palmas de Gran Canaria, Spain, [2]Hospital Universitario de Gran Canaria Doctor Negrín, Radiation Oncology, Las Palmas de Gran Canaria, Spain, [3]Complejo Hospitalario Universitario Insular Materno-Infantil, Obstetric and Gynaecology, Las Palmas de Gran Canaria, Spain, [4]Complejo Hospitalario Universitario Insular Materno-Infantil, Medical Oncology, Las Palmas de Gran Canaria, Spain, [5]Hospital Universitari de Bellvitge, Pathology, Barcelona, Spain, [6]Hospital Universitari Arnau de Vilanova, Pathology, Lleida, Spain

Background & Objectives: The molecular classification of endometrial carcinoma has recently been included in the latest FIGO 2023 clinicopathological staging classification. Its implementation requires the use of immunohistochemical and molecular techniques. This classification differentiates four groups: POLE-mutated, P53-mutated, microsatellite instability (MSI), and no specific alterations. Specific and discriminatory markers allows for the "Histo-Molecular" classification of endometrial carcinoma, which has gained widespread acceptance ("ProMisE classifier"). Here, we applied next generation sequencing for a proper molecular classification of endometrial carcinoma samples based on the latest criteria.
Methods: A total of 113 endometrial carcinoma patients, aged between 30 and 88 were studied. The tumour types included 29 endometrioid G1, 30 endometrioid G2, 22 endometrioid G3, 16 serous papillary, 8 clear cells, 4 carcinosarcomas, and 4 mixed with a high-grade component, all collected between 1996 and 2003. A custom panel of nineteen genes was designed (ThermoFisher Scientific™) and Ion GeneStudio S5 System was used to sequence DNA extracted from frozen tumour samples of our centre's Biobank. Bioinformatics analysis was performed on the Ion Reporter™ Software 5.18 platform (ThermoFisher Scientific™).
Results: Genetic variants were most frequently found in PTEN, followed by PIK3CA, ARID1A, TP53, KRAS, and CTNNB1. Copy number alterations were observed in PIK3CA, BRCA2, BRCA1, and ERBB2. Low-grade tumours exhibited a higher number of alterations in PTEN, PIK3CA, ARID1A, KRAS, PIK3R1, CTNNB1, and FGFR2, while high-grade tumours showed more alterations in TP53 and PPP2R1A. A total of 23 POLE mutations were detected in 14 samples, of which seven (6.19%) were pathogenic variants. The remaining mutations are not classified as pathogenic/likely pathogenic.
Conclusion: Next generation sequencing is a useful tool for the molecular classification of endometrial carcinoma. The most important targets (TP53 and POLE), as well as microsatellite instability genes, are covered by this technology.

Funding: This study was supported by grants from Fundación Canaria Instituto de Investigación Sanitaria de Canarias (FIISC) through the project PIFIISC22/01 and Fundación MAPFRE Canarias and Fundación DISA

PS-04-012

Implementation of the oncomine precision assay panel for the study of non-small cell lung cancer biomarkers. A tertiary hospital experience

E. Fraile Bethencourt[1], S. Galeano Reyes[1], S. Lacerenza[1], M. Santana Verano[1], C. Camacho Garcia[1], A. Estival Gonzalez[2], G. Benitez Lopez[2], P. Soto Rojas[2], D. Rodriguez Abreu[2], M. Andujar Sanchez[1]
[1]Complejo Hospital Universitario Insular Materno Infantil, Pathology Department, Las Palmas de Gran Canaria, Spain, [2]Complejo Hospital

Universitario Insular Materno Infantil, Oncology Department, Las Palmas de Gran Canaria, Spain

Background & Objectives: The development of drugs targeting specific mutations has made molecular diagnosis a necessity in the clinical routine for non-small cell lung cancer (NSCLC). Clinical guidelines recommend next-generation sequencing (NGS) panels for biomarker analysis. Our Pathology Department has incorporated the Oncomine Precision Assay (OPA, ThermoFisher®) into the molecular diagnosis routine of non-squamous NSCLC.
Methods: A total of 236 paraffin-embedded non-squamous NSCLC samples were sequenced between September 2023 and December 2024. Nucleic acids were extracted using the RecoverAll™ Multi-Sample RNA/DNA kit (ThermoFisher®). The most relevant genetic alterations identified using the OPA panel are presented.
Results: Among the 236 samples of non-squamous NSCLC, 190 (80.5%) were altered. Single nucleotide variants (SNVs) were detected in 169 cases (89%), being *TP53* (32.7%), *KRAS* (30.9%) and *EGFR* (14.7%) the most altered genes. *TP53* mutations were spread throughout exons included in the panel (5 to 8) and R278L/W/Q and R273L/H were the most common variants. *EGFR* most detected alterations were EX19del and L858R. *KRAS* mutations were found mostly in exon 2 (89.5%), being G12C the most prevalent variant. 27 cases (14%) presented copy number variations in *FGFR3, ERBB2, EGFR, KRAS* and *MET*. RNA was altered in 19 cases (10%), being *MET* exon14 skipping (3.7%) and *ALK* fusion (2.6%) the most common alterations.
Conclusion: The OPA panel is useful for the molecular diagnosis of non-squamous NSCLC. Alterations in driver genes were found in 80.5% of the patients. *TP53, KRAS*, and *EGFR* variants respresent 78.3% of these alterations. *TP53* SNVs were widely distributed, with R278L/WQ and R273L/H being the most frequent; EX19del and L858R variants represented the 84% of *EGFR* variants; and the 89.5% of *KRAS* variants were found in exon 2. *FGFR3* and *ERBB2* were the most amplified genes. Finally, 10% of the samples bore RNA alterations, being *MET* exon14 skipping the most frequent, followed by *ALK* fusion.

PS-04-013

A pilot study on the epigenomic profiling of neuroendocrine neoplasms of the lung

T.F.J. Kraus[1], I. Deleyto Rösner[1], B. Alinger-Scharinger[1], G. Hutarew[1], K. Sotlar[1]
[1]Institute of Pathology, University Hospital Salzburg, Salzburg, Austria

Background & Objectives: Neuroendocrine neoplasms (NEN) of the lung have very different therapeutic approaches and outcomes. Thereby, differentiation of typical carcinoids (NET) and small cell lung carcinomas (NEC) can be challenging. Consequently, the accurate identification and classification of NENs in the lung are of paramount importance for the provision of high-quality patient care. The objective of this study was to perform epigenomic profiling of NETs and NECs of the lung to identify distinct epigenomic signatures.
Methods: In this pilot study, we performed epigenome-wide methylation analysis on 16 NENs, with 8 NETs and 8 NECs. Utilizing the Illumina Infinium EPIC bead chip array, we were able to interrogate more than 850,000 methylation-sensitive CpG sites in parallel. Subsequent computational analyses were then performed to identify differentially methylated genes.
Results: A computational analysis revealed that there were distinct epigenomic differences in NETs compared with NECs. Differential methylation analysis revealed distinct differences in the DNA-methylation landscape. At specific genomic loci, a substantial variation in the degree of methylation was observed.
Conclusion: In summary, the findings of this pilot study demonstrate that DNA methylation profiling enables to differentiate epigenomic profiles of NETs and NECs of the lung. These findings have the potential to serve as valuable markers in future classification of NENs of the lung.

PS-04-014

Analysis of 35 liquid biopsy samples from stage 3 and 4 newly diagnosed lung cancer patients using Pillar Biosciences OncoReveal™ Core and Fusion Next Generation Sequencing panels

S. Nugteren[1,2], M. Nowak[1], K. Charles[1], A. Fair[1], N. Chadderton[1], L. James[1], B. O'Sullivan[1], P. Taniere[1]
[1]Queen Elizabeth Hospital Birmingham, University Hospitals Birmingham NHS Foundation Trust, Molecular Pathology Diagnostic Service, Birmingham, United Kingdom, [2]Erasmus Medical Centre, Pathology, Rotterdam, The Netherlands

Background & Objectives: We report on the implementation of the Pillar Biosciences Next Generation Sequencing (NGS) platform in our department for the molecular profiling (single nucleotide variants, insertions and deletions, copy number variations, microsatellite instability and fusion detection) of circulating tumour nucleic acid extracted from liquid biopsies from advanced lung cancers in parallel with FFPE sample assessment. We are also performing an in-house comparison to existing standard of care testing.
Methods: We collected whole blood in either Streck or Paxgene tubes from 35 patients; cell-free total nucleic acid (cf-TNA) was extracted from 5ml plasma using the QIAamp Nucleic Acid extraction kit; cf-DNA quantity, quality and integrity was assessed by Qubit and Tapestation, 10-30ng of input DNA/RNA was used in conjunction with the Pillar Biosciences OncoRevealTM Core and Fusion Liquid Biopsy (LBx) NGS kit to create libraries for sequencing. The Pillar NGS panels use SLIMPamp® (stem-loop inhibition mediated amplification) amplicon-based technology providing targeted analysis of 104 genes. NGS library preparation workflow took 12 hours to complete, with Fusion and Core samples prepared in parallel. Sequencing of libraries was performed using paired-end read length of 121bp (2x121) and two indexing reads of 8 cycles each. This was sequenced on the Ilumina NextSeq 550 platform to a depth of 33,000x and 200,000x for DNA and RNA respectively. Data analysis was performed using Pillar Biosciences' PiVAT® automated secondary bioinformatics software with tertiary analysis.
Results: Tissue and plasma testing results for the targetable driver alterations were highly concordant. All patients tested also had assessment with another validated assay. A detailed comparison analysis is ongoing at the time of submission of this abstract.
Conclusion: We show here that we successfully implemented a NGS panel for ctDNA analysis in routine practice. We are initiating the use for other tumour types such as advanced breast carcinomas as well.

PS-04-015

NGS-based liquid biopsy for ESR1 hotspot mutations in breast cancer: development and clinical experience

S. Tsuriel[1], V. Hannes[1], D. Hershkovitz[1,2]
[1]Tel Aviv Sourasky Medical Centre, Institute of Pathology, Tel Aviv, Israel, [2]Tel Aviv University, Pathology, Tel Aviv, Israel

Background & Objectives: A new treatment has been approved for patients with oestrogen receptor-positive (ER+) breast cancer harbouring ESR1 hotspot mutations, whose disease has progressed after prior therapies. Ongoing studies are also advancing additional drugs targeting these mutations, which drive resistance to endocrine therapy. Liquid biopsy, a minimally invasive method analysing circulating tumour DNA (ctDNA), is the recommended approach for detecting ESR1 mutations. Here, we describe the development, validation, and use of a new in-house next-generation sequencing (NGS)-based liquid

biopsy assay for identifying ESR1 hotspot mutations to enable precise, personalized treatments.
Methods: Primers with Ion Torrent adaptors were designed to cover ESR1 hotspot mutation regions. Validation included eight G-blocks oligos with the hotspot mutations and two wild-type (WT) G-blocks. Additionally, cfDNA was extracted from five WT plasma samples. For the clinical study, blood was collected in EDTA tubes, and plasma was separated within an hour. cfDNA was extracted from 4 mL of plasma and sequenced on an Ion Torrent S5 machine with >20,000 reads per amplicon.
Results: Validation achieved 100% coverage uniformity. The WT noise level was 0.0019%±0.0023, and the detection limit was set to 0.2%. Sequencing of diluted Gblocks at 2% and 0.5% showed 100% agreement with expected results. In a clinical cohort of 87 patients, ESR1 hotspot mutations were detected in 21 cases (24%), with an average allele frequency of 3.36%±5.16. Among these, 15 patients had one mutation, and six had multiple.
Conclusions We developed a reliable, cost-effective assay for ESR1 hotspot detection via liquid biopsy. Clinical results align with previous findings, though improved patient filtering could enhance detection rates.
Conclusion: We developed a reliable, cost-effective assay for ESR1 hotspot detection via liquid biopsy. Clinical results align with previous findings, though improved patient filtering could enhance detection rates.

Funding: Stemline Israel

PS-04-016
Ultra-fast detection of hotspot mutations in cell-sparce supernatants from Transbronchial Needle Aspiration (TBNA): proof of concept and comparison to tissue-based Next-generation Sequencing (NGS)
J.-O. Dahlberg[1,2], Y. Kottwitz[1], H. Witte[3], D. Gagiannis[1], K. Steinestel[1], A. Arndt[1]
[1]Bundeswehrkrankenhaus Ulm, Institute of Pathology and Molecular Pathology, Ulm, Germany, [2]Växjö Hospital, Pathology and Cytology, Växjö, Sweden, [3]Bundeswehrkrankenhaus Ulm, Haematology and Oncology, Ulm, Germany

Background & Objectives: Molecular testing is essential in non-small cell lung cancer (NSCLC), with tissue-based next-generation sequencing (NGS) as the gold standard. However, traditional sample processing, including formalin fixation, paraffin embedding, and DNA isolation, requires 2–3 days, and tissue scarcity can limit molecular studies. This study evaluated the feasibility of small-panel NGS-based mutation detection using cell-sparse DNA from the supernatant of transbronchial needle aspiration (TBNA) samples, comparing results to standard tissue-based NGS.
Methods: DNA was extracted from TBNA supernatants and 37 samples were subjected to small-panel NGS (AmpliSeq for Illumina Cancer HotSpot v2). The impact of sample storage length and conditions on DNA integrity as well as sequencing quality, were assessed. Results were compared to standard tissue-based NGS from the respective patients.
Results: 37 samples were examined. In under 80% of cases, pathological mutations were detected, despite low overall DNA content. Supernatants stored in saline showed superior DNA amplification and sequencing results, while prolonged formalin storage (>2 months) led to severe degradation and test failures. Shorter storage durations were associated with improved sequencing quality.
Conclusion: Small-panel NGS on TBNA supernatants enables ultra-fast mutation detection and offers a potential alternative when tissue is scarce. Avoiding prolonged formalin exposure significantly improves DNA integrity and sequencing success. This method could complement or replace tissue-based molecular testing in NSCLC diagnostics.

PS-04-017
Digital spatial profiling of tumour budding in head and neck cancer
I. Ourailidis[1,2], M. Ball[1], D. Kazdal[1], M. Kirchner[1], V. Vogel[1], S. Böning[3], S. Duensing[3], K. Steiger[4], C. Mogler[4], P. Schirmacher[1], A. Stenzinger[1], F. Stögbauer[4], M. Boxberg[4], J. Budczies[1]
[1]Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany, [2]Faculty of Biosciences, Heidelberg University, Heidelberg, Germany, [3]Department of Urology, University Hospital Heidelberg, Heidelberg, Germany, [4]Institute of General and Surgical Pathology, Technical University of Munich, Munich, Germany

Background & Objectives: Tumour budding, defined as clusters of up to four tumour cells dissociated from the tumour bulk, is an adverse prognostic factor in head and neck squamous cell carcinoma (HNSCC). We leveraged spatial transcriptomics to investigate the underlying gene expression patterns by both intertumoral (bulk of budding vs non-budding tumours) and intratumoral (tumour buds vs bulk) comparisons.
Methods: FFPE tissue sections from 24 budding and 19 non-budding HPV-negative HNSCC (TUM-HNSCC cohort) were analysed using the DSP whole transcriptome atlas (NanoString Technologies, Inc.). Regions of interest were selected to include tumour buds, as well as bulk of budding and non-budding tumours, with separate compartmental analysis for tumour and stroma cells. Differential gene expression analyses identified budding-specific signatures and a tumour budding score (TBS) was derived from consistently overexpressed genes in tumour buds. The TBS was applied to bulk-RNAseq data from the Cancer Genome Atlas (TCGA-HNSC) and drug response data of SCC cell lines from the PRISM lab (PRISM-SCC).
Results: In TUM-HNSCC, the intertumoral comparison revealed 11 tumoral and 5 stromal differentially expressed genes (DEGs), while the intratumoral comparison identified 379 tumoral and 10 stromal DEGs. The sets of tumoral DEGs were enriched by functions in epithelial-mesenchymal transition, coagulation, and others. The TBS, consisting of a 28-gene signature, distinguished tumour buds from all other spatial compartments with an AUC of 0.97 (p=1e-12). In TCGA-HNSC, the TBS successfully separated budding from non-budding tumours (AUC=0.8, p=6e-09) and correlated with poor overall survival (HR = 1.5, p=0.02). In PRISM-SCC, TBS predicted the response to MEK-inhibitors.
Conclusion: Spatial transcriptomics was feasible from HNSCC FFPE tissues and revealed tumour buds-specific transcriptional programs. The TBS separated tumour buds from other tumour regions, distinguished budding from non-budding tumours in bulk-RNAseq data, predicted prognosis, and could help identify therapeutic vulnerabilities.

PS-04-018
Clinical impact and therapeutic implications of the discordance between immunochemical and molecular tests for the diagnostic definition of microsatellite instability in endometrial cancer
S. Vatrano[1], C. Alario[1], A. Chiarandà[1], P. Gasparri[1], G. Musicò[2], A. Abbate[2], C. Messina[3], S. Russo[3], F. Fraggetta[1]
[1]Gravina Hospital, Pathology Unit, Caltagirone, Italy, [2]ARNAS Civico Benfratelli Hospital, Department of Gynaecologic Oncology, Palermo, Italy, [3]ARNAS Civico Benfratelli Hospital, Department of Oncology, Palermo, Italy

Background & Objectives: To investigate the discordance between immunohistochemistry (IHC) and molecular testing in endometrial cancer (EC) to better identify patients with microsatellite instability (MSI) or stability (MSS), considering the extended utility of molecular profiling for risk stratification, therapeutic decision making and enrolment in clinical trials.

Methods: Molecular profiling of 122 patients with EC collected at Gravina Hospital (Caltagirone, Italy) was routinely performed with Targeted Next Generation Sequencing (T-NGS), IHC and Bethesda panel for microsatellite instability polymerase chain reaction (MSI-PCR) analyses, using both surgical and biopsy specimens. The Pentaplex panel with melting analysis was performed in discordant cases for MSI and deficit of mismatch repair system (dMMR) , while the methylation test was performed to identify Lynch syndrome in cases of MSI/dMMR with loss of MLH1.
Results: All cases were successfully genotyped and the molecular risk stratification data of the patients matched the literature. For MSI identification, 101 (83%) cases were classified concordantly (68% MSS/pMMR; 32% MSI/dMMR), while 21 (17%) cases had discordant results showing an ambiguous phenotype and/or genotype, with correct reclassification by a third method or retesting (16/21). Finally, in 5 (4%) cases, the data were inconclusive as the IHC staining was abnormal without MSI status, leading to difficult classification. These cases had a low rate of MLH1 promoter methylation or genetic mutations in hereditary cancer predispositions.

Conclusion: Our study confirms the possibility of routinely applying molecular classification in patients with EC to ensure correct clinical and therapeutic management. The determination of MSI remains a complicated issue where the rules used for colorectal cancer are not always optimal for EC. The use of appropriate molecular methods, such as the use of an expert team for IHC analysis, is essential for correct MSI identification in EC patients who may benefit from immunotherapy or are carriers of mutations predisposing to a hereditary genetic syndrome.

PS-04-019

Molecular profiling of lung cancer and colorectal carcinoma: mutation prevalence, clinical characteristics and diagnostic timelines: a single-centre study

A. Pomoni[1], D.S. Gkanetsou[1], P. Sakellaraki[1], E. Kourea[2], P. Bosgana[3], M. Gkermpesi[1], E. Geropoulou[1], D. Koumoundourou[1], K. Kekempanou[1], M. Melachrinou[2], V. Bravou[4], V. Zolota[2], V. Tzelepi[2]
[1]University Hospital of Patras, Department of Pathology, Patras, Greece, [2]University of Patras, School of Medicine, Department of Pathology, Patras, Greece, [3]General Hospital of Patras, Department of Pathology, Patras, Greece, [4]University of Patras, School of Medicine, Department of Anatomy-Histology-Embryology, Patras, Greece

Background & Objectives: Molecular profiling plays a crucial role in the personalized management of non-small cell lung carcinoma (NSCLC) and colorectal carcinoma (CRC). This study examines the prevalence of *EGFR*/*KRAS*/*BRAF* mutations in NSCLC, as well as *KRAS*/*NRAS*/*BRAF* mutations and microsatellite instability (MSI) status in CRC, in a major academic centre in Greece. Special focus was placed on diagnostic turnaround times (TAT) to identify barriers to timely clinical decision-making.
Methods: Molecular (qPCR) and MSI (immunohistochemistry) testing data from NSCLC and CRC cases diagnosed at our institution in 2024 were collected. Clinical and pathologic data, including diagnosis date, date of test request and date of result availability, were analysed.
Results: In total, 192 patients with NSCLC and 200 with CRC were identified. Mutations were detected in 32% of NSCLC (45% in non-squamous and 6% in squamous histologies) and 58% of CRC cases. The detected frequencies for NSCLC were 4,6% for *EGFR*, 26% for *KRAS* and 1,6% for *BRAF*, and for CRC 44,5% for *KRAS*, 4,5% for *NRAS* and 10% for *BRAF*. MSI-H prevalence (7.5%) correlated with *BRAF* mutations ($p<0.001$). The median time intervals for NSCLC and CRC, respectively, were: 19 and 37 days from diagnosis to test request, 8 and 7 days from request to molecular results and 28 and 44 days from diagnosis to molecular results. Median time from diagnosis to request was shorter in metastatic tumours and biopsies (compared to primary tumours and resections), though still over 25 days for CRC, with no difference in request-to-result time based on specimen type or origin.
Conclusion: The findings support the implementation of reflex molecular testing to expedite result availability and therapy decisions for each NSCLC and CRC case. The low EGFR mutation rate that was observed in our study may reflect population-specific factors or potential limitations of the testing methodology used.

PS-04-020

Comparison of immune-checkpoint inhibitor therapy efficacy according to the predictive marker tests, microsatellite instability (MSI) and mismatch-repair deficiency (dMMR), used for patient selection

M. Nádorvári[1], I. Kenessey[1], E. Rásó[1], J. Kocsis[2], G. Bodoky[3], Z. Pápai[4], M. Dank[5], M. Nádorvári[6], A. Maráz[7], K. Boér[8], J. Tímár[1]
[1]Semmelweis University, Department of Pathology, Forensic and Insurance Medicine, Budapest, Hungary, [2]Bács-Kiskun County Hospital, Department of Oncoradiology, Kecskemét, Hungary, [3]St László Teaching Hospital, Department of Oncology, Budapest, Hungary, [4]Military Hospital Budapest, Department of Oncology, Budapest, Hungary, [5]Semmelweis University, Department of Internal Medicine and Oncology, Budapest, Hungary, [6]Jósa András Szabolcs-Szatmár-Bereg County Hospital and University Teaching Hospital, Department of Oncoradiology, Nyíregyháza, Hungary, [7]University of Szeged, Department of Oncotherapy, Szeged, Hungary, [8]Szent Margit Hospital, Department of Medical Oncology, Budapest, Hungary

Background & Objectives: International guideline recommendations consider immunohistochemistry (IHC) for dMMR or molecular techniques (PCR, NGS) for MSI-high determination equal, although there are scattered reports contradicting to this presumption. Here we aimed to analyse if the efficacy of ICI (immune-checkpoint inhibitor) therapies is influenced by the diagnostic method based on patient selection.
Methods: In this multi-centre retrospective analysis, we have directly compared 84 anti-PD1 immune-checkpoint inhibitor treated patients' OS (overall survival) and PFS (progression free survival) according to the qualifying diagnostic method: four MMR protein IHC or Pentaplex MSI-PCR. 35 patients were diagnosed with MMR IHC and 49 with MSI PCR tests. 30 male and 54 female patients were involved in the study and 62 patients had colorectal cancer. The mean age of the patients was 68 years ±9 years, and 67±10 years for the colorectal part of the cohort. The follow-up was set for four years. (SE-RKEB37/2024).
Results: For the entire cohort, the PFS of the MSI group at 48 month was 52.6% as compared to the 59.5% of the dMMR group. Concerning OS, at 48 months 72.4% of MSI patients were alive compared to 69.9% of the dMMR group. The Kaplan-Meier analysis did not show significant differences neither in PFS ($p=0.751$) nor in OS ($p=0.454$). This analysis was repeated for the colorectal cancer subcohort ($n=62$). At 48 months, the PFS of MSI patients was 57.0% compared to 71.5% of the dMMR group. At 48 months, the OS of the colorectal cancer patients was 77.9% for the MSI group and 75.5% for the dMMR group. The Kaplan-Meier analysis again, did not demonstrate significant differences, neither in PFS ($p=0.757$) nor in OS ($p=0.529$).
Conclusion: Our study demonstrated that the therapeutic efficacy of the anti-PD1 antibodies in cancer patients is independent from the predictive markers used for patient selection (MSI-PCR, MMR-IHC).

PS-04-021

ITGB1-driven chondrogenic differentiation in mesenchymal stem cell-like populations of pleomorphic adenomas

E. Park[1], H. Kim[2], B. Jang[1,3]
[1]Jeju National University College of Medicine, Department of Pathology, Jeju, Republic of Korea, [2]Jeju National University College of Medicine, Department of Convergence Biomedical Science, Jeju,

Republic of Korea, [3]Jeju National University Hospital, Department of Pathology, Jeju, Republic of Korea

Background & Objectives: Pleomorphic adenomas (PAs) are the most common salivary gland tumours, characterized by high recurrence and potential malignant transformation. Chondroid metaplasia, a hallmark of PAs, involves tumour cells with mesenchymal stem cell (MSC)-like properties enabling chondrogenic differentiation. Integrins, particularly ITGB1, mediate cell-ECM interactions and are crucial in differentiation. ITGB1 regulates mesenchymal cell condensation, a critical step in chondrogenesis. However, its role in PA chondroid metaplasia is not well understood. This study aimed to identify MSC-like subpopulations in PAs and investigate the role of ITGB1 in chondrogenic differentiation, elucidating the mechanisms underlying chondroid metaplasia.
Methods: We performed spatial transcriptomics on PA tissues to analyse gene expression within chondroid metaplasia regions and their surrounding microenvironment. PA primary cell lines were induced to undergo chondrogenic differentiation using differentiation media. RT-qPCR and immunostaining validated gene and protein expression dynamics during chondrogenic induction. Lentiviral knockdown of SOX transcription factors assessed their roles in nodule formation and early differentiation. Single-cell RNA sequencing was employed to characterize PA cellular composition, identifying ITGB1-high populations with enhanced chondrogenic potential and distinct transcriptomic profiles.
Results: Spatial analysis showed chondrogenic marker expression in chondroid regions, as well as in the mesenchymal cluster surrounding the chondroid region, indicating a supportive niche for differentiation. PA cells formed condensations and expressed SOX transcription factors, crucial for chondrogenesis and cellular organization. SOX4 and SOX9 knockdown inhibited effective nodule formation, highlighting their importance in condensation and early differentiation. Immunostaining confirmed ITGB1 expression in myoepithelial cells, and anti-ITGB1 antibodies affected nodule formation by regulating migration, adhesion, and cell-matrix interactions. ITGB1-high populations exhibited upregulated chondrogenic factors and enhanced ECM remodelling, suggesting higher chondrogenic potential.
Conclusion: ITGB1 is a critical regulator of chondrogenesis in PAs, promoting MSC-like differentiation and enhancing chondrogenic potential, highlighting its central role in chondroid metaplasia and the progression of chondroid differentiation.

PS-04-022

Sensitive, fast and cost-effective FLT3-ITD measurable residual disease monitoring using Oxford Nanopore MinIon devices

K. Kashofer[1], E. Winter[1], S. Sauer[1], A. Reinisch[2], A. Zebisch[2], M. Zacharias[1], F.R. Vagena[1]
[1]Medical University of Graz, Diagnostic- and Research-Institute of Pathology, Graz, Austria, [2]Medical University of Graz, Division of Haematology, Graz, Austria

Background & Objectives: Measurable residual disease (MRD) monitoring is essential during treatment of acute myeloid leukaemia (AML). NGS assays for FLT3-ITD MRD frequently rely on Illumina long read technology from MiSeq or NextSeq instruments which present high consumables costs, large batch effects, long run times and are limited in maximum detectable ITD length.
Methods: DNA was extracted from peripheral blood and bone marrow samples of patients with FLT3-ITD mutated AML on Promega Maxwell RSC. A wetlab and bioinformatics procedure was established using Oxford Nanopore MinIon and the getITD tool (https://github.com/tjblaette/getitd) to detect MRD.
Results: PCR primers spanning Exons 14-15 of the FLT3 gene were adapted with an 2x8bp dual sample barcode. Amplification using 200ng DNA in triplicates in a 50µl volume yielded consistent results and ascertained sensitivity down to 0,005 % allelic frequency. Amplification on primary AML samples with FLT3-ITD confirmed by fragment analysis created the expected 329 bp band on Tapestation. Sequencing of up to 9 PCR products on an Oxford Nanopore MinIon device yielded approximately 20mio reads in 20hrs with no restriction on ITD length. After basecalling, barcode splitting and removal of low quality reads each PCR reaction yielded 600-800k individual reads. Flow cells could be re-used after up to two days to perform a second run with similar quality and yield. The getITD software was modified for faster search and adapted to Nanopore reads. Limiting dilution of FLT3-ITD positive material demonstrated linearity of measurement down to 50 fragments. getITD was able to detect FLT3-ITD in all initial AML samples (5/5) and in 6/10 post-transplant remission samples. The assay showed superior sensitivity to gold-standard fragment analysis and reaches comparable sensitivity when compared to NPM1 qPCR in patients with FLT3 and NPM1 co-mutation.
Conclusion: Oxford Nanopore sequencing presents a fast, unrestricted and cost-effective solution to low volume, quick turnaround FLT3-ITD MRD detection in AML patients.

PS-04-023

Inter-laboratory variability in DNA yield and quality – results from the 2024 DNA extraction from formalin fixed paraffin embedded (FFPE) tissue EQA

F. Moon[1], Z.C. Deans[1]
[1]GenQA, NHS Lothian, Laboratory Medicine, Edinburgh, United Kingdom

Background & Objectives: Efficiency of DNA extraction and the resulting quality of the DNA can have major implications for downstream testing. The benchmarking of the quality and quantity of DNA extracted between laboratories provides a mechanism to determine the proficiency of the extraction process. GenQA provides a DNA extraction from FFPE tissue external quality assessment (EQA).
Methods: Participating laboratories were provided with tissue from the same source (3 different cases) and were required to extract DNA using routine extraction methodology and return to GenQA for analysis. The quantity of DNA extracted was determined using digital PCR and volume of DNA, and the quality was assessed using the mean peak size in base pairs (bp) by tapestation.
Results: The yield of DNA extracted was variable. Four laboratories were within the top 10% of mass extracted for 2 out of 3 samples. Five laboratories were in the lower 10% for extracted mass in 2 out of 3 samples, and 1 laboratory was in the lower 10% for all three samples. The mass of DNA extracted from the lung tissue sample ranged from 0.21µg to 4.48µg, endometrial tissue from 0.34µg to 10.96µg and uterine tissue sample from 0.82µg to 12.04µg. The mean bp size varied across the different samples, laboratories and methods. The average mean peak size for the lung sample was 1165bp, for endometrial sample was 609bp and the uterine sample was 1062bp. The lower mean peak for the endometrial sample is indicative of a poorer initial FFPE tissue sample, which may be due to ischemia, or conditions during the fixation process.
Conclusion: The variability of mass and quality of DNA extracted by participants demonstrates the need for improvement and standardisation of extraction protocols. This is pertinent for the increase in more advanced technologies into routine practice which require DNA of high quality.

PS-04-024

Validation of a comprehensive genomic profiling liquid biopsy profiling assay, retrospective analysis of biomarker yield and clinical utilization

A. Oszwald[1], L. Schöpfer[1], L. Müllauer[1]
[1]Medical University of Vienna, Department of Pathology, Vienna, Austria

Background & Objectives: Since 2023, comprehensive genomic profiling (CGP) of cell-free DNA is offered at the Department of Pathology of the Vienna General Hospital using the AmoyDx® Comprehensive Assay. At establishment, the intent was to provide diagnostic support for patients where a tissue biopsy was impossible or otherwise unavailable. Here, we describe our experience, including technical performance, biomarker yield, retrospective assessment of clinical utilization, and a browser-based software to assist in reporting and archiving of results.
Methods: The AmoyDx® Comprehensive Assay was performed using cfDNA prepared from plasma according to manufacturer's specifications. A browser-based software for annotation, reporting, interpretation and archiving of the AmoyDx analysis output was developed using R Statistics. Retrospective biomarker analysis included 411 samples, whereas clinical analysis was restricted to 126 consecutive patients. Retrospective biomarker analysis was performed using Cancer Genome Interpreter, whereas clinical data was assessed by review of hospital and prescription records.
Results: Regarding small variants, using optimized filtering criteria and reference standards at 0.5% variant allele fraction (VAF), the assay achieved an analytical sensitivity of 98%, with a limit of blank of 0.05% VAF across representative positions. We identified actionable biomarkers in 40.8% of cases, with documented clinical decision support through testing in 11.7%. In 4.7% of cases, the test identified actionable alterations that were followed by documented specific therapy. Biomarker yield and documented indication, acknowledgement and utilisation of the report showed considerable variability between submitting institutions.
Conclusion: The hard-coded filtering criteria of the AmoyDx® pipeline should be challenged for optimal sensitivity. While the assay detects biomarkers and/or confirmed decision support in a relevant number of cases, inconsistent clinical documentation limits confident retrospective assessment of its true clinical usefulness. We propose that in non-profit institutions, novel and expensive tests such as liquid biopsy-based CGP should be coupled to a prospective study design to accurately monitor clinical utility.

PS-04-025
Assessing the quality of molecular tumour boards
J. Fairley[1], Z.C. Deans[1]
[1]GenQA, Edinburgh, United Kingdom

Background & Objectives: Comprehensive genomic testing for solid tumours requires discussion and interpretation of complex results in multi-disciplinary molecular tumour board meetings. There is a need to look at the quality of output from such meetings as it play a critical role in the reporting of accurate genomic testing.
Methods: Participants were provided with a mock non-small cell lung cancer clinical case, genomic test results for multiple genes, and clinical details of the patient. They were requested to discuss the case in their usual molecular tumour board and submit the work up performed prior to the discussion including classification of the variants found, the outcome of the discussion in the tumour board and the report which would be produced. Results were benchmarked with those of the other participating centres with input from a clinical oncologist and clinical scientists.
Results: Eight centres submitted results for this study. The majority of laboratories submitted work up for the case which included classification of the variants provided. All eight centres identified the same *RET* fusion as being of the highest clinical significance and recognised that inhibitors are available which target the variant. However, due to local differences in approvals and reimbursement of associated treatments the recommendations were variable.
In addition to the main actionable variant the case also included details of other variants which could potentially have clinical implications, the discussion of these was more variable between participating centres.
Conclusion: The returns demonstrate the differences in the outcome of molecular tumour boards which may reflect local approvals for precision medicines. In order for high quality reporting and best outcomes for patients there is a need for harmonisation and education which can be facilitated through external quality assessment.

PS-04-028
AI-driven automation of biomarker and NGS report analysis: advancing quality monitoring in pathology
C. Garnier[1], J. Calafell[1], A. Pereira[1], A. Almela[1], J. Mir[1], M.F. Paz[1]
[1]Connect by Circular-Lab, Madrid, Spain

Background & Objectives: Standardized biomarker reporting is critical for precision oncology, yet pathology laboratories face challenges in structuring diagnostic data. The Spanish Society of Pathology (SEAP) has developed national quality programs (e.g., ConfirmaHER2, LungPath), but manual data entry limits efficiency and completeness. This study evaluates C-LAB®, an AI-powered platform, for automating biomarker data extraction and standardization within SEAP's Quality Program and a national Next-Generation Sequencing (NGS) harmonization initiative.
Methods: A multi-centre study was conducted across 51 hospitals: 7 for pathology report automation and 44 for NGS analysis. C-LAB® processed 11,199 pathology reports (5,376 breast, 5,823 lung cancer) and 258 NGS reports. The platform extracted structured data on sample characteristics, testing methodologies (IHC, FISH, qPCR, NGS), biomarker results, and genomic alterations.
Results: Pathology report analysis: C-LAB® achieved 92.22% accuracy and a 93.33% F1-score in biomarker extraction, reducing processing time by 90% compared to manual entry. Real-time analysis enabled biomarker quality monitoring, with key positivity rates identified in breast (such as HER2, ER, PR, PD-L1) and lung (such as EGFR, ALK, ROS1, PD-L1, NTRK, RET, MET, KRAS) cancers.
NGS report analysis: NGS report analysis revealed variability in reporting practices: while 87.6% of reports listed tested genes and 81.7% included interpretations, only 34.1% provided therapeutic recommendations, and 5.8% mentioned clinical trial options, highlighting a gap in structured reporting. The most frequently identified biomarkers were: EGFR, ALK, MET and KRAS.
Conclusion: C-LAB® revolutionizes biomarker data management by automating extraction and standardization in SEAP's Quality Program and NGS harmonization. It enhances efficiency, accuracy, and benchmarking across centres, overcoming manual data entry challenges. Future expansion aims to integrate more specialties, cancer types, and clinical data, advancing precision medicine and healthcare accessibility.

PS-05 Poster Session Cytopathology

PS-05-001
Vitreous cytology: comprehensive assessment and diagnostic utility in neoplastic and non-neoplastic disorders
O.C. Eren[1], C. Aydin Mericoz[1], T. Akan[2], C. Kesim[3], O. Dogan[1], M. Hasanreisoglu[3], P. Firat[1]
[1]Koç University Hospital, Department of Pathology, Istanbul, Turkey, [2]Koç University Hospital, Flow Cytometry Laboratory, Istanbul, Turkey, [3]Koç University Hospital, Department of Ophthalmology, Istanbul, Turkey

Background & Objectives: Cytologic evaluation of the vitreous is a reliable method for diagnosing various pathologies, including infections, hematolymphoid malignancies, and metastases. Given the limited and viscous nature of vitreous, we outline our approach to vitreous cytology.
Methods: Vitreous aspiration fluid, typically gelatinous, is initially processed by centrifuging at 1000 rpm for 20 minutes (NF200). The

resulting pellet is then processed (Cellspin, THARMAC) at 500 rpm for 15 minutes, generating up to 10 slides. Two slides are air-dried for May-Grunwald Giemsa staining, and two are placed in alcohol for Papanicolaou staining. Additional slides are reserved for histochemical stains and immunohistochemistry. On most occasions, subsequent saline wash fluid of the vitreous chamber is submitted separately by the clinicians. If clinically relevant, 5 ml is sent for flow cytometry, and the remainder follows the same processing. Cell blocks are created when possible.
Results: To validate our approach, 16 vitreous samples were collected from 15 patients (median age 56 years, M:F ratio 1:1.14). Immunohistochemistry was performed on 9 samples: 5 using cytospin slides, 3 with cell blocks, and 1 with both. Histochemical stains (GMS and iron stain) were used in 2 cases to detect hyphae and hemosiderin, respectively. Flow cytometry was conducted on 12 samples. Diagnoses included high-grade lymphoma (n=5), fungal endophthalmitis (n=1), subacute haemorrhage (n=1), and reactive or benign hematolymphoid cells (n=6), with flow cytometry supporting the findings. From the same patient, n=2 samples required further evaluation (T-cell clonality studies) for definitive diagnosis. In n=1 case, the sample was deemed insufficient for evaluation due to scarcity and low cellularity.
Conclusion: Vitreous cytology, supported by ancillary studies such as histochemistry, immunohistochemistry, and flow cytometry, provides a valuable and reliable diagnostic tool for both neoplastic and non-neoplastic conditions.

PS-05-002
Sensitive next generation sequencing evaluation of routine EUS-FNA smears from solid pancreatic lesions: a pilot study
F. Tutucu[1], H.M. Schutz[2], P.N. Atmodimedjo[1], R. Quispel[2], L. van Driel[3], K. Biermann[1], H. Dubbink[1], M. van Velthuysen[1]
[1]Erasmus MC Cancer Institute University Medical Centre, Department of Pathology and Clinical Bioinformatics, Rotterdam, The Netherlands, [2]Reinier de Graaf Gasthuis, Department of Gastroenterology and Hepatology, Delft, The Netherlands, [3]Erasmus MC Cancer Institute University Medical Centre, Department of Gastroenterology and Hepatology, Rotterdam, The Netherlands

Background & Objectives: Pancreatic ductal adenocarcinoma is a highly heterogeneous and diverse disease, characterized by a pronounced desmoplastic microenvironment. This often results in limited cell yield from endoscopic ultrasound(EUS)-guided fine needle aspirations (FNA) or biopsies (FNB) of these lesions, hindering cytomorphological evaluation. Sensitive next generation sequencing analysis (NGS) analysis with Unique Molecular Identifiers (UMI-NGS) might overcome this limit of material.
Methods: Forty EUS-derived FNA smears from solid pancreatic leasions were retrospectively analysed.
UMI-NGS was performed on all samples. In addition, when enough material was available NGS with a pan-cancer diagnostic panel was performed. The results of both cytology and NGS analyses were compared with the definitive diagnosis obtained after surgery or follow-up and pan-cancer diagnostic panel of follow-up material when available.
Results: Molecular analysis using UMI-NGS was successful in 70% of samples (28/40), while only 5 of those samples yielded NGS results with the pan-cancer diagnostic panel. In 19 of 20 samples that were morphologically classified as malignancy, UMI-NGS detected mutations that supported the diagnosis of malignancy. UMI-NGS showed KRAS mutations in 2 of the 7 samples that were morphologically classified as 'negative for malignancy (benign)' both revealed to be benign in the follow-up. In 2 of the 5 samples initially diagnosed as "suspect malignant," UMI-NGS found mutations that led to reclassification as malignant.
Conclusion: UMI-NGS demonstrated to be reliable in detecting mutations in cytological smears of pancreatic lesions and much more sensitive than NGS without UMIs. Samples classified cytologically as non-diagnostic, benign, or atypical were found to either contain insufficient material for UMI-NGS or to contain no tumour. Consequently, repeated sampling can be considered in these cases.
Based on these results, we propose the implementation of a workflow incorporating UMI-NGS into clinical pathology to improve diagnostic accuracy for solid pancreatic lesions.

PS-05-003
Deep learning for lymphoma diagnosis: a cytology-based study using digitized lymph node imprints
P. Goineau[1], I. Jagour[2], T. Neveu[2], A. Ahaggache[2], F. Maxime[1], É. Cornet[3], C. Quintyn[4], Y. Chahir[2], M.-L. Quintyn-Ranty[1]
[1]Caen Univeristy Hospital, Pathological Anatomy and Cytology, Caen, France, [2]University of Caen, GREYC, Caen, France, [3]Caen Univeristy Hospital, Biological Haematology, Caen, France, [4]CY Cergy Paris Université, Paris, France

Background & Objectives: Lymphoma diagnosis through cytology remains a complex task due to inter-observer variability and the inherent subjectivity of manual evaluation. This study explores the potential of deep learning models to improve lymphoma detection from digitized lymph node cytological imprints.
Methods: Using a dataset of 148 annotated slides from Caen University Hospital, Normandy, we systematically evaluated three segmentation architectures: U-Net, U-Net++, and DeepLabV3+. Annotations were initially performed by a pathology resident and subsequently reviewed and refined by an expert pathologist to ensure accuracy and consistency.
Results: Quantitative results showed that U-Net achieved the highest accuracy (0.7563) and Dice score (0.7586), while U-Net++ demonstrated superior sensitivity (0.9405), making it particularly effective for detecting malignant regions. DeepLabV3+ exhibited strong boundary detection capabilities, despite lower overall performance. Expert pathologists assessed the clinical relevance of model outputs, revealing that U-Net++ provided the most interpretable segmentations for diagnostic use.
Conclusion: These findings highlight the potential of AI-assisted cytology to enhance diagnostic accuracy, particularly for less experienced pathologists. By integrating automated segmentation models with expert validation, deep learning can help standardize lymphoma diagnosis, reduce diagnostic variability, and improve patient management. Future work will focus on expanding datasets, refining classification of lymphoma subtypes, and optimizing model interpretability for clinical deployment.

PS-05-004
A comparison of SDHB immunostain on cytological and histological specimens for gastrointestinal stromal tumours
L. Chen[1,2], E. Olkhov-Mitsel[1], Z. Ghorab[1,2]
[1]Sunnybrook Health Sciences Centre, Anatomic Pathology, Toronto, Canada, [2]University of Toronto, Laboratory Medicine and Pathobiology, Toronto, Canada

Background & Objectives: Gastrointestinal stromal tumour (GIST) is the most common mesenchymal neoplasm of the gastrointestinal tract. Most GISTs are associated with known molecular genetics pathways, making biomarker testing critical for guiding treatment. While over 80% GISTs are driven by activating *KIT* or *PDGFRA* mutations that respond to tyrosine-kinase receptor inhibitors (TKRI), succinate dehydrogenase (SDH)-deficient GIST accounts for approximately 5%-10% and largely resistant to TKRI. Germline testing is recommended for all SDH-deficient GISTs. Currently, SDH subunit B (SDHB) immunohistochemistry is used as a surrogate marker for SDH deficiency, typically performed

on surgical resection specimens. However, initial tissue sampling of GISTs is often obtained by endoscopic ultrasound–guided fine-needle aspiration (EUS-FNA). Therefore, this study aimed to investigate the feasibility of testing SDHB on cell blocks derived from cytological specimens.
Methods: Paired cytological (FNA) and histological (resection) specimens from 33 GISTs were immunohistochemically examined for SDHB expression. The status (retention or loss), pattern (focal, patchy or diffuse), and intensity (weak, moderate or strong) of the stains were assessed by a cytopathologist and a GI pathologist independently for all the specimens.
Results: Three cases were SDHB deficient, while 30 cases retained SDHB. The concordance rate for SDHB status (retention or loss) between cytology and histology was 100%. While the patterns of staining had no significant difference (p=0.105), the staining intensity in cytological specimens (3 weak, 11 moderate, and 16 strong) was stronger compared to histological specimens (14 weak, 9 moderate and 7 strong) (p = 0.004). Three histological specimens showed focal very weak staining which could be easily overlooked.
Conclusion: We have shown a 100% concordance rate between SDHB immunostain performed on cell blocks of cytological specimens and formalin-fixed paraffin-embedded histological specimens. Using cytological specimens for SDHB staining could potentially have a lower rate of false-negatives compared to histological specimens.

PS-05-005
From smear to diagnosis: the role of ancillary techniques in lymph node fine-needle cytology
E. Maffei[1], G. Di Motta[1], R. Ruotolo[1], A. Caputo[2], P. Zeppa[2]
[1]University Hospital of Salerno, Pathology, Salerno, Italy, [2]University of Salerno, Medicine and Surgery, Salerno, Italy

Background & Objectives: Diagnostic accuracy of lymph node fine-needle aspiration cytology (LN-FNAC) relies on proper management of diagnostic material and ancillary techniques (AT). AT play a crucial role in diagnosing LN-FNAC in reactive processes, Hodgkin lymphoma (HL), non-Hodgkin lymphoma (NHL), and metastases. While the role of AT in LN-FNAC has been extensively highlighted, their actual impact on diagnostic accuracy remains underexplored in the literature. This study aims to analyse the impact of AT on the diagnostic accuracy of LN-FNAC.
Methods: A retrospective analysis was conducted on 452 LN-FNAC samples, retrieved from the database of the Pathology Department at the University Hospital of Salerno (Italy). AT were applied in 187 cases. All these cases were reclassified according to the Sydney System, initially without AT and subsequently with AT information. The impact of AT on diagnoses was categorized as follows: "non-contributory", for cases where AT yielded inadequate results; "confirmed", when AT confirmed the initial diagnosis; "improved", when AT further refined the diagnosis, and "allowed", when AT enabled a diagnosis that could not have been reached without AT.
Results: A comparison of diagnostic categories before and after applying AT revealed a significant impact on the final diagnosis. The analysis showed the following results: AT **confirmed** the FNAC diagnosis in 19.79% of cases (n = 37/187); AT **improved** the FNAC diagnosis in 36.36% of cases (n = 68/187); AT **allowed** a diagnosis that otherwise could not have been made in 37.97% of cases (n = 71/187); and AT was **non-contributory** in 5.88% of cases (n = 11/187).
Conclusion: This analysis shows that AT refined diagnoses in nearly 95% of cases, showing either improvement, confirmation, or completely new diagnosis made possible by AT. These findings highlight the importance of utilizing and incorporating AT in the LN-FNAC to achieve more precise and reliable diagnoses, ultimately enhancing patient management and outcomes.

PS-05-006
Diagnostic utility of the third edition of The Bethesda system for reporting thyroid cytopathology with emphasis on the grey zone categories
M. Rao[1], A. Arora[1], P. Elhence[1], A. Nalwa[1], S. Khera[1], D. Vedant[1], V. Vishwajeet[1], D. Aggarwal[1], V. Verma[1], A. Purohit[1], P. Khera[2], K. Soni[3], J. Vishnoi[4], M. Lodha[5]
[1]All India Institute of Medical Sciences (AIIMS), Pathology & Lab Medicine, Jodhpur, India, [2]All India Institute of Medical Sciences (AIIMS), Diagnostic and Interventional Radiology, Jodhpur, India, [3]All India Institute of Medical Sciences (AIIMS), Otorhinolaryngology, Jodhpur, India, [4]All India Institute of Medical Sciences (AIIMS), Surgical Oncology, Jodhpur, India, [5]All India Institute of Medical Sciences (AIIMS), General Surgery, Jodhpur, India

Background & Objectives: The Bethesda System for Reporting Thyroid Cytopathology (TBSRTC) establishes a standardized and category-based framework for reporting thyroid fine-needle aspiration (FNA) for the purpose of management. Challenges persist in accurately categorizing grey zone Non-Diagnostic (ND) and Atypia of Undetermined Significance (AUS) cases. We risk stratified thyroid FNA cases as per the 3rd edition TBSRTC and analysed the Risk Of Malignancy (ROM) for these newer suggested subcategories.
Methods: This study retrospectively reviewed 1597 thyroid FNAs from January 2019 to December 2023. Cases diagnosed as ND and AUS were sub-categorized according to the 3rd edition of TBSRTC and the ROM for each subcategory was calculated.
Results: Of the 1597 cases, 185 (11.6%) cases were ND, with predominant sub-category being others, among which the most common sub-group was blood only (67.6%). The risk of malignancy (ROM) among ND cases was 7.6%. ROM for cyst fluid was 14.3%, and for the others subcategory, it was 8.2%. AUS category constituted 147 cases (9.2%), with ROM of 12.5%. Within the AUS subcategories, Under AUS category, ROM was higher for the subcategory nuclear atypia (14.0%) than the subcategory others (12.1%).
Conclusion: The study highlights the challenges and importance of refined subcategorization in the TBSRTC, 3rd edition, and its role in enhancing diagnostic accuracy of the grey zone categories and further guiding patient management in thyroid nodules. Subcategorization may provide more precise risk stratification and therapeutic decisions.

PS-05-007
Application of telepathology for rapid on-site evaluation of touch imprint cytology in CT-guided percutaneous transthoracic core needle biopsy of pulmonary nodules: the experience of our multidisciplinary thoracic tumour board
M. Montella[1], S. Lucà[1], R. Monti[2], C.M. Della Corte[3], A. Cantisani[1], I. Cozzolino[1], E. Clery[1], M. Amato[1], G. Ferrara[1], L. Marone[2], F. Capasso[4], F. Morgillo[3], A. Fiorelli[4], G. Vicidomini[4], R. Franco[1]
[1]University of Campania "Luigi Vanvitelli", Department of Mental and Physical Health and Preventive Medicine, Pathology Unit, Napoli, Italy, [2]University of Campania "Luigi Vanvitelli", Department of Precision Medicine, Radiology Unit, Napoli, Italy, [3]University of Campania "Luigi Vanvitelli", Department of Precision Medicine, OncologyUnit, Napoli, Italy, [4]University of Campania "Luigi Vanvitelli", Department of Traslational Medicine, Thoracic Surgery Unit, Napoli, Italy

Background & Objectives: Lung cancer remains the leading cause of cancer-related mortality, with most cases diagnosed at advanced stages, requiring minimally invasive tissue sampling for diagnosis and molecular profiling. To maintain the high quality of these small samples, the most effective technique is rapid on-site evaluation (ROSE). However, the shortage of pathologists and frequent logistical challenges make this technique difficult to implement. The application of Telepathology can resolve these critical issues. This study evaluates the

implementation of telepathology for ROSE using touch imprint cytology (TIC) during CT-guided percutaneous transthoracic core needle biopsy (CNB) of pulmonary nodules.
Methods: We conducted prospectively from September 2024 to January 2025, the study involved 50 patients with lung nodules, analysed with CNB, and TIC samples evaluated either on-site or remotely via telecytology using a fully remote-controlled microscope system (OCUS®). TIC was performed by various operators, including pathologists, radiologists, and trained assistants.
Results: The evaluation showed that 86% of TICs were diagnostically adequate, with full concordance between on-site and remote evaluations. The average scan area of 11x9.75 mm required approximately 140 seconds for telecytology assessment, with the total adequacy evaluation time averaging 160 seconds per case. Histological analysis confirmed non-small cell lung cancer (NSCLC) as the most frequent diagnosis. The study highlighted telecytology's diagnostic accuracy and effectiveness in overcoming logistical challenges, especially the actual "shortage" of pathologists and the physical distance between radiology and pathology departments. Moreover, the results demonstrated the feasibility of involving trained non-pathologists in TIC preparation without compromising slide quality.
Conclusion: Telepathology allowed optimal use of pathologists' time, avoiding unnecessary delays in diagnosis. While scanning time remains a limitation, it did not impact procedural success or specimen quality. The findings support the integration of telecytology-based ROSE in routine practice, particularly in resource-limited settings, with implications for improved workflow efficiency and diagnostic performance.

PS-05-008
High-risk HPV prevalence and distribution in cervical cancer screening: biomarker-based approach with extended genotyping, cytology, and p16/Ki67 dual staining
M. Trzeszcz[1,2], K. Mazurec[2], M. Mazurec[2], R. Jach[3], A. Halon[4]
[1]University Hospital in Wroclaw, Division of Pathology and Clinical Cytology, Wroclaw, Poland, [2]Corfamed Woman's Health Centre, Wroclaw, Poland, [3]Jagiellonian University Medical College, Division of Gynaecologic Endocrinology, Krakow, Poland, [4]Wroclaw Medical University, Department of Clinical and Experimental Pathology, Division of Clinical Pathology, Wroclaw, Poland

Background & Objectives: The prevalence of high-risk human papillomavirus (HR-HPV) in cytology combined with p16/Ki67 status using limited and two types of extended HPV genotyping has not yet been described.
Methods: A total of 32,724 screening tests results between 2015-2024 were retrieved, including HR-HPV testing, cytology and p16/Ki67. For HPV limited genotyping the Abbott RealTime High Risk HPV molecular assay was performed. For HPV extended genotyping two assays were used: Alinity m HR HPV and BD Onclarity HPV Assay. Immunoprofile assessment was performed by a qualified and experienced gynaecological cytopathologist. All cytology samples were assessed based on the Bethesda 2014 system. The analysed results were categorized and trends in age-specific, cytology-specific, and p16/Ki67-specific HR-HPV prevalence and distribution were observed, and differences between limited and extended genotyping were examined. Statistical methods included chi-square and McNemar's tests for study groups comparisons.
Results: The overall HR-HPV-positivity rate was 15.0%. HR-HPV prevalence in the limited genotyping group was 13.9%, in extended genotyping 1 (17.8%), in extended genotyping 2 (17.2%), with a statistically significant difference in the proportions of positive/negative cases ($p<0.0001$). No statistically significant difference was observed between extended genotyping groups ($p=0.706$). Extended genotyping group 1: the highest p16/Ki67-positivity was observed for HR-HPV 33/58 (100.0%) and 31 (58.8%), while the lowest was for HR-HPV 45 (18.2%), 18 (25.0%) and 59/56/66 (28.9%). Extended genotyping group 2: the highest p16/Ki67-positivity was observed for HR-HPV 16 (66.7%) and 31/33/52/58 (58.8%).
Conclusion: These findings, derived from analysis of 10-year of HPV-based screening test results, may contribute to cervical cancer prevention, thereby introducing a novel capability for optimizing national screening programs. A combined approach integrating new biomarker-based diagnostic technologies could support decision-making processes and help healthcare providers make more informed decisions about patient care.

PS-05-009
Usefullnes of PLAG1 and HMGA2 immunohistochemistry in salivary gland cytology
K. Bulut[1], S. Erkilic[1]
[1]Gaziantep University Medical Faculty, Pathology, Gaziantep, Turkey

Background & Objectives: Although the pleomorphic adenoma gene (PLAG1) and high-mobility group AT-hook 2 (HMGA2) immunohistochemical stains represent rearrangements in pleomorphic adenoma, there are studies in the literature showing that they can also stain in other salivary gland tumours. In this study, we investigated the contribution of PLAG1 and HMGA2 immunohistochemical staining in differentiating salivary gland tumours in cytology specimens.
Methods: A total of 64 cell blocks of salivary gland FNAC were included in the study. They were prepared using the Thin Prep liquid-based cytology method. All cytologies had histopathologic follow-up; 41 pleomorphic adenomas (PA), 6 Warthin tumours (WT), 4 mucoepidermoid carcinomas (MEC), 1 adenoid cystic carcinoma (AdCC), 2 basal cell adenoma/adenocarcinoma (BCA/BCAC), 2 acinic cell carcinomas (ACC), 2 epithelial myoepithelial carcinoma (EMC), 2 salivary duct carcinoma (SDC), 1 myoepithelioma and 3 carcinoma ex pleomorphic adenoma. Nuclear staining was considered positive for both antibodies.
Results: In the cell blocks, positive staining for PLAG1 was detected in 24 tumours (21 PA, 1 BCA/BCAC, 1 ACC, and 1 carcinoma ex PA) and for HMGA2 in 13 tumours (12 PA and 1 carcinoma ex PA). PLAG1 had a specificity of 86.9%, a sensitivity of 51.22% and an accuracy of 64% in differentiating PA, while for HMGA2 these rates were 95.6%, 29.2% and 51.6%, respectively. In the combination of PLAG1 or HMGA2, specificity was 82.6%, sensitivity was 73.17% and accuracy was 75.5%.
Conclusion: In salivary gland cytology, PLAG1 and HMGA2 have high specificity and low sensitivity for pleomorphic adenoma. Better results are obtained when both are used together.

Funding: Gaziantep University Scientific Research Projects Management Unit

PS-05-010
Intraoperative sentinel lymph node cytology of breast cancer patients following primary systemic therapy
G. Ivády-Szabó[1], A. Szente[1], A. Ribiánszky[1], E. Tóth[2]
[1]National Institute of Oncology, Department of Cytopathology, Budapest, Hungary, [2]National Institute of Oncology, Surgical and Molecular Pathology Department, Budapest, Hungary

Background & Objectives: The axillary lymph node status is the most important prognostic factor for breast cancer patients even following primary systemic therapy (PST). The surgical treatment of axilla has been changed, and based on new indications, intraoperative sentinel lymph node assessment recommended a smaller subgroup of patients. At the same time, PST causes several cytopathological regression changes in lymph nodes (cytopathic effects, decreased

cellularity, fibrosis and necrosis) that could potentially affect the diagnosis of intraoperative lymph node cytology.
Methods: In our study we investigated 439 patients' intraoperative sentinel lymph node cytology. Two groups were created. The non-PST group, in which patients had sentinel lymph node biopsy (SNLB) and intraoperative cytology without preoperative treatment, and PST group in which, patients had SNLB and intraoperative cytology after PST. The intraoperative results were compared with histology as the gold standard, and sensitivity, specificity and accuracy were determined in both groups.
Results: The sensitivity of the non-PST group was: 86,08%, the specificity: 100% and the accuracy: 91,39%. Of the PST group the sensitivity was: 57,14%, the specificity: 99,55% and the accuracy: 88,44%.
The intraoperative cytology findings of the non-PST group were, as we previously seen, but in the PST group we saw various cytological appearance depending on changes caused by PST.
The cellularity of the smears was variable due to intranodal fibrosis and decreasing number of lymphocytes. Foamy macrophages and reactive fibroblasts appeared more frequently. The tumour cells were in small clusters or as single cells and showed variable cytopathic changes, like bizarre nuclei and hyperchromasia. These cytological changes were appropriate with the well-defined histological subgroups of regression patterns.
Conclusion: The low cellularity, the reactive fibroblasts and the single cell pattern can cause differential diagnostic challenge for cytopathologists. For the future intraoperative cytologic evaluation of sentinel lymph nodes remain a reliable tool in the management of breast cancer patients.

PS-05-011
Malignancy risk in category III (AUS) of the 3rd edition of Bethesda System for Thyroid Cytopathology: a study of cyto-histopathological correlation
A. Canastra[1], A. T. Alves[1]
[1]CUF Descobertas Hospital, Pathology Department, Lisbon, Portugal

Background & Objectives: The 2023 revision of the Bethesda System for Reporting Thyroid Cytopathology redefined the category of Atypia of Undetermined Significance (AUS) into AUS-Nuclear and AUS-Other to reflect its heterogeneity. This study evaluates the malignancy risk for each subcategory based on histologic correlation.
Methods: A retrospective analysis was conducted on thyroid fine-needle aspiration cases diagnosed as AUS, between January 2023 and January 2025 in the Department of Pathology. Among 763 AUS cases, 110 with available resection specimens were selected for histologic correlation. These cases were further subcategorized into AUS-Nuclear and AUS-Other (architectural or oncocytic atypia). The malignancy rates for each category were determined based on final histopathological diagnoses, which included non-neoplastic disease, benign neoplasm, low-risk neoplasm and malignant neoplasm.
Results: Of the 110 AUS cases, 40 were classified as AUS-Nuclear, 32 as AUS-Other (architectural atypia), and 38 as AUS-Other (oncocytic atypia). The overall risk of malignancy for the AUS category was 16.4%, with a negative predictive value of 83.6%. The malignancy rates for each subcategory were: 30.0% (12/40) for AUS-Nuclear, including 9 papillary carcinomas, 1 oncocytic carcinoma, 1 poorly differentiated carcinoma, and 1 medullary carcinoma; 9.4% (3/32) for AUS-Other (architectural atypia), including 1 oncocytic carcinoma, 2 trabecular hyalinizing tumours and 1 NIFTP; and 7.9% (3/38) for AUS-Other (oncocytic atypia), including 1 papillary carcinoma, 1 oncocytic carcinoma, and 1 follicular carcinoma.
Conclusion: Consistent with the recent literature, AUS-Nuclear carries the highest malignancy risk, reinforcing its clinical significance. In contrast, AUS-Other subcategories exhibit lower malignancy rates, suggesting that a more conservative approach may be appropriate. These findings highlight the need for refined risk stratification within the Bethesda System to optimize the clinical management of thyroid nodules.

PS-05-012
Comparison of diagnostic yield between percutaneous ultrasound-guided fine needle aspiration and core needle biopsy in solid pancreatic lesions
D.P. Baran[1], S. Önder[1], M.G. Gedikoğlu[1], C. Sökmensüer[1], O. Kurtulan[1]
[1]Hacettepe University Hospital, Medical Pathology, Ankara, Turkey

Background & Objectives: Since most pancreatic malignancies are inoperable at diagnosis, small samples are essential for confirmation of diagnosis and molecular analysis. Our study compares the diagnostic yield of cytology and histology samples from percutaneous ultrasound-guided fine needle aspiration (US-FNA) and core needle biopsy (US-CNB) in solid pancreatic lesions.
Methods: We retrospectively reviewed patients who underwent US-FNA or US-CNB for solid pancreatic lesions at Hacettepe University Hospital between 2022 and 2024 using an electronic database. Two authors analysed cytology/pathology reports and classified the diagnostic outcomes for each technique as inadequate, benign, atypical, suspicious for malignancy (SM), or malignant.
Results: Overall, 136 cases were identified. After exclusion of 12 cases with cystic lesions, a total of 124 cases of 113 patients were reviewed. There were 63 FNA cases from 57 patients (mean age 62.3), and 61 CNB cases from 56 patients (mean age 60.3). Cell block was available for review in 37 (58.7%) FNA cases. In the US-FNA group, 43 cases were diagnosed as malignant, 3 as SM, 6 as atypical, 3 as benign, and 8 as inadequate. In the US-CNB group, 44 cases were diagnosed as malignant, 2 as SM, 7 as atypical, 5 as benign, and 3 as inadequate. There were no false positive diagnoses. The definitive diagnosis of malignancy was achieved 68.2% and 72.1% of cases in US-FNA and US-CNB, respectively (Fisher's exact test: p=0.697). The overall adequacy rate of US-FNA and US-CNB was 87.3% and 95%, respectively, indicating no statistically significant difference (Fisher's exact test: p=0.206).
Conclusion: Our study demonstrates that while US-CNB showed a slightly higher diagnostic yield for malignancy and overall adequacy rate compared to US-FNA, the differences were not statistically significant. These findings suggest that both methods can be reliably used for diagnosis with technique selection depending on patient-specific factors, lesion characteristics, and institutional expertise.

PS-05-013
Opportunistic cervical cancer screening using liquid-based cytology: insights from a tertiary care centre
S. Bhalla[1], S. Kumar[1], N. Shabeer[1], S. Raghuvanshi[1], P. Agarwal[1], A. Pandey[2]
[1]King George Medical University, Pathology, Lucknow, India, [2]King George Medical University, Obstetrics and Gynaecology, Lucknow, India

Background & Objectives: Cervical screening is a reliable method for early detection, with opportunistic screening for hospital patients serving as a key approach. Additionally, ensuring consistency in interpreting cytology results is essential for diagnostic accuracy and quality patient care. This study aims to review the Liquid-Based Cytology (LBC) cervical smears across age groups, clinical presentations, and per speculum findings, focusing on epithelial cell abnormalities and inter-observer variability.
Methods: Comprehensive clinical data and LBC smears from January 2018 to December 2023 were retrieved from departmental

archives. All smears were interpreted based on the 2014 Bethesda System. Three observers with varying levels of experience in reporting LBC smears conducted the reviews.
Results: Of the 13,754 cases, the most common age group was the fourth decade, accounting for 36.8% of women. The inadequacy rate was just 0.43%. 94.2% of smears were reported as Negative for Intraepithelial Lesion or Malignancy (NILM), with inflammatory changes in 91.1%. Epithelial cell abnormalities were seen in 5.72% cases, with Low grade squamous intraepithelial lesion (LSIL) accounting for 44.19%, ASC-US (28.48%), HSIL (11.11%), and squamous cell carcinoma (3.96%)cases. Glandular lesions were 0.77% AGC and 0.13% Adenocarcinoma. Upon review, 19.16% of initially diagnosed NILM cases were reclassified as low-grade epithelial abnormalities. The highest agreement was observed in the LSIL category, followed by ASC-US, with a statistically significant Kappa statistic of 0.501, indicating moderate agreement between observers. Agreement in more severe categories like HSIL and SCC was more consistent, with a Kappa statistic of 0.323 indicating fair agreement.
Conclusion: Opportunistic cervical screening offers an alternative method in absence of a robust population based mass screening program. It enhances detecting premalignant and malignant cervical lesions efficiently. In our study, epithelial cell abnormality rate was 5.72%. Addressing inter-observer variability is also crucial for optimizing screening programs and improving patient care in tertiary healthcare settings.

PS-05-014
Cytomorphological analysis and histologic correlation of salivary gland neoplasms of uncertain malignant potential (SUMP) category in salivary gland fine needle aspirations: a liquid-based cytology experience
O. Sahin[1], E. Karatay[2], G. Gungor Sahin[2], N. Berker[2], D. Vuralli Bakkaloglu[2], Y. Ozluk[2]
[1]Umraniye Training and Research Hospital, Pathology, Istanbul, Turkey, [2]Istanbul University Istanbul Faculty of Medicine, Pathology, Istanbul, Turkey

Background & Objectives: The Milan System for Reporting Salivary Gland Cytology (MSRSGC) categorizes neoplastic lesions into "benign neoplasia" and "salivary gland neoplasm of uncertain malignant potential (SUMP)". SUMP includes both benign and malignant neoplasms, with an average malignancy risk of 26%. This study compares SUMP cases with tissue diagnoses, focusing on cytomorphological and background features.
Methods: Salivary gland fine-needle aspiration (SGFNA) cases reported from 2018 to 2025 using liquid-based cytology were documented. SUMP cases were classified by cell morphology, background and matrix features. Tissue biopsy diagnoses for SUMPs were also documented.
Results: Of 596 cases, 167(28%) were non-diagnostic, 54(9%) non-neoplastic, 42(7%) atypia of uncertain significance (AUS), 192(32%) benign neoplasms, 70(12%) SUMP, 20(3%) suspicious for malignancy, and 51(9%) malignant. Parotid tumours were the most common (58[82.9%]). Epithelial/myoepithelial, basaloid, oncocytic, and spindle cell morphologies were observed in 36(51.4 %), 16(22.9 %), 15(21.4 %), and 3(4.3 %), respectively. Fibrillary matrix appeared in 27/42(64.3%) with matrix features, dark/hyaline matrix in 13(31%), and minimal matrix in 2(4.8%). Background features included lymphoid (4/11[36.4%]), mucoid (4[36.4%]), cystic (2[18.2%]), and granular (1[9.1%]). Among 43(61.4%) cases with tissue follow-up, 8(18.6%) were malignant. In SUMP, the risks of malignancy (ROM) and neoplasia (RON) were 18.6% and 100%, respectively. The dark/hyaline matrix type was more frequent in malignant cases (66.7%;p=0.059). No significant association was found between cell morphology and malignancy (p=0.259). The presence of matrix was higher in malignant cases (75%;p=0.434). Background features had no relationship with malignancy (p=0.574).
Conclusion: This study supports the existing literature, showing a low malignancy risk in SUMP cases. While evaluating the background and matrix in liquid-based cytology samples is challenging, it is feasible. The study has advantages, such as being single-centreed, using consistent preparation technique, and having all cases evaluated by a cytopathologist. However, limitations include a low number of cases and a high number without tissue follow-up.

PS-05-015
Results from the second round of a HPV-based opportunistic cervical cancer screening program in Barcelona, Spain
P. Santiago-Díaz[1], G. Lugon[2], A. Moncusí[2], I. Vázquez[1], I. Sánchez[1], L. Serrano[1], S. Clavé[1], A. Quiñonero[1], M. Bautista[1], G. Picas[3], M.-A. Agüero[3], J.M. Solé[3], A. Burón[2], B. Lloveras[1,4]
[1]Hospital del Mar, Department of Pathology, Barcelona, Spain, [2]Hospital del Mar, Department of Epidemiology, Barcelona, Spain, [3]Hospital del Mar, Department of Gynaecology, Barcelona, Spain, [4]Xarxa de Diagnòstic Biomèdic i per la Imatge, Department of Pathology, Barcelona, Spain

Background & Objectives: In 2018, a HPV-based opportunistic cervical cancer screening program started for women aged 30–70 in an area of Barcelona. Beginning in 2021, it expanded sequentially to consecutive age groups, culminating in 2023 with full coverage through primary HPV testing. We aim to report HPV, cytology, and biopsy findings from the first year of the second round of screening.
Methods: Women 30 to 70 y.o. attended in public primary care centres and due for cervical cancer screening were offered to perform a HPV test. High-risk-HPV (hrHPV) detection is performed by Cobas-HPV Test (Roche). Cytologies are evaluated after any positive hrHPV test by cytotechnologists using ThinPrep cytology and Imager assisted screening (Hologic).
Results: A total of 6,540 women (≥30 years) were screened with hrHPV testing. The hrHPV positivity rate was 14.8%, declining with age (from 23.7% in 30–35 years to 7.4% in ≥65 years), a trend consistent with the previous phase. HPV16 and/or HPV18 were detected in 25.9% of hrHPV-positive tests (3.8% of all screened women), compared to 24.3% in the earlier phase. Among 966 smears, 48.4% were ≥ASCUS (52.7% in younger vs. 41.7% in older women), a slight drop from 53.5% previously. By genotype, 68.8% of abnormal cytologies were associated with hrHPV no-16/18, 24.8% with HPV16, 6.0% with HPV18, and 0.4% with both, consistent with previous findings. Colposcopic evaluation led to biopsies in 283 women, with results of: 0.4% insufficient, 23.0% normal, 44.3% LSIL, 31.1% CIN2+ (1.3% of all women screened).
Conclusion: During the first year of the second round of HPV-based screening, the overall hrHPV positivity rate was 14.3%, with a considerable number of abnormal cytologies in triage, though fewer than previous phase that did not yet include all older age groups under HPV screening. hrHPV positivity accounted for 3.8% of screened patients, but only 1.3% had CIN2+ lesions.

PS-05-016
Detection of high-grade serous carcinoma cells in PAP smears: evidence of tumour cell migration from the fallopian tube
E. Su[1], C.M. Nemes[2], W. Jochum[2], R. Hornung[1]
[1]HOCH, Cantonal Hospital St.Gallen, Clinic for Gynaecology and Obstetrics, St.Gallen, Switzerland, [2]HOCH, Cantonal Hospital St. Gallen, Institute of Pathology, St.Gallen, Switzerland

Background & Objectives: High-grade serous carcinoma (HGSC) of the ovary/fallopian tube has poor survival rates, largely due to

late-stage diagnosis. While the fallopian tube is widely recognized as the primary site of origin, the presence of tumour cells in the lower genital tract remains underexplored. This study aimed to assess the frequency of HGSC cells in PAP smears and to investigate their potential migration via the tubal lumen.
Methods: This retrospective study re-evaluated archival fallopian tube specimens and PAP smears from HGSC patients. Immunostaining for p53 and Ki-67 was performed when tumour cells or precursor lesions were not initially detected. A control group of PAP smears from breast cancer patients was included to validate specificity. All patients had undergone hysterectomy, ensuring that other glandular lesions of the cervix and corpus were histologically excluded. Samples were collected between 2008 and 2025 from the archives of the Institute of Pathology at the Cantonal Hospital of St.Gallen.
Results: Tumour cells were detected in multiple PAP smears, with a mean PAP-to-adnexectomy interval of five months. In one particular case, tumour cells were present nearly two years before surgery but not recognized as HGSC at the time. In several cases, tumour cells in PAP smears were initially misclassified as atypical glandular cells (AGC-N). In contrast, all PAP smears from the control group remained negative. Re-evaluation of fallopian tube specimens of HGSC patients revealed numerous precursor lesions and free-floating tumour cells among the fimbriae.
Conclusion: Our findings suggest a potential role for cytological screening in the early diagnosis of HGSC of the ovary/fallopian tube. The presence of HGSC cells in PAP smears provides further evidence of the intraluminal spread of carcinoma cells via fallopian tubes and uterine cavity. Further research is needed to assess its diagnostic utility and impact on risk stratification.

Funding: Our study is supported by grants from the Research Committee of the Cantonal Hospital St. Gallen (grant number MD 24/12), the Cancer League Eastern Switzerland (grant number 2024-05), and the Manja Gideon Foundation (no grant number)

PS-05-017

Comparison and classification of liver cytopathology and histopathology in light of the WHO reporting system for liver cytology

I. Guvendir Bakkaloglu[1], S. Hallac Keser[1], S. Sengiz Erhan[1], D. Celik[1]
[1]Kartal Dr. Lutfi Kirdar City Hospital, Pathology, Istanbul, Turkey

Background & Objectives: Although many organs have established cytological classification systems, liver cytopathology still lacks standardization. This study aims to reclassify liver cytology reports from our institution and determine the risk of malignancy (ROM) for each category.
Methods: Cytology reports and corresponding tru-cut biopsies performed at our institution between 2017 and 2024 were retrospectively reviewed. Cases were categorized based on demographic, radiological, and clinical follow-up(CFU) data. Cytological diagnoses were classified into five categories: I – Non-diagnostic;II – Benign;III – Atypical;IV – Suspicious for malignancy;and V – Malignant. ROM was assessed using both histopathological findings and final clinical follow-up.
Results: The study included a total of 438 cases, of which 238 (54.3%) were female (F/M ratio: 1.2 /1). The mean age was 61.24 years. Malignant lesions were classified as either primary or metastatic. Histopathological evaluation of tru-cut biopsies revealed that 118 cases (26.9%) were benign, and 320 cases (73.1%) were malignant. According to CFU, 66 cases (15.1%) were considered benign, and 372 (84.8%) were malignant. The concordance rate between cytological and histopathological diagnoses was 74.4%, while the concordance between cytological diagnosis and CFU was 82.9%.
The ROM based on histopathological outcomes for each cytological category was as follows: Category I, 66.6%; Category II, 44.4%; Category III, 77.7%; Category IV, 90.1%; and Category V, 83.8%. Based on CFU, ROM was calculated as follows: Category I, 73.3%; Category II, 52.9%; Category III, 88.8%; Category IV, 96%; and Category V, 100%. No statistically significant difference was observed between cytological and tru-cut biopsy diagnoses with respect to CFU correlation ($p = 0.127$).
Conclusion: Liver FNA demonstrates diagnostic accuracy comparable to tru-cut biopsy and is particularly useful for differentiating benign from malignant lesions. The relatively high ROM in the benign category may reflect both limitations in targeted biopsy and the absence of standardized definitions in current classification systems. Clarifying these uncertainties is essential for better clinical decision-making.

PS-05-018

Multiplexed cry-immunostaining: application in a routine cytopathology laboratory to minimize sample wastage

S. Miceska[1], S.C. Bhakdi[2,3], V. Kloboves Prevodnik[1,4]
[1]Institute of Oncology Ljubljana, Department of Cytopathology, Ljubljana, Slovenia, [2]Faculty of Science, Mahidol University Bangkok, Department of Pathobiology, Bangkok, Thailand, [3]X-ZELL Biotech Pte Ltd., Singapore, Singapore, [4]University of Maribor, Department of Pathology, Maribor, Slovenia

Background & Objectives: Multiplex cryo-immunostaining with the X-ZELL platform enables up to 8 markers on a single slide, addressing multi-slide staining challenges in cytopathology. However, X-ZELL's cytospin preparation and fixation protocols differ from routine methods. This study evaluated whether routinely prepared cytospins provide comparable immunomorphological preservation and compatibility with X-ZELL's cryo-immunostaining protocol.
Methods: Mini lymphoma (CD45/CD3/CD20/DAPI) and mini carcinoma (EpCAM/CK7/CK20/DAPI) multiplex immunostaining panels were established. FNAB and effusion samples were analysed within three days of collection. Two preparation methods were compared: (1) the validated X-ZELL protocol (X-ZELL slides, cytofuge, cryofixation, and cryostaining) and (2) a standard method using Superfrost Plus slides (Epredia), cytocentrifuge (Shendon), and 4°C methanol fixation, followed by X-ZELL cryofixation and cryostaining. Single-marker ICC staining served as a control. Slides were evaluated blindly by an immunofluorescence specialist and a cytopathologist. Results were provided descriptively.
Results: Ten cases were included: 7 FNAB (5 lymphomas, 2 reactive) with the lymphoma panel, as well as 2 FNAB and 1 effusion case (adenocarcinomas) with the carcinoma panel. No significant difference in the percentage of evaluated cells was found between X-ZELL and routinely prepared cytospins, except for CD20 in one sample, with results comparable to ICC controls. X-ZELL cytospins demonstrated superior morphology and staining intensity without background staining, while routinely prepared cytospins showed slightly weaker intensity, particularly for dim fluorophores like CD20-APC (allophycocyanin) in the lymphoma panel. In the carcinoma panel, FNAB samples showed strong staining for cytoplasmic markers (CK7), while membrane markers (EpCAM) showed weaker intensity linked to loss of nuclear morphology. Effusion samples showed superior intensity for both markers in both methods.
Conclusion: The X-ZELL platform can be applied to routinely prepared cytopathology samples, particularly for effusions. For FNAB samples, improvements can be made by using X-ZELL slides, ice-cold methanol, and avoiding dim channels for critical markers to enhance staining consistency.

PS-06 Poster Session Dermatopathology

PS-06-001
Effect of PRMT1 and ZEB1 expression on survival in patients diagnosed with Kaposi Sarcoma

M. Urgancı Gökpinar[1], B. Öğüt[1], Y.C. Edek[2], E. Adışen[2], Ö. Erdem[1]
[1]Gazi University, Pathology, Ankara, Turkey, [2]Gazi University, Dermatology, Ankara, Turkey

Background & Objectives: Kaposi sarcoma (KS) is a tumour originating from vascular endothelial cells, typically occurring in immunocompromised individuals. The clinical course is highly variable; it progresses slowly in some patients, while in others, it may follow an aggressive course. In recent years, transcription factors associated with epithelial-mesenchymal transition, such as PRMT1 and ZEB1, have attracted attention due to their effects on cancer cell invasion and metastasis. However, the role and prognostic significance of PRMT1 and ZEB1 in KS are not fully understood. This study aims to investigate the possible effects of PRMT1 and ZEB1 expression on the clinical course of KS by analysing the intensity and percentage of their expression in KS biopsies.
Methods: We selected paraffin blocks from 92 biopsies of 70 patients diagnosed with KS and HHV-8 positive between 2011 and 2021. PRMT1 and ZEB1 antibodies were applied, with positive controls. Overall survival data were retrieved from the Hospital Information Management System and Medulla System, determining if patients were alive as of March 2025.
Results: A total of 92 biopsies from 70 patients with a median age of 66.8 (29-93) were included in the study. Cox regression multivariate analysis showed significant survival differences associated with PRMT1 expression percentage (p=0.03) and ZEB1 expression percentage (p=0.01). Patients with high PRMT1 and ZEB1 expression percentages had longer survival compared to those with low expression. This suggests that PRMT1 and ZEB1 could serve as biomarkers associated with a good prognosis.
Conclusion: Our findings suggest that PRMT1 and ZEB1 expression could be considered prognostic markers in Kaposi sarcoma, with high expression levels independently contributing to improved overall survival. However, no significant relationship was found between the intensity of PRMT1 and ZEB1 expression and survival. These results indicate that PRMT1 and ZEB1 may play a role in KS progression, and further studies in larger patient cohorts are needed.

PS-06-002
PRAME expression in mammary and extramammary Paget's disease

C. Topalidis[1], K. Boulogeorgou[1], G. Karayannopoulou[1], T. Koletsa[1], J. Kanitakis[2,3]
[1]AHEPA University Hospital, Aristotle University of Thessaloniki, Department of Pathology, Thessaloniki, Greece, [2]Lyon-Sud Hospital Centre, Laboratory of Pathology, Pierre Bénite, France, [3]Ed. Herriot Hospital (Pav. R), Department of Dermatology/CliMA, Lyon, France

Background & Objectives: PRAME (PReferentially-expressed Antigen in MElanoma) is a testis-cancer antigen that has been extensively studied for the diagnosis of ambiguous melanocytic neoplasms, as it is preferentially expressed in melanomas compared with benign lesions. In normal skin, PRAME is expressed in the cytoplasm of sebocytes, apocrine sweat glands and in a subset of cells of eccrine gland secretory coils. Accordingly, PRAME is expressed by the majority of sebaceous tumours and less frequently (ca. 20%) by tumours and hyperplasias of sweat glands. Mammary (MPD) and extramammary (EMPD) Paget's disease are apocrine adenocarcinomas with epidermal involvement. So far, very few data exist on the expression of PRAME in MPD and EMPD.
Methods: We investigated the immunohistochemical expression of PRAME in 33 cases of Paget's disease (13 MPD, 20 *in situ* or invasive EMPD), using the ERP20330 antibody and an automated immunohistochemistry stainer device (Ventana). Sebaceous and/or apocrine glands present in each section served as positive internal controls.
Results: All 13 cases of MPD (from female patients) expressed PRAME to various degrees (strongly in 10 cases and weakly in 3 cases). In most cases, both the intraepidermal Paget cells and the underlying breast carcinomas were PRAME-positive. Among the 20 cases (12 women) of EMPD (6 vulvar, 5 perianal, 9 other), 12 cases were strongly PRAME-positive, 5 cases showed weak immunoreactivity, and 3 cases were negative. The expression of PRAME was nuclear and/or cytoplasmic, both in MPD and EMPD cases.
Conclusion: These results expand the spectrum of cutaneous epithelial/glandular malignancies expressing PRAME, and should be known when using this antigen as a diagnostic immunohistochemical biomarker. Studies are ongoing to assess the utility in differentiating primary (cutaneous) from secondary (associated with underlying malignancies) EMPD, and the potential prognostic or predictive value of PRAME expression on MPD, as has been recently suggested for breast carcinomas.

PS-06-003
PRAME expression in Spitz nevus and Atypical Spitz tumour in children

G.A. Dumbrava[1], A. Vilaia[2,3], R.T. Andrei[1], D. Cerea[1], S.A. Zurac[2,1]
[1]Colentina University Hospital, Department of Pathology, Bucharest, Romania, [2]University of Medicine Carol Davila, Department of Pathology, Bucharest, Romania, [3]Gral Medical - Oncofort Hospital, Department of Pathology, Bucharest, Romania

Background & Objectives: PRAME (Preferentially expressed Antigen in Melanoma) expression is well documented in cutaneous melanomas, but knowledge of its expression pattern in Spitz nevi and Atypical Spitz tumours is limited.
Methods: We performed a detailed microscopic reexamination of the original haematoxylin and eosin slides from 33 paediatric patients aged 1 to 18 years. A total of 28 Spitz nevi and 5 Atypical Spitz tumours were included in the study. PRAME immunohistochemistry was performed on all samples. Cases were classified on a scale from 0 (no expression) to 4+ (>75% positive melanocytic nuclei).
Results: The majority (23/28) of the Spitz nevi analysed were completely negative for PRAME. Only 7.14% (2/28) of Spitz nevi showed a 2+ heterogeneous immunoreactivity in 50% of melanocytes from both the junctional and dermal components. Three Spitz nevi (10.71%) showed weak nuclear positivity in less than 25% of melanocytes (1+). Only one (1/5) Atypical Spitz tumour from a 4-year-old patient showed faint nuclear PRAME expression corresponding to a 1+ score. Non-specific, diffuse, membranous, and cytoplasmic PRAME positivity was observed in normal sebocytes from all samples.
Conclusion: PRAME expression is not limited to malignant melanocytic tumours; Spitz nevi and Atypical Spitz tumours can infrequently express PRAME in a heterogeneous pattern. A constant membranous and cytoplasmic positivity in sebocytes was identified. PRAME should be interpreted carefully in the context of histomorphological findings.

PS-06-004
Immunofluorescence: is fresh tissue necessary?

F. Kelly[1,2], E. Carroll[1,2], C. Brennan[1], A.M. Quinn[1,2], L. Lydon[1]
[1]Galway University Hospital, Histopathology, Galway, Ireland, [2]University of Galway, Galway, Ireland

Background & Objectives: Direct immunofluorescence(DIF) is a technique allowing the visualization of a specific protein in tissue sections by binding a specific antibody conjugated with a fluorescent dye.

The sample can be processed fresh or transported in Michel's solution. This complicated process demands significant time and attention, and when fresh is difficult for senior scientists given staffing constraints. Workforce shortages in Ireland have created wide gaps in scientific support staff, causing significant disruption to laboratory processes and workflow. When received in Michel's, samples can be batched and the lengthy process completed in tandem, saving the senior scientists valuable time.
The objective was to prove the equivalence of tissue in Michel's solution to fresh tissue.
Methods: Retrospective single centre audit of skin samples analysed by DIF in Galway University Hospital(GUH) from 2021-2023. Biopsies were studied which had been sent either fresh or in Michel's solution. The 100 most recent cases from GUH were the fresh group. The 100 most recent cases from Sligo University Hospital were the Michel's group.
Results: Sligo 2021-2023: 28 cases showed positive staining. 99 of 100 had a positive internal control and 98 of 100 had a negative internal control.
Galway 2023: 32 cases showed positive staining. 100 of 100 had a positive internal control and 99 of 100 had a negative internal control.
Conclusion: 32 of 100 fresh samples from GUH tested positive for at least one immunofluorescence stain(2023). 28 of 100 samples in Michel's solution from SUH tested positive for at least one immunofluorescence stain(2021-2023). This audit demonstrates the efficacy of Michel's solution as a transport medium for skin samples sent for immunofluorescence.
Tissue in Michel's remains as diagnostically accurate as fresh tissue and can be reliably used for specimens for DIF. Following completion of this audit, dermatologists have begun sending samples in Michel's solution.

PS-06-005
Clinicopathologic analysis of overall survival rates for cutaneous melanoma in Turkey
S. Kestel[1], B. Öğüt[2], Ö. Ekinci[2], F.P. Uyar Göçün[2], Ö. Erdem[2]
[1]University of Health Sciences Türkiye, Başakşehir Çam and Sakura City Hospital, Department of Pathology, İstanbul, Turkey, [2]Gazi University, Faculty of Medicine, Department of Pathology, Ankara, Turkey

Background & Objectives: The current study aimed to investigate the clinicopathological prognostic factors of melanoma in a country with low incidence rates, primarily among individuals with low-risk cutaneous phototypes.
Methods: The study analysed 233 cases of invasive and micro-invasive primary cutaneous melanoma (CM) pathologically diagnosed at a tertiary university hospital between January 2008 and March 2020.
Results: A total of 233 patients were included in the study, comprising 103 females and 130 males. The average age at diagnosis was 57 years, with a median age of 59 years (ranging from 1 to 95 years). The overall survival (OS) rates at 1, 2, 5, and 10 years were 92%, 84%, 70%, and 62%, respectively. Favorable prognostic factors identified included female gender, nevus-associated melanoma, solar elastosis, the presence of tumour-infiltrating lymphocytes (TILs), melanoma thickness of 1 mm or less, Clark level below III, and microinvasive melanoma. When comparing patients who survived for less than 5 years with those who survived for 5 years or more, interesting associations with 5-year survival status emerged, particularly relating to ulceration, TILs, and mitotic rate values with different cut-off levels.
Conclusion: A Cox multiple regression model indicated that gender, Breslow thickness, surgical margin, TILs, lymphovascular invasion (LVI), pN status, and age at diagnosis were independent predictors of overall survival. We have significant predictors of survival. We can even predict some molecular features of cutaneous melanoma using light microscopy.

PS-06-006
Pigmentation in melanoma: what it means and its importance
S. Kestel[1], B. Öğüt[2], Ö. Ekinci[2], F.P. Uyar Göçün[2], Ö. Erdem[2]
[1]University of Health Sciences Türkiye, Başakşehir Çam and Sakura City Hospital, Department of Pathology, İstanbul, Turkey, [2]Gazi University, Faculty of Medicine, Department of Pathology, Ankara, Turkey

Background & Objectives: A recent study conducted in Germany found that pigmented melanomas have a better prognosis than non-pigmented melanomas. Our research, which was carried out in 2020 as part of a pathology graduation thesis in Turkey, aims to share some intriguing findings regarding the relationship between pigmentation and histopathological prognostic factors. We believe these insights will enhance the understanding of melanoma's phenotype, the deadliest form of skin cancer originating from melanocytes.
Methods: We statistically analysed 122 metastatic melanoma cases and 233 primary cutaneous melanoma cases with Chi-Square or Fisher's test according to pigmentation association with histopathologic variables.
Results: In primary cutaneous melanoma cases, pigmentation was associated with histopathologic subtype (Low cumulative sun-damage melanoma/superficial spreading melanoma is the most frequently pigmented subtype) ($p<0.001$), location of melanoma ($p=0.023$) (extremity and trunk were the two most frequent location for pigmented melanoma), melanoma related to a nevus ($p=0.037$, nevus-associated melanomas were more frequently pigmented than de novo melanomas), lower pT stage ($p=0.018$) (pT1 cases dramatically were frequent in pigmented melanomas), absence of lymphovascular invasion (LVI) ($p=0.017$), BRAF-mutation status ($p=0.011$), absence of ulceration ($p<0.001$), Clark level ($p=0.038$, pigmented melanomas were mostly Clark levels II or III), skin appendages involvement ($p=0.013$), regression status ($p=0.005$), presence of radial growth phase (RGP) ($p<0.001$, 170 cases with RGP were also pigmented), mitotic rate ($p=0.013$) (Cases with zero mitoses were all pigmented).
Conclusion: According to some of these (such as the absence of LVI) and previous results, pigmentation may also have an immunologic role in response to melanoma. These findings open new possibilities for understanding and potentially treating melanoma, offering hope for improved patient outcomes.

PS-06-007
Major histocompatibility complex class I (MHC-I) and β2-microglobulin loss are common tumour progression events in cutaneous melanoma, a tertiary institutional experience
Y.C. Chang Chien[1], C. Prementine[2], G. Emri[3], J. Bedekovics[1], G. Méhes[1]
[1]University of Debrecen, Clinical Centre, Department of Pathology, Debrecen, Hungary, [2]University of Debrecen, Clinical Centre, Faculty of Medicine, Debrecen, Hungary, [3]University of Debrecen, Clinical Centre, Department of Dermatology, Debrecen, Hungary

Background & Objectives: Cutaneous melanoma(CM) is one of the most "immunogenic" tumours, avoiding immune surveillance. The PD-1/PD-L1 axis is a prototypical immune escape mechanism adopted by neoplastic cells. However, regarding CM, different scoring systems exist for PD-L1 expression assessment such as combined positive score(CPS), and melanoma scoring system(MEL) which make interpretation a matter of debate. The effectiveness of immunotherapy with PD-1/PD-L1 inhibitors is also varied among studies, indicating alternative cytotoxic dysregulation pathway also contributes to tumour escaping. Among those, down-regulation of major histocompatibility complex class-I(MHC-I) is the most frequent one. This phenomenon is well documented in many carcinomas, and haematological malignancies, but has rarely been addressed in melanomas. We questioned

the possible mechanism for MHC-I suppression, notably the synthesis of the β2-microglobulin subunit of MHC-I. These potential cellular alterations triggered our interest to correlate between CPS and MEL scores and identify the MHC-I, and β2-microglobulin status in CMs.
Methods: We collected 25 advanced, CMs, with average follow-up period 71 months. Eleven cases with nodal metastasis were also included. We evaluated CPS and MEL scores by PD-L1(clone 22C3) immunohistochemistry(IHC) and performed correlation analysis between these 2 systems. We carried-out IHC for MHC-I and β2-microglobulin to evaluate the signal loss in percentage in primary/metastatic tumours. Furthermore, we also correlated MHC-I loss and tumour-infiltrating lymphocyte(TIL).
Results: We found a strong correlation between CPS and MEL score. Twenty-one cases(84%) of primary tumour showed significant HMC-I(>25%) loss, largely in the invasive regions associated with decreased TIL(r: - 0.44) and concurrent loss of β2-microglobulin. Significant further loss of MHC-I in metastatic tumours was also observed(p: 0.0017).
Conclusion: CPS and MEL has high concordance and can be used interchangeably in CMs. Concurrent MHC-I and β2-microglobulin loss is a common tumour-progression event in CMs, which may contribute to treatment failure. Our data points out that MHC-I could serve as a potential biomarker in CMs.

PS-06-008

LEF1 expression in melanocytic tumours cannot accurately predict *CTNNB1* mutational status acting as a potential pitfall in combined lesions

N. Katsoulas[1,2], D. Goutas[1,2], M. Michelaki[1], M. Nifora[2], N. Koufopoulos[3], A. Stofas[1], P. Papadakis[1], E. Lakiotaki[1], I. Panayiotides[3], A. Saetta[1], P. Korkolopoulou[1], V. Damaskou[3], A. de la Fouchardiere[4,5,6]
[1]School of Medicine, National & Kapodistrian University of Athens, 1st Department of Pathology, Athens, Greece, [2]Istomedica Private Anatomic Pathology Lab, Athens, Greece, [3]School of Medicine, National and Kapodistrian University of Athens, Attikon University Hospital, 2nd Department of Pathology, Athens, Greece, [4]Centre Leon Berard, Department of Biopathology, Lyon, France, [5]University of Lyon, Universite Claude Bernard, Department of Research, Lyon, France, [6]Cancer Research Centre of Lyon, Lyon, France

Background & Objectives: Majority of melanocytic lesions develop along a genetic spectrum, progressing from a nevus to melanoma. Melanocytomas represent an intermediate category of tumours that lay within that spectrum and are characterized by additional genetic alterations, which can occasionally alter their phenotype. Currently, the three categories of melanocytomas, recognized by WHO, are pigmented epithelioid melanocytomas (PEMs), BAP1 inactivated melanocytomas (BIMs), and WNT-activated melanocytomas (WAMs). Among them, WAMs represent an under-recognized entity, which can occasionally be misinterpreted as other biphenotypic pigmented lesions or as melanomas. LEF1 was recently suggested as a marker of increased utility in the diagnosis of WAMs against other histologic mimics.
Methods: In this study, we analysed the expression of LEF1 in a series of 55 melanocytic tumours, including 10 Spitz nevi, 16 blue nevi, 9 common nevi, 1 clonal nevus, 10 melanomas of various subtypes, 7 WAMs and 2 PEMs. Beta-catenin expression was also assessed in all biphenotypic cases. Furthermore, molecular analysis was performed for the identification of *CTNNB1* mutations in all cases that were LEF1 positive.
Results: Thirty-seven (37) out of 55 cases displayed LEF1 positivity independent of *CTNNB1* mutational status. Specifically, LEF1 nuclear expression was present in 6/10 (60%) Spitz nevi, 5/16 (31%) blue nevi (4/5 combined BN, 0/5 dendritic BN and 1/6 cellular BN), 9/9 (100%) common nevi, 0/1 clonal nevus, 10/10 melanomas (100%), 7/7 (100%) WAMs and 0/2 PEMs. Subsequent examination for *CTNNB1* exon 3 mutations did not reveal any alterations. Beta-catenin was positive in all WAM cases (7/7) and displayed a normal membranous staining pattern in the remaining combined lesions examined.
Conclusion: These data suggest that LEF1 expression should be interpreted with caution in ambiguous pigmented and/or combined melanocytic lesions, where beta-catenin expression cannot be easily assessed. Therefore, we suggest that LEF1 positivity should be assessed in conjunction with beta-catenin or with a *CTNNB1* molecular confirmation.

PS-06-009

Trans- and dedifferentiated primary and metastatic melanoma: the challenging diagnosis and diagnostic significance of PRAME staining

M. Senchenko[1,2,3], T. Zaslavskaia[4], G. Tsaur[4], Y. Sitnikova[4], D. Korobova[1], G. Setdikova[3], D. Rogozhin[1,5]
[1]N.N. Blokhin National Medical Research Centre of Oncology, Pathology, Moscow, Russia, [2]Dmitry Rogachev National Medical Research Centre of Paediatric Haematology, Oncology and Immunology, Pathology, Moscow, Russia, [3]Moscow Regional Research and Clinical Institute, Pathology, Moscow, Russia, [4]Regional Children's Hospital, Laboratory of Molecular Biology, Immunophenotyping and Pathology, Ekaterinburg, Russia, [5]Pirogov Russian National Research Medical University, Moscow, Russia

Background & Objectives: In primary, or more commonly, metastatic cases of malignant melanoma (MM) there may be a complete loss of melanocytic markers with the acquisition of signs of heterologous differentiation in some cases. This phenomenon may cause diagnostic difficulties. Here we present six cases of MM with signs of dedifferentiation (n=3) or de-/transdifferentiation (n=3).
Methods: In each case immunohistochemistry (IHC) was performed with S100, SOX-10, Melan A, HMB45, in four cases with PRAME. Molecular analysis for BRAF mutations using direct sequencing of exon 15 was performed in five case.
Results: Our study included one primary dedifferentiated and five metastatic de-/transdifferentiated cases of MM (M – 3, F – 3, aged 43 to 63 years, median – 61.5). Primary dedifferentiated neoplasm had small focus with retained melanocytic expression and epithelioid/rhabdoid morphology, dedifferentiated component had spindle cell morphology. Two metastatic dedifferentiated cases with unknown primary site located in axillary area, had epithelioid/rhabdoid morphology and were totally negative for melanocytic markers. In one case there was diffuse PRAME expression. Three metastatic cases with total or subtotal loss of melanocytic markers expression showed heterologous differentiation (right upper arm – 1, inguinal lymph node – 2): pleomorphic leiomyosarcoma, (Desmin+, SMA-, Myogenin/MyoD1-, melanoctyc markers-, PRAME weakly+), fibrosarcoma-like tumour with immature cartilaginous islands (SOX-10+ in cartilaginous component, PRAME+, S100/Melan A/HMB45-), spindle cell rhabdomyosarcoma with focal rhabdoid morphology and osteoproduction, (Desmin+, Myogenin/MyoD1+/-, H3K27Me-, S100/Melan A focal+, HMB45 single cells+, PRAME+). In the first two cases, the primary site was known with confirmed skin MM. BRAF mutation was detected in all dedifferentiated cases.
Conclusion: Awareness of de-/transdifferentiation phenomenon is important for making accurate diagnosis of MM. MM may have various types of heterologous differentiation and IHC for PRAME can be useful in difficult cases, but it should be considered in the context of clinical history, morphology and immunophenotype, as other high-grade sarcoma may also show postive expression.

PS-06-010

Distribution of IL-17-positive cells and IgG4-positive plasma cells in patients with bullous dermatoses

N. Uzunov[1], M. Ivanov[1], J. Ananiev[1]

[1]Medical Faculty, Trakia University, Department of General and Clinical Pathology, Forensic Medicine, Deontology and Dermatovenerology, Stara Zagora, Bulgaria

Background & Objectives: Bullous dermatoses are a group of autoimmune-mediated diseases affected squamous epithelia, such as the skin and oral mucosa. The aim of our study is to investigate the relation between different subtypes of immune cells and the development of bullous pemphigoid and pemphigus vulgaris patients.
Methods: We investigated 24 patients with bullous pemphigoid (BP) and 14 with pemphigus vulgaris (PV) with antibodies against IL-17 and IgG4 by immunohistochemistry. The correlation between density of markers-positive cells, morphological and clinicolaboratory data were evaluated.
Results: We found infiltration by IL-17-positive cells and IgG4-positive plasma cells in all studied specimens. IL-17-positive cells could be found in all cases, with a median number of 28.4 cells/mm^2 (SD±3.92) and IgG4-positive plasma cells with median number of 16.9 cells/mm^2 (SD±2.2). Comparing the density of the two types of cells, we found that IL-17-positive cells are significantly more in comparison with IgG4-positive plasma cells (p=0.013, t-test). There was a tendency - in patients with BP there was a greater number of IL-17-positive cells compared with PV (x2=3.44, p=0.098). No significant results was found between and other clinicopathological parameters.
Conclusion: Based on the IHC findings and the comparison of the data, we suggest that there is a strong relationship between the activation of both immune cell populations in bullous dermatoses and the severity of the disease.

Funding: This research was funded by the Bulgarian Ministry of Education and Science (MES) in the frames of the Bulgarian National Recovery and Resilience Plan, Component "Innovative Bulgaria", Project No. BG-RRP-2.004-0006-C02, "Development of research and innovation at Trakia University in service of health and sustainable well-being"

PS-06-011

The value of peritumoral lymphocyte infiltration in progression-free survival (PFS) of NRAS, TERT and CHEK2 mutant melanoma

S. Isajevs[1], T. Zablocka[1], D. Pjanova[2]
[1]University of Latvia, Faculty of Medicine and Life Sciences, Riga, Latvia, [2]Latvian Biomedical Research and Study Centre, Riga, Latvia

Background & Objectives: The presence of tumour infiltrating lymphocytes (TIL) is a favourable prognostic factor in cutaneous melanoma. However, TIL infiltration in *NRAS*, *TERT* and *CHEK2* Stage I and II mutant melanoma is still controversial. The current study's objective have been to compare the *NRAS*, *TERT* and *CHEK2* mutation status with peritumoral lymphocytic infiltration and PFS in Stage I and II melanoma.
Methods: Altogether, 118 patients who underwent melanoma surgical treatment at the Riga East University Hospital at the stage IA-IIC were retrospectively enrolled in the study. *TERT* and CHEK2 mutational status was assessed by NGS testing. The *Qiagen* pan-cancer-multimodal panel gene kit was used (Cat. No. / ID: 334942). *NRAS* mutations was assessed by digital droplet PCR (ddPCR) using *NRAS Q61* (#12001006) and *NRAS G12/G13* (#12001627) Screening Assays (*Bio-Rad*, USA) as per the manufacturer's instructions.
Results: Patients with *TERT* mutation had significant worse PFS compared to *TERT* wild melanoma (HR=13.8, 95 % C.I = 6.8–31.0; P<0.0001). In additional, patient with *TERT* mutation and low TIL had significant better PFS compared to patients with *TERT* mutation and high TIL infiltration (HR = 4.80; 95 %, C.I = 2.30–7.890, P=0.002). *CHEK2* mutation status did not associated with PFS. However, patients with CHEK2 had increased TIL infiltration compared to *CHEK2* wild melanoma (P<0.0001). Patients with *NRAS* mutant melanoma had significant worse PFS compared to *NRAS* wild type melanoma (HR = 12.30; 95 %, C.I = 5.78–26.21, P < 0.0001). However, the association between NRAS mutant melanoma, TIL infiltration and PFS have not been observed.
Conclusion: *TERT* and *NRAS* mutant melanoma characterized by worse PFS compared to *TERT and* NRAS wild melanoma. Increased TIL infiltration contributed to the better PFS in *TERT* mutant melanoma. However, TIL infiltration did not associate with even better or worse PFS in *NRAS and CHEK2* mutant melanoma.

PS-06-012

Pathological and prognostic insights from SLN biopsy in melanoma: a single centre study of 1181 cases

V. Kushnarev[1], D. Chuglova[2], V. Emtseva[2], M. Gafton[2]
[1]High School of Oncology, Pathology, Saint Petersburg, Russia, [2]National Medical Centre of Oncology named after N.N.Petrov, Pathology, Saint Petersburg, Russia

Background & Objectives: Melanoma prognosis is primarily determined by certain pathological features of the primary tumour and the status of regional lymph nodes. This study analyzes a cohort of melanoma patients with sentinel lymph node biopsy (SLNB) to identify prognostic and predictive markers, correlating tumour morphology with survival outcomes.
Methods: We analysed primary tumour pathology characteristics (Breslow thickness, ulceration, mitotic activity, Clark level, LVI, neurotropism) and SLNB results from January 2021 to December 2024 in the National Cancer Research Centre named after N.N.Petrov. Kaplan-Meier survival analysis was performed to estimate survival distributions and compare groups by log-rank tests. Cox proportional hazards regression was used for multivariate analysis of prognostic factors.
Results: A total of 1181 patients were analysed. Sentinel lymph node (SLN) biopsy was positive in 206 cases (17.4%) and negative in 975 cases (82.6%). Significant correlations were found between positive SLN status and major pathological prognostic factors: Breslow thickness (Chi-squared test, p < 0.001), ulceration (p < 0.001), mitotic rate (p < 0.001), and lymphovascular invasion (LVI) (p < 0.001). Positivity rates for SLN biopsies notably increased with greater Breslow thickness (>4 mm had the highest positivity), presence of ulceration, higher mitotic rates (≥5 mitoses/mm²), and presence of LVI. A total of 758 melanoma patients with available survival follow-up were included (median age ~55 years; 54% female). The median follow-up was 30 months. There were 19 melanoma-related deaths (2.5%) during the study period. Thickness >2 mm carried an HR ~10 (95%CI 1.4–79, p=0.03) for mortality compared to ≤2 mm.
Conclusion: Breslow thickness, ulceration, SLN status, mitotic rate, and LVI are confirmed as key prognostic indicators in melanoma. Thickness remains the dominant predictor of overall survival – thicker melanomas have drastically worse outcomes

PS-06-013

Divergent epigenetic landscapes and stem cell dynamics in psoriasis versus atopic dermatitis

F. Repetto[1], H. Nguyen[2], S. Xu[3], J. Billingsley[4], E. Partan[4], S. Ho Sui[4], G.F. Murphy[1], C.G. Lian[1]
[1]Mass General Brigham and Harvard Medical School, Program in Dermatopathology, Department of Pathology, Boston, USA, [2]Boston University, Chobanian & Avedisian School of Medicine, Boston, USA, [3]Mass General Brigham and Harvard Medical School, Department of Pathology, Boston, USA, [4]Harvard T.H. Chan School of Public Health, Harvard Chan Bioinformatics Core, Boston, USA

Background & Objectives: Atopic dermatitis (AD) and psoriasis (PS) are among the most common and clinically impactful chronic

inflammatory skin disorders worldwide, affecting hundreds of millions of individuals. They exhibit overlapping clinical features but distinct immune mechanisms. Both exhibit epidermal hyperplasia, but the mechanisms driving this hyperplasia are not fully understood, particularly the contributions of keratinocyte stem cells (KSCs) and epigenetic regulation. We aimed to delineate disease-specific epigenetic landscapes and KSC dynamics by analysing the distribution of 5-hydroxymethylcytosine (5-hmC), a key epigenetic mark, alongside markers for stem cells and transit-amplifying cells (TACs) in PS versus AD.
Methods: Human skin biopsies and mouse models of PS (imiquimod-induced) and AD (ovalbumin-induced) were evaluated. Immunofluorescence for 5-hmC, CK15 (KSCs), and FABP5 (TACs) was used to assess the epidermal stem cell and TCAs compartments. Additionally, NanoString GeoMx Digital Spatial Profiling (DSP) was performed on epidermal and dermal regions to measure expression of proteins related to stem cell regulation and immune signalling
Results: Psoriatic lesions confirmed prior observations of near-complete loss of 5-hmC in basal and suprabasal keratinocytes, accompanied by marked depletion of CK15+ KSCs and robust expansion of FABP5+ TCAs. DSP analysis established significantly elevated expression of keratinocyte activation and innate immune markers in PS (e.g., CD44, CD11b). In contrast, AD epidermis retained 5-hmC throughout the basal and suprabasal layers, with preserved CK15+ KSCs and minimal TCAs expansion. Proteomic profiling in AD highlighted a Th2-skewed immune response and barrier dysfunction, but not the pronounced epigenetic and stem cell alterations observed in PS.
Conclusion: These findings suggest that epidermal hyperplasia in psoriasis is driven by 5-hmC epigenetic dysregulation, KSC exhaustion, and excessive transit amplification cell accumulation, whereas AD maintains DNA hydroxymethylation and KSC homeostasis. This mechanistic divergence raises the prospect of distinct therapeutic approaches: epigenetic and stem cell restoration in PS versus abrogation of Th2 pathways and barrier repair in AD.

PS-06-014

Identification of BRAF/NRAS-mutated melanocytic lesions with spitzoid morphology versus true Spitz tumours using deep learning on histopathological whole slide images

A. Mosquera[1,2], L. Launet[3], V. Naranjo[4,5], C. Monteagudo[6]
[1]Universitat de València, Faculty of Medicine, Valencia, Spain, [2]Clínica Colsanitas, Pathology Laboratory, Bogota, Colombia, [3]Universitat Politécnica de València, Valencia, Spain, [4]CVBLab, Instituto Universitario de Investigación en Tecnología Cen- trada en el Ser Humano (HUMAN-Tech), Valencia, Spain, [5]Universitat Politècnica de València, Valencia, Spain, [6]Universitat de València, Valencia, Spain

Background & Objectives: According to the World Health Organization's classification of skin tumours, it is recommended to distinguish BRAF-mutated melanocytic lesions with spitzoid morphology from true Spitz tumours, including both Spitz melanocytomas/atypical Spitz tumours and Spitz melanomas, which are characterized by wild-type BRAF and NRAS status. This study focuses on differentiating these entities by applying deep learning models to predict BRAF and NRAS mutational status directly from histopathological whole slide images (WSIs)
Methods: A total of 36 whole slide images (WSIs) were analysed, comprising 18 mutation-positive cases (harbouring BRAF or NRAS mutations) and 18 mutation-negative cases, all corresponding to atypical(melanocytomas) or malignant melanocytic spitzoid tumours. From these slides, a total of 286,391 image patches were extracted. Two convolutional neural network (CNN) architectures were evaluated: ResNet18 and InceptionV3. Each model was trained using 5-fold cross-validation, and performance was assessed using accuracy, sensitivity and specificity.
Results: Among the three evaluated models, ResNet18 achieved the best overall performance, with an accuracy of 0.9742 ± 0.0084, sensitivity of 0.9607 ± 0.0187, and specificity of 0.9497 ± 0.0244, indicating a balanced and robust ability to identify both mutated and non-mutated cases. In comparison, InceptionV3 showed good performance, with an accuracy of 0.9113 ± 0.0476, sensitivity of 0.9004 ± 0.0657, and specificity of 0.9360 ± 0.0280. These results confirm the superior ability of ResNet18 to distinguish between BAMS and true Spitz tumours using histopathological image data.
Conclusion: This study demonstrates the potential of deep learning models to detect BRAF and NRAS mutations in melanocytic tumours directly from histological images. ResNet18 outperformed other models in all evaluated metrics and may serve as a useful tool to support molecular diagnosis in melanocytic tumours.

Funding: This work was funded by grant PI23/01408, Instituto de Salud Carlos III and FEDER European Funds

PS-06-015

Merkel cell carcinoma (MCC) is a neuroendocrine skin cancer with high metastatic potential. Identifying prognostic biomarkers is crucial due to its aggressiveness. PRAME, studied in melanocytic tumours, is also expressed in various neoplasms. Prior studies reported PRAME expression in 30% of MCC cases, suggesting its role as a molecular driver. This study aims to confirm PRAME as a prognostic biomarker in our MCC cases

R. Rendón[1], J. Machuca Aguado[1], C.M. Alfonso Rosa[1], M.J. Ríos Moreno[2], J.J. Ríos Martín[1]
[1]Hospital Universitario Virgen Macarena, Seville, Spain, [2]Hospital Virgen Macarena, UGC Anatomía Patológica, Seville, Spain

Background & Objectives: Merkel cell carcinoma (MCC) is a neuroendocrine skin cancer with high metastatic potential. Identifying prognostic biomarkers is crucial due to its aggressiveness. PRAME, studied in melanocytic tumours, is also expressed in various neoplasms. Prior studies reported PRAME expression in 30% of MCC cases, suggesting its role as a molecular driver. This study aims to confirm PRAME as a prognostic biomarker in our MCC cases.
Methods: We analysed 34 MCC patients diagnosed between 2003 and 2025, with a median follow-up of 20.5 months. Tumour samples were reviewed by three pathologists. PRAME immunohistochemical expression was correlated with survival using Log Rank analysis. Metastatic lymph nodes were also assessed for PRAME expression.
Results: Of 34 cases, 16 (47%) exhibited PRAME positivity in primary tumours. Median disease-free survival was 14.5 months. PRAME-positive MCC patients had increased recurrence risk (HR: 6.7; p=0.005) and shorter disease-free survival (7 vs. 24 months). Median overall survival was 20.5 months; PRAME-positive cases showed reduced survival (15 vs. 24 months) and higher mortality risk, though not statistically significant (HR: 1.52; p=0.36). Metastatic lymph nodes (n=12, 35.3%) maintained PRAME staining patterns, except one case. This tumour was PRAME-negative, but 4/12 metastatic nodes exhibited focal PRAME positivity, showing a subclonal "island-like" pattern, also found in two primary tumours.
Conclusion: PRAME expression correlates with shorter disease-free survival in MCC, supporting its prognostic significance. PRAME may act as a molecular driver, suggesting potential for targeted anti-PRAME therapies in aggressive cases. Its subclonal expression pattern implies molecular heterogeneity, possibly as an acquired event in disease progression, similar to TP53 mutations in endometrial carcinoma. This finding could help refine risk stratification and guide therapeutic strategies in MCC. Further studies are necessary to confirm its role and explore therapeutic implications.

PS-06-016

Claudin-4 - an emerging biomarker for neoplastic lesions, serving as a specific diagnostic tool for skin melanoma

J. Makstiene[1], T. Sparnauskas[2], L. Mikulytė[2], M. Kuprytė[1], L. Poškienė[1]
[1]Hospital of Lithuanian University of Health Sciences Kauno Klinikos, Pathological Anatomy, Kaunas, Lithuania, [2]Lithuanian University of Health Sciences, Kaunas, Lithuania

Background & Objectives: Even though claudins, as a protein component of intercellular tight junctions, are native in human tissues, some studies hypothesize about claudin-4 being a marker for invasive skin melanoma phenotype. Objective of the study is to determine specific features of claudin-4 expression in skin melanoma.
Methods: An immunohistochemical reaction with monoclonal claudin 4 (CLDN4) antibody was performed for selected cases of compound nevi (n=15) and metastatic skin melanoma (n= 15), scanning these samples with „Pannoramic Viewer (3D Histech)". Each digitalized histological view was analysed in digital microimaging software „Slideviewer". 100 consecutive melanocytic neoplastic cells were ranked according to their membranous reaction intensity scale from 0 (no reaction) to 4 points (high intensity reaction) in one 20x microscopic magnification field (approx. 0.785 mm) for each sample (Cohen's kappa coefficient>0.9). Statistical analysis was applied ($p<0.05$).
Results: High intensity claudin-4 expression was greater in metastatic skin melanoma (median=26, interquartile range=34) compared to benign nevi, where no cases exhibited a high reaction ($p<0.001$). Similarly, moderate expression was observed exclusively in melanoma (median=37, interquartile range=40), while benign nevi demonstrated no moderate staining ($p<0.001$). Mild expression also followed this pattern, with corresponding melanoma cases (median=22, interquartile range=23) compared to the absence of mild staining in benign nevi ($p<0.00l$).
Conclusion: Study of claudin-4 immunohistochemical expression in melanocytic lesions suggest that benign nevi consistently lack any intensity of claudin-4 expression and may serve as an appropriate negative control group for evaluating benign and malignant melanocytic neoplastic lesions. Metastatic skin melanomas exhibit predominantly moderate to high intensity of claudin-4 expression, suggesting the potential diagnostic role of this immunohistochemical marker in clinic pathology practice testing for malignant melanocytic lesions.

PS-06-017

CD20 expression in tumour-stage mycosis fungoides: a retrospective analysis of 51 cases

G. Gungor Sahin[1], G. Yegen[1], T. Atci[2], C. Baykal[2], S. Ozturk Sari[1]
[1]Istanbul University Istanbul Faculty of Medicine, Pathology, Istanbul, Turkey, [2]Istanbul University Istanbul Faculty of Medicine, Dermatology, Istanbul, Turkey

Background & Objectives: Mycosis fungoides(MF) is the most common primary cutaneous T-cell lymphoma,typically presenting as patches,plaques,or tumours.Although MF is T-cell lymphoma,B-cell marker expression has been observed in some cases.CD20 expression in MF is an understudied area in the literature,yet it is not particularly rare.This phenomenon can create diagnostic challenges in patients with tumour-stage mycosis fungoides (TMF).This study aimed to investigate the percentage and distribution of CD20-positive cells in TMF cases and to determine whether this cellular population represents reactive B-cell infiltration or aberrant expression by neoplastic T-cells.
Methods: We retrospectively analysed 51 TMF patients diagnosed between 2004-2024. All cases underwent immunohistochemical staining for B-cell markers CD20,CD79a,and PAX5, in addition to the previously performed pan T-cell markers.The percentage and distribution of CD20+ lymphocytes were evaluated by two pathologists.Double immunostaining for CD4-PAX5 and CD4-CD20 was performed in cases with >50% CD20 expression.
Results: Our cohort(mean age 56.5±16.0 years, 66.7% male) included various MF subtypes: follicular(58.8%), classical(27.5%), and rare variants(13.7%).Twenty-five patients had TMF at the time of diagnosis. Large cell transformation was observed in 35.3% of the patients. CD20 was negative in 8 patients(15.7%) and positive in 43 patients(84.3%). Among CD20 positive cases, 24 cases had less than 10% staining, with 6 of these showing scattered staining.13 cases had 10-50% ,and 6 cases(12%) showed greater than 50% staining. The expression patterns of CD79a and PAX5 were similar to that of CD20.Dual immunostaining showed that CD20 and PAX5 reactivity was confined to B cells, whereas CD4 marked T-cells.
Conclusion: This study demonstrates the substantial prevalence of CD20 expression in TMF.The co-expression patterns of CD20 with other B-cell markers(CD79a and PAX5) and the results of our dual immunostaining strongly indicate that this represents reactive B-cell infiltration rather than aberrant expression by neoplastic T-cells.These results contribute to our understanding of the immunophenotypic complexity of TMF and highlight the importance of comprehensive immunohistochemical evaluation.

PS-06-018

Clinico-pathological profile and MMR status of sebaceous carcinoma: a 22-year retrospective study

N. Abdessayed[1], Y. Fejji[2], M. Belkahla[3], M. Mokni[1]
[1]Farhat Hached University Hospital, Pathology, Sousse, Tunisia, [2]Ibn Jazzar University Hospital, Pathology, Kairouan, Tunisia, [3]Farhat Hached University Hospital, Dermatology, Sousse, Tunisia

Background & Objectives: Sebaceous carcinoma (SC) is a rare malignant adnexal tumour that occurs sporadically or as part of Muir-Torre syndrome (MTS), which is associated with germline mutations in mismatch repair (MMR) protein genes. Immunohistochemistry (IHC) is a key tool for MTS screening.
Methods: This cross-sectional study analysed the clinico-pathological profile and MMR status of 22 SC cases diagnosed at the pathology department of Farhat Hached Hospital over 22 years. IHC was performed on tissue microarray (TMA) blocks using MLH1, PMS2, MSH6, MSH2, p53, and RA antibodies.
Results: The cohort included 15 men (68.2%) and 7 women (31.8%) with a median age of 77.5 years. SC cases were classified as extraocular (68.1%) and ocular (31.8%), with most tumours located in the head and neck region (81.8%). The mean tumour size was 25 mm, and half of the cases were classified as grade III. Vascular emboli and perineural invasion were observed in 18.2% and 22.7% of cases, respectively, while pagetoid spread was noted in one ocular SC case. Immunohistochemical analysis revealed RA expression in 40.9%, p53 overexpression in 31.8%, and a dMMR phenotype in 36.4% of cases. No statistically significant differences were found between the dMMR and pMMR groups regarding epidemiological, clinical, or pathological features. Surgical resection was performed in most cases, with positive margins in 36.4% of cases. Recurrence occurred in 36.4% of cases, and the median overall survival was 13 months.
Conclusion: These findings highlight SC as an aggressive malignancy and underscore the importance of IHC as a screening tool for identifying dMMR cases and guiding genetic counselling for patients at risk of MTS.

PS-07 Poster Session Digestive Diseases Pathology - Liver/Pancreas

PS-07-001

Diagnosis and management of combined hepatocellular-cholangiocarcinomas

N. Vicente[1], N. Ruiz[1], B. Kaliullayev[1], D. Ayquipa-Arróspide[1], E. Ramos[2], D. Leiva[3], T. Serrano[1]
[1]Bellvitge University Hospital, Pathology, Barcelona, Spain, [2]Bellvitge University Hospital, Liver Transplantation Unit, Barcelona, Spain, [3]Bellvitge University Hospital, Radiology, Barcelona, Spain

Background & Objectives: Combined hepatocellular-cholangiocarcinoma (cHCC-CCA) is a rare primary liver carcinoma, which contains unequivocal elements of both hepatocarcinoma and cholangiocarcinoma. It is a tumour of complex morphology and immunohistochemical diversity, whose diagnosis and management are still under discussion.
Objective: Analyse the outcomes of patients with cHCC-CCA undergoing liver transplantation (LT), in comparison with partial resection, in order to investigate whether LT can be considered a therapeutic option.
Methods: A retrospective study was carried out in 15 patients diagnosed with cHCC-CCA after undergoing partial or total hepatectomy at our centre from January 2004 to August 2021. Sociodemographic, clinical, and histopathological variables were collected, and statistical analysis was performed.
Results: The median age was 57 years old (30-74) and 11 patients (73,3%) were men. 12 cases (80%) had underlying liver disease, being hepatitis C virus the most common aetiology. Six patients (40%) received a LT and nine patients (60%) underwent partial hepatectomy. The median cancer-specific survival in transplanted patients was 122 months and in non-transplanted patients, 27 months (p-value 0.081). Tumour recurrence was observed in five patients (33,3%), all of whom died as a result of cHCC-CCA. Among the five relapsed patients, four had undergone partial resection, while only one had received a transplant. The median cancer-specific survival for patients with tumours equal to or smaller than 5 cm was 107 months, and 14 months for tumours larger than 5 cm (p-value 0.017). The median cancer-specific survival in cases with vascular invasion was 52 months, and 109 months for tumours without invasion (p-value 0.182).
Conclusion: Since the survival of transplant patients was not worse than that of those who underwent partial resection, we believe that patients with cHCC-CCA should be considered as potential LT recipients, especially those within the Milan criteria. The most relevant prognostic factors were tumour size and vascular invasion.

PS-07-002

Compliance with reporting guidelines for intraductal papillary mucinous neoplasms of the pancreas: a retrospective audit

S. Treacy[1], L. Clarke[1], N. Swan[1]
[1]St. Vincent's University Hospital, Histopathology, Dublin, Ireland

Background & Objectives: The pathological features of intraductal papillary mucinous neoplasms (IPMN) are important predictors for the risk of recurrence post resection and malignant transformation to pancreatic adenocarcinoma. Comprehensive reporting of resected cases is essential for optimal patient management. The aim of our audit was to assess the completeness of reporting on pancreatic resections for IPMN over a 10-year period and to assess the impact of the introduction of a standardised template (ST).
Methods: Reports with a diagnosis of IPMN between January 2015 and December 2024 were extracted from the laboratory information system of a single tertiary hospital. Report completeness was assessed based on the criteria recommended by Del Chiaro & Verbeke (Histopathology, 2017). Key features included location, tumour size, duct type, epithelial type, grade of dysplasia, margin status, background pathology and lymph node status.
Results: 100 cases were identified, 46 cases prior to the introduction of the ST and 54 cases reported post-ST. Overall compliance to the standard was 87% with an improvement from 82.61% pre-ST to 90.74% post-ST. The most commonly omitted criterion was tumour size (38.46% of incomplete reports). Additionally, in 45.45% (5/11) of cases involving an invasive tumour, one or more key features of IPMN were missing. Of the 22 cases with high-grade dysplasia, 86.36% (19/22) were classified as mixed or main duct type, 1 as branch duct type, and 2 were unknown due to omissions. The most frequent type of differentiation was gastric (49% of cases).
Conclusion: The introduction of a standardised reporting template resulted in an improvement in report completeness for pancreatic resection specimens containing IPMNs. This audit also identifies areas for improvement, particularly the omission of key IPMN features in malignant cases.

PS-07-003

Morphomolecular characterization of hepatocellular adenomas: a single-centre experience

K. Skok[1], F. Sarocchi[1], M. Tóth[1], K. Kashofer[1], M. El-Mahrouk[2], D. Kniepeiss[2], A. Aigelsreiter[1]
[1]Diagnostic and Research Institute of Pathology, Medical University of Graz, Graz, Austria, [2]Division of General, Visceral, and Transplant Surgery, Department of Surgery, Medical University of Graz, Graz, Austria

Background & Objectives: Hepatocellular adenoma (HCA) is a benign liver neoplasia composed of hepatocellular-differentiated cells. However, certain cases present diagnostic challenges due to inconclusive morphological and immunohistochemical (IHC) findings. The most common differential diagnose in biopsy specimens being focular nodular hyperplasia (FNH). The aim of this study was to evaluate the utility of a next-generation sequencing (NGS) liver adenoma panel in diagnosing HCAs, particularly in cases with ambiguous histopathological and IHC results. We report our single-centre retrospective experience from 2022 to 2024.
Methods: A cohort of 18 patients with hepatic lesions underwent a comprehensive diagnostic evaluation, including haematoxylin and eosin (HE) staining, IHC markers (glutamine synthetase [GS], liver fatty acid-binding protein [LFABP], serum amyloid A [SAA], and β-catenin), and targeted NGS analysis using the liver adenoma panel. Cases were classified based on morphomolecular characteristics.
Results: After extensive workup, the 18 cases showed the following mutations: HNF1A (n = 1), IL6ST (gp130) (n = 5), FRK (n = 1), and CTNNB1 mutations (exon 3: n = 2, exon 7/8: n = 2). No mutations were detected in STAT3, GNAS, or JAK1 genes. These cases were classified as follows HNF1A-inactivated HCAs (H-HCAs): n = 1, Inflammatory adenomas (IHCAs): n = 6, β-catenin-activated HCAs (b-HCAs): n = 2, β-catenin-activated inflammatory IHCAs (b-IHCAs): n = 2, Unclassified: n = 5, Focal nodular hyperplasia (FNH): n = 2.
Conclusion: The implementation of the NGS liver adenoma panel proved beneficial, particularly in some mixed-phenotype cases such as β-catenin-activated inflammatory HCA, where conventional IHC and morphology alone were not sufficient for definitive classification. This molecular approach enhances diagnostic precision and aids in the appropriate classification of challenging HCA cases.

PS-07-004

A single-centre experience on histomorphological features of porto-sinusoidal vascular disease: is Glutamine Synthetase (GS) helpful in detecting the early subtle lesions of PSVH?

A. Sert[1], G. Akyol[1], K. Moral[2]
[1]Gazi University Faculty of Medicine, Department of Pathology, Ankara, Turkey, [2]Gazi University Faculty of Medicine, Department of Gastroenterology, Ankara, Turkey

Background & Objectives: Non-cirrhotic portal hypertension (NCPH) traditionally described portal hypertension without cirrhosis. Recently,

the term porto-sinusoidal vascular disorder (PSVD) has been introduced to describe vascular lesions of the portal venous system and sinusoids in non-cirrhotic livers, with or without portal hypertension. Histologically, PSVD includes specific and non-specific features. Early lesions may be subtle and under-recognized.
Glutamine synthetase (GS), normally expressed in perivenous hepatocytes, and has been suggested as a potential marker for lobular vascular flow changes and microvascular remodelling in PSVD.
This study aims to classify histopathological findings in PSVD-spectrum cases and assess GS zonal expression in relation to clinical and histological features, particularly in patients with subtle, non-specific changes—potentially identifying early PSVD.
Methods: Twenty-seven liver biopsies were retrospectively analysed: cases previously diagnosed within the NCPH spectrum: nodular regenerative hyperplasia (NRH, n=8), hepatoportal sclerosis (HPS, n=7), PSVD (n=5), obliterative portal venopathy (OPV, n=2), controls (n=5, congenital hepatic fibrosis and non-lesional liver tissue). GS immunostaining was evaluated for zonal distribution. Clinical and histological features were recorded.
Results: Sinusoidal dilatation was observed in 59% (16/27), portal vein abnormalities in 52% (14/27), and mild periportal or perisinusoidal fibrosis in 37% (10/27). These non-specific features were frequently found in PSVD-spectrum cases, including those without clinical signs of portal hypertension. In contrast, GS expansion into midzonal or periportal zones observed in 46% (6/13) of the PSVD-spectrum biopsies. These GS-positive cases often coincided with sinusoidal dilatation, portal vein abnormalities; and also observed in patients without clinical portal hypertension. Although the limited statistical analysis, these findings suggest a potential association between GS zonal distribution and early lobular microvascular changes.
Conclusion: Zonal GS expansion may reflect early lobular vascular remodelling in PSVD. GS zonal distribution is a potentially useful histologic marker in early/subtle NCPH. However, our investigation involves a small group of patients as a preliminary study; further studies are needed.

PS-07-005

The role of PCSK9 in tumour microenvironment and drug resistance in Hepatocellular carcinoma

W.-L. Wang[1], C.-J. Yen[1]
[1]National Cheng Kung University, Department of Oncology, National Cheng Kung University Hospital, College of Medicine, Tainan, Taiwan

Background & Objectives: PCSK9, originally well-known for its critical role in cholesterol metabolism, has emerged as a tumour-promoting gene in various types of cancer, including Hepatocellular carcinoma (HCC). Noticeably, we demonstrate that proprotein convertase subtilisin/kexin type 9 (PCSK9) plays a crucial role in the oncogenic process of HCC. However, little is known about the molecular roles and clinical values of PCSK9 in governing the tumour microenvironment (TME) and drug resistance in HCC.
Methods: We use web-based bioinformatics tools to determine the clinical correlation and transcriptional factor binding sequence in the indicated promoter. Molecular mechanisms are primarily revealed by conducting immunoblotting, lentivirus-mediated shRNA knockdown or CRISPR/Cas9 sgRNA knockout, MILLIPLEX Multiplex Assays, and ELISA analysis.
Results: Herein, we find that sorafenib treatment dramatically downregulated PCSK9 protein expression in HepG2 cells. Conversely, PCSK9 expression is markedly upregulated in sorafenib-resistant HepG2 cells. Interestingly, SREBP2, a well-characterized transcriptional activator of PCSK9, is greatly increased in sorafenib-resistant HepG2 cells. Clinically, high-level SREBP2 and PCSK9 are significantly observed in HCC patients with sorafenib non-responder in comparison to sorafenib responders, as revealed by Gene Expression Omnibus (GEO) database. Notably, Kaplan-Meier analysis using web-based bioinformatics tools shows that elevated PCSK9 expression significantly correlates with poorer overall survival in sorafenib-treated HCC patients. In addition, co-culturing shPCSK9-expressing HepG2 cells with PMA-activated THP-1 cells results in lower IL-6 levels compared to shRNA control utilizing MILLIPLEX Multiplex Assays. Meanwhile, recombinant PCSK9 proteins markedly induce IL-6 expression in PMA-activated THP-1 cells. Importantly, the promoter of SREBP2 contained potential STAT3 binding sites, suggesting that the IL-6/STAT3 signalling pathway may regulate SREBP2 expression, thus facilitating PCSK9 expression.
Conclusion: In conclusion, this study aims to explore the molecular mechanisms and clinical significance underlying driving PCSK9 expression in resistance development and explore the interplay between the tumour microenvironment (TME) and HCC, ultimately leading to the development of more effective therapeutic strategies for HCC treatment.

PS-07-006

Prevalence of claudin 18.2 expression in patient subgroups and co-expression of claudin 18.2 with the KRAS G12D mutation in patients with locally advanced unresectable or metastatic pancreatic ductal adenocarcinoma in Germany

P. Wild[1], M. Gross-Langenhoff[2], C. McCabe[3], J. Bein[4], A. Hof[5], M. Glasstetter[5], G. Gourgioti[3], L. Chang[6], A. van Oosten[7], H. Dasghaib[6], M. Jänicke[5], K. Potthoff[5]
[1]Goethe University Frankfurt, Dr. Senckenberg Institutes of Pathology and Human Genetics, University Hospital Frankfurt, Frankfurt, Germany, [2]Astellas Pharma GmbH, Munich, Germany, [3]Astellas Pharma Europe Ltd., Addlestone, United Kingdom, [4]University Clinic Frankfurt, Frankfurt, Germany, [5]iOMEDICO AG, Freiburg, Germany, [6]Astellas Pharma, Inc., Northbrook, IL, USA, [7]Astellas Pharma Europe B.V., Leiden, The Netherlands

Background & Objectives: The tight junction protein claudin 18.2 (CLDN18.2) is a potential predictive biomarker in pancreatic ductal adenocarcinoma (PDAC). We aimed to determine the prevalence of CLDN18.2 expression in locally advanced unresectable or metastatic PDAC (la/mPDAC) and examine co-expression with KRAS G12D, a common mutation.
Methods: Tumour Registry Pancreatic Cancer, an open, non-interventional, prospective, multicentre clinical research platform in Germany (NCT02089269), provided medical and biobank data. Participants initiated first-line treatment (2013–2022) for la/mPDAC at registry enrolment and donated tumour samples. For this study, in centralized testing in 2024, immunohistochemistry staining for CLDN18.2 expression was considered positive if ≥75% of tumour cells demonstrated moderate to strong membranous staining. KRAS G12D was detected by PCR. Descriptive statistics of CLDN18.2 expression included distribution by patient subgroups and co-expression with KRAS G12D.
Results: Among 245 enrolled patients, 66 (26.9%) had CLDN18.2-positive tumours and 179 (73.1%) had CLDN18.2-negative tumours. In patient subgroups, proportions of patients with CLDN18.2-positive tumours were as follows: age ≥70 years (27/109 [24.8%]) and <70 years (39/136 [28.7%]); male (32/131 [24.4%]) and female (34/114 [29.8%]); locally advanced unresectable disease (stage III; 5/13 [38.5%]) and metastatic disease (stage IV; 61/232 [26.3%]); sample site of primary tumour (22/88 [25.0%]), local recurrence (0/1 [0%]), distant metastases/lymph nodes (28/106 [26.4%]), and unknown (16/50 [32.0%]); and sample type of biopsy (24/117 [20.5%]), resection (20/62 [32.3%]), and unknown (22/66 [33.3%]). Eighty (32.7%) patients had KRAS G12D, and 148 (60.4%) patients did not; KRAS G12D status was missing in 17 (6.9%) patients. Nineteen of 66 (28.8%) patients with CLDN18.2-positive tumours and 61 of 179 (34.1%) patients with CLDN18.2-negative tumours had KRAS G12D.

Conclusion: Across most subgroups, 20.5%–38.5% of patients had CLDN18.2-positive tumours, and 28.8% of patients with CLDN18.2-positive tumours had KRAS G12D. Improved understanding of CLDN18.2 prevalence and co-expression with KRAS G12D may support development of targeted therapies for la/mPDAC.

PS-07-007

Frequency of IDH1 mutation in intrahepatic cholangiocarcinoma

V. Kropelnytskyi[1], R. Gulkovskiy[2], N. Chepur[1], I. Romasko[1], J. Zaivelieva[3]
[1]Shalimov National Scientific Centre of Surgery and Transplantation, Pathology and Oncogenetics, Kyiv, Ukraine, [2]Institute of Molecular Biology and Genetics NASU, Human Genomics, Kyiv, Ukraine, [3]Shalimov National Scientific Centre of Surgery and Transplantation, Oncology, Kyiv, Ukraine

Background & Objectives: IDH1 mutation is one of the new targets for cholangiocarcinoma precise therapy. According to the literature IDH1 mutations are detected in 10-20% of intrahepatic cholangiocarcinoma cases and up to 5% of extrahepatic cholangiocarcinoma cases. The study aim was to evaluate frequency of IDH1 mutation in intrahepatic cholangiocarcinoma in Ukrainian patient cohort with the use of cheap NGS hotspot panel.
Methods: The study included 75 patients who underwent liver core biopsy or liver resection procedure for intrahepatic cholangiocarcinoma during the 2019-2023. Ethics approval and informed consent were obtained. DNA was extracted from the FFPE blocks. Genomic DNA was sequenced using IonAmpliSeq Cancer-Hotspot Panel and Ion S5 sequencer. Results were filtered using Franklin by Gennox. NGS was supported by NRFU [grant- 2021.01/0024]
Results: A total of 74 significant variants were found in 21 genes. The largest number of mutations was identified in genes: IDH1, TP53, RET, KRAS, PIK3CA, IDH2 (17, 8, 8, 5, 5, 2 respectively). Of the variants that have been identified 17 IDH1, 3 NRAS and 2 BRAF mutations are alterations for which a targeted therapy has been validated. IDH1 mutation was detected in 17% cases (22,6%). From those 17 IDH1-cases R132C was found in 6 samples (35,3%), R132L - in 5 samples (29,4%), R132G – 3 in samples (17,6%) and R132H in 1 sample (5,9%). 2 cases were non-R132X (11,8%). All IDH1-positive cases have small duct type morphology.
Conclusion: With the help of NGS hotspot panel IDH1 mutation was found in 22,6% of patients. This figure is slightly higher than in literature (10-20%). Considering the relative cheapness of such a test, it is recommended to test all intrahepatic cholangiocarcinoma samples. These data might help guide targeted therapies selection for patients treatment.

Funding: NGS was supported by NRFU [grant- 2021.01/0024

PS-07-008

Establishment of the Spanish childhood liver cancer biorepository: advancing clinical and pathological prognostic validation

S. Planas[1], C. Jou[1], C. Armengol[2], Spanish Group for the Study of Childhood Liver Cancer
[1]Hospital Sant Joan de Déu, Pathology, Barcelona, Spain, [2]Germans Trias i Pujol Research Institute, Badalona, Spain

Background & Objectives: Childhood liver cancer is a rare disease. Limited biological samples have hindered understanding their molecular nature, affecting translational research. Our aims were (i) establish a Spanish biorepository of clinically-annotated biological samples from paediatric patients with liver cancer, (ii) set-up a national pathology review and (iii) identify prognostic clinical, and pathological parameters.
Methods: Establish a collaborative network with the main Spanish paediatric hospitals to collect samples (tissue, plasma) and clinical data,offer a national pathology review and fully annotate tumour samples (e.g. diagnosis type and subtype, histology, main epithelial component).
Results: From 2010-2024, 569 biological samples were collected from 128 patients: 119 HB (median age: 37.8 months, 55% male, 18% PRETEXT IV, 18% metastasis, 8% mortality) and 9 HCC (median age: 132 months, 45% male, 40% mortality). Pathology review confirmed HB in 95% of cases and reclassified 5% of them as HCN-NOS. HCC and HCN-NOS were associated with poor outcome. For HB patients, significant factors associated to survival included patient age $\geq$ 8 years, PRETEXT IV, multifocality, metastasis and high-risk CHIC-HS.
Conclusion: We established a unique biorepository of childhood liver cancer in Spain of clinically and pathologically annotated specimens and validated key prognostic clinical and pathological features.

Histopathological evaluation of high-grade and undifferentiated thyroid carcinomas: a retrospectives analysis

I. Yıldız[1], A. Yavuz[1], E.S. Aktı[2], N. Yılmaz[2], G.A. Ocak[1], İ.E. Gürer[1]
[1]Akdeniz University, Pathology, Antalya, Turkey, [2]Akdeniz University, Internal Medicine, Antalya, Turkey

Background & Objectives: Thyroid carcinomas encompass a spectrum of biological behaviour, ranging from indolent well-differentiated tumours to highly aggressive undifferentiated carcinomas. Poorly differentiated thyroid carcinoma (PDTC) and high-grade differentiated thyroid carcinoma (HG-DTC) represent intermediate forms, whereas anaplastic thyroid carcinoma (ATC) is characterized by rapid progression, resistance to therapy, and poor prognosis. Given their overlapping histological features but distinct clinical courses, accurate subclassification is crucial. This study evaluates the histopathological and clinical characteristics of patients diagnosed with PDTC, HG-DTC, and ATC.
Methods: A retrospective analysis was conducted on 33 patients(20 females,13 males).Parameters assessed included tumour localization, mitotic activity, necrosis, invasion patterns and proliferation markers. Both Ki-67 and Phh3 indices were utilized to evaluate proliferative activity. A maximum of 75 blocks were sampled in a single case, with an average of 29 blocks per tumour. Treatment modalities and follow-up data were also recorded. The number of sampled tissue blocks was also evaluated to reflect diagnostic sampling density.
Results: The mean age at diagnosis was 55 years. Among the six PDTC cases, mitotic counts ranged from 3–14 per 10 high-power fields (HPF), with necrosis present in four cases and Ki-67 indices ranging from 10% to 60%.Three PDTC patients had lung metastases at diagnosis, and two died from the disease. HG-DTC cases (n=22) exhibited mitotic activity between 5–10/10 HPF, necrosis in nine cases, and Ki-67 up to 30%.One HG-DTC patient had tracheal and oesophageal invasion with nodal metastasis. ATC cases (n=5) showed markedly aggressive behaviour with high mitotic and proliferative activity(Ki-67 up to 60%), frequent necrosis, vascular invasion, and widespread metastases in one patient. Consistent proliferative activity assessment was observed across mitotic count,necrosis,Ki-67 and Phh3.
Conclusion: In contrast to previous studies reporting more frequent lymph node involvement in HG-DTC, our cohort showed nodal metastases predominantly in PDTC cases (4/6),with three of these also presenting with pulmonary dissemination at diagnosis. The combined use

of Ki-67 and Phh3 provided a comprehensive evaluation of proliferative potential, aiding tumour stratification.

PS-08-002

Identification of mutations in follicular cell-derived non-anaplastic thyroid neoplasms: a clinical experience

S. Moles Caparros[1], A.S. Veliz Dominguez[1], N. Cadavid Fernandez[1], A.G. Tenelanda Santillan[1], A. Santón[1], T. Caniego-Casas[1], H. Pian-Arias[1], S. Aso-Manso[1], T. Alonso-Gordoa[2], J. Molina-Cerrillo[2], I. Ruz-Caracuel[1], J. Palacios[1]
[1]Hospital Universitario Ramon y Cajal, Department of Pathology, Madrid, Spain, [2]Hospital Universitario Ramon y Cajal, Department of Oncology, Madrid, Spain

Background & Objectives: Follicular cell-derived thyroid carcinomas generally have an excellent prognosis. However, a small percentage of patients progress to advanced disease. In this setting, tumours harbouring translocations (most commonly RET, followed by NTRK) can be treated with personalized targeted therapies. Since there are multiple approaches to diagnosing these alterations, our centre opted to perform DNA- and RNA-based next-generation sequencing (NGS) in these tumours. Here, we present the results obtained over a five-year period.
Methods: We reviewed the NGS results of follicular cell-derived thyroid carcinomas analysed at our centre over the past five years. During this period, three different Oncomine Assay panels (ThermoFisher Scientific) were successively implemented, all capable of detecting RET, NTRK, and ALK translocations.
Results: Over the five-year period, 44 NGS analyses were performed, including 20 papillary thyroid carcinomas (PTCs), 15 high-grade carcinomas, 8 follicular carcinomas, and 1 oncocytic carcinoma. Molecular alterations were identified in 34 tumour samples (77.3%). Seven samples (15.9%) did not meet the RNA quality requirements, necessitating additional FISH studies to rule out translocations.
Three actionable mutations were detected: two ***CCDC6::RET*** fusions, identified in an infiltrative follicular variant of PTC and in a PTC with tall cell areas; and one ***NCOA4::RET*** fusion, found in a diffuse sclerosing PTC. Additionally, a ***NSD3::NUTM1*** translocation was observed in a poorly differentiated carcinoma. The most frequent molecular alterations were **14 *BRAF* mutations**, followed by **6 *NRAS* mutations** and **3 *HRAS* mutations**. High-grade carcinomas exhibited the lowest mutation detection rate (53.3%).
The number of NGS analyses performed on follicular cell-derived thyroid carcinomas steadily increased over the study period, from 4 in 2019 to 10 in 2024.
Conclusion: At our centre, our detection strategy has enabled the identification of actionable targets in 6.8% of follicular cell-derived thyroid carcinomas requiring systemic targeted treatment.

PS-08-003

Development and validation of an integrated model to predict BRAF V600E mutation in Papillary thyroid cancer from Cytological Slides and CT images

Y. Chen[1], Y. Yang[1], Y. Tong[2]
[1]Fujian Medical University Union Hospital, Pathology, Fuzhou, China, [2]Fuzhou University Affiliated Provincial Hospital, Radiology, Fuzhou, China

Background & Objectives: The BRAF gene plays an essential role in papillary thyroid carcinoma (PTC). However the detection is time-consuming and expensive. We try to investigate the potential of an integrated model based on Cytological Slides and CT images in predicting BRAFV600E mutation in calcified PTC.
Methods: This study included 465 patients with pathology-confirmed PTC and proven BRAF V600E status by PCR. All patients underwent CT scan and fine needle aspiration cytology before surgery. They were randomly divided into the training/validation cohort (n = 295/100) and the testing cohort (n =70). The Integrated model was constructed by machine learning on the basis of two features: radiomics CT features and pathomics nucleus features. The accuracy for the prediction of BRAF V600E status was verified in retrospective internal validation cohort and further validated in a multicentre, prospective observational study. Model performances were evaluated using area under the curve (AUC), sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV).
Results: Integrated model had favourable accuracy in the training cohort (AUC 0·864 [95% CI 0·826–0·901]), and in validation cohort (0·866 [0·819–0·913]). In the prospective validation study, Integrated model had an AUC of 0·812 (95% CI 0·716–0·903), sensitivity of 0·889 (0·729–0·998), specificity of 0·739 (0·590–0·876), NPV of 0·927 (0·861–0·994), and PPV of 0·513 (0·314–0·712). It also significantly outperformed single-modality prediction models (AUC 0·631 [0·509–0·755] for the radiomics CT model, and 0·739 [0·620–0·843] for the pathomics nucleus model; all $p<0·0001$).
Conclusion: Multimodal integration of pathomics and radiomics improved mutation risk score prediction relative to the single models.

PS-08-004

An integrated radiomic and pathomic approach for the detecting of BRAF V600E mutations in papillary thyroid cancer

Y. Chen[1], Y. Yang[1], Y. Tong[2]
[1]Fujian Medical University Union Hospital, Pathology Department, Fuzhou, China, [2]Fuzhou University Affiliated Provincial Hospital, Radiology, Fuzhou, China

Background & Objectives: Papillary thyroid cancer (PTC) is the most prevalent form of malignancy among all thyroid cancers. It is characterized by BRAF mutations (mainly V600E) with more aggressive and iodine-resistant phenotypes. Because of the mutation detection is unaffordable and time-consuming for a considerable number of patients, predicting gene mutations based on routine clinical radiological scans or whole-slide images of tissue with AI-based methods has become a hot issue in actual clinical practice. In this study, we try to develop and validate an artificial intelligence integrated model using pretreatment CT and ThinPrep cytological slides as a highly potential decision-support tool to aid oncologists in future cancer treatment management.
Methods: This study included 465 patients with pathology-confirmed PTC and proven BRAF V600E status by PCR. All patients underwent CT scan and fine needle aspiration cytology before surgery. They were randomly divided into the training/validation cohort (n = 295/100) and the testing cohort (n =70). The Integrated model was constructed by machine learning on the basis of two features: radiomics CT features and pathomics nucleus features. The accuracy for the prediction of BRAF V600E status was verified in retrospective internal validation cohort and further validated in a multicentre, prospective observational study. Model performances were evaluated using area under the curve (AUC), sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV).
Results: Integrated model had favourable accuracy for the prediction of BRAF V600E mutation in the training cohort and in validation cohort . It also significantly outperformed single-modality prediction models for the radiomics CT model, and for the pathomics nucleus model.
Conclusion: Multimodal integration of pathomics and radiomics improved mutation risk score prediction relative to the single models,which not only aid in accurate diagnosis but also provide useful information in guiding clinical decision-making in patients with thyroid cancer.

PS-08-005

Are micropapillary thyroid carcinomas indolent? Multiparameter description and comparison of a Colombian Cohort

P.C. Castro-Quiroga[1], S.D. Cruz Romero[1], S. González[1], J. Hakim[2], D. González-Devia[3], M. Baldion[1], P.A. Rodriguez-Urrego[1]
[1]University Hospital Fundacion Santa Fe de Bogota, Pathology Department, Bogotá, Colombia, [2]University Hospital Fundacion Santa Fe de Bogota, Head and Neck Division, Bogotá, Colombia, [3]University Hospital Fundacion Santa Fe de Bogota, Endocrine Division, Internal Medicine Department, Bogotá, Colombia

Background & Objectives: Papillary thyroid carcinoma (PTC) is the most common malignant thyroid neoplasm. Its rising incidence is attributed to the increased use of diagnostic imaging. Papillary thyroid microcarcinoma (PTMC), defined as a tumour ≤1 cm, is generally indolent; however, a subset may present aggressive behaviour. This study aims to describe and compare the clinical, histological, and molecular features of a Colombian PTMC cohort to conventional PTC cases (>1 cm).
Methods: A retrospective analysis was conducted on 229 patients diagnosed with PTC between 1993 and 2011 at Fundación Santa Fe de Bogotá, as part of the TIROSEC study. Clinical, epidemiological, and histopathological features were analysed. Molecular profiling was performed using next-generation sequencing (NGS) with the SOPHiA Solid Tumour Solution kit.
Results: Of the 229 PTC cases, 97 (42%) were classified as PTMC. Most PTMC patients were women under 55 years old (84.5%), and 78% were diagnosed incidentally. Compared to PTC, PTMC showed lower nodal involvement (71% vs. 80%), more frequent aggressive histologic variants (70% vs. 41%, p<0.001), and lower rates of positive surgical margins (31% vs. 47%, p=0.02), less lymphovascular invasion (11% vs. 30%, p<0.001), less perythyroideal soft tissue involvement (42% vs. 69%, p<0.001), no extrathyroidal extension (0% vs. 5%, p=0.04); absecence of mitosiss (0% vs. 5%, p=0.04), received less radioactive iodine therapy (65% vs. 85%, p=0.001), and had lower local recurrence (8% vs. 19%, p=0.03) and mortality at 15 years (2% vs. 5%, p=0.36). BRAF (69% vs. 72%) and RAS (7% vs. 6%) mutation frequencies were similar between groups.
Conclusion: Despite their size, PTMCs in this cohort showed a relatively high incidence, nodal involvement, and BRAF mutation rate. Prognostic factors include aggressive histological subtype, margin status, and molecular alterations. The application of risk stratification criteria, such as the Porto classification, may enhance management strategies. Further studies are required to evaluate environmental factors influencing these outcomes.

PS-08-006

Increasing utility of Ki67 and p53 immunohistochemistry in the diagnostic workup of pituitary neuroendocrine tumours

J. Jotanovic[1,2], F. Adlmann[1], P. Burman[3], O. Casar-Borota[1,2]

[1]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden, [2]Department of Clinical Pathology, Uppsala University Hospital, Uppsala, Sweden, [3]Department of Endocrinology, Skåne University Hospital, Lund University, Malmö, Sweden

Background & Objectives: Pituitary neuroendocrine tumours (PitNETs)/pituitary adenomas typically show indolent clinical course. However, up to 1% of PitNETs are designated aggressive pituitary tumours (APT) due to continuous growth and/or hormone hypersecretion despite adequate treatment. Rare patients (0,1-0,5%) develop metastasizing pituitary carcinoma (PC). Recent reports indicate a role of *TP53* mutations in PitNET aggressiveness.
Histological markers, including Ki67 index and p53 expression, are recommended for evaluation of PitNETs behaviour according to the European Society of Endocrinology guidelines. These markers are routinely assessed in PitNETs diagnostic workup and are integrated into proposed prognostic clinicopathologic classification systems.
In the first surgery specimens from 38 APT/PC and 12 benign PitNETs we recently showed significant heterogeneity in Ki67 and p53 immunolabeling in the APT/PC subgroup.
To facilitate the assessment of Ki67 and p53 immunohistochemistry (IHC) in the PitNETs diagnostic workup, we explored the performance of an AI tool as a quantification method.
Methods: Ki67 and p53 IHC expression, evaluated as a percentage of immunopositive cells in hot spots foci, was analysed in 26 APT/PC samples and 12 benign PitNETs. Two IHC-scoring methods were used and compared: manual microscopical evaluation (method 1) and automatized assessment using QuPath digital image analyser (method 2).
Results: We found a complete correlation between the manual and automatized Ki67 and p53 IHC-scoring methods when benign PitNETs samples were analysed, and relatively high concordance (>80%) in the APT/PC group.

Conclusion: Automatized AI-based methods may be useful and time-saving in the quantitative assessment of Ki67 index and p53 expression in PitNETs, especially in APT/PC where cell proliferation and p53 expression may largely vary. Studies on the larger cohorts of PitNETs of different behaviours and correlation with molecular genetic data are needed to optimise the utilisation of Ki67 and p53 IHC in routine diagnostic workup of PitNETs.

PS-08-007

Molecular and immunohistochemical characterization of cribriform-morular thyroid carcinoma: insights into origin and therapeutic targets

J.Y. Koo[1], K.-H. Lee[1], Y.-D. Choi[1], N.-I. Kim[1], S.S. Kim[1], J.Y. Lee[1]
[1]Chonnam National University Medical School, Pathology, Gwangju, Republic of Korea

Background & Objectives: Cribriform-morular thyroid carcinoma (CMTC) is a rare malignant thyroid tumour with distinctive morphological features that can occur in association with familial adenomatous polyposis (FAP) or arise sporadically. While CMTC is known to involve activation of the WNT/β-catenin pathway, its cellular origin remains controversial, and comprehensive molecular and immunohistochemical analyses have been limited.
Methods: We retrospectively identified five CMTC cases diagnosed between January 2012 and December 2022 at Chonnam National University Hospital and Chonnam National University Hwasun Hospital. Next-generation sequencing (NGS) analysis and immunohistochemical analyses were performed to investigate potential therapeutic targets.
Results: All patients were female (age range: 19-47 years, mean: 28 years). Four cases presented as single nodules, while one exhibited multifocal and bilateral disease. Tumour size ranged from 7 to 28 mm (mean: 19.4 mm), with no lymph node metastasis observed in any case. All tumours displayed characteristic cribriform and solid/morular architecture, with nuclear β-catenin positivity present in four of five cases. Immunohistochemical analysis revealed low-level HER2 expression and CD56 positivity across all cases. No patients had APC germline mutations or associated clinical symptoms. Molecular profiling identified APC or CTNNB1 mutations in all cases, with one case harbouring an additional FBXW7 mutation. High tumour mutation burden (TMB) was detected in two cases.

Conclusion: Our study demonstrates that all CMTC cases exhibited APC/CTNNB1 mutations alongside CD56 positivity. This supports the hypothesis that CMTC originates from thyroid follicular epithelial cells and develops an endodermal (intestinal-like) phenotype following characteristic mutational events. The observation of HER2 positivity across all cases and high tumour mutation burden in two cases suggests additional therapeutic options may be available for aggressive presentations of this rare malignancy.

PS-08-008

When thyroid pathology becomes a clue to PTEN hamartoma tumour syndrome

A. Azueta Etxebarria[1], I. Fernández de la Prieta[1], L. Aguirrezabal Marcotegui[1], R.I. Cuenca Alvarado[1], P. Calvo Torio[1], S. Fernández Ferrer[1], M. Castaños Bueno[1], J. Pérez de Arenaza Marquínez[1], D. Rodríguez Villar[2], C. Zac Romero[3], S. López Agulló[4]
[1]Hospital Universitario Basurto, Osakidetza, Pathology, Bilbao, Spain, [2]Hospital Universitario Cabueñes, Pathology, Gijón, Spain, [3]Hospital Universitario y Politécnico La Fe de Valencia, Pathology, Valencia, Spain, [4]Instituto Valenciano de Oncología (IVO), Pathology, Valencia, Spain

Background & Objectives: Phosphatase and tensin homolog (PTEN) hamartoma tumour syndrome (PHTS) is a rare autosomal dominant disorder caused by mutations in the PTEN tumour suppressor gene. It causes hamartomatous overgrowth in the thyroid, gastrointestinal tract, and skin. Patients with this disease are at increased risk of thyroid, breast, renal, endometrial, and possibly colorectal cancers. PHTS includes Cowden syndrome (CS), PTEN-related Proteus síndrome (PS), Bannayan-Riley-Ruvalcaba syndrome (BRRS), and Proteus-like syndrome. Harach et al. were the first to note the histologic findings of multiple adenomatous goiters and multiple follicular adenomas, including adenolipomas.
Methods: We present four PHTS, collected in three different hospitals.
Results: All patients were young and microscopically presented unusual thyroid histology with multiple follicular adenomas with monomorphic microfollicular growth patterns, numbering more than 4, and measuring up to 3,5 cm. They all were well-demarcated with most of them with fibrous capsule with medium to large vessels. Capsular or vascular invasion was not observed. A mixture of lipomatous metaplasia and follicles and chronic lymphocytic thyroiditis was characteristic. Based on these aspects PHTS was suspected. PTEN immunohistochemistry was performed. Proliferative thyroid lesions presented loss of expression for PTEN proteins, whereas the normal background thyroid tissue was positive, compatible with PTHS. Further examination of the patient's history in three cases revealed family history of multiple polyps in the gastrointestinal tract, and cutaneous haemangiomas. In one case, thyroid pathology was the first manifestation in a 13-year-old girl. According to the National Comprehensive Cancer Network guidelines for CS/PTHS, genetic testing was done and all of them had mutations in PTEN gen.
Conclusion: We aim to demonstrate the importance of recognizing the thyroid histology, and the clinical and immunophenotypical features that will aid pathologists and clinicians in properly diagnosing PHTS, which is critical for cancer screenings and genetic counselling.

PS-08-009

Clinicopathological features of high-grade differentiated thyroid carcinoma: five years' experience of a single hospital

S. Spiric[1], B. Kovacevic[1,2], M. Macar[1], S. Cerovic[1,2], D. Marinkovic[3], D. Slavkovic[4]
[1]Institute of Pathology and Forensic Medicine, Military Medical Academy, Belgrade, Serbia, [2]Medical Faculty of the Military Medical Academy, University of Defence, Belgrade, Serbia, [3]Clinic for Endocrinology, Military Medical Academy, Belgrade, Serbia, [4]Clinic for General Surgery, Military Medical Academy, Belgrade, Serbia

Background & Objectives: High-grade differentiated thyroid carcinoma (HGDTC) refers to any differentiated thyroid carcinoma, including papillary thyroid carcinoma (PTC), follicular carcinoma, or oncocytic carcinoma (OTC), that exhibits at least five mitoses per 2 mm² and/or tumour-type necrosis without an anaplastic component. HGDTC belongs to the group of follicular cell-derived malignancies with intermediate biological behaviour. We analysed the frequency and clinicopathological features of HGDTC over a five-year period.
Methods: The study included HGDTC diagnosed at our Institute from 2020 to 2025. Besides frequency of HGDTC, the following features were analysed for each case: age, gender, tumour type, tumour size, presence of lymph node metastasis (LNM), extrathyroidal extension (ETE), and vascular invasion.
Results: During the study, 544 thyroidectomies were analysed pathohistologically. Malignant cases totaled 243 (44.66%), with PTC being the most common (197; 81.06%), followed by OTC (14; 5.76%), follicular carcinoma (11; 4.52%), medullary thyroid carcinoma (10; 4.11%), and anaplastic carcinoma (1; 0.41%). HGDTCs accounted for 10 (4.11%) cases, including eight HGPTCs and two HGOTCs. Six patients were male and four female, with an average age of 57.8±17.02 years (range 31–80 years) and a mean tumour size of 43.4±31.17 mm. Two PTC cases were subcentimetric: one was a 2 mm incidental finding, and the other presented with multiple regional LNM. Gross ETE was observed in three cases. Pathological T3 and T4 stages were found in four and one case, respectively. Distant metastasis was noted in one case, with LNMs in two cases and vascular invasion in eight cases.
Conclusion: HGDTCs are rare yet not uncommon, with the majority of cases being diagnosed in male patients. A significant number of HGDTCs have a high pathological T stage and/or exhibit LNM. Distant metastasis at the time of HGDTC diagnosis occurs sporadically. Most HGDTCs belong to a PTC type, and high-grade features may also occur in subcentimetric PTCs.

PS-08-010

Clinicopathologic correlates of tumour size in paediatric, adolescent and young adult neuroendocrine tumours: a cohort from fundación Santa Fe de Bogotá (2004–2022)

R.d.P. López-Panqueva[1], L. Chacón Zambrano[2], K.J. Quintero Gil[2], M.A. Forero[2]
[1]Fundación Santa Fe de Bogotá, Colombia-Universidad de Los Andes, Pathology and Laboratories, Bogotá, Colombia, [2]Universidad de los Andes - Fundación Santa Fe de Bogotá, School of Medicine - Pathology and Laboratories, Bogotá, Colombia

Background & Objectives: Neuroendocrine tumours (NETs) in children and adolescents are rare, with variable clinical behaviour and anatomical distribution. Diagnosis and management are challenging due to non-specific symptoms, clinical heterogeneity, and the lack of paediatric-specific guidelines. Some NETs are linked to genetic predisposition syndromes such as MEN and von Hippel-Lindau (VHL), requiring early and tailored surveillance.
Appendiceal NETs are the most frequent and typically indolent; pulmonary and pancreatic NETs are less common but may be more aggressive, particularly in hereditary contexts. Tumour size is a critical factor influencing surgical management and prognosis. This study aimed to characterize clinicopathologic correlations with tumour size in paediatric and young patients diagnosed with NETs over an 18-year period.
Methods: A retrospective cohort of 106 patients under 26 years of age diagnosed with NETs between 2004 and 2022 at Fundación Santa Fe de Bogotá was analysed. Variables included age, gender, tumour location, histologic grade, Ki-67 index, and tumour diameter. Descriptive

statistics were followed by ANOVA, Spearman correlation, and multivariable linear regression.
Results: The most frequent location was the cecal appendix, followed by bronchopulmonary tree, pancreas, and liver (metastases). Unusual anatomical sites were found like cervix, merkel cell carcinoma and biliar duct. Tumour diameter showed no correlation with age, gender, or Ki-67 index. However, it was significantly associated with both tumour location and histologic grade. Grade 2 tumours had significantly larger diameters than Grade 1 ($p < 0.05$), and tumours with hepatic metastases were significantly larger than those in other locations ($p < 0.05$). Multivariable analysis confirmed Grade 2 and liver metastases as independent predictors of larger tumour size.
Conclusion: Tumour grade and hepatic metastases are the main determinants of tumour size in this cohort. These findings highlight the prognostic relevance of tumour size and support the need for integrated clinicopathologic assessment and paediatric-specific management guidelines for NETs.

PS-08-011
High-grade papillary thyroid carcinoma: rarity, risks and outcomes
Y. Loukil[1], Y. Houcine[1], E. Kedous[2], S. Kamoun[1], S. Dhambri[2], I. Bettaieb[1], A. Goucha[1], M. Driss[1]
[1]Salah Azeiz Institute, Pathology Department B, Tunis, Tunisia, [2]Salah Azeiz Institute, Maxillo-Facial and ORL Surgery Department, Tunis, Tunisia

Background & Objectives: Differentiated high-grade thyroid carcinoma is a newly defined diagnostic entity, first introduced in the 2022 WHO classification. These tumours are rare, typically diagnosed in the sixth to seventh decade, and uncommon in young adults. This study aims to compare clinicopathological characteristics and oncologic outcomes between high-grade papillary thyroid carcinoma (HGPTC) and low-grade papillary thyroid carcinoma (LGPTC) in a young adult population.
Methods: We collected cases of papillary thyroid carcinoma in patients from our institutional archives between 2020 and 2022. Histological diagnoses were reviewed, and the tumours were subsequently reclassified into HGPTC and LGPTC.
Results: The cohort included 145 patients, consisting of 135 females and 10 males, aged 9 to 72 years. The carcinomas were classified as HGPTC (n=44) and LGPTC (n=101). The latter was further subclassified into one case of the tall cell subtype, 91 cases of the classic subtype, and 54 cases of invasive EFVPTC. The mean tumour size was 30 mm for HGPTC and 15 mm for LGPTC ($p = 0.878$). Extrathyroidal extension was noted in 15 cases (10,3%) of HGPTC and 7 cases (4,8%) of LGPTC ($p = 0.193$).
Among HGPTC cases, 21 (14,4%) had lymph node metastases, while 7 (4,8%) of LGPTC cases had lymph node metastases ($p = 0,143$). Recurrence was noted in 8 HGPTC cases (5,5%) and 4 LGPTC cases (2,7%) ($p = 0,232$). Distant metastases were observed in 9 HGPTC patients (6,2%) and 4 LGPTC patients (2,7%) ($p = 0.094$). All patients were alive at the last follow-up.
Conclusion: Although HGPTC is rare, our findings suggest that its clinicopathological profile and oncologic outcomes do not significantly differ from those of LGPTC in this population. However, the higher frequency of lymph node and distant metastases in HGPTC, although not statistically significant, underscores the need for close monitoring and further studies to better characterize its prognosis.

PS-08-012
The unencapsulated follicular subtype of papillary thyroid carcinoma is associated with nodal metastasis, but not distant metastasis: a single-centre study
A.S. Harahap[1,2], M.F. Ham[2], D. Khoirunnisa[2]
[1]Department of Anatomical Pathology, Faculty of Medicine, Universitas Indonesia, Dr. Cipto Mangunkusumo Hospital, Jakarta 10430, Indonesia, [2]Human Cancer Research Centre-Indonesian Medical Education and Research Institute, Faculty of Medicine, Universitas Indonesia, Jakarta 10430, Indonesia

Background & Objectives: The follicular subtype of papillary thyroid carcinoma (PTC) is common and exhibits various phenotypes. Encapsulated morphology often displays a favourable prognosis. This study aims to describe the clinicopathological features of follicular subtype of PTC and explore the association between unencapsulated phenotype and aggressive tumour outcomes.
Methods: We retrospectively collected all PTC cases diagnosed as follicular subtype at Dr. Cipto Mangunkusumo Hospital, Jakarta, Indonesia, from 2019 to 2022. The Chi-square test was performed to analyse the association between unencapsulated tumours with nodal and distant metastasis.
Results: There were 84 cases of follicular subtype of PTC. Most patients were female (79.8%) and under 55 years of age (77.4%), with a mean age of diagnosis at 43.7 years (SD=15.1 years). The tumour is frequently multifocal (64.3%) with a median tumour size of 2.9 cm (range = 0.3—12 cm). Most of the patients were classified according to the 8th American Joint Committee on Cancer as stage I (83.3%), followed by stage II (11.9%), and stage IV (4.8%). All cases exhibited PTC nuclei, with 64.3% of patients displaying a total nuclear score of 2. *RAS* mutation was identified in 32 patients and *BRAF*V6000E in 5 patients. We found 31 tumours were unencapsulated infiltrative and 53 were invasive encapsulated follicular subtype of PTC. Unencapsulated infiltrative follicular subtype of PTC was associated with nodal metastasis (p=0.04; OR [95% CI]= 3.2 [1-10.1]). We found no significant association between unencapsulated tumours with distant metastasis.
Conclusion: This study found a significant association between unencapsulated infiltrative follicular subtype of PTC with nodal metastasis, but not distant metastasis.

PS-09 Poster Session Haematopathology

PS-09-001
Assessment of CD19 expression in diffuse large B-cell lymphoma using QuPath: correlation with prognostic factors
S. Özdüzgün Polat[1], E. Özhamam[1], A. Albayrak[1], A. Kılıçarslan[2], M. Doğan[2], E. Karakuş[1]
[1]Ankara Bilkent City Hospital, Medical Pathology, Ankara, Turkey, [2]Ankara Yıldırım Beyazıt University Faculty of Medicine, Medical Pathology, Ankara, Turkey

Background & Objectives: Despite significant advances in first-line treatments for diffuse large B-cell lymphoma (DLBCL), approximately one-third of patients still require subsequent therapy for relapsed or refractory disease. About 50% of refractory DLBCL patients achieve durable responses with CD19-targeted CAR-T therapy. This study aimed to assess CD19 expression in DLBCL patients and examine its relationship with prognostic factors.
Methods: Eight paraffin blocks were prepared using the tissue microarray technique, with each core having a diameter of 5 mm. Immunohistochemical staining for CD19 (clone BT5E) was performed, and slides were digitized for quantitative analysis using QuPath (version 2.1). The percentage of CD19 expression and H-scores were recorded.
Results: In the 78 evaluated DLBCL cases, CD19 expression percentages ranged from 0 to 97.68, and H-scores ranged from 0 to 264.91. No statistically significant correlation was observed between CD19 expression (percentage or H-score) and gender, nodal/extranodal disease, relapse status, Ann Arbor stage, IPI score, GCB/ABC subtype, or overall survival ($p > 0.05$).

Conclusion: Existing literature shows inconsistencies regarding the association of CD19 expression with survival, IPI score, and relapse status in DLBCL. These variations may result from small sample sizes and differences in assessment methods. In this study, objective analysis using QuPath found no significant association between CD19 expression and prognostic parameters.

PS-09-002

Clinicopathological characterization of primary large B-cell lymphomas of immune-privileged sites: a case series

C. Pinto[1], P. Canão[1,2]
[1]Unidade Local de Saúde de São João, Pathology Department, Porto, Portugal, [2]Faculdade de Medicina da Universidade do Porto, Pathology Department, Porto, Portugal

Background & Objectives: Primary large B-cell lymphomas (LBCLs) of immune-privileged sites (IP-LBCLs) are LBCLs that arise as primary neoplasms in the central nervous system (PCNS-LBCL), vitreoretina (PVR-LBCL) and testis (PT-LBCL) in immunocompetent patients. This case series aimed to study the clinicopathological features of IP-LBCLs diagnosed at a Portuguese tertiary centre since 2014.
Methods: We selected all IP-LBCLs (2014-2024) and reviewed their clinicopathological features.
Results: We identified 49 cases: 42 (85.7%) in the CNS and 7 (14.3%) in the testis. The median age at diagnosis was 69 years (range: 34-88). Regarding PCNS-LBCL, 16 (38.1%) patients were male. Median overall survival was 3 months (range: 0-127); 2 months (range: 0-127) in the PCNS-LBCL group and 8 months (range: 2-29) in the PT-LBCL group. Morphologically, 22 (44.9%) cases had a diffuse pattern, 3 (6.1%) a perivascular pattern, and 24 (49.0%) both. Six (12.2%) cases showed necrosis, and 11 (22.9%) had a starry-sky pattern. Among PCNS-LBCL cases, 21 (50.0%) exhibited reactive perivascular T-cell infiltrates. Regarding the immunoprofile, 4 (8.2%) cases were CD10-positive, and 39 (79.6%) were Bcl2-positive. The majority had a high Ki67 proliferation index (median 80%, interquartile range 80-90%). There was no significant difference in survival based on Bcl2 expression or necrosis status. The starry-sky pattern was associated with worse prognosis (median survival: 1 month vs. 5 months; P=0.006). In PCNS-LBCL, there was a trend toward higher survival in cases with reactive perivascular T-cell infiltrates (p=0.174).
Conclusion: Most IP-LBCLs arose in the CNS, had CD10-negative immunoprofile, and high Ki67 proliferation index, as expected. In this study, we demonstrated that there are potential factors that can carry prognostic value, namely the presence of reactive perivascular T-cell infiltrates and a starry-sky pattern.

PS-09-003

LMO2 as a promising immunohistochemical surrogate marker of MYC-rearrangement: our experience with high-grade lymphomas

C. Rodríguez Gilabert[1], M. Veras Lista[1], E. Revilla Sánchez[1], L. Astilleros Blanco de Córdova[1]
[1]University Hospital 12 Octubre, Pathology, Madrid, Spain

Background & Objectives: MYC is commonly rearranged in high-grade lymphomas (HGL) and other aggressive large B cell lymphomas (LBCL). Immunohistochemical (IHC) positivity for MYC does not accurately predict MYC rearrangements (MYC-R), and molecular studies such as FISH are required for confirmation. Previous studies have demonstrated that the RNA and protein expression of LMO2, a germinal centre (GC) marker, is down-regulated in LBCL carrying MYC-R, and suggested its possible role for screening these cases through IHC staining. Our objective is to establish the association between the IHC expression of LMO2 and other GC markers, and MYC-R in a series of HGL.
Methods: This is a retrospective series of HGL diagnosed over the last five years in our centre. Cases where MYC-R was studied by FISH at the time of sign-off were selected, and LMO2 IHC (SP51 clone) was performed. Clinical data, morphology, IHC staining and molecular alterations were analysed. No cut-off for LMO2 positivity was established.
Results: 12 cases of HGL were selected; the majority of them were women. Average age was 64 years, with one paediatric case. 90.0% showed IHC staining of MYC (EP121 clone) and 63.6% stained for LMO2. 81.8% were CD10-positive (56C6 clone). 50.0% were MYC-R; of those, 16.7% also carried a BCL2-R, and 50% were triple hits. 75% of cases showed an inverse association between LMO2 expression and MYC-R: 71% of LMO2-positive cases showed no MYC-R, and 80% of LMO2-negative cases carried the translocation.
Conclusion: These results support those from previous studies. LMO2 IHC positivity is inversely associated with MYC-R in 75% of cases, suggesting that it could be used as a surrogate marker to screen MYC-R, in combination with other IHC markers such as CD10 and MYC. The use of these three markers improves the sensibility of the screening over the use of MYC protein alone.

PS-09-004

Evaluation of automated special stainers in reticulin fiber staining of bone marrow: a retrospective, multicentre study

Y. Chen[1], Y. Yang[1], L. Chen[1], X. Hu[1], H. Fu[2], Y. Chen[3]
[1]Fujian Medical University Union Hospital, Pathology Department, Fuzhou, China, [2]The Affiliated Hospital of Qingdao University, Pathology Department, Qingdao, China, [3]West China Hospital,Sichuan University, Pathology Department, Chengdu, China

Background & Objectives: Advancements in pathology laboratory instruments have played an increasingly important role in histochemistry, including in haematoxylin and eosin, immunohistochemical, and special staining techniques. However, a review of these instrument systems is critical to ensure proper staining. This study aimed to investigate the quality of automated platforms on special stains.
Methods: We retrospectively evaluated 1906 bone marrow biopsies from three different hospitals .All cases have been diagnosed correctly based on a manually modified Gordon and Sweets method. Fibrosis gradings were independently determined by two experienced hematopathologists using the European Consensus on grading of bone marrow fibrosis(MF-0: 830 cases, MF-1: 589 cases, MF-2: 401 cases and MF-3: 86cases). Reticulin fiber staining was performed again with a Ventana BenchMark Special Stains automated slide stainer.Fibrosis gradings were classified as the same.
Results: The automatic system, using a commercially available staining kit, demonstrated weak staining compared with manual procedures in MF-1 and MF-2.There was no statistically significant difference in MF-0 and MF-3.
Conclusion: Ventana BenchMark Special Stains platform may offer a new level of automation for special stains that improves turnaround times and optimizes workflow, further consideration for its use in reticulin fiber staining in bone marrow may be necessary.

PS-09-005

In Kikuchi-Fujimoto Disease (KFD), apoptosis and pyroptosis signalling are simultaneously induced to form lesions

S. Asano[1], K. Yamazaki[1], K. Shikano[1], Y. Sogame[2], Y. Hashimoto[3], S. Kawana[3], M. Kashimura[4], Y. Nakamura[5], R. Yamada[6], Y. Komohara[6], S. Hakozaki[2], Y. Saito[2]
[1]Iwaki CIty Medical Centre, Pathology, Iwaki, Japan, [2]National Institute of Technology Fukushima College, Department of Applied Chemistry & Biochemistry, Iwaki, Japan, [3]Fukushima Medical University, School of Medicine, Department of Diagnostic Pathology, Fukushima, Japan, [4]Shin Matsudo Central General Hospital, Department of

Haematology, Matsudo, Japan, [5]Tohoku Medical and Pharmaceutical University, Department of Pathology, Sendai, Japan, [6]Graduate School of Medical Sciences, Faculty of Life Sciences, Kumamoto University, Department of Cell Pathology, Kumamoto, Japan

Background & Objectives: At the earlier meeting of this society, we reported that the endoplasmic reticulum stress (ER stress)-induced apoptosis is induced in Kikuchi-Fujimoto disease (KFD). In this study, we reported that pyroptosis was also induced in addition to apoptosis, and we will report this result together with our discussion.
Methods: Using electron microscopy, paraffin-embedded and frozen samples, we performed histopathological, immune-histochemical, and molecular biological studies.
Antibody used: PERK, ATF6, IRE1, CHOP, bcl-2, p53, GRP78(Bip), CD68, CD163, CD204, CD169, cCaspase 3, cGasdermin D.
Results: ①Apoptosis is induced by the extrinsic and intrinsic pathways and is processed by macrophages via efferocytosis.
② Pyroptosis form the holes in the cell membrane by activated GSDMD and takes part in secondary necrosis.
Conclusion: It was suggested that in this disease, apoptosis occurs in lymphocytes, while pyroptosis occurs in macrophages. These processes prevent infection and the spread of pathogens, activate the body's immune system, and help other immune cells defend against infection.

PS-09-006

Spanish idiopathic Multicentric Castleman Disease (iMCD) Registry. Epidemiology of iMCD in Spain (ARCANA) - prevalence cohort

S. Montes Moreno[1], F. Climent[2], M. Fraga[3], A. González García[4], J.T. Navarro Ferrando[5]
[1]Hospital Universitario Marqués de Valdecilla/IDIVAL, Santander, Spain, [2]Hospital Universitari de Bellvitge, IDIBELL, Barcelona, Spain, [3]Hospital Clínico Universitario de Santiago de Compostela, Santiago de Compostela, Spain, [4]Hospital Universitario Ramón y Cajal, IRYCIS, Madrid, Spain, [5]Institut Català d'Oncologia (ICO-Badalona). Josep Carreras Leukaemia Research Institute. Universitat Autònoma de Barcelona, Barcelona, Spain

Background & Objectives: Multicentric Castleman Disease (MCD) is a rare lymphoproliferative disorder involving multiple lymph nodes, leading to systemic inflammation, cytopenias, and multiorgan dysfunction[1]. Approximately 33-50% of cases are human herpesvirus-8 (HHV-8) negative and classified as idiopathic (iMCD) after excluding infections, malignancies and autoimmune diseases[2] with CD-like features in lymph node biopsies. Diagnosis is challenging due to clinical and histopathological heterogeneity. Key features include a spectrum of regressed or hyperplastic germinal centres, follicular dendritic cells prominence, hypervascularization, and plasmacytosis[2]. Low incidence and clinical and histopathological overlap with mimicking conditions[2] often lead to misdiagnosis/unrecognized cases[3]. Given the limited prevalence data in Western countries[4-6], the Spanish iMCD Registry was proposed to provide real-world data on demographics, pathology, symptoms, treatments, and outcomes.
Methods: This observational, multicentre, prospective study aims to improve knowledge of iMCD epidemiology and treatment outcomes in Spain. It aims to enrol 60 patients from 20 centres, including a prevalence cohort (PC) (historical iMCD patients to describe clinical characteristics and treatment patterns), and an incidence cohort (IC) (newly diagnosed iMCD patients, followed prospectively).
Results: To date, 41 patients have been enrolled, 33 meeting diagnostic criteria (30PC / 3IC). Preliminary PC results: 30 patients from 15 sites. All underwent excisional lymph node biopsies, with histopathological features consistent with iMCD. Six cases (20%) had initial core biopsies before excision. Clinical subtypes were iMCD-NOS (76.6%) and TAFRO (23.3%). Histopathological patterns included plasmacytic (43.3%), mixed (33.3%), and hypervascular (13.3%), with 10% undetermined. Estimated iMCD prevalence was 0.51 cases per 100.000 (95% CI:0,32567-0,68863).
Conclusion: This is the first study assessing iMCD prevalence in Spain, with results consistent with previous reports. Excisional biopsies are crucial for accurately assessing histopathological features and differentiating iMCD from other lymphoproliferative disorders, supported by ancillary techniques (immunohistochemistry, flow cytometry, molecular methods) and clinicopathological correlation[7]. The study provides valuable epidemiological data that enhances global understanding of this rare disease.

PS-09-008

Histiocytic/dendritic cell neoplasms and stroma-derived neoplasms of lymphoid tissues: a retrospective analysis from a tertiary cancer centre of North India

S.A. Saraf[1], P. Majumdar[2], K. Kadali[2], Z. Chowdhury[2]
[1]V. G. Saraf Memorial Hospital, Pathology, Kochi, India, [2]Mahamana Pandit Madan Mohan Malviya Caner Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Department of Oncopathology, Varanasi, India

Background & Objectives: Histiocytic/dendritic cell neoplasms and stroma-derived neoplasms of lymphoid tissues (HDCN & SDNLT) are rare, accounting for <1% of all neoplasms occurring in lymph nodes and extramedullary locations. We aim to illustrate the clinicopathological characteristics of these rare disorders that pose significant clinical and diagnostic challenges.
Methods: A retrospective analysis was undertaken over a period of 4 years at a tertiary cancer centre after due approval from the institutional ethics committee.
Results: A total of 46 cases of HDCN & SDNLT were identified during this period, amongst which majority were paediatric males. Histiocytic sarcoma [HS] was the predominant neoplasm, followed by Langerhans cell histiocytosis [LCH], follicular dendritic cell sarcoma [FDCS], Langerhans cell sarcoma [LCS], Rosai-Dorfman disease, and Erdheim-Chester disease. Unisystem LCH predominantly involved the skeletal system whereas in multisystem LCH, lymph nodes and skeletal lesions were the commonest sites. The handy immunohistochemistry markers for diagnosing HDCN & SDNLT were CD68, CD163, CD4, CD1a, CD21 & CD23. Chemotherapy was the main modality of treatment (62.5%) due to multisystem involvement in the case of LCH or metastasis in other disease. Surgery was performed in 55% patients while radiotherapy was administered post-operatively in 15% patients. On a mean follow-up of 9.25 months, 13 patients were found to have no evidence of disease, 13 are alive with disease and 4 died of disease.
Conclusion: HDCN & SDNLT are extremely rare and intriguing diseases that ought to be ascertained using a combination of meticulous morphological examination and an array of immunohistochemistry markers to rule out mimics such as carcinoma, lymphoma, and neuroendocrine tumours and for precise subclassification of these lesions. Accurate subset diagnosis will contribute to enhanced data as well as treatment outcome analysis of these rare disorders in the future.

PS-09-009

Demystifying anaplastic large cell lymphoma: a clinicopathologic analysis from a tertiary cancer centre of North India

Z. Chowdhury[1], I. Makker[1], I. Dhal[1], S. Singh[2], S. Rajule[3], A. Singh[4], S.A. Saraf[5], R. Ranjan[6]
[1]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Oncopathology, Varanasi, India, [2]Lotus Diagnostic & Imaging Centre, Pathology, Hisar, India, [3]Inlaks and Budhrani Hospital, Histopathology, Pune, India, [4]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Medical Oncology,

Varanasi, India, [5]V G Saraf Memorial Hospital, Pathology, Kochi, India, [6]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Paediatric Oncology, Varanasi, India

Background & Objectives: Anaplastic large cell lymphomas (ALCLs) are high grade T cell lymphomas characterized by large pleomorphic cells, and expression of CD30, accounting for 2-8% of Non-Hodgkin lymphoma in adults and 10-15% in children. ALCL can be classified as ALK positive (ALK+) and ALK negative (ALK-) ALCL depending upon the expression of ALK protein by immunohistochemistry.
To comprehensively evaluate the entire spectrum of the clinical, histopathological, immunohistochemical and survival characteristics of ALCLs treated at our centre.
Methods: All cases diagnosed as ALCL on histomorphology and immunohistochemistry over a period of 6 years were explored.
Results: A total of 104 cases were identified, with an almost equal distribution of ALK+ (n=54) and ALK- (n=50) ALCL. Median age of presentation was 17years in ALK+ (2-64 years) while it was 46years (8-82 years) in ALK- group. While the most common presenting complaint was lymphadenopathy, 43% patients presented with B symptoms. Extranodal involvement was perceived in 75% cases, with the most common sites being soft tissue and bone, followed by skin, lung, stomach, intestine, etc. ALCL presented with diverse histomorphology, because of which immunohistochemistry was mandatory for accurate diagnosis. LCA was immunoreactive in 91% cases, while a potential pitfall was the negativity of CD3 in nearly 40%. On a median followup period of 9months, 31% patients experienced disease progression and 17% patients succumbed to disease, 38% ALK+ and 62% ALK-. The 3-year progression-free survival rate of the cohort was 50±7%, that of ALK+ 59.4±8.8% and ALK- 39.9±10.6%. The 3-year overall survival rate of the cohort was 72.6±6% (ALK+ 83.6±5.8%, ALK- 61.6±9.9%).
Conclusion: Meticulous histopathologic assessment is crucial in precise detection of ALCL, since it has a varied histomorphology with numerous close differentials including Hodgkin lymphoma, Diffuse Large B cell Lymphoma, Peripheral T cell lymphoma, as well as metastatic carcinomas, melanomas and sarcomas.

PS-09-010
Spatial transcriptional diversification of splenic extramedullary haematopoiesis in primary hematopoietic defect and cancer
C. Tripodo[1], E. Savino[1], G. Cicio[1], G. Bertolazzi[2], V. Cancila[3], A. Di Napoli[4], A. Aprile[5], G. Ferrari[5], L. Bongiovanni[6], M. Ponzoni[6]
[1]The AIRC Institute of Molecular Oncology - IFOM - ETS, Advanced Pathology Laboratory, Milan, Italy, [2]Kore University of Enna, Enna, Italy, [3]University of Palermo, Health Sciences, Palermo, Italy, [4]Sapienza University of Rome, Rome, Italy, [5]San Raffaele-Telethon Institute for Gene Therapy, Milan, Italy, [6]San Raffaele Hospital (IRCCS), Unit of Pathology, Milan, Italy

Background & Objectives: Extramedullary haematopoiesis (EMH) arises in response to hematopoietic stress due to bone marrow dysfunction, including primary hematopoietic stem cell defects and malignancies. The spleen is the principal EMH site, where the red pulp vascular niche supports expansion of immature progenitors. In cancer, EMH sustains myelopoiesis and reshapes immune architecture, yet its spatial transcriptional programs remain incompletely characterized. Here, we aimed at defining the splenic spatial organization and transcriptional regulation of EMH in mouse models of ineffective erythropoiesis due to haemoglobin beta mutation (Th3/+) and advanced breast cancer (MMTV-PYMT).
Methods: Spatial transcriptomics (Visum, 10x) was performed on spleens from tumour-free wild-type (WT) mice (n=3), tumour-free thalassemic (Th3) mice (n=3), and MMTV-PYMT tumour-bearing mice (n=2).
Results: Five spatial transcriptional clusters were expanded and three contracted in Th3 and PYMT spleens compared to WT controls. Three of the expanded clusters were transcriptionally associated with erythropoiesis. The first, dominant across red pulp areas, was enriched in early progenitors expressing *Mybl2*, *E2f2*, *Klf1*, and *Ccnd3*, alongside *Spic* and *Tcf21*, transcription factors implicated in red pulp macrophage/stroma specification and stromal remodelling. The second, particularly expanded in Th3, displayed a zonal distribution within the red pulp and expressed late-stage erythroid genes*(Hbb-bt, Fech, Alas2, Trim58, Epor).* The third, expanded in PYMT and confined to the red pulp–white pulp interface, showed co-expression of erythroid maturation genes (*Bpgm*, *Tfrc*) and macrophage-associated transcripts (*Marco*, *Stab2*), suggesting erythroid differentiation in proximity to white pulp myeloid elements. The remaining expanded clusters reflected granulocytic and megakaryocytic programs, while the contracted clusters were associated with T- and B-cell programs, indicating reduced adaptive immunity in EMH.
Conclusion: We described the emergence of transcriptionally and spatially divergent clusters that differentially characterize EMH in the context of a primary hematopoietic defect and in cancer.

Funding: The study has been supported by the Italian Cancer Research Foundation (AIRC)

PS-09-011
CD10 negative Burkitt lymphoma
S. Li[1], J. Xu[1]
[1]MD Anderson Cancer Centre, Haematopathology, Houston, USA

Background & Objectives: Burkitt lymphoma (BL) is an aggressive B-cell neoplasm characterized by *MYC* rearrangement (*MYC*-R) and a defined immunophenotype: CD10+, BCL-6+, BCL-2 negative (or dim small subset), and a Ki-67 proliferative rate of ~100%. In daily practice, there are some B-cell lymphomas with BL morphology, *MYC*-R, and an immunophenotype mostly compatible with BL except no CD10 expression (named CD10-negative BL-like lymphoma, or CD10-neg BLL, here). How to classify these lymphomas is challenge.
Methods: We identified 3 cases of CD10-neg BLL and compared them with 13 cases of typical BL and 16 cases of high-grade B cell lymphoma, not otherwise specified (HGBL-NOS) with *MYC*-R diagnosed at the same period. Immunophenotyping was performed by immunohistochemistry and/or flow cytometry immunophenotypic analysis. CD10, BCL6, BCL2 and MYC expression were designated as ≥30%, ≥30%, ≥50%, and ≥40%, respectively. *MYC, BCL2*, and *BCL6* status were assessed by fluorescence in situ hybridization analysis. The gene expression profile (GEP) of these neoplasms was assessed on a subset of cases using the HTG Whole transcriptome panel.
Results: The clinicopathologic features of these 3 cases of CD10-neg BLL were very similar to those of typical BL ($p>0.05$ for all) except CD10 expression ($p=0.002$). By gene expression profile (GEP) consisting of the top 40 differentially expressed genes between BL and HGBL-NOS with *MYC*-R, the 3 cases of CD10-neg BLL showed a GEP similar to BL and significantly different from HGBL (Figure). Two patients received R-EPOCH and one patient received R-HCVAD induction therapy. The median overall survival of these 3 patients with CD10-neg BLL was similar to that of the typical BL ($p=0.74$).
Conclusion: Our data shown that the clinicopathologic features as well as GEP of B-cell lymphoma with typical BL morphology and

immunophenotype but lacking CD10 expression is very similar to cases of typical BL. Therefore, such cases should be classified as BL.

PS-09-012

Intravascular lymphoma: a rare and challenging diagnosis – case report series from a single tertiary centre

C.S. Sucubulak[1], O.O. Kizilkaya[1], A.M. Onenerk Men[1], S. Cin[1], A.S. Demiroz[1]
[1]Istanbul University Cerrahpasa, Pathology, Istanbul, Turkey

Background & Objectives: Intravascular lymphoma (IVL) is a rare but aggressive lymphoma primarily affecting blood vessels, leading to multisystem involvement, including the CNS, kidneys, and lungs.
Methods: Between 2005 and 2024, 5 cases of IVL cases have been reviewed based on their clinical and pathological data from Istanbul University-Cerrahpasa.
Results: The mean age was 67 (53–98), and all patients were female. Symptoms included B symptoms (2), pancytopenia (1), bicytopenia (1), and an abdominal mass (1). One patient had mild FDG PET uptake suggestive of vasculitis, another had ecchymosis-like lesions. Biopsies were taken from bone marrow (2), skin, abdominal mass, and lymph node.
The biopsies of the abdominal mass, lymph node, and skin revealed vascular proliferation and dilation, filled with thrombus formed by tumoral cells characterized by round/irregular nuclei, fine chromatin, 1–3 nucleoli, and wide cytoplasm. Bone marrow biopsies showed hypercellular marrow with CD20(+) large intravascular and intrasinusoidal cells. The biopsy taken from the abdominal mass is an incisional biopsy. No tumour was observed in the parenchyma, only an intravascular tumour component was present.
Immunohistochemically, four cases were CD20(+), while one biopsy from skin was CD20(-) but expressed CD3, CD4, CD56, TIA-1, Granzyme-B, and EBER. The Ki-67 proliferation index was very high (80-100%) in two cases. In one case, the Ki-67 result could not be concluded due to high activity in the bone marrow.
Molecular subtyping with FISH was performed on two patients; one showed 3q27 region rearrangement in 15% of interphase nuclei, while the other was negative (del5q33-34, del7q31, del20q12, del5q31, trisomy 8, t(3;3)(q26.2;q21.3)).
Four patients were diagnosed with large B-cell IVL, and one with NK/T-cell IVL.
Conclusion: IVL is difficult to diagnose due to its rapid progression and lack of detectable mass. Its insidious intravascular involvement complicates early diagnosis, often leading to fatal outcomes.

PS-09-013

Clinicopathological features of splenectomy cases: an 11-year experience with rare and common disorders

S. Yilmaz Erozbek[1], A. Cakir[1], H.S. Bekoz[2]
[1]Istanbul Medipol University, Pathology, Istanbul, Turkey, [2]Istanbul Medipol University, Haematology, Istanbul, Turkey

Background & Objectives: The spleen plays a critical role in hematologic and immune functions. Splenectomy is performed for various indications, including hematologic disorders, oncologic conditions, trauma, and mass lesions. This study aims to categorize and analyse splenectomy cases over a 11-year period, evaluating their clinical presentations, underlying aetiologies, diagnosis and presenting interesting and rare pathological findings.
Methods: Retrospective review was conducted on 292 splenectomy cases received at our university hospital pathology department between 2014-2024. Cases were categorized based on their indications, including primary splenic lesions, hematologic disorders, oncologic conditions (during carcinoma surgery), trauma, infectious causes, inflammatory processes, and portal hypertension. Clinical and pathological data, including patient demographics, preoperative diagnoses, and histopathological findings, were analysed using descriptive statistics to evaluate their distribution and clinicopathological characteristics.
Results: The mean age was 54 years (range: 3-96 years), 11 cases were paediatric. The most common splenectomy indication was oncologic conditions (58.56%; n=171), with 6.97% (n=12) showing splenic parenchymal infiltration. Hematologic disorders accounted for 20.89% (n=61), including 18 cases with neoplastic involvement, primarily B-cell lymphomas (n=10), T-cell lymphomas (n=6), and myeloid neoplasms (n=2).
Primary splenic lesions represented 5.48% (n=16) and included cysts, lymphangiomas, haemangiomas, hamartomas, sclerosing angiomatoid nodular transformation, and angiosarcomas. Among 32 malignant cases, 6.25% were primary malignant neoplasms, 56.25% were hematologic malignancies, and 37.5% were metastases of oncologic tumours. Other splenectomy indications included portal hypertension (7.88%; n=23), trauma (2.74%; n=8), inflammatory processes (2.74%; n=8), and infectious causes (1.36%; n=4), which included parasitic (leishmaniasis), fungal (aspergillosis), and bacterial infections. Additionally, one case was operated on due to polycystic kidney disease.
Conclusion: Oncologic and hematologic conditions are the leading indications for splenectomy, with metastatic involvement more common than primary splenic malignancies. Understanding the clinicopathological characteristics of splenectomy cases provides valuable insights into disease patterns, enhances diagnostic accuracy and patient management.

PS-09-014

Proteasome localization as a predictive marker and therapeutic target in multiple myeloma

I. Livneh[1,2], P. Stein[1], A. Dahan[1], Y. Zohar[1], A. Ciechanover[2]
[1]Rambam Health Care Campus, Institute of Pathology and Cytology, Haifa, Israel, [2]Technion - Israel Institute of Technology, Faculty of Medicine, Haifa, Israel

Background & Objectives: We recently showed that cellular stress—such as amino acid deprivation—induces proteasome translocation from the nucleus to the cytosol, enhancing proteolysis to restore amino acid pools. This adaptive response is essential for cancer cell survival, and its inhibition triggers apoptosis. Interestingly, nuclear retention of the proteasome can be induced through a "false satiety" signal using tyrosine, tryptophan, and phenylalanine (YWF), which activate anabolic pathways without resolving the underlying stress. Here, we investigated whether proteasome localization correlates with therapeutic response in multiple myeloma (MM)—a malignancy treated with proteasome inhibitors—and whether YWF-driven nuclear sequestration can overcome drug resistance.
Methods: Proteasome localization was assessed in bone marrow biopsies from MM patients and in patient-derived cells, comparing treatment-sensitive and -resistant cases. Resistant cells were treated with either a proteasome inhibitor or the aromatic triad YWF, to test whether nuclear proteasome sequestration could overcome resistance to proteasome inhibitors.
Results: In resistant MM cells, the proteasome was predominantly cytosolic, even under nutrient-rich conditions, while in sensitive cells it remained nuclear. YWF treatment drove nuclear relocalization and induced marked cytotoxicity in resistant cells (93.2% efficacy, $p = 1.88 \times 10^{-7}$), representing a 14.7-fold increased efficacy relative to the effect of velcade, a clinically used proteasome inhibitor, on the same cells ($p = 1.26 \times 10^{-9}$). In diagnostic bone marrow samples, nuclear proteasome localization strongly correlated with favourable treatment response, while cytosolic localization predicted resistance (NPV = 0.89, $p = 0.001$). During relapse, a shift from nuclear to cytosolic proteasome localization was associated with treatment failure and a significantly shorter time to relapse (HR = 0.54, $p = 0.01$).
Conclusion: Proteasome subcellular localization is a potential predictive biomarker in MM, reflecting both treatment response and tumour

aggressiveness. Reinstating nuclear proteasome retention via YWF may represent a novel therapeutic strategy to overcome drug resistance in relapsed or refractory MM.

PS-09-015

Gastric diffuse large B-cell lymphoma: clinical, pathological and molecular characterization of 88 cases

N. Moulai[1], M. Guermi[1], R. Bennoui[1], Z. Moussaoui[1], W. Ouahioune[1]
[1]Faculty of Medicine, Saad Dahlab University 1, Laboratory of Cancer Research, Blida, Algeria

Background & Objectives: Gastric diffuse large B-cell lymphoma (DLBCL) is the most common extranodal lymphoma of the gastrointestinal tract. This study aims to characterize the clinicopathological and molecular features of primary gastric DLBCL, with emphasis on cell-of-origin classification, age-related patterns, and associations with infectious agents.
Methods: We retrospectively evaluated 88 cases of primary gastric DLBCL diagnosed between 2019 and 2024. Immunohistochemistry was performed to determine the COO subtype using the Hans algorithm (CD10, BCL6, MUM1). Additional markers, including BCL2 and c-MYC, were assessed. Epstein-Barr virus (EBV) infection was assessed by EBER in situ hybridization, and Helicobacter pylori status by histological examination. Statistical significance was defined as $p<0.05$.
Results: The median patient age was 60 years (range: 26-85), with a slight male predominance (54.2%). The non-GCB subtype predominated overall (66.3%), with significant age-related differences: GCB was more frequent in patients <50 years (61.9%) compared to ≥50 years (21.3%; p=0.002). H. pylori infection was detected in 20 cases (22.7%), suggesting a potential pathogenic role in a subset of gastric DLBCLs. EBER positivity was observed in 4 cases (4.8%), all in patients >60 years. One double-hit case (MYC/BCL2 co-expression) was identified in an older patient.
Conclusion: Gastric DLBCL exhibits distinct age-related molecular profiles, with younger patients displaying significantly higher rates of the prognostically favourable GCB subtype. The detection of H. pylori in 22.7% of cases highlights the heterogeneous aetiology of gastric DLBCL, potentially identifying a subset that might benefit from H. pylori eradication therapy as part of treatment. The predominance of non-GCB phenotype in older patients and occasional EBV association suggest multiple pathogenic pathways. These findings support age-stratified and aetiology-adapted therapeutic approaches in the management of gastric DLBCL.

Background & Objectives: C3 glomerulopathy (C3G) and primary Immune Complex-Membranoproliferative Glomerulonephritis (IC-MPGN) are complement-mediated diseases driven by C3 dysregulation with excessive accumulation of C3 breakdown products in the kidney. Pegcetacoplan (PEG), a C3/C3b inhibitor, targets the central components of the complement pathway, inhibiting C3 overactivation and preventing further deposition of C3 breakdown products in the glomeruli. VALIANT (NCT05067127) is the first Phase 3 trial investigating PEG in a broad cohort, including adolescents (≥12 yrs) and adults with native or post-transplant recurrent C3G or primary IC-MPGN.
Methods: VALIANT is a randomized, double-blind, placebo (PBO)-controlled trial evaluating PEG efficacy and safety. 124 patients (pts) were randomized to PEG (n=63) (twice weekly subcutaneous infusion) or PBO (n=61) for 26 weeks. The primary endpoint was log-transformed UPCR ratio at week 26 vs PBO. Key secondary endpoints at week 26 included the proportion of patients achieving ≥50% UPCR reduction, reduced C3c renal biopsy staining of ≥2 OOM, and eGFR change. Safety was assessed by treatment-emergent adverse events (TEAE) frequency and severity.
Results: The primary endpoint was met, with PEG demonstrating a 68.1% (95% CI: –76.2, –57.3) mean UPCR reduction vs PBO at week 26 ($p<0.0001$). Results were consistent across all subgroups (disease type, age, and transplant status). 60.3% of PEG-treated pts achieved ≥50% UPCR reduction vs 4.9% in PBO. Robust reductions in C3c staining (25 [71.4%] PEG patients achieved zero staining at Week 26) and clinically meaningful eGFR stabilization (adjusted LS mean difference +6.3 mL/min/1.73 m^2) were observed with PEG. Treatment-emergent AE frequency and severity were similar between arms. None of the 4 serious infections (3 PEG; 1 PBO) were attributed to encapsulated bacteria.
Conclusion: PEG achieved significant and clinically meaningful reductions in proteinuria (68.1% vs. PBO), C3c staining and eGFR stabilization in pts ≥12 yrs with C3G or primary IC-MPGN, was well tolerated with no new safety signals observed.

PS-10-002

Multimodal spatial profiling of the microvascular inflammation in kidney allografts

A. Sannier[1], E. Morgand[1], V. Goutaudier[1], M. Sablik[1], F. Mezine[1], T. Thalamas[1], A. Certain[1], O. Aubert[1], C. Lefaucheur[1], A. Loupy[1]
[1]Paris Institute for Transplantation and Organ Regeneration, Paris, France

Background & Objectives: Microvascular inflammation (MVI) in kidney allografts can occur in the absence of donor-specific antibodies (DSA) and C4d deposition. This MVI DSA- C4d- phenotype, newly recognized in the Banff 2022 classification, has an unclear pathogenesis. In this context, we aimed to decipher its immuno-molecular landscape.
Methods: MVI cases were identified in a multicentric cohort of kidney transplant patients and compared to MVI-negative controls (total n=309). Biopsies were graded according to Banff 2022 classification and sequenced using the Banff Human Organ Transplant panel. Whole-transcriptome spatial profiling and cell deconvolution were performed using the Nanostring® GeoMx platform. Microvascular infiltration

was characterized by multiplex immunofluorescence targeting CD34, CD68, CD3, NKp46, CD15, and CD20.
Results: Three MVI phenotypes were analysed: 1) MVI DSA- C4d- (n = 49, 15,9%), 2) MVI DSA+ C4d- (n = 45, 14,6%), 3) MVI DSA+ C4d+ (n = 46, 14.9%), along with non-MVI cases (n = 169, 54,6%). All MVI cases shared a common molecular signature, characterized by an upregulation of genes associated with antibody-mediated injury, interferon-gamma response, and activation of macrophages, NK cells, and T cells. This common signature was less intense in MVI DSA- C4d- cases, particularly for interferon-gamma response. Spatial profiling revealed that this molecular signal was more prominent in peritubular capillaries than in glomeruli. Cell deconvolution demonstrated that MVI DSA- C4d- cases were particularly associated with NK cells and conventional dendritic cells. Automated quantification of immunofluorescence staining revealed that microvascular infiltration was predominantly composed of CD68+ macrophages, CD3+ T cells, and NKp46+ NK cells.
Conclusion: We demonstrate that the immuno-molecular signature of kidney allograft MVI DSA- C4d- is moderate in intensity compared to DSA+ phenotypes and is predominantly associated with NK cells and conventional dendritic cells, as revealed by cell deconvolution analysis. These findings provide insights into the pathophysiology of MVI and support the development of mechanism-based therapeutic strategies.

PS-10-003
C4d in primary focal segmental glomerulosclerosis – not only passive entrapment?
N. Zagorec[1,2], M. Horaček[3], P. Šenjug[4,3], I. Horvatić[1,5,2], K. Galešić[1,5], D. Galešić Ljubanović[3,4,2]
[1]Dubrava University Hospital, Nephrology and Dialysis, Zagreb, Croatia, [2]University of Zagreb, Faculty of Pharmacy and Biochemistry, Zagreb, Croatia, [3]School of Medicine, Institute of Pathology, Zagreb, Croatia, [4]Dubrava University Hospital, Division of Nephropathology and Electron Microscopy, Zagreb, Croatia, [5]School of Medicine, Zagreb, Croatia

Background & Objectives: The role of the complement system (CS) in primary focal segmental glomerulosclerosis (pFSGS) is poorly understood. Here we tried to determine prognostic significance of C4d deposits in pFSGS.
Methods: Patients >18y with pFSGS, excluding those with kidney failure (KF) at the moment of kidney biopsy (KBx) and <1 non-globally sclerosed glomerulus (nGSG), were recruited from the Hospital registry of KBx from 2003-2021. Every KBx was analysed by light, immunofluorescent and electron microscopy and additional IHC for C4d was performed on paraffin-embedded tissue using monoclonal rabbit antibody (Ventana BenchMark Ultra). Every nGSG was classified as being C4d+ or C4d-. Based on ratio of C4d+ nGSG/total N of nGSG and C4d+ nonsclerotic glomeruli (NSG)/total N of NSG, patients were stratified into two groups: <50% and ≥50%. Primary outcome was defined as composite of KF and baseline eGFR decline >50%. Failure to meet criteria for remission at the last follow-up visit (KDIGO 2021 Guidelines) was defined as treatment failure (TF).
Results: A total of 58 patients were included (median age 50y, 58% males). During follow-up (median 90.7mo), 9 patients reached KF and 19 decline in eGFR. Patients with ≥50% of nGSG being C4d+ had higher proportion of TF (P=0.002) and worse renal survival (P=0.005). In multiple Cox regression model (age, eGFR, proteinuria, serum albumin, IFTA, % of C4d+ nGSG) only IFTA (HR=1.052, P=0.002) and ≥50% C4d+ nGSG (HR=4.077, P=0.035) remained independent predictors of outcome. Patients with ≥50% of C4d+ NSG had higher proportion of TF (P=0.030) and worse renal survival (P=0.037).
Conclusion: C4d deposition is an independent predictor of disease progression and TF in pFSGS. Components of CS were thought to be passively entrapped within sclerosis in pFSGS, but we showed that even C4d outside segmental sclerosis is associated with worse prognosis which may indicate active role of CS in pFSGS pathogenesis or even sclerosis development.

PS-11-001
Case series of six patients with epithelioid malignant peripheral nerve sheath tumour: a rare subtype
O.O. Kizilkaya[1], C.S. Sucubulak[1], I. Sertbudak[1], A.M. Onenerk Men[1], C. Turker Saricoban[1], S. Arslan[2], M.K. Ozsahin[3], I. Gurses[1], N. Comunoglu[1]
[1]Cerrahpasa Faculty of Medicine, Department of Pathology, Istanbul, Turkey, [2]Cerrahpasa Faculty of Medicine, Department of Neuroradiology, Istanbul, Turkey, [3]Cerrahpasa Faculty of Medicine, Department of Orthopedics and Traumatology, Istanbul, Turkey

Background & Objectives: Epithelioid Malignant Peripheral Nerve Sheath Tumour (EMPNST) is a rare subtype of MPNST that differentiates from epitheloid schwannomas and it is commonly not associated with NF1 mutation. This study presents 6 different cases of this rare variant and displays its histopathological characteristics.
Methods: IHC and H&E slides were reviewed and additional stains were conducted.
Results: Mean age of the patients were 45.17 ranging from 20 to 71. Variable tumour localization was observed, with three cases involving the bones of the extremities, one in the trapezius muscle, one in the brachial plexus, and one unusually in the bladder.
Histologically, all tumours exhibited predominantly epithelioid morphology, characterized by eosinophilic to clear cytoplasm and prominent nucleoli, arranged in nests, clusters, or sheets within a multinodular growth pattern. High Ki-67 and mitotic count (≥5/10 HPF in all cases) indicated aggressive behaviour, with three cases demonstrating multiple metastases.
Immunohistochemically, diffuse and strong positivity for S-100 and SOX10 was consistent across all patients. All cases were negative for melanoma, neuroendocrine, and muscle markers. Except focal positivity in heterologous elements in 2 cases, epithelial markers were negative. H3K27me3 expression was retained, while SMARCB1 (INI-1) loss was identified in 3 cases, notably including both patients under 40 years of age (20 and 26 years). The final diagnosis of EMPNST was established after excluding other entities in the differential diagnosis.
Conclusion: The genetic background of EMPNST is still not fully understood. SMARCB1 loss is considered a key oncogenic event in the development of EMPNST. In this case series, SMARCB1 loss was observed in younger patients, while those over 40 were less likely to exhibit this alteration, suggesting the possible existence of an unknown sporadic mutation in older individuals.

Background & Objectives: Paediatric-type diffuse high-grade gliomas, H3-wildtype and IDH-wildtype (pHGGs, H3-/IDH-WT) have recently been defined in the 2021 WHO CNS classification. Despite their clinical relevance, their histopathological and immunophenotypic profiles remain incompletely characterized. This multicentre Italian study aims to describe the clinical, histological, immunohistochemical, and molecular features of this novel tumour entity.
Methods: We retrospectively analysed 50 cases of pHGGs, H3-/IDH-WT. Data included clinical course, neuroimaging, surgical findings, histopathology, immunohistochemistry, molecular alterations, and DNA methylation profiling.
Results: Patients ranged from 1 to 26 years. Most tumours were located in the cerebral hemispheres (n=44); others involved the cerebellum (n=2), brainstem (n=1), thalamus (n=1), spinal cord, (n=1) and fourth ventricle (n=1). MRI consistently showed T1 hypo- to iso-intensity and T2 hyper-intensity, with 32 cases demonstrating inhomogeneous contrast enhancement. Histologically, tumours exhibited marked heterogeneity and diverse morphologies, including embryonal-like, pleomorphic xanthoastrocytoma-like, pseudosarcoma-like, pilocytic astrocytoma-like, and astroblastoma-like features. All tumours were GFAP-positive; Olig2 was partially expressed, and synaptophysin was variably positive, especially in embryonal-like areas. ATRX loss was observed in 6 cases. *CDKN2A/2B* homozygous deletions (n=3), *MYCN* amplification (n=4), and *MYC* gains (n=3) were also noted. DNA methylation profiling assigned all tumours to the diffuse paediatric-type high-grade glioma category, including RTK1 (n=21), RTK2 (n=12), and MYCN (n=9) subgroups.
Conclusion: This study underscores the significant histological and molecular diversity of pHGGs, H3-/IDH-WT. The combination of morphology, immunohistochemistry, and methylation profiling is essential to accurately diagnose these challenging tumours. Our findings enhance the current understanding of this emerging entity and support the integration of molecular diagnostics in routine practice.

PS-11-003
Spatial single-cell profiling reveals CD147 as a marker of tumour aggressiveness in paediatric posterior fossa ependymoma

Background & Objectives: Ependymoma (EPN) is the third most common malignant central nervous system (CNS) tumour in the paediatric population. The spatial and temporal heterogeneity of neoplastic cell populations is believed to influence tumour adaptation within the tumour microenvironment (TME). This study aimed to characterize spatial immune dynamics and investigate the role of CD147 in posterior fossa type A ependymomas (PF-A EPN), classified as CNS WHO grades 2 and 3.
Methods: Bioinformatic analysis of public datasets revealed increased CD147 expression in gliomas, correlating with worse survival and elevated mutational burden. Spatial TME profiling was performed on PF-A EPN samples using multiplex immunofluorescence panels to evaluate immune, microglial, endothelial, and neoplastic components. In parallel, single-cell RNA-sequencing data from spinal ependymomas were analysed to identify tumour-associated macrophage (TAM) subsets.
Results: Grade 2 PF-A EPN exhibited higher infiltration of T lymphocytes, particularly cytotoxic CD8+ cells, compared to Grade 3 counterparts. Spatial analysis revealed reduced intercellular distance between CD4+ and CD8+ T cells in Grade 3 PF-A EPN, suggesting increased T cell–T cell interaction in higher-grade lesions. Two functionally distinct TAM subsets were identified (CD68+MCP1+ and CD68+CD44+), with a significant enrichment of CD68+CD44+ macrophages in Grade 3 tumours. CD147+ microglia were found in closer proximity to both CD8+ T cells and CD147+ proliferating tumour cells in Grade 2 tumours; in contrast, in Grade 3 tumours, CD4+ T cells were closer to CD147+ microglia and more distant from CD8+ lymphocytes and CD147+ tumour cells.
Conclusion: Our findings suggest that CD147+ microglia may contribute to immune evasion in PF-A EPN by promoting CD8+ T cell exclusion, particularly in higher-grade tumours. This study underscores the relevance of spatial TME remodelling in PF-A EPN and supports the potential role of CD147 as a modulator of tumour-immune interactions and disease progression.

PS-11-004
Using a non-human primate model to trace human BoDv-1 zoonosis: comparing intranasal and subcutaneous inoculation
P. Grochowski[1], N. Jungbäck[1], Z. Mielewczyk[1], T. Mögele[2], F. Feldmann[3], H. Feldmann[4], G. Saturday[3], B. Märkl[2], M. Beer[5], K. Schlottau[5], F. Liesche-Starnecker[1]
[1]Pathology, Medical Faculty, University of Augsburg, Department of Neuropathology, Augsburg, Germany, [2]Pathology, Medical Faculty, University of Augsburg, Augsburg, Germany, [3]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rocky Mountain Veterinary Branch, Division of Intramural Research, Hamilton, USA, [4]National Institute of Allergy and Infectious Diseases, National Institutes of Health, Laboratory of Virology, Division of Intramural Research, Hamilton, USA, [5]Institute of Diagnostic Virology, Friedrich-Loeffler-Institut, Greifswald-Insel Riems, Germany

Background & Objectives: Borna disease virus 1 (BoDV-1) is a known cause of fatal encephalitis in humans and animals, though its

dissemination mechanisms within the brain are not fully understood. This study explores the histopathological effects of BoDV-1 in a non-human primate model. Twelve macaques were inoculated with BoDV-1, six intranasal to simulate the natural entry route and six subcutaneous to model peripheral infection. The primary aim of this investigation is to evaluate the viral distribution within the brain and compare the effects of these two infection routes.

Methods: Complete sagittal brain sections were immunohistochemically stained for BoDV-1 nucleoprotein, lymphocytic marker CD45, glial marker GFAP, microglial marker Iba1, and digitally reconstructed for detailed analysis. Quantitative assessment was performed using CellQuant with the NuclearQuant module and QuPath for quantitative analysis of cell distribution. Three macaques showed no detectable virus presence, correlating with their clinical presentation, as they were euthanized before symptom onset due to the expiration of the observation period. They were excluded for further analysis.

Results: Upon analysis, it became evident that several subcutaneously inoculated macaques exhibited substantial CNS involvement, indicating that the infection route does not determine the extent of CNS infection. Both intranasal and subcutaneous routes led to similar patterns of viral dissemination within the CNS, suggesting that factors beyond the entry site, such as specific cellular receptors or systemic mechanisms, may drive CNS infection. BoDV-1 may depend on particular receptor proteins on neural or glial cells to enter the CNS. Additionally, the virus's ability to bypass the blood-brain barrier or use neural pathways, including retrograde transport, could be critical in determining CNS involvement.

Conclusion: These findings provide insights into BoDV-1 pathogenesis, emphasizing the need to explore systemic factors influencing neurotropic virus dissemination, rather than focusing solely on the entry portal. Further research is needed to understand the mechanisms underlying BoDV-1 CNS involvement.

PS-11-005

Chemokine receptor expression profile in malignant melanoma and bain-specific metastases

R. Gassner[1], M. Leonie[1], S. Schauer[1], E. Richtig[2], A. Deutsch[3], B. Ehall[4], G. Richtig[5], A. Aigelsreiter[6]

[1]D&F Institute for Pathology, Medical University of Graz, Graz, Austria, [2]Medical University of Graz, Department for Dermatology and Venereology, Graz, Austria, [3]Medical University of Graz, Division of Haematology, Department of Internal Medicine, Graz, Austria, [4]Division of Endocrinology and Diabetology, Department of Internal Medicine, Medical University of Graz, Graz, Austria, [5]Division of Oncology, Department of Internal Medicine, Medical University of Graz, Graz, Austria, [6]Diagnostic and Research Institute of Pathology, Medical University of Graz, Graz, Austria

Background & Objectives: Cutaneous malignant melanoma is a common and potentially fatal malignancy in industrial countries, the development of metastases is associated with poor prognosis. One of many mechanisms involved in its developing process is the expression of chemokine receptors. Since expression patterns of different chemokine receptors in the development of brain metastases in primary malignant melanomas are still not known exactly, this thesis aimed on that issue. Furthermore, results in that field could be gate opening regarding the establishment of new therapeutical opportunities.

Methods: This thesis' target was to find out differences in expression patterns of chemokine receptors in primary malignant melanomas and their brain specific metastases. In total nine samples of primary melanomas and 25 samples of brain specific metastases as well as corresponding surrounding tissues were analysed regarding their chemokine expression patterns by using RT-qPCR.

Results: Five chemokine receptors (CCR4, CCR6, CCR9, CXCR4 and CXCR6) showed consistent expression patterns. All three CC chemokine receptors showed a decreased expression in melanomas in relation to control tissues as well as to metastases. Comparing CC chemokine receptor expression in melanomas and their surrounding skin tissue, significantly elevated levels of chemokine gene products were detected in melanoma's surrounding tissue ($p < 0.05$). Overall, CXCR4 was expressed in lower levels in all samples compared to control tissue. These results resembled to those of CXCR6

Conclusion: Chemokine expression patterns in melanomas are different to those in brain specific metastases. Furthermore, the chemokine profile is significantly different in primary melanomas compared to their surrounding skin tissue.

PS-11-006

CD80/CD163 macrophage signature identifies high-risk glioblastoma patients

E. Belcastro[1], C. Scatena[1], V. Ortenzi[2], L. Beldramme[1], F. Di Cocco[1], F. Pasqualetti[3], N. Montemurro[1], A. Szumera-Ciećkiewicz[4], A.G. Naccarato[1], G.N. Fanelli[1]

[1]University of Pisa, Department of Translational Research and New Technologies in Medicine and Surgeli, Pisa, Italy, [2]Pisa University Hospital, Oncology, Pisa, Italy, [3]University of Padua, Department of Surgery, Oncology and Gastroenterology, Padua, Italy, [4]Maria Sklodowska-Curie National Research Institute of Oncology, Department of Pathology and Laboratory Diagnostics, Warsaw, Poland

Background & Objectives: Glioblastoma (GBM) is the most common and aggressive glioma in adults, characterized by a highly immunosuppressive tumour immune-microenvironment (TIME). Tumour-associated macrophages (TAMs), which constitute nearly one-third of the TIME, are key regulators of tumour behaviour and treatment response. This study investigate the prognostic impact of macrophage polarization in a well-characterized cohort of primary and recurrent GBM patients.

Methods: Surgical specimens from 59 adult GBM patients were retrospectively collected, including recurrent tumour tissue when available. Formalin-fixed, paraffin-embedded samples were used to construct tissue microarrays in triplicate, including peritumoral/normal-like and tumour tissue. Clinical data on treatment, recurrence, and survival were gathered. Immunohistochemical expression of CD68, CD80, and CD163 was digitally quantified. Differences between tumour and peritumoral tissues were evaluated using non-parametric tests while survival analyses using Kaplan–Meier curves and log-rank tests.

Results: CD68, CD80, and CD163 were significantly upregulated in tumour tissues compared to peritumoral areas in primary GBM ($p<0.0002$, $p=0.0421$, and $p<0.0001$, respectively), whereas in recurrent GBM only CD163 remained significantly elevated ($p<0.0024$). When comparing primary *vs* recurrent GBM, a significant decrease in CD68 ($p=0.0023$) and an increase in CD80 ($p=0.0020$) were observed in tumour tissue, along with significantly higher CD163 expression in both tumour ($p<0.0001$) and peritumoral regions ($p=0.0078$). Patients classified in the CD163High/CD80High subgroup exhibited shorter overall survival (14.2 vs 23.4 months; HR=2.24; 95% CI: 1.2–4.4; $p=0.027$) and reduced progression-free survival (12.9 vs 15.1 months; HR=1.41; 95% CI: 0.8-2.5; $p=0.213$) compared to other subgroups.

Conclusion: This study highlights the complexity and dynamic architecture of the GBM TIME, driven by multifaceted interactions and cellular plasticity. It challenges the traditional M1/M2 polarization model by revealing synergistic behaviour among TAMs subpopulations. In particular, the CD80High/CD163High phenotype emerged as a distinct subset associated with poor prognosis. These findings highlight the prognostic relevance of TAMs polarization and support their potential use as therapeutic targets.

PS-11-007

Automated mitosis detection in meningioma pathology: a comparative analysis of AI vs. pathologist-based Grading

S. Borsekofsky[1], S. Tsuriel[1], R. Hagege[1], B. Gabay[1], V. Hannes[1], D. Hershkovitz[1]
[1]Tel Aviv Sourasky Medical Centre, Pathology, Tel Aviv, Israel

Background & Objectives: Mitotic count is a key factor in meningioma grading, directly impacting prognosis and treatment decisions. However, manual mitotic figure identification is time-consuming and subject to intra- and inter-observer variability. This study evaluates an artificial intelligence (AI)-based algorithm designed to automatically detect mitotic figures and hot spots in whole-slide images of meningiomas, comparing its performance to pathologist-based grading and assessing its potential impact on tumour classification.
Methods: Fifty-two meningioma cases (632 slides) were analysed using an AI algorithm to detect mitotic figures within predefined high-power fields (2 mm^2 and 1.6 mm^2). Initial AI-generated mitotic counts were compared to manual pathologist assessments. To improve accuracy, pathologists performed a secondary review of AI-identified mitotic figures, confirming or rejecting them as true mitoses. Statistical analyses included mean mitotic count differences, intra-case variability, and t-tests to evaluate the impact of AI refinement on grading outcomes.
Results: The AI identified 26,163 mitotic figures across the dataset. Variability between slides of the same case was observed in 51 cases. Compared to pathologists, AI alone overestimated mitotic counts, with an average difference of 3.43 ± 4.83 ($p = 0.0018$). After expert review, the difference decreased to 0.88 ± 1.91 ($p = 0.0014$). AI-based grading resulted in an upgrade in 12.7% of cases (from WHO grade 1 to 2) and 1.8% of cases (from grade 2 to 3).
Conclusion: Automated mitosis detection offers a promising tool for enhancing accuracy and efficiency in meningioma grading. By reducing variability and mitigating the risk of missing mitotic hot spots, AI-assisted pathology could improve diagnostic precision and clinical decision-making. Further validation is required before clinical implementation.

PS-12 Poster Session Paediatric and Perinatal Pathology

PS-12-001

Shallow placental implantation in placental abruption: a significant link with foetal vascular malperfusion

O. Karatepe[1], E. Karakuş[1]
[1]Ankara Bilkent City Hospital, Pathology, Ankara, Turkey

Background & Objectives: Placental abruption (PA) is the premature separation of the placenta, classified as early (<34 weeks) or late (≥34 weeks) due to differing pathophysiological mechanisms. This study aimed to assess shallow placental implantation in these subgroups within a tertiary centre cohort.
Methods: A total of 135 placentas from pregnancies between 19 and 40 weeks were analysed retrospectively. Examined variables included maternal age, gestational age, maternal vascular malperfusion (MVM), foetal vascular malperfusion (FVM), villitis, intervillitis, ascending infection, and shallow placental implantation (chorionic pseudo cysts, maternal floor multinucleated trophoblasts, and excessive extravillous trophoblasts). Statistical analyses included chi-square tests for categorical variables and t-tests for continuous variables ($p<0.05$).
Results: Among 135 cases, 83 were classified as early PA and 52 as late PA. Maternal age was similar (32 ± 6 years, p=1.00). Chorionic pseudo cysts were present in 18% of early and 23% of late PA cases (p=1.00). Excess extravillous trophoblasts were found in 55% of early and 65% of late PA cases (p=0.33). Maternal floor multinucleated trophoblasts were observed in 39% of early and 26% of late PA cases (p=0.18). MVM was more frequent in early PA (60% vs. 44%, p=0.10). FVM was significantly associated with shallow implantation (p=0.03), while no significant links were found with MVM (p=0.89), ascending infection (p=0.37), or villitis (p=0.97).
Conclusion: Shallow placental implantation did not differ significantly between early and late PA. However, its association with FVM suggests a potential link between foetal vascular malperfusion and shallow implantation in placental abruption.

PS-12-002

Paediatric liver disease in transfusion-dependent thalassemia major

M.H. Kışlal[1], E. Karakuş[1]
[1]Ankara Bilkent City Hospital, Medical Pathology, Ankara, Turkey

Background & Objectives: Thalassemia is an inherited hematologic disorder characterized by the production of abnormal haemoglobin. Patients with thalassemia major present with severe anaemia and related clinical symptoms. It is a prevalent condition in Türkiye and other Mediterranean countries. This study aims to investigate the histopathological features of the liver in patients with transfusion-dependent thalassemia major.
Methods: Liver biopsies were performed on 42 patients prior to allogeneic bone marrow transplantation between 2011 and 2025. Iron deposition was graded using the Scheuer method (grades 0–4), and fibrosis was assessed using the Ishak scoring system. Histological evidence of hepatitis was also evaluated. Statistical analysis included Pearson correlation to assess relationships between variables, with significance set at $p < 0.05$. Descriptive statistics were used to summarize the distribution of scores.
Results: The distribution of Scheuer scores and fibrosis levels demonstrated that 69.05% of patients had grade 4 (heavy) iron deposition, and 26.19% exhibited minimal fibrosis (grade 1). Correlation analysis revealed significant relationships between certain histopathological features. The most notable associations were observed between portal inflammation and interface hepatitis ($r = 0.66$, $p < 0.01$) and between fibrosis and portal inflammation ($r = 0.45$, $p < 0.05$). These findings highlight the impact of increased liver iron content on the progression of hepatic inflammation and fibrosis in transfusion-dependent thalassemia major patients.
Conclusion: Our findings indicate that severe haemosiderosis and hepatic fibrosis are common histopathological features in transfusion-dependent thalassemia major patients. The significant correlations between liver iron deposition, inflammation, and fibrosis emphasize the importance of early monitoring and management to mitigate hepatic complications in these patients.

PS-12-003

Placenta, the black box of stillbirth: a single-centre retrospective observational study

D. Burlacu[1], A. Burlacu[1], B. Szabo[2], I. Jung[1], T. Mezei[1]
[1]University of Medicine and Pharmacy, Science and Technology George Emil Palade, Pathology, Targu-Mures, Romania, [2]University of Medicine and Pharmacy, Science and Technology George Emil Palade, Obstetrics and Gynaecology, Targu-Mures, Romania

Background & Objectives: Occurring worldwide at every 16 seconds, stillbirth is defined as the birth of a baby after 28 weeks of pregnancy who dies before or during labour. Maternal conditions, foetal growth restriction and placental abnormalities represent the most significant causes. The aim of this study was to examine the demographic data and placental findings from a series of autopsies following stillbirth.
Methods: We conducted a retrospective observational study including all singleton stillbirths autopsy reports from the Emergency Clinical

County Hospital of Targu-Mures between January 2020-December 2024. The autopsy reports of stillbirth from twin pregnancies were excluded. Histopathological findings of the placenta and maternal clinical records of the autopsy reports were examined.
Results: Of a total of 57 registry-identified stillbirth autopsies during the study period, 42 cases (73.68%) met the inclusion criteria. Our data indicated the following maternal portrait: multiparous (61.90%) without any remarkable medical records (76.19%) of average age 27±7.3. 59.52% of stillborns were of female sex. 45.23% of all foetal demise occurred at late foetal stage (37-39 weeks). Microscopically immature foetal pulmonary parenchyma represented the main diagnosis in 85.71% cases. Placental abruption was present in 33.3% cases. Nuchal umbilical cord was reported in 14.28% of cases. Histopathological findings of the placenta described foetal vascular malperfusion lesions in 47.6% cases and maternal vascular malperfusion lesions in 42.85% cases.
Conclusion: Our study highlights the importance of placental examination and the inclusion of histopathological findings in the final reporting of stillbirth cases. Frequently the evaluation of the foetus does not provide sufficient insight into the possible causes of the foetal demise, however placental findings may do. The identification of placental pathologies represent an essential assessment in cases of unexplained stillbirth. It is therefore mandatory for residents who perform stillbirth autopsies to have a basic understanding of placental pathology.

PS-12-004
Clinico-pathological and imaging correlation of non-Wilm's renal tumours of childhood
P. Kshire[1], P. Panjwani[1], M. Ramadwar[1], B. Parambil[2], M. Prasad[2], G. Chinnaswamy[2], S. Qureshi[2], J. Manjali[2], N. Khanna[2], A. Baheti[3], V. Patil[3], S. Shah[2], V. Gollamudi[2]
[1]Tata Memorial Hospital, Pathology, Mumbai, India, [2]Tata Memorial Hospital, Mumbai, India, [3]Tata Memorial Hospital, Radiology, Mumbai, India

Background & Objectives: The diagnosis of paediatric renal tumours comprising of Wilm's tumours (WT) and Non-Wilm's tumours (NWT) relies on radiological imaging since preoperative biopsy is not recommended in routine WT cases. Thus, some NWT are misdiagnosed as WT on prior imaging.
International Society of Paediatric Oncology (SIOP) recommends neo-adjuvant chemotherapy followed by nephrectomy for treating WT. Thus, sometimes benign NWT cases misdiagnosed as WT on antecedent imaging may inadvertently receive chemotherapy and get exposed to its hazards.
Determining clinical, imaging and histopathological features of NWT and correlating the final histopathological diagnosis with prior imaging.
Methods: Retrospective data collection of paediatric NWT (<18 years of age, from 2014-2024). 98 cases were included in the study. History of NACT and preoperative diagnosis of WT on imaging were recorded. Clinico-pathological correlation was established for NWT cases categorized as WT on prior imaging studies.
Results: Radiological inference was divided principally into 3 subgroups: WT, NWT and indeterminate. The pathological and imaging discordance was 43.86% (42 cases of NWT were incorrectly diagnosed as WT on prior imaging). Amongst NWT, clear cell sarcoma was the most frequently diagnosed tumour (n=39), showing sheeted architecture, thin arborizing vasculature and positivity for CyclinD1 and BCOR on immunohistochemistry(IHC). Malignant rhabdoid tumour of the kidney was the second most frequent tumour (n=19) exhibiting abundant eosinophilic cytoplasm, eccentric vesicular nucleus, prominent nucleolus and loss of INI-1 staining on IHC. Translocation-associated renal cell carcinoma (n=10) showed nuclear TFE3 positivity in 8 cases.
Conclusion: No pathognomonic imaging characteristics exist to distinguish WT from NWT. A differential of NWT should be considered in a child more than 5 years/ less than 1 year of age with large lymphadenopathies, pulmonary metastasis and imaging characteristics of hyper-enhancing lesions, multiple calcifications with extrarenal extension and infiltrating margins. In these situations, a preoperative biopsy is advised before administering cytotoxic therapy.

PS-12-005
Paediatric-type follicular lymphoma in WHO-HAEM5 vs ICC 2022: diagnostic criteria and classification differences
A. Alotaibi[1], A.S. Moustafa[2], A. Hanbai[1]
[1]Jordan University of Science and Technology, Pathology, Irbid, Jordan, [2]Northwest Healthcare, Internal Medicine, Tucson, USA

Background & Objectives: Paediatric-type follicular lymphoma (PTFL) is a distinct entity recognized in both the World Health Organization's 5th Edition Classification of Haematolymphoid Tumours (WHO-HAEM5) and the International Consensus Classification (ICC) 2022. PTFL primarily affects children and adolescents, with unique clinical and pathological features distinct from adult follicular lymphoma. Accurate diagnosis and management require understanding these differences. We compare diagnostic criteria and definitions of PTFL from WHO-HAEM5 (2022) and ICC (2022), highlighting key similarities and differences.
Methods: A thorough review of WHO-HAEM5 and ICC 2022 publications was conducted, focusing on sections pertaining to PTFL. Key aspects such as clinical presentation, histopathological features, immunophenotypic profiles, genetic characteristics, and recommended diagnostic approaches were extracted and compared.
Results: • Definition and Clinical Features: Both recognize PTFL as a localized nodal B-cell lymphoma occurring primarily in paediatric and adolescent patients. The typical presentation includes painless lymph node enlargement, often in the head and neck region, without systemic B-symptoms.
• Histopathological Characteristics: Both describe PTFL as exhibiting a purely follicular growth pattern with enlarged, irregularly shaped germinal centres. The neoplastic follicles are composed of intermediate-sized blastoid or large cells, often retaining a "starry sky" pattern due to tangible body macrophages.
• Immunophenotype: PTFL cells express germinal centre markers such as CD10, BCL6, and HGAL. Notably, both classifications highlight the absence or weak expression of BCL2 protein, distinguishing PTFL from typical adult follicular lymphoma.
• Genetic Features: Both WHO-HAEM5 and ICC note that PTFL lacks BCL2, BCL6, and IRF4 gene rearrangements. However, mutations in MAP2K1 and TNFRSF14 genes have been identified in some cases, suggesting alternative oncogenic pathways.
Conclusion: WHO-HAEM5 (2022) and ICC (2022) provide consistent criteria for diagnosing PTFL, emphasizing its distinct clinical and pathological features. Both classifications underscore the importance of recognizing PTFL as a separate entity from adult follicular lymphoma, ensuring appropriate clinical management and prognosis.

PS-12-006
Molecular and epigenetic characterization of Rhabdomyosarcomas within the first two years of life
F. Arienzo[1], E. Miele[2], S. Barresi[1], I. Giovannoni[1], A.M. Buccoliero[3], G. Bisogno[4], V.G. Vellone[5], S. Patrizi[2], L. Pedace[2], S. Scuderi[6], G.M. Milano[2], I. Russo[2], A. Stracuzzi[1], R. Alaggio[1], N. Caldonazzi[7]
[1]IRCCS Bambino Gesù Children's Hospital, Pathology Unit, Roma, Italy, [2]IRCCS Bambino Gesù Children's Hospital, Department of Haematology and Oncology, Cell and Gene Therapy, Roma, Italy, [3]Meyer Children's Hospital IRCCS, Pathology Unit, Firenze, Italy, [4]University Hospital, Paediatric Haematology-Oncology Division, Padova, Italy, [5]IRCCS Istituto Giannina Gaslini, Pathological Anatomy, Genova, Italy, [6]Sapienza University, Department of Medical and Surgical

Sciences and Biotechnologies, Latina, Italy, [7]University and Hospital Trust of Verona, Department of Diagnostics and Public Health, Section of Pathology, Verona, Italy

Background & Objectives: Rhabdomyosarcomas (RMS) are the most common paediatric soft tissue sarcomas, and are stratified in *PAX3/7::FOXO1* (F+) and fusion-negative (F-). This study aims to characterize the molecular and epigenetic features of RMS diagnosed in the first two years of life.
Methods: 26 RMS in patients <24 months, diagnosed between 2017 and 2024, were re-evaluated. Histology was integrated with whole RNA sequencing and methylation analysis.
Results: Age range was 19-726 days (less than 6 months in 11 patients). At histology there were: 7 alveolar RMS (ARMS), 8 embryonal RMS (ERMS), 1 ectomesenchymoma, 7 spindle cell RMS (ScRMS) and 3 RMS not otherwise specified (nos). At molecular characterization, among ARMS four were F+ and 2/3 F- showed *PAX3::NCOA1* and *MYB::NBAS* fusions, respectively. Among ERMS, two cases showed *FUS::ACVR1B* and a *PAX3::NCOA1* fusions, respectively, and one case a *PTCH* duplication. Among ScRMS, 2 were *VGLL2* rearranged (infantile fibrosarcoma-like histology), 2 *SFR::NCOA2* (myoid-like, MyoD1+/myogenin+), 1 *PAX3::NCOA2* (mixed blue round and spindle cells), 1 *PTCH* duplication, and one had no fusions. Among RMS nos, a case with *NSD3:NCOA2* (predominantly epithelioid morphology) was reclassified as ScRMS; two showed a *SMARCA4* mutation with an additional *BRCA1* mutation in one. At methylation (20/26 cases analysed), 4 F+ and 2 F- (*PAX3::NCOA1; MYB::NBAS* fusion) classified as ARMS; the classifier was unreliable for ERMS and ScRMS, except for the two *PAX3::NCOA1/2* (an ERMS and an ScRMS, respectively), which clustered as ARMS. An internally developed bioinformatics pipeline showed similar results.
Conclusion: Three novel fusions were identified in an ARMS (*MYB::NBAS*), in an ERMS (*FUS::ACVR1B*), and in a ScRMS (*NSD3::NCOA2*). The morphology of two *SMARCA4* RMSs was unique. All *PAX3::NCOA1/2* clustered as ARMS independently from morphology, suggesting that methylation may contribute to redefining this group as F+.

PS-12-007

The spectrum of placental findings of first trimester cytomegalovirus infection related to the presence of symptoms in the newborns and stillbirths

E.M. Pena Burgos[1], R.M. Regojo Zapata[2], Á. Caballero Ferrero[3], C. Martínez Payo[4], M.D.C. Viñuela Benéitez[4], M. De La Calle Fernández-Miranda[5]
[1]Hospital General Universitario Gregorio Marañón, Pathology, Madrid, Spain, [2]Hospital Universitario La Paz, Pathology, Madrid, Spain, [3]Facultad de Medicina Universidad Autónoma de Madrid, Madrid, Spain, [4]Hospital General Universitario Gregorio Marañón, Obstetrics and Gynaecology, Madrid, Spain, [5]Hospital Universitario La Paz, Obstetrics and Gynaecology, Madrid, Spain

Background & Objectives: Cytomegalovirus (CMV) is one of the most common congenital infections worldwide and one of the main causes of prenatal neurological disorders, sensorineural deafness and stillbirths. Placental factors involved in the CMV transmission from the mother to the foetus are not yet well known. Our aim is to evaluate the histopathological placental findings of first trimester CMV infection related to stillbirth and the presence of symptoms in the newborns.
Methods: This is a retrospective case-control study that analysed those pregnancies with first trimester CMV infection followed up on two tertiary referral hospitals between 2012 and 2024. The symptomatic newborns with the asymptomatic ones and the symptomatic newborns with the stillbirths were compared. A univariate statistical study was performed.
Results: A total of 40 placentas were studied, 23 of the asymptomatic newborns, 11 of the symptomatic newborns and 6 of the stillbirth cases. Smaller placentas with higher chronic plasma cell deciduitis, chronic villitis (without avascular villi, breakdown villi, necrosis or hemosiderin deposits), more CMV inclusions in fibroblasts and positive CMV immunostaining were observed in the symptomatic newborns' placentas when compared with the asymptomatic ones. Higher rates of chronic villitis (with avascular villi, breakdown villi, necrosis or hemosiderin deposits), intervillous fibrin deposits, CMV inclusions in endothelial cells and trophoblasts, maternal and foetal malperfusion pattern were present in the stillbirth's placentas when compared with the symptomatic newborns' placentas.
Conclusion: The greater villous and vascular barriers involvement, both directly and indirectly, appears to be related to a greater foetal involvement probably allowing greater transmission of the virus to the foetus. Complementary treatments that could attenuate the villi and vascular damage may be useful in reduction newborns symptoms and stillbirths due to first trimester CMV infection.

PS-12-008

Triplet pregnancies conceived through oocyte donation: placental pathological findings and clinical outcomes in 77 triplets

E.M. Pena Burgos[1], M. De la Calle Fernández-Miranda[2], J.J. Pozo Kreilinger[3], R.M. Regojo Zapata[3]
[1]Hospital General Universitario Gregorio Marañón, Pathology, Madrid, Spain, [2]Hospital Universitario La Paz, Obstetrics and Gynaecology, Madrid, Spain, [3]Hospital Universitario La Paz, Pathology, Madrid, Spain

Background & Objectives: Triplet pregnancies have increased over the past few decades due to an increase in assisted reproductive technology (ART), especially in the oocyte donation cases. Oocyte donation pregnancies develop high complications rate but their placentalpathological findings are not well known. Our aim is to study if triplet placentas conceived by oocyte donation present more placental abnormalities and pregnancy complications than those conceived by non-oocyte donation-ART.
Methods: This was a retrospective case-control study. It includes all triplet pregnancies followed up in a tertiary referral hospital between 2000 and 2024 and whose placentas were analysed in a Pathology Department. The control group included non-oocyte donation ART triplet pregnancies, and the case group included oocyte donation-conceived triplet pregnancies. Univariate and multivariate statistical analyses were performed.
Results: A total of 77 triplet pregnancies were analysed: 29 triplet pregnancies in the oocyte donation conception group and 48 triplet pregnancies in the non-oocyte donation group. Multivariate analysis revealed that pregnancy-induced hypertension (p=0.03) and preeclampsia (p=0.03) were significantly more frequent in the oocyte donation group. The foetal growth restriction (p=0.04) and foetal death (p=0.01) rates were higher in the oocyte donation group. Gross intraparenchymatous infarcts were observed in more oocyte donation placentas (P =0.04). Chronic inflammatory findings (chronic villitis, p=0.02; chronic deciduitis, p=0.03), foetal vascular malperfusion data (avascular villi, p=0.02; stromal-vascular karyorrhexis, p=0.01), and intervillous fibrin deposits (p=0.02) were present in more oocyte donation placentas.
Conclusion: The higher rates of placental abnormalities in oocyte-donation triplet pregnancies may justify the higher rates of maternal and foetal complications in these cases. Placental evaluation should be performed in these cases because it is key to understanding pregnancy outcomes. Further studies analysing the possible immunological and vascular mechanisms underlying these findings are needed.

PS-12-009

The ıncıdence and prognostıc value of ALK and Pan-TRK proteın expressıons ın neuroblastoma, ganglıoneuroblastoma and ganglıoneuroma patıents

B. Konuk Demiröz[1], İ. Güvendir Bakkaloğlu[2], A.E. Taşkale[3]
[1]Kocaeli City Hospital, Pathology, Kocaeli, Turkey, [2]Kartal City Hospital, Pathology, Istanbul, Turkey, [3]Umraniye Resarch and Training Hospital, Pathology, Istanbul, Turkey

Background & Objectives: Targeted therapies for mutations in *NTRK* and *ALK* genes have recently emerged, though they are not yet widely adopted. Immunohistochemical staining using pan-TRK and ALK antibodies is effective in identifying mutations involved in tumour pathogenesis and is recommended for diagnostic and predictive screening purposes. This study aims to evaluate the impact of ALK and pan-TRK expression on tumour biology and prognosis in patients diagnosed with neuroblastoma (NB), ganglioneuroblastoma (GNB), and ganglioneuroma (GN).
Methods: A total of 39 cases (24 NB, 6 GNB, and 9 GN) diagnosed between 2016 and 2024 at Ümraniye Training and Research Hospital Pathology Department were retrospectively reviewed. ALK and pan-TRK expression was assessed via immunohistochemistry and correlated with clinical parameters such as age, tumour type, stage, and treatment outcomes. Statistical analyses included Pearson correlation, Mann-Whitney U, Kruskal-Wallis H, and Kaplan-Meier survival tests.
Results: ALK positivity was significantly more frequent in NB cases ($p=0.004$), with higher staining intensity observed in poorly differentiated subtypes ($p<0.001$). ALK expression increased with higher risk categories ($p=0.019$, $p=0.007$) and decreased with age ($p=0.034$, $p=0.050$). Among patients with 11q23 mutations, 80% showed strong and diffuse ALK positivity. Pan-TRK expression decreased significantly post-treatment ($p=0.048$) and was more prominent in favourable histology ($p=0.01$, $p=0.042$). Surviving patients exhibited higher pan-TRK levels ($p=0.028$, $p=0.006$), and expression correlated positively with survival duration ($p=0.027$, $p=0.015$). Pan-TRK intensity decreased with advancing stage and risk level ($p=0.045$, $p=0.025$). In 75% of MYCN-positive and 80% of 11q23-positive cases, pan-TRK expression exceeded 50% with moderate to strong intensity.
Conclusion: ALK expression is associated with poor prognosis in neuroblastic tumours and appears unaffected by chemotherapy, supporting the potential benefit of ALK inhibitors in NB treatment. In contrast, pan-TRK expression correlates with better outcomes and may be enhanced by chemotherapy, suggesting a synergistic role for NTRK-targeted therapies. These findings may guide personalized therapeutic strategies in neuroblastic tumours.

PS-12-010

Clinicopathological correlations in placentas of pregnancy after Assisted Reproductive Technology

E. Nardi[1,2], V. Arena[2]
[1]University of Florence, Section of Anatomic Pathology, Department of Health Sciences, Florence, Italy, [2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Area of Pathology, Department of Woman and Child Health and Public Health, Rome, Italy

Background & Objectives: The American Centre for Disease Control defines Assisted Reproductive Technologies (ART) as any fertility-related treatments in which eggs or embryos are manipulated. These techniques play an important role in the treatment of infertile couples. Infertility is outlined by the World Health Organization as a disease of the male or female reproductive system characterized by the failure to achieve a pregnancy after 12 months or more of regular unprotected sexual intercourse.
Methods: We analysed the clinical data and data referable to placental histopathology of 34 patients treated with ART in comparison with a cohort of 18 patients with a spontaneous pregnancy. The case group was further divided into two group depending on the type of ART: homologous (14) or heterologous (20).
Results: In relation to SGA babies, a different incidence was observed, as this occurrence was more frequent in the group of ART pregnancy (+6%).
The mean age showed a statistically significant difference in the group of patients treated with heterologous ART compared to patients treated with homologous PMA (p-value=0.007).
As well, the gestational age at birth was lower in patients treated with heterologous techniques compared to patients treated with homologous techniques (p-value= 0.006).
Finally, the incidence of placental hypoplasia presented a statistically significant difference, being higher in the group of heterologous ART pregnancies compared to the group of homologous ART pregnancies (p-value = 0.03).
Conclusion: In this retrospective study, our results are consistent with the literature: the gestational age at delivery is lower in ART pregnancies than in spontaneous. This data was also associated with a higher rate of admission to neonatal intensive care unit due to preterm birth. Histologically, in placentas derived from ART pregnancies we observed a higher incidence of lesions attributable to maternal vascular malperfusion, inflammation, anomalous villous development and fibrinoid material deposits.

PS-12-011

Silent witness: placental abnormalities in SARS-CoV-2 infection and autoimmune disease contributing to adverse pregnancy outcome

B. Trimmel[1], K. Rosta[2], U. Heber[1], S. Dekan[1], A. Szlatinay[3], A. Mazzucato-Puchner[3], Z. Bago Horvath[1]
[1]Medical University of Vienna, Department of Pathology, Vienna, Austria, [2]Medical University of Vienna, Department of Obstetrics and Gynaecology, Clinical Division of Gynaecological Endocrinology and Reproductive Medicine, Vienna, Austria, [3]Medical University of Vienna, Department of Internal Medicine III, Division of Rheumatology, Vienna, Austria

Background & Objectives: Pregnancies of patients with autoimmune diseases and SARS-CoV-2 infections are frequently subjected to complications that negatively impact maternal and foetal outcome. Current evidence shows that immunological processes affecting placental development and function might contribute to pathologies in both maternal autoimmune disorders and SARS-CoV-2 infection. Our study investigated placental histological abnormalities in patients with autoimmune disorders and SARS-CoV2 infection.
Methods: 142 patients treated at the Department of Obstetrics and Gynaecology of the Medical University of Vienna were included in our study. Our cohort comprised 55 patients with autoimmune disease and 24 patients with SARS-CoV-2 infection during pregnancy. 63 patients were included as healthy controls. Placentas of all patients were examined histologically according to the Amsterdam classification of placental pathologies. Statistical association between underlying disease and histological anomalies was investigated using univariable multinomial logistic regression, separately for each fixed factor.
Results: Placentas of patients with autoimmune disease and SARS-CoV2 infection both showed increased intervillous fibrin depositions and signs of maternal and foetal vascular malperfusion. However, incidence of these changes did not show significant association with autoimmune diseases. In contrast, signs of maternal (33.3% vs. 3.3%, $p<0.0001$) as wells as foetal (95.8% vs. 58.1%, $p<0.0001$) vascular malperfusion were significantly more often identified in SARS-CoV-2 infection compared to controls. In particular, presence of segmental avascular villi demonstrated a significantly increased incidence (83.3% vs 53.2%; $p=0.014$). SARS-CoV2 infection was also associated with

a significant increase in chorangiosis (33.3% vs. 14.3%; p=0.033) and intervillous fibrin depositions (45.8% vs 9.7%; p=0.001).
Conclusion: Our study points to the involvement of common biological pathways in maternal autoimmune disease and SARS-CoV-2 infection that contribute to placental pathologies. The incidence of changes appear higher in SARS-CoV2 infection when compared to autoimmune disease. Further studies that identify these pathways to develop effective preventive strategies for maternal and foetal morbidities are warranted.

PS-12-012
Pathological changes in the heart in toxic damage in foetuses of 18-22 weeks of gestation according to autopsy data
O. Sudareva[1], E. Ignatyeva[1], S. Lezhenina[1], L. Lyubovtseva[1], E. Guryanova[1,2]
[1]Chuvash State University by I.N. Ulianov, Cheboksary, Russia, [2]Postgraduate Doctors Training Institute, Cheboksary, Russia

Background & Objectives: Pathomorphological changes in the neuronal structures of the heart in foetal alcohol syndrome (FAS) are extremely poorly described in the scientific literature. We analysed the dynamics of macro- and pathomorphological indices in the heart in toxic damage in foetuses of 18-22 weeks of gestation, born to mothers who abused alcohol during pregnancy.
Methods: Retrospective analysis of 10 FAS cases and 10 controls included cardiac macrometry (weight, chamber dimensions, ventricular index), histochemical staining (haematoxylin-eosin, van Gieson, Bielschowsky-Gross, Lee), and immunohistochemistry (NSE, S-100, synaptophysin). Statistical/correlation analyses assessed gestational age-dependent trends.
Results: The main lethal factors in the study group compared to the examined group were malformations, intrauterine infection and foetal hypoxia. Intrauterine growth retardation of the foetus was observed in 60% of cases. Cardiac macrometry was hemodynamically significant and directly depended on the gestational age of the foetus and the underlying cause of death. In all cases, an increase in the weight of the heart was noted, mainly due to the right chambers of the heart, myogenic dilation of its cavities. FAS was accompanied by signs of endocardial fibrosis, perivascular sclerosis, focal necrosis in contractile and vacuolar degeneration in conductive cardiomyocytes, fuchsinophilic degeneration in the muscle bundles of the interventricular septum; in the epicardium, rhythmogenic zones and myocardium along the vessels, extremely scanty positive staining of S-100 and NSE of neuroblasts and neurocytes in the nerve ganglia of the study group (80%) was noted; weakly expressed synaptophysin expression correlated with signs of sclerosis and hypoganglionosis in the intracardiac nerve ganglia.
Conclusion: The dynamics of macrometric indices and pathomorphological changes in the autonomic ganglia, contractile and conductive cardiomyocytes in miscarriages with FAS have a direct dependence on the gestational age ($r > 0.65$). The noted macrometric indices force us to reconsider the existing standards for examining the heart in foetuses born to mothers who abuse alcohol.

PS-12-013
Bone marrow evaluation in neuroblastomas: bone marrow aspirates have little additional value over trephine biopsies
R. Bruinsma[1], A. van Barneveld[1], B. Meussen[1], M. Fiocco[1,2,3], A. Heijlaerts-Klever[1], G. den Engelsman[1], M. Dierselhuis[1], G. Tytgat[1], M. van Noesel[1,4], M. Wijnen[1], R. de Krijger[1,4], A. van der Steeg[1]
[1]Princess Máxima Centre for Paediatric Oncology, Utrecht, The Netherlands, [2]Leiden University Medical Centre, Department of Biomedical data Science, Section Medical Statistics, Leiden, The Netherlands, [3]Leiden University, Mathematical Institute, Leiden, The Netherlands, [4]University Medical Centre Utrecht, Utrecht, The Netherlands

Background & Objectives: Bone marrow involvement is essential for staging, evaluating treatment response, and detecting progression or relapse in neuroblastoma patients. Currently, bilateral trephine biopsies (TBs) and bilateral bone marrow aspirates (BMAs) are used for this evaluation. Recent addition of immunohistochemical stains has improved the diagnostic accuracy of TBs. Furthermore, no study has investigated clinical implications of relying solely on TBs for morphological examination of bone marrow. Therefore we aim to evaluate the diagnostic accuracy of TBs and the additional value of BMAs cytomorphology.
Methods: Data were collected from all patients diagnosed at our centre over a period of 7 years. Complete bone marrow evaluation (combined bilateral TBs and BMAs) was performed at diagnosis and at predefined time points according to the treatment protocol. Cohen's kappa was used to compare test results. Representativeness was assessed for each TB and BMA and presence or absence of tumour infiltration was reported.
Results: A total of 197 neuroblastoma patients underwent bone marrow evaluation, which yielded 1,880 biopsies (947 procedures) and 1,856 aspirates (934 procedures). Bilateral TBs were technically adequate for histological evaluation in 94.9%, bilateral BMAs in 76.8% and complete bone marrow evaluation was achieved in 98.4%. Bone marrow infiltration was reported in 40.1% of all patients. TBs reported infiltration in 35.5% and BMAs in 19.7%. There was an almost perfect agreement when comparing TBs with complete evaluation ($\kappa = 0.901$, $p<0.001$).
Conclusion: TBs showed higher sensitivity and are more frequently representative than cytomorphology of BMAs. In 4.6% of procedures, the biopsy was negative while the aspirate was positive. In none of these patients the treatment strategy was altered based on positive aspirate only. These findings suggest that bilateral TBs alone may be sufficient to detect bone marrow involvement.

PS-12-014
Automated segmentation of placental structures using AI: a quantitative morphological analysis
C. Wizeman[1,2], O. Greenberg[1], B. Gabay[1], V. Hannes[1], S. Tsuriel[1], R.R. Hagege[1], D. Hershkovitz[1,2]
[1]Tel Aviv Sourasky Medical Centre, Institute of Pathology, Tel Aviv, Israel, [2]Tel Aviv University, Faculty of Medicine, Tel Aviv, Israel

Background & Objectives: The placenta is essential for foetal development, facilitating nutrient exchange, oxygen supply, and immune protection. Traditional pathological assessments are manual, time-consuming, and subjective. This study developed an AI-based segmentation system for automated identification of placental structures (villi, blood vessels, nuclei, and stromal cells) to improve diagnostic accuracy and enable quantitative, reproducible assessments.
Methods: Histological samples from FFPE placental blocks were scanned, and a CNN model was trained using manually segmented structures and IHC staining to mark trophoblasts. Model performance was evaluated using intersection over union (IoU), and overlap ratios. The model was then evaluated in a number of clinical scenarios including detection of avascular villi, chorangiomatosis and Delayed Villous Maturation (DVM).
Results: The segmentation accuracy was evaluated using a classification system where **1:1** represents a perfect overlap between the AI-predicted and manually annotated regions, **1:2** or **2:1** indicates partial agreement with under-segmentation or over-segmentation, and **1:0** denotes false positives. Villi segmentation achieved an IoU of 0.88 ± 0.12 (IoU), with 60.18% perfect overlap (1:1) and 22.55% partial agreement (1:2, 2:1). Vessel segmentation accuracy had IoU of 0.30 ± 0.05 (IoU), with 58.11% perfect overlap (1:1) and 38.13% false positives (1:0). The algorithm was able to identify avascular villi and patches with villi showing chorangiomatosis. Analysis of placentas with DVM

showed reduced vascular area at the periphery of the villi (0.045 ± 0.021) compared to normal controls (0.061 ± 0.026, p<0.001).
Conclusion: The AI-based segmentation model showed high accuracy in placental morphology analysis, demonstrating its potential as a tool for quantitative placental evaluation. Future research will refine segmentation boundaries to enhance accuracy.

PS-12-015
TRIM28 immunohistochemistry in an Indian institutional cohort of Wilms tumours
A. Kakkar[1], S. Meet[1], V. Iyer[1], S. Agarwala[2], R. Seth[3]
[1]All India Institute of Medical Sciences, Pathology, New Delhi, India, [2]All India Institute of Medical Sciences, Paediatric Surgery, New Delhi, India, [3]All India Institute of Medical Sciences, Paediatrics, New Delhi, India

Background & Objectives: *TRIM28* gene on 19q13.4 is a transcriptional co-repressor that plays a role in nephrogenesis. *TRIM28* germline loss-of-function mutations predispose to familial and non-familial Wilms tumour (WT). These *TRIM28*-mutated WTs are typically described in infantile, stage I, low-risk, favourable histology WTs with excellent outcomes. Loss of immunoexpression of TRIM28/KAP1 protein is a reliable method for identifying *TRIM28*-mutant WT, with complete concordance with molecular analysis.
Methods: WT cases of all histological subtypes diagnosed between 2019 and 2024 were retrieved. HE-stained slides were reviewed. TRIM28 immunohistochemistry was performed on whole tissue sections.
Results: Ten of 92 WTs (11%) showed TRIM28 loss. Age range was 0.5 to 11 years; sex ratio was 1.5. Six cases (60%) showed epithelial predominance, with epithelial component in more than 80%. Two cases (20%) showed diffuse anaplasia; one had predominance of epithelium (70%) and the other had 28% epithelial component. The remaining two cases were regressive and blastemal types, with epithelial component in 35% and 15%, respectively. One of the epithelial predominant tumours showed multiple variably sized cysts lined by flat epithelial cells and had been reported as "Wilms tumour with lymphangioma-like areas". Similar cysts and tubules lined by flattened cells were seen focally in six other cases. TRIM28 loss WTs spanned stages I to III.
Conclusion: Unlike most previous reports that have focussed on epithelial WT, we have assessed the entire histological spectrum of WT to identify *TRIM28*-deficient tumours. *TRIM28* loss is seen in 11% of WT in Indian patients, and occurs across stage I to III. While epithelial WT seems to be the predominant subtype among *TRIM28*-mutated tumours, blastemal WT or anaplasia does not exclude the possibility of *TRIM28* mutation. Lastly, *TRIM28*-mutant tumours dominated by thin-walled cysts lined by flattened cells are likely to be misdiagnosed as other less malevolent neoplasms, which may lead to undertreatment.

Funding: AIIMS intramural grant

PS-13 Poster Session Pathology in Favour of Developing Countries

PS-13-001
Prognostic significance of Ki-67 in diffuse large B-cell lymphoma: a retrospective analysis in a developing country
D. Nakuci[1]
[1]University Hospital of Obstetrics and Gynaecology'Queen Geraldine'Tirana Albania, Tirana, Albania

Background & Objectives: Diffuse Large B-Cell Lymphoma (DLBCL) is the most common subtype of non-Hodgkin's lymphoma (NHL), accounting for approximately 30% of cases worldwide. Research has shown that Ki-67, a proliferation marker, plays a crucial role in prognosis, with high Ki-67 expression associated with poorer outcomes and lower levels linked to better therapeutic responses. This study aims to evaluate Ki-67 as a prognostic indicator and analyse survival outcomes in NHL, with a specific focus on DLBCL patients in Albania, representing the first study of its kind in this population.
Methods: This retrospective study analysed malignant lymphomas, particularly DLBCL, from 2010 to 2017 at two major diagnostic and treatment centres. A total of 88 DLBCL cases, diagnosed through H&E morphology and IHC per WHO classification. Patient data included age, sex, region, and Ki-67 index, categorized as low (<65%) or high (>65%). Standard follow-up lasted approximately five years. Overall survival (OS) was measured from diagnosis to death or last follow-up.
Results: This study analysed 88 DLBCL cases.
Key Findings:• Ki-67 & Survival: High Ki-67 (>65%) was found in 67% of cases and was significantly correlated with older age and male sex ($P < 0.005$).
• OS & Follow-up: High Ki-67 cases had poor survival (3–4 years), while low Ki-67 cases had better outcomes (5–10 years+). Long-term OS analysis was challenging due to early deaths, treatment migration, and non-lymphoma-related mortality.
Conclusion: In the study 67 % of the patients that demonstrated a high value of Ki-67 presented a worse prognosis and survival than those with a low value.
Some of the correlations in a study were significant between Ki-67 and age and gender showing that age is an important predictive factor and the male were most affected from DLBCL.These findings highlight Ki-67 as a crucial prognostic marker in DLBCL, warranting further study with extended follow-up.

PS-13-002
Enhancing diagnostic capacity in Jordan through AI and telepathology: insights from EU collaborations and the Hakeem initiative
A. Alotaibi[1], M.A. AlSalkhadi[1]
[1]Jordan University of Science and Technology, Pathology, Irbid, Jordan

Background & Objectives: Pathology services in developing countries face challenges such as limited subspecialty expertise, high workloads, and disparities in access to diagnostic services. In Jordan, these obstacles are compounded by geographic and resource constraints. However, the national Hakeem Program, Jordan's first electronic health record (EHR) initiative, provides a robust digital infrastructure that can support the integration of artificial intelligence (AI) and telepathology services. Recent EU-Jordan collaborations, including the REAYAH Project and the Strategic and Comprehensive Partnership (2025), have further enhanced digital health capacity and provide a framework for implementing innovative pathology solutions. This project explores how existing EU-funded programs and the Hakeem digital health system can be leveraged to integrate AI-powered diagnostics, telepathology, and capacity building for pathology services in Jordan.
Methods: We reviewed the Hakeem Program's nationwide EHR network and its potential to support telepathology workflows and AI-based diagnostic tools. Additionally, we analysed recent EU-Jordan healthcare collaborations, focusing on infrastructure improvements (REAYAH Project) and capacity-building initiatives (Erasmus+ medical training programs.
Results: The Hakeem Program's digital infrastructure, combined with EU-supported health facility upgrades and staff training, creates an opportunity to expand telepathology services and introduce AI algorithms for diagnostic support. Integrating these technologies could enhance diagnostic accuracy, reduce turnaround times, and improve access to expert pathology consultation, particularly in underserved areas. Capacity-building programs further ensure sustainable adoption through workforce development.

Conclusion: By leveraging the Hakeem Program and EU-Jordan collaborations, Jordan has a unique opportunity to advance digital pathology. Implementing AI and telepathology solutions can address diagnostic gaps, improve patient outcomes, and position Jordan as a leader in digital healthcare transformation within the region.

PS-13-003

Histopathological characteristics and prognostic outcomes of paediatric Hodgkin lymphoma in Albania: a 5-year cohort study

D. Nakuci[1]
[1]University Hospital of Obstetrics and Gynaecology 'Queen Geraldine', Tirana, Albania

Background & Objectives: Hodgkin lymphoma (HL) accounts for less than 1% of all cancers but 5–6% of childhood malignancies. This study evaluates the impact of early diagnosis, HL subtypes, and prognostic factors (age, BMI, disease stage, OS) in Albanian paediatric patients (2012–2017). It also highlights the role of an inter professional team in optimizing follow-up and treatment outcomes.
Methods: This retrospective cohort study analysed 37 paediatric Hodgkin lymphoma (HL) cases in Albania (2012–2017). IHC on lymph node biopsies (CD15, CD30, CD3, CD20, CD45, CD79a, PAX5, EBV LMP-1) confirmed diagnoses, classified per WHO criteria. Clinical data (symptoms, age, BMI, stage) were reviewed. OS was assessed over 5 years using Kaplan–Meier survival analysis and chi-square tests, alongside a literature review on paediatric HL.
Results: We identified 36 cases of primary dcHL and one case of NLPHL. Cervical lymph nodes were most frequently involved (11 cases), followed by axillary and supraclavicular nodes. To assess the BMI-HL association, BMI was calculated (weight/height²) using primary care records when available. Among confirmed HL cases, only 9 children had a normal BMI, while the majority were obese. Statistical analysis showed a significant correlation ($P < 0.05$) between higher BMI and HL, consistent with findings from meta-analyses and prospective studies.
Conclusion: The retrospective ,cohort study conducted by an oncology centre in a developing country , even though with a small number confirmed cases (n=37) , tried to provide a little help not only in diagnosis but also in careful follow-up in dynamic.
HL as a systemic disorder is best managed by an multidisciplinary team for best outcomes. Regular follow-up visits are necessary to detect relapses and long-term sequelae as early as possible.

PS-13-004

Enhancing gastric lesion diagnosis: a retrospective analysis with an AI-enabled approach in Boyacá, Colombia

B.M. Bernal Gomez[1]
[1]Universidad Pedagógica y Tecnologica de Colombia, Medicina GIBP, Tunja, Colombia

Background & Objectives: In Boyacá, the diagnosis of gastric lesions heavily relies on the endoscopy and quality of biopsy preparations and adherence to standardized protocols like the Sydney protocol. Aims to understand histopathological characteristics and the prevalence of precursor lesions in midle-risk populations on historical slide archives of Tunja´s University hospital before 2000, while exploring the potential of artificial intelligence (AI) to enhance risk stratification based on image analysis platforms like QuPath and CAMYLEON.
Methods: A total of 200 gastric biopsy from 1989 and 1994 preparations were analysed. The study assessed compliance with the Sydney protocol and comparison around 1991; the prevalence of diagnoses according to OLGA (Operative Link on Gastritis Assessment) and OLGIM (metaplasia) categories, and only histopathological findings. Additionally, specific types of gastric cancer were identified, emphasizing their diversity. The study also evaluated the educational impact on medical students engaging with gastric pathology.
Results: Eighty percent of the biopsy preparations did not meet the criteria of the Sydney protocol, highlighting significant diagnostic gaps. OLGA IV and III were the most common categories, with prevalences of 33.6% and 32.7%, respectively, indicating relevant presence of advanced lesions and frequently anecdotal cases. Histopathological findings included chronic atrophic gastritis with lymphoid follicles (59.3%) and in them, colonic metaplasia (66.4%). Gastric cancer types identified were intestinal adenocarcinoma (8.8%), adenosquamous carcinoma (0.9%), and signet-ring cell carcinoma (3.5%).
Conclusion: The results emphasize the need to improve compliance with diagnostic protocols and encourage interdisciplinary research, including AI, to optimize early detection and management of precancerous lesions. Moreover, this investigation inspires medical students to deepen their understanding of gastric pathology, strengthening their educational foundation and commitment to public health. Training on diagnostic protocols and modernizing by merging evidence-based practices with AI-driven innovations creates curricula for medical students and early pathologists, enhancing detection and management of gastric lesions to advance community public health.

Funding: Universidad Pedagógica y Tecnológica de Colombia

PS-14 Poster Session Thymic and Mediastinal Pathology

PS-14-001

Thymoma in children, a rare mediastinal tumour: pathological study of 6 cases and review of the literature

R. Ayadi[1], R. Yaiche[1], I. Hadhri[1], S. Jedda[1], Y. Barbirou[1], Y. Dhouibi[1], E. Braham[1], O. Ismail[1], N. Ben Jamaa[1], A. Ayadi[1]
[1]Abderrahmane Mami Hospital, Pathology, Tunis, Tunisia

Background & Objectives: Mediastinal tumours in children are rare. Around 25% of them can be malignant. The thymoma is an uncommon neoplasm, and during adulthood it corresponds to 30% of anterior mediastinum tumours. The peak incidence is between 55-65 years.
The aim of this study was to describe clinocopathological characteristics of this entity with literature review.
Methods: Between 2004 and 2024, 6 children with thymomas were diagnosed at our department of pathology. Hospital files were reviewed for presenting complaints, clinical, radiologic, and pathological characteristics.
Results: There were 2 male and 4 female patients, aged between 12 and 19 years, with a mean of 15,5. Most common initial complaints were dyspnea, cough, chest pain, and fever. Chest x-rays and/or thoracic computed tomographies displayed masses in anterior mediastinum accompanied by pulmonary metastases ($n = 1$), and cervical lymph node metastasis ($n = 1$). Five cases underwent initial tumour resection; one case experienced trucut biopsies. On gross examination, tumours size ranged between 7 and 15 cm with mean of 9,87 cm. Histological examination identified type B1 thymomas in 4 cases, type B2 in one case and type AB thymoma in one case. Immunohistochemically, epithelial cells expressed EMA and cytokeratin, while immature T lymphocytes expressed CD1a, TdT, and CD99 markers. The outcome was satisfactory in all cases.
Conclusion: Thymoma in children are rare tumours but should be considered in the differential diagnoses for mediastinal anterior lesion. It poses a significant challenge due to its unclear histogenesis and its atypical clinical presentation. Early diagnosis and complete resection are the basis for management and prognosis.

PS-14-002

Cystic lesions of the mediastinum: the clinical spectrum and histopathological analysis

S. Jedda[1], Rahma Ayadi, Rahma Yaiche, Yasmine Dhouibi, Yasmine Barbirou, Emna Brahem, Olfa Ismail, Nadia Ben Jamaa, Aida Ayadi
[1]Abderrahmane Mami Hospital, Department of Pathology, Ariana, Tunisia

Background & Objectives: The mediastinal cysts are rare lesions, comprising 12% to 18% of all mediastinal tumours. They form a group of heterogeneous lesions of congenital or inflammatory conditions. These cysts may cause diagnostic challenges : they can simulate both benign and malignant lesions.
The aim of our study was to assess the major characteristics of these entity.
Methods: We performed a retrospective study of mediastinal cystic lesions diagnosed at our department of pathology, from 2010 to 2024. Cystic teratomas, cystic thymomas, cystic thymic carcinomas and cystic lymphomas weren't included.
Results: This study included 107 cases. There were 66 females and 41 males. The mean age of the patients was 47.84 years, average from 3 to 84 years. The most frequent reason for consultation was respiratory symptoms including chest pain, thoracic pain, haemoptysis or dyspnea. The lesions were located in the anterior mediastinum in 20 cases, the middle mediastinum in 49 cases and the posterior mediastinum in 38 cases. All patients underwent a surgical resection. On gross examination, mean size of the masse accounted for 4.85 cm, average (1-17cm). Histologically, the pleuropericardial cysts were the most frequent and represented 41.12% of all lesions (n=44) followed by bronchogenic cysts in 33.65% (n=36), thymic cysts in 15.89% (n=17) and lymphangiomas in 3.74% (n=4). Oesophageal and hydatid cysts are rare in our series, represented respectively 1.87% and 0.93% of the cases. The final diagnosis was based on the microscopic exam. No recurrence was observed after a follow-up period of 12 months.
Conclusion: The clinicopathological features of the mediastinal cysts in our study are similar to those reported in the literature. These cysts may be located in any part of the mediastinum and may be difficult to diagnose. The treatment is based on surgical excision and the diagnosis is based on the microscopic analysis of the cystic wall.

PS-14-003

Clinicopathological analysis of cystic masses in the anterior mediastinum: A mixed bag of non-neoplastic and neoplastic aetiologies

S. Jedda[1], Rahma Ayadi, Rahma Yaiche, Yasmine Barbirou, Yasmine Dhouibi, Emna Brahem, Olfa Ismail, Nadia Ben Jamaa, Aida Ayadi
[1]Abderrahmane Mami Hospital, Department of Pathology, Ariana, Tunisia

Background & Objectives: Cystic anterior mediastinal masses include a variety of entities with overlapping radiologic manifestations. The pure cystic masses are generally benign cysts, and many changes may occur by the degenerations. Many anterior mediastinal tumours can undergo a cystic degeneration and demonstrate a cystic mass with solid portion at computed tomography.
The aim of our study was to assess the clinical presentation and histologic subtypes of cysts in the anterior mediastinum.
Methods: All patients who underwent surgical resection of anterior mediastinal cyst mass from January 2004 to December 2024 were included in the study. Patients' personal characteristics and histopathological data were analysed.
Results: Of the 156 cases included in our study, 88 were females and 68 were males. The mean age of the patients was 43.26 years, average from 3 to 84 years. The majority of the patients were symptomatic (96.8%). The most common pathology was benign lesion, represented by pleuropericardial cysts in 32% of cases (n=50), followed by bronchogenic cysts in 25% of cases (n=39), 25 cases of thymic cysts (16%), 3 cases of hydatid cysts (7.92%) and 2 cases of oesophageal cysts (1.28%) which are rare. In contrast, malignant cystic masses often display aggressive histopathology. The most common pathology was cystic thymomas in 9.61% (n=15) followed by cystic teratomas in 8.97% of cases (n=14) contain ectodermal, mesodermal and endodermal derivatives, with malignant transformations seen in immature variants and lymphomas in 0.64% of cases (n=1).
Conclusion: Cyst mediastinal masses create significant diagnostic dilemma for the clinicians, radiologists and histopathologists. While imaging studies help in narrowing the differential diagnosis, accurate histopathological assessment is essential for prognosis and management.

PS-14-004

Next generation sequencing analysis of enteric-type adenocarcinoma of the thymus

K. Na[1], H. Kim[1], C.J. Kim[2], S.-I. Do[3]
[1]Kyung Hee University Hospital, Kyung Hee University College of Medicine, Department of Pathology, Seoul, Republic of Korea, [2]Dong-A University College of Medicine, Department of Medical Humanities, Busan, Republic of Korea, [3]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Department of Pathology, Seoul, Republic of Korea

Background & Objectives: Enteric-type thymic adenocarcinoma (ETA) is an exceptionally rare and poorly characterized subtype of thymic carcinoma, defined by its morphological enteric differentiation and distinctive immunohistochemical features. This study presents a comprehensive clinicopathological and molecular analysis of ETA cases and incorporates a systematic review of previously published cases to expand the understanding of this rare tumour and explore potential therapeutic targets.
Methods: We comprehensively reviewed 41 previously reported ETA cases regarding their clinicopathological features, immunostaining results and genetic alteration. We performed immunostaining and targeted next generation sequencing analysis in our 2 cases.
Results: In a total of 43 patients, the mean age of ETA patients is 48.3 years, with a slight male predominance. Chest pain or discomfort was the most common presenting symptom. Elevated carcinoembryonic antigen (CEA) and carbohydrate antigen (CA) 19-9 levels were reported in more than half of the tested cases. Immunohistochemically, ETA demonstrated positivity for at least one of CK20, CDX2, or MUC2, which are characteristic of enteric differentiation. Treatment strategies varied across cases and included surgery, chemotherapy, and radiotherapy in different combinations. In 9 cases of NGS analysis (8/9) and KRAS mutational analysis (1/9), molecular profiling revealed a heterogeneous genomic landscape with recurrent mutations in TP53 (5/8), KRAS (2/9), CDKN2A (2/8), and EGFR (2/8).
Conclusion: Our findings provide insights into the clinicopathological and molecular features of ETA, understanding of this rare entity. These results highlight the need for further molecular studies to elucidate the pathogenic mechanisms of ETA and to identify opportunities for personalized therapeutic strategies.

PS-15-001

Histopathological patterns of myocarditis in Sudden Death: insights from 23 years of forensic autopsies

L. Hato Salmón[1], J. Arrieta[1], J. Lamas-Ruiz[1], B. Morentin[1], È. Iglesias-Martínez[1]
[1]Basque Institute of Legal Medicine., Forensic Pathology, Bilbao, Spain

Background & Objectives: Cardiac disease accounts for 80 % of sudden deaths (SD). Although myocarditis is a rare cause, it remains significant, especially among young individuals. Its diagnosis relies on histopathological examination. The aetiology of myocarditis varies, with infectious agents, particularly viruses, being the most common. Furthermore, the histological pattern often correlates with the underlying cause, which underscores the importance of comprehensive histopathological analysis in SD cases.
Methods: Forensic autopsies performed in the province of Bizkaia (Spain) between 2002 and 2024 were analysed. The study followed the European guidelines of the AECVP, including a standardized cardiac examination, histopathological analysis, and toxicological tests. Histological patterns were evaluated, and microbiological and immunohistochemical studies were carried out in selected cases.
Results: Thirty-eight cases of SD due to myocarditis were identified (18 females), with a mean age of 40 ± 20 years (range: 2 to 85 years). Among these cases, 20 were diagnosed as bearing lymphocytic myocarditis, 13 as neutrophilic myocarditis, and 4 with eosinophilic myocarditis. The aetiologies included infections, sarcoidosis, autoimmune diseases, toxins, and hypersensitivity reactions. Eosinophilic myocarditis was observed only in adults.
Conclusion: Myocarditis is an uncommon cause of SD that requires histopathological evaluation for diagnosis. It seems hence crucial to identify its specific histological pattern in order to steer the investigation toward the likely provocative agent. Therefore, forensic pathology services should include a pathologist with expertise in SD.

PS-15-002
CAR-T therapy and bispecific antibodies, ICANS and its post-mortem neuropathological correlation: a review of 7 cases
B. Ardaya[1], F. Arias[1], F.J. Menarguez Palanca[1], H. Galindo-Guzmán[1], Á. Gómez Graña[1], M.Á. Tribaldos Villar[1], A. Jiménez García[1], F.J. Díaz Crespo[1]
[1]University General Hospital Gregorio Marañon, Pathology, Madrid, Spain

Background & Objectives: CAR-T cell therapy has transformed the treatment of hematologic malignancies. By modifying autologous T lymphocytes to express a chimeric antigen receptor (CAR), these cells can specifically target tumour antigens like CD19 or BCMA, leading to effective tumour cell destruction. While highly effective in leukemias and lymphomas, CAR-T therapy is associated with complications such as cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). Despite extensive clinical documentation of ICANS, few studies explore its correlation with cerebral histopathological changes.
Methods: We analysed the brains of 7 patients treated with cellular therapies. This series included 5 patients who died during treatment, 1 who died from disease progression post-treatment, and 1 with multiple myeloma treated with bispecific BCMA antibodies suspected of having ICANS. Collected between 2019 and 2025, these cases underwent detailed neuropathological examination to identify treatment-related alterations or structural changes.
Results: The patients' average age was 45 years (range: 22-63), with a male predominance (57%). Six received CAR-T targeting CD19, and one received therapy targeting BCMA. The most common diagnosis before therapy was diffuse large B-cell lymphoma (DLBCL) (5/7). All patients who received CAR-T developed ICANS, with five cases classified as grade 4 severity. All patients experienced CRS, with grade 2 being the highest severity recorded. Among the 5 patients who died during treatment, the median survival was 41 days (range: 18-80). The most common histopathological findings included cerebral oedema and gliosis. Notably, four of the five patients who died during CAR-T treatment showed interstitial, perivascular, and meningeal CD3/CD8+ lymphocyte infiltration.
Conclusion: Studies on neuropathological findings in CAR-T patients are limited. Our post-mortem analysis explored the link between ICANS and brain histopathological changes. While cerebral oedema and gliosis were common but nonspecific, notable CD8+ lymphocyte infiltration was observed. Further research is needed to understand the mechanisms of CAR-T-related neurotoxicity and improve patient management.

PS-15-003
Accuracy of a novel simplified protocol for minimally invasive tissue sampling in stillbirths
F. Fernandes[1], A. Guisseve[2], L. Marimon[3], N. Rakislova[3]
[1]Maputo Central Hospital, Pathology, Maputo, Mozambique, [2]Eduardo Mondlane University, Pathology, Maputo, Mozambique, [3]ISGLOBAL, Pathology, Barcelona, Spain

Background & Objectives: Stillbirth rates remain unacceptably high in low- and middle-income countries (LMICs). Understanding the causes of death (CoD) is mandatory to develop effective strategies to reduce this high mortality. Minimally invasive tissue sampling (MITS) is a promising alternative to conventional autopsy (CA) but its validation in stillbirths remains limited. Existing evidence indicates that most samples of conventional MITS (c-MITS) lack diagnostic relevance in stillbirths. This study aimed to validate c-MITS against CA in stillbirths and design and assess a cost-efficient, simplified MITS (s-MITS) protocol.
Methods: The study comprised two subsets of stillbirths occurring at the Maputo Central Hospital, Mozambique. The first cohort (n=90; 2017-2018), in which both c-MITS and CA were performed, was used to validate c-MITS and to determine the diagnostic value of each sample and design a s-MITS. The second cohort (n=98; 2021-2022), which included only s-MITS, was used to evaluate CoD in the same population but during a different time period.
Results: Almost perfect overall agreement (Kappa=0.82) was observed between the c-MITS and CA-attributed CoD. Lung and placenta samples were identified as the most informative in cMITS. When using only lung and placenta results to model an s-MITS, substantial agreement (Kappa=0.79) was found between the s-MITS-derived CoD and those attributed by CA. Similar CoD distributions were observed when applying the s-MITS to a MIBio cohort, while the costs reduced by 55.7%. The leading CoDs were primarily related to maternal conditions and pregnancy complications (70.0–72.4%) and infectious diseases (25.6–27.6%.
Conclusion: c-MITS is a simpler and cost-effective alternative to CA for determining CoD in stillbirths. s-MITS has a similar diagnostic accuracy to c-MITS, while significantly reducing costs, making it adequate for implementation in routine clinical practice in LMICs.

PS-15-004
Resuscitation-associated thoracic injuries observed in autopsies: analysis from a large Irish autopsy centre
C. Hannigan[1], N. Roche[1]
[1]University Hospital Waterford, Histopathology, Waterford, Ireland

Background & Objectives: Cardiopulmonary resuscitation (CPR) is a life-saving intervention that can lead to observable thoracic injuries at autopsy. Understanding the patterns and extent of thoracic injuries caused by CPR is crucial in distinguishing them from ante-mortem trauma. The reporting of rib fractures varies between practitioners as no guidelines exist in this area. University Hospital Waterford (UHW) is a large centre providing autopsy services to the south-east region of Ireland. In 2024, UHW completed over 500 autopsy investigations.
Methods: A retrospective analysis of 148 autopsy reports from 2024 specifically stating the use of CPR in the clinical details was conducted. Data was categorised based on laterality, number of rib

fractures on either or both sides and whether an automatic CPR device was utilised. Additional factors such as the type of automatic CPR device used and whether the sternum was fractured were considered.
Results: Rib fractures were reported bilaterally in 40% cases, a further 28% were reported as "anterior rib fractures'" with no laterality. No rib fractures were observed in 25% cases. Only 2% cases reported unilateral rib fractures. The most commonly observed pattern of rib fractures were the 3^{rd}-6^{th} ribs on the right side and the 2^{nd}-6^{th} on the left side. An automatic CPR device was utilised in 36% cases and of those cases, 46% involved the use of a LUCAS machine. Sternal fractures were observed in 25% cases. Of the cases where sternal fracture was recorded, 39% involved the use of a LUCAS machine. Three cases recorded a sternal fracture only. A LUCAS machine was used in all three of those cases.
Conclusion: Understanding and accurately reporting injury patterns in autopsies is crucial to gold standard death investigation. This is particularly important where autopsy training is being undertaken. This study details the variation in rib fracture reporting practices in a large autopsy centre.

PS-15-005
Clinical and morphological analysis of the interrelationships of acute pancreatitis and acute myocardial infarction in patients in the postoperative period
V. Mironov[1], V. Romanov[2], E. Guryanova[1,3], N. Zhuravleva[3], V. Diomidova[3], N. Ukhterova[3]
[1]Postgraduate Doctors Training Institute, Cheboksary, Russia, [2]The Republican Bureau of Forensic Medical Examination of the Ministry of Health of the Chuvash Republic, Cheboksary, Russia, [3]Chuvash State University by I.N. Ulianov, Cheboksary, Russia

Background & Objectives: The study highlights the need to integrate surgical and cardiological approaches to reduce mortality in postoperative patients. The logistic model of moderate accuracy allows patients to be singled out for aggressive cardioprotection.
Methods: A retrospective analysis of patients (192 patients, 108 men, 84 women) with acute pancreatitis (ICD-10:K85) who underwent abdominal surgery was performed. The main focus is on adverse outcomes (61 deaths), including acute myocardial infarction (11 patients). Clinical, autopsy, and histological data were evaluated.
Results: Acute myocardial infarction in patients occurred on average 3.2 ± 2.1 days after surgery. The key predictors of acute myocardial infarction after laparotomy in acute pancreatitis are: age over 47 years, presence of cardiovascular diseases and type 2 diabetes mellitus, increased white blood cell count ($>14.5\times109$/l), hypocalcemia, dynamic decrease in APTT, increased fibrinogen (up to 4 g/l) and increased amylase (>115 Units/l). The temporary marker of the onset of acute myocardial infarction is the level of troponin I and ECG changes, which is confirmed histologically. Women have a slightly higher risk of death from acute myocardial infarction, while overall postoperative mortality is higher in men, especially in the older age group. The logistic model (AUC=0.75, F1=0.75) confirmed the predictive value of these parameters.
Conclusion: The study highlights the need to integrate surgical and cardiological approaches to reduce mortality in postoperative patients. The logistic model of moderate accuracy allows patients to be singled out for aggressive cardioprotection.

PS-15-006
A compilation of 101 medical autopsy cases – a way to learn pathology and medicine
N. Kakkar[1]
[1]Post Graduate Institute of Medical Education and Research (PGIMER), Histopathology, Chandigarh, India

Background & Objectives: Medical Autopsy is the strongest teaching tool in medicine and has no substitute. It is the most scientific method to learn pathology and medicine, by correlating the clinical details and pathology of a patient via the 'Clinico- Pathologic Conferences'. Unfortunately, the practice of medical autopsy has declined worldwide. Dept of Histopathology, PGIMER, still performs 500 – 600 medical autopsies per year which include adults, children, infants, neonates, still births and previable foetuses. Three clinicopathological conferences are held every week in PGIMER, attended by the entire medical fraternity. These conferences are also relayed 'LIVE' by our 'Telemedicine Department' world wide and are a **'Pride of PGIMER'**. Apart from this, neonatal and still birth mortality rounds are conducted where the obstetricians, neonatologists and the pathologists meet once a month and discuss all the autopsied cases.
Methods: All medical autopsy cases (adult and paediatric) over the last 30 years on whom clinicopathological conferences were conducted or were discussed in the paediatric rounds, formed a part of this compilation.
Results: Each autopsy case was a complete journey of the deceased and has been concisely discussed under the following headings – title, highlights of the case, clinical details, investigations, clinical diagnosis, complete histopathological/ autopsy findings with a gallery of gross and microscopic photographs, final autopsy diagnosis, review of literature and take home message. The cases have been grouped in the following order- Hematologic disorders, malignancies, infections, hepatobiliary/pancreatic disorders, cardiovascular disorders, systemic vasculitides, primary renal mucormycosis, histiocytosis, primary immunodeficiencies, infantile Nephrotic Syndromes, congenital heart disease, storage disorder, paediatric renal cystic disease etc .
Conclusion: Each compiled case is an infinite 'Wealth of Knowledge' proving the point that 'Medical autopsy is the strongest teaching tool in medicine'. This is the first such compilation of 767 pages of medical autopsy cases in the world.

PS-16 Poster Session Cardiovascular Pathology

PS-16-001
Benign cardiac neoplasia: study of local trends in rare cardiovascular pathology
M. Kuprytė[1,2], A. Mahluf[2], N. Valtienė[1,2], L. Poškienė[1,2]
[1]Hospital of Lithuanian University of Health Sciences Kauno Klinikos, Pathological Anatomy, Kaunas, Lithuania, [2]Lithuanian University of Health Sciences, Kaunas, Lithuania

Background & Objectives: Benign cardiac neoplasm (BCN) is a relatively uncommon cardiac pathology with a significant impact on cardiac mechano-electrophysiological activity and a highly invasive therapeutic approach. Its benign biological nature is confirmed by specific histomorphological features. Study objective is to identify specific local morphological trends of BCNs.
Methods: Histological type, size, anatomical localization of BCN, patient's age, and sex in 43 selected BCNs cases of surgical material processed and analysed by light microscopy in local pathology laboratory from 2001 through 2021. Descriptive statistics (frequency, mean (standard deviation)), $\chi 2$, and Kruskal-Wallis tests were applied ($p<0.05$). Local bioethical committee approval no. BEC-MF-164.
Results: 53% (n=43) males and 47% (n=20) females (p=0.418) were confirmed with BCNs (mean age - 56.8 (18.51) years old). Myxoma was confirmed in 65.1% (n=28), with less common cases of papillary fibroelastoma (23.3%, n=10). The least common cases of BCN were diagnosed as fibroma (4.7%, n=2), haemangioma, rhabdomyoma, and teratoma (2.3%, n=1 per each type of neoplasm). No significant sex predominance was detected among different BCN histological

types (p=0.221). Myxoma was predominantly located in left cardiac atrium (48.8%, n=21), while papillary fibroelastoma was mostly detected in aortic / mitral cardiac valve (13.9%, n=6; p=0.01). The largest neoplasms identified were teratoma, rhabdomyoma (4 cm), and myxoma (3.62 cm, p=0.07).
Conclusion: Considering rarity of this cardiovascular pathology, accurate characterization of BCNs in local population is presented in the context of histological type, size, anatomical localization. Predominating trends of BCNs histological type, anatomical site, size, and patient's sociodemographic features that align with global epidemiological data are detected. This may contribute to optimization of local population-focused diagnostic criteria and local population-targeted treatment strategies.

PS-16-002
Early remodelling of cardiomyocytes: searching for morphological and immunohistochemical markers of pre-symptomic ischemic heart failure
M. Kuprytė[1,2], D. Pangonytė[2], V. Lesauskaitė[3]
[1]Lithuanian University of Health Sciences Kauno Klinikos, Pathological Anatomy, Kaunas, Lithuania, [2]Lithuanian University of Health Sciences, Institute of Cardiology, Laboratory of Cardiac Pathology, Kaunas, Lithuania, [3]Lithuanian University of Health Sciences, Institute of Cardiology, Laboratory of Molecular Cardiology, Kaunas, Lithuania

Background & Objectives: Early protein expression and corresponding shape changes within cardiomyocytes exposed to ischemia can eventually exhaust their potential during remodelling, leading to HF. Study objective is to determine morphometric and immunohistochemical criteria for early cardiomyocyte remodelling and pre-symptomatic ischemic HF.
Methods: 84 male patients of study were classified as risk HF (n=25), pre-HF (n=23), and symptomatic/advanced HF (n=34) groups according to ACC / AHA classification. Men who died suddenly with no prior cardiovascular diseases were a control group (n=25). Left cardiac ventricular myocardium of selected cases stained by Heidenhain's azan trichrome were analysed by light microscopy, calculating cardiomyocytes' volume. Immunohistochemical reactions with antibodies against desmin, osteopontin, gremlin 1, and iRNA heterogenous nucleic ribonucleoprotein C were performed and evaluated in cardiomyocytes. Statistical analysis was applied (p<0.05). Local bioethical committee approval no. BE-2-77.
Results: Volume of cardiomyocytes was already increasing in a risk HF group compared to the control group (p<0.001). This parameter continued to increase in pre-HF group, comparing to the risk HF (p<0.001) and control groups. Volume of cardiomyocytes was the greatest in the symptomatic / advanced HF group, compared to the pre-HF (p<0.001), risk HF (p<0.001), and the control groups (p<0.001). Strong correlation was detected between the volume of cardiomyocyte and intensity of immunohistochemical reaction against desmin (r_S=0.681; p<0.001), osteopontin (r_P=0.524; p<0.001), and gremlin 1 (r_P=0.701; p<0.001). Correlation between cardiomyocytes' volume and iRNA heterogenous nucleic ribonucleoprotein C was weak (r_S=0.248; p<0.05).
Conclusion: Volume of cardiomyocytes already increases in the early remodelling during at risk HF of ischemic origin and continues to increase significantly in pre-HF of ischemic origin compared to control group. Changes of cardiomyocytic geometry correlate significantly with protein expression changes within cardiomyocytes. Therefore, morphometric and immunohistochemical data reflecting the earliest cardiomyocytic geometry and protein expression shifts during remodelling can contribute to ancillary diagnostics detecting early pathological remodelling before symptomatic ischemic HF.

PS-16-003
Morphometric assessment of myocardial vascular network depending on age
I.E. Pleşea[1,2], M.-S. Şerbănescu[3], L.E. Nica[4], V.T. Grigorean[5,6], I.D. Avramescu[7], L. Eftimie[8], R.M. Pleşea[9]
[1]"Carol Davila" University of Medicine and Pharmacy, Doctoral School, Bucharest, Romania, [2]"Bagdasar-Arseni" Emergency Clinical Hospital, Pathology, Bucharest, Romania, [3]University of Medicine and Pharmacy, Medical Informatics and Biostatistics, Craiova, Romania, [4]University of Medicine and Pharmacy, Doctoral School, Craiova, Romania, [5]"Carol Davila" University of Medicine and Pharmacy, 10th Clinical Department - General Surgery, Bucharest, Romania, [6]"Bagdasar-Arseni" Emergency Clinical Hospital, General Surgery, Bucharest, Romania, [7]Emergency University Hospital, Pathology, Bucharest, Romania, [8]"Carol Davila" Central Military Emergency University Hospital, Pathology, Bucharest, Romania, [9]University of Medicine and Pharmacy, Cellular and Molecular Biology, Craiova, Romania

Background & Objectives: Aging is one of the influential factors of cardiac wall remodelling both regarding their structural and functional components. The authors compared the variations of myocardial interstitial capillary network density-VD between the different cardiac wall regions during patients´ ageing.
Methods: Five epicardium-to-endocardium cross sections (left ventricle walls-LVWs: anterior-LV_AW, lateral-LV_LW and posterior-LV_PW, interventricular septum-IVS and right ventricle wall-RVW) were taken during autopsy from 95 patients with different ages (0-24 years-AP_01, 25-44 years-AP_02, 45-64 years-AP_03 and >64 years-AP_04) died and autopsied in the hospital. Tissue samples were processed and immunomarked with CD34 antibody. Slides were digitized. The VD was measured with an "in-house" designed software. Average values-AV were compared using Pearson's test.
Results: The VD increases slowly since youth to elderly in LV_Ws and decreases with age in the IVS and RVW. It has the lowest values in LV_Ws till AP_03 and in RVW in elderly. The highest values are in RVW till 44 years and then in IVS.
VD has higher values in women than in men along the cardiac wall`s regions and a divergent behaviour in the two sexes with age. Thus, in men, VD has an increasing trend with age from LV_AW to RVW (Correlation Matrix-CM positive, "p"value>0.05) whereas in women, the trend is decreasing with age from LV_AW to RVW (CM negative, "p"value>0.05), excepting IVS where it increases (CM positive).
Conclusion: Myocardial interstitial capillary network density is generally higher in women than in men and is remodelling with aging in different ways both along the cardiac wall`s regions and in the two sexes.

PS-16-004
Expression of desmin in myocardium of rats with low and high stress resistance in post-traumatic period of experimental blunt cardiac injury
A. Krasnova[1], A. Zolotov[2], E. Klyuchnikova[2], S. Mozgovoi[1], A. Kononov[1], A. Priymak[2], O. Korpacheva[2]
[1]Omsk State Medical University, Pathology, Omsk, Russia, [2]Omsk State Medical University, Pathophysiology, Omsk, Russia

Background & Objectives: High- and low-stress-resistant individuals may have different changes in the expression of the cytoskeletal protein desmin in the posttraumatic period of cardiac contusion after blunt cardiac trauma modeling.To evaluate the expression of desmin structural protein in myocardium of rats with high and low stress resistance in the dynamics of posttraumatic period of cardiac contusion.

Methods: The study was carried out on 106 white rats. The control group included subgroups with high and low stress resistance, the experimental group included subgroups with high and low stress resistance and experiment duration of 6, 12, 24 hours. The experimental group simulated cardiac injuries, extracted hearts, made histological slices, conducted immunohistochemical research with monoclonal mouse anti-Desmin antibodies (clone GM007, RTU, PrimeBioMed).
Results: Immunohistochemical study revealed a statistically significant decrease in the expression of desmin and the number of insertion discs in the myocardial damage zones of the experimental group compared with the control group, regardless of the stress resistance status. However, subgroups of low-stress-resistant animals showed lower values compared to highly resistant animals. After 6 hours posttraumatic period, the expression level of desmin in the myocardium of highly stress-resistant rats was higher than that of low stress-resistant individuals. Quantification of insertion discs in the myocardium of highly stress-resistant rats also revealed higher values compared with low-resistant individuals. Similar differences in desmin expression and number of insertion discs between high- and low-stress-resistant animals were observed 12 h and 24 h after injury.
Conclusion: In the posttraumatic period there is a gradual decrease in the expression of cytoskeletal protein desmin in the areas of myocardial damage. Expression status is differ in animals with high and low stress resistance. The level of reduction in low-stress-resistant animals is more pronounced compared with highly resistant ones and reflects more significant structural damage of cardiomyocytes in the posttraumatic period of cardiac contusion.

PS-16-005
METTL3/METTL14 RNA methyltransferase complex drives NLRP3 inflammasome priming in atherosclerotic apolipoprotein E knockout mice
A. Manea[1], M.-L. Vlad[1], A.-G. Lazar[1], S.-A. Manea[1]
[1]Institute of Cellular Biology and Pathology 'Nicolae Simionescu', Functional Genomics Department, Bucharest, Romania

Background & Objectives: Dysregulated epitranscriptomic mechanisms have emerged as important triggers of key pathological processes associated with different forms of cancer. Hitherto, the potential implication of epitranscriptomic-related pathways in atherosclerosis remains incompletely understood. METTL3/METTL14 RNA methyltransferase complex controls RNA metabolism and function by regulating the status of m6A RNA methylation. NLRP3 inflammasome priming and activation leading to enhanced production of IL1β and IL18 cytokines are important pro-inflammatory processes underlying atherosclerotic plaque development. We aimed to determine whether a functional connection exists among dysregulated METTL3/METTL14 and NLRP3 inflammasome priming in atherosclerosis.
Methods: Human carotid artery-derived non-atherosclerotic and atherosclerotic tissue specimens, apolipoprotein E-deficient (ApoE-/-) mice, and human macrophages (Mac) were examined by real-time PCR, western blot, and immunofluorescence microscopy. The METTL3 catalytic inhibitor STM2457 (5 mg/kg), or its vehicle, were administered to ApoE-/- mice fed a normal or a high-fat, cholesterol-rich diet, for 4 weeks. Mac were subjected to in vitro polarization and activation procedures toward a pro-inflammatory (M1) or an anti-inflammatory (M2) phenotype, and further exposed to STM2457/vehicle for 24 hours.
Results: We determined significant increases in METTL3 and METTL14 gene and protein expression levels in human atherosclerotic tissue specimens, aorta of atherosclerotic mice, and pro-inflammatory Mac. Long-term treatment of atherosclerotic ApoE-/- mice with the STM2457 pharmacological inhibitor significantly decreased the aortic mRNA and protein levels of NLRP3, caspase-1, IL1β, and IL18. Blockade of METTL3 catalytic activity prevented the up-regulation of NLRP3, caspase-1, IL1β, and IL18 transcript levels in cultured M1-Mac.
Conclusion: We present evidence supporting the functional implication of METTL3/METTL14 RNA methyltransferase complex in mediating NLRP3 inflammasome priming in experimental atherosclerosis. METTL3/MTTL14-oriented pharmacological interventions may be considered as potential supportive therapeutic modality to mitigate inflammation in atherosclerosis-associated cardiovascular disorders.

Funding: Work supported by Romanian Ministry of Research, Innovation and Digitization, UEFISCDI (PN-III-P4-ID-PCE-2020-1898) and Romania's National Recovery and Resilience Plan, PNRR-III-C9-2022-I8, CF148/15.11.2022, 760061/23.05.2023

PS-16-006
MLL1 histone methyltransferase mediates the up-regulation of NADPH oxidase expression in atherosclerotic mice
S.-A. Manea[1], M.-L. Vlad[1], A.-G. Lazar[1], A. Manea[1]
[1]Institute of Cellular Biology and Pathology 'Nicolae Simionescu', Functional Genomics Department, Bucharest, Romania

Background & Objectives: Changes in specific epigenetic mechanisms have a significant impact on atherosclerotic disease development and clinical outcome. Mixed lineage leukaemia 1 (MLL1) histone methyltransferase is an important epigenetic regulator of gene transcription. MLL1 is functionally related to active gene expression via increased abundance of H3K4me3 across regulatory regions of the target genes. Excess formation of reactive oxygen species (ROS), potentially generated by up-regulated NADPH oxidases (Nox) is a hallmark of atherosclerosis. We hypothesized that MLL1 may contribute of Nox up-regulation in atherosclerosis.
Methods: Carotid endarterectomy-derived non-atherosclerotic and atherosclerotic human tissue samples, apolipoprotein E knockout (ApoE-/-) mice, and cultured human macrophages (Mac) were investigated using real-time PCR, western blot and immunofluorescence microscopy techniques. Male ApoE-/- mice fed a standard rodent chow or an atherogenic diet were randomized to receive 5 mg/kg MI-503, a specific MLL1 pharmacological inhibitor, or vehicle, for 4 weeks. In vitro, resting and activated pro-inflammatory (M1)/anti-inflammatory (M2) Mac were subjected to MI-503 intervention.
Results: MLL1 gene expression and H3K4me3 were found significantly elevated in human atherosclerotic specimens, atherosclerotic aorta of ApoE-/- mice, and in M1-Mac. MLL1 protein was detected in endothelial cells, vascular smooth muscle cells, and infiltrated immune cell within human atherosclerotic lesions. Pharmacological inhibition of MLL1 mitigated the gene and protein expression of Nox1, Nox2, and Nox4 subtypes, and attenuated the formation of 4-hydroxynonenal-protein adducts in the atherosclerotic aorta of mice. MI-503-induced inhibition of MLL1 function reduced Nox1, Nox2, Nox4, Nox5 and p22phox transcript levels in cultured M1-Mac.
Conclusion: Here, we report that MLL1 plays a role in mediating the up-regulation of Nox expression, an important mechanism leading to ROS overproduction in experimental atherosclerosis. Pharmacological inhibition of MLL1 could become an additional therapeutic target to attenuate oxidant stress in atherosclerotic cardiovascular disorders.

Funding: Work supported by Romanian Ministry of Research, Innovation and Digitization, UEFISCDI (PN-III-P4-ID-PCE-2020-1898) and Romania's National Recovery and Resilience Plan, PNRR-III-C9-2022-I8, CF148/15.11.2022, 760061/23.05.2023

PS-16-007

Insights into amyloid burden and fibrosis in myocardial interstitial expansion: a study on transplanted hearts

L. Di Sciascio[1,2], C. Baldovini[1], M. Barbagallo[1], A. Borriello[1], A. De Giovanni[3], M. Riefolo[3,2]

[1]Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS) Azienda Ospedaliero-Universitaria di Bologna, Italy, Pathology Unit, Bologna, Italy, [2]University of Bologna, Medical and Surgical Science, Bologna, Italy, [3]Pathology Unit, Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS) Azienda Ospedaliero-Universitaria di Bologna, Italy, Bologna, Italy

Background & Objectives: Cardiac amyloidosis represents an interstitial disease caused by the accumulation of transthyretin (TTR) or immunoglobulin light chain (AL) proteins in the myocardial interstitial space. The aim of this study is to quantify the extent and distribution of cardiac fibrosis and amyloid burden in explanted hearts of patients with terminal cardiac amyloidosis undergoing transplantation.
Methods: We used trichrome staining and AI-assisted Upath analysis to examine 6 whole explanted hearts (3 TTR, 3 AL) discriminating myocytes from fibrosis and amyloidosis. Virtual sampling of common biopsy site was performed in various areas of the heart, including the right and left ventricle and bilateral interventricular septum, to compare the results with cardiac MRI.
Results: The results demonstrate that amyloidosis is the major factor in myocardial extracellular space expansion (52,76%) with minimal contribution from interstitial fibrosis (3,77%). Although the presence of fibrosis was observed in all examined hearts, its quantification by endomyocardial biopsy specimens proved to be highly variable and not reflective of the total amyloid burden, therefore biopsy cannot be used as a surrogate for the quantification of amyloid in the heart. Also, inflammation is not an accompanying feature of end-stage cardiac amyloidosis and, therefore, does not contribute to expansion of the myocardial interstitium.
Conclusion: This study highlights the predominance of amyloidosis over fibrosis in contributing to interstitial space expansion in hearts with end stage disease. The potential reversibility of cardiac amyloidosis, suggested by the reduction of amyloid burden following specific treatments, offers new perspectives for the treatment, underscoring the importance of proper quantification of amyloid burden.

PS-16-008

A human stem cell–derived model of cardiac transthyretin amyloidosis reveals structural and functional pathomechanisms

I. Livneh[1,2], S. Glatstein[2], L. Gepstein[2,3]

[1]Rambam Health Care Campus, Institute of Pathology and Cytology, Haifa, Israel, [2]Technion - Israel Institute of Technology, Faculty of Medicine, Haifa, Israel, [3]Rambam Health Care Campus, Cardiology, Haifa, Israel

Background & Objectives: Cardiac transthyretin (TTR) amyloidosis is an underdiagnosed cause of heart failure and arrhythmias. The lack of relevant human cardiac tissue models has hindered mechanistic understanding of the disease and stalled therapeutic development due to the absence of effective preclinical screening tools. We aimed to establish a human in vitro model of cardiac amyloidosis using induced pluripotent stem cell–derived cardiomyocytes (hiPSC-CMs) and aggregated TTR, and to investigate the structural and functional changes associated with amyloid deposition.
Methods: Wild-type and mutant TTR proteins were aggregated and applied to cultured hiPSC-CMs in single-cell, two-dimensional, and physiologically relevant three-dimensional configurations. Amyloid deposition was confirmed using histological stains and immunohistochemistry. Cellular phenotypes were assessed via oxidative stress assays, cell viability tests, transmission electron microscopy (TEM), calcium and voltage imaging, and proteomic analysis by mass spectrometry.
Results: TTR aggregates deposited robustly within hiPSC-CM tissue models. Exposed cells exhibited elevated reactive oxygen species production and pronounced structural abnormalities. TEM revealed sarcomeric disarray and mitochondrial pathology—including swollen cristae and disrupted membranes—particularly in response to mutant TTR. Morphological alterations extended to both cell and population levels, including cell shrinkage and tissue scarring, resulting in impaired conduction and arrhythmogenic activity. Viability of cardiomyocytes was reduced, and functional assays demonstrated aberrant calcium handling, characterized by oscillatory and double-peaked transients. Proteomic profiling revealed consistent alterations in pathways related to stress response, metabolism, proteostasis, and immune signalling.
Conclusion: This human stem cell–derived model recapitulates key features of cardiac TTR amyloidosis, including oxidative stress, ultrastructural damage, conduction abnormalities, and calcium dysregulation. Proteomic analysis identifies potential disease mechanisms and therapeutic targets. Ongoing perturbation studies are investigating the roles of candidate proteins, paving the way for translational applications and preclinical drug screening.

PS-16-009

Unveiling the pathogenesis of hypertrophic cardiomyopathy: a 3D approach to explore vascular alterations in the natural feline model

F. Prisco[1], A. Luchian[2], L. Ressel[2], A. Kipar[1]

[1]Institute o.f Veterinary Pathology, Vetsuisse Faculty, University of Zurich, Zurich, Switzerland, [2]Department of Veterinary Anatomy, Physiology and Pathology, Veterinary and Ecological Sciences, University of Liverpool, Liverpool, United Kingdom

Background & Objectives: Hypertrophic cardiomyopathy (HCM) is a relevant cardiac disorder in humans, characterized by unexplained left ventricular hypertrophy with myocyte disarray, interstitial fibrosis and microvascular alterations, leading to impaired cardiac function. Feline hypertrophic cardiomyopathy (fHCM), with a prevalence of 15% the most common cardiomyopathy in cats, shares many pathological features with its human counterpart, offering itself as a valuable natural animal model to study the disease pathogenesis. Here, we present a novel three-dimensional (3D) approach to investigate myocardial microvascular alterations.
Methods: Forty consecutive sections (5 µm) were prepared from formalin-fixed, paraffin embedded left ventricular free wall samples collected from cats with fHCM and without cardiac disease. Sections were immunohistochemically stained for the endothelial cell marker CD31 and digitalized. Using the HeteroGenius Medical Image Manager (MIM) software, a convolutional neural network (CNN) classified structures such as vessels, cell cytoplasm, and nuclei. The data was processed using Visiopharm, QuPath and 3D Slicer softwares to quantify the classified components in two and three dimensions.
Results: In the fHCM myocardium, we observed a decrease in the number of blood vessels (mainly capillaries), yet these vessels exhibited increased volume and surface area and were more widely spaced. Myocardial nuclei were fewer, smaller in size, and had a significantly lower volume. The overall cell volume was markedly reduced, while the interstitial space was notably enlarged compared to the controls.
Conclusion: This 3D approach corroborates earlier 2D findings of reduced overall cellularity and vascular density in the fHCM myocardium. The increased vessel volume and surface area suggest compensatory mechanisms as an attempt to offset the loss of functional myocardial tissue, a feature that could also play a role in human HCM.

PS-17 Poster Session Gynaecological Pathology

PS-17-001

Prostatic metaplasia of the uterine cervix: histopathologic and immunohistochemical findings in patients with gender-affirming hysterectomies

Z. Cantürk[1], A. Bayram[1], S. Bağbudar[1], S. Önder[1], E. Yavuz[1]
[1]Istanbul Faculty of Medicine, Pathology, Istanbul, Turkey

Background & Objectives: Prostatic metaplasia in the female genital tract is a rare phenomenon, often attributed to various aetiologies including exogenous androgen exposure. This study aimed to investigate the presence of prostatic metaplasia in uterine cervical specimens from patients undergoing hysterectomy for gender-affirming.
Methods: This retrospective study included two groups. The case group consisted of 24 patients who underwent hysterectomy for gender-affirming between 2010 and 2024. The control group comprised 17 patients who underwent hysterectomy for benign gynaecological indications between 2018 and 2020. Cervical tissue samples from both groups were evaluated morphologically, and immunohistochemically using prostatic acid phosphatase (PAP) and prostate-specific antigen (PSA) antibodies.
Results: The mean age was 32.8 years (range: 22–56) in the case group (n=24) and 35.35 years (range: 27–39) in the control group (n=17). The cervical tissue from the gender-affirming therapy group showed superficial clusters of small basophilic cells, and surface prostatic metaplasia. Combined evaluation of PAP and PSA immunostaining revealed positive expression in 8 patients (33.3%) in the case group, whereas no immunoreactivity was observed in the control group samples.
Conclusion: Immunohistochemical expression of PAP and PSA in cervical tissue was observed in a subset of patients with gender-affirming who had undergone hysterectomy, with no expression detected in the control group. These findings suggest a potential androgen-induced epithelial differentiation or metaplastic transformation within mullerian-derived tissues under long-term exogenous hormonal influence. The absence of staining in the control group supports a correlation with androgen exposure rather than incidental ectopic prostatic rests. Further investigations are warranted to determine the prevalence, pathogenesis, and diagnostic relevance of this finding.

PS-17-002

Intraoperative Pap smear, HPV testing, endocervical curettage and histological evaluation of the cone margins as predictors of persistent/recurrent disease after conization

K. Darecka[1], N. Rakislova[1], M. del Pino[2], A. Torné[2], L. Sisuashvili[1], L. Marimón[1], C. Martí[2], S. Hoya[1], M. Cuenca[2], J. Bruch[2], J. Ordi[1], A. Saco[1]
[1]Hospital Clinic de Barcelona, Pathology, Barcelona, Spain, [2]Hospital Clinic de Barcelona, Gynaecology, Barcelona, Spain

Background & Objectives: To evaluate the diagnostic performance of intraoperative diagnostic tests in predicting residual or recurrent disease after conization for high-grade squamous intraepithelial lesions (HSIL/CIN2–3) of the uterine cervix.
Methods: A total of 666 women (mean age 39 ± 10 years; range 22–74) with histologically confirmed HSIL treated by conization were included. Immediately after the surgical procedure, an endocervical sample was collected intraoperatively using a cytobrush and preserved in PreservCyt medium (Hologic) for cytology and HR-HPV testing (Cobas HPV, Roche). All patients also underwent endocervical curettage (ECC), and cone margins were histologically evaluated. Patients were followed for at least 12 months. The diagnostic accuracy of intraoperative tests—including cone margin status, ECC, cytology, and HPV testing—was assessed for predicting residual or recurrent disease.
Results: Residual/recurrent disease was confirmed in 60 of 666 patients (9%). Intraoperative HPV testing showed the highest sensitivity (85%) with acceptable specificity (65%), with recurrence rates of 19% and 2% among HPV-positive and HPV-negative patients, respectively ($p < 0.0001$). The sensitivity and specificity of the other tests were 60% and 90% for cytology, 55% and 72% for margin evaluation, and 37% and 95% for ECC. Adding other tests to HPV testing had minimal benefit, with the best-performing combinations being HPV plus cytology and HPV plus margin evaluation. These two combinations slightly increased sensitivity, but reduced specificity (sensitivity 88%, specificity 61% for HPV + cytology; sensitivity 88%, specificity 51% for HPV + cone margin evaluation).
Conclusion: Intraoperative HPV testing using endocervical samples collected immediately after conization shows high diagnostic accuracy for identifying patients at risk of residual or recurrent disease. The addition of other tests offers minimal additional benefit. Incorporating this approach into routine clinical practice could reduce unnecessary diagnostic procedures and follow-up visits, optimizing post-treatment surveillance.

PS-17-003

Genomic features associated with survival status in endometrial endometrioid carcinoma of no specific molecular profile

Y. Cakir[1], Z. Bayramoglu[1]
[1]Dokuz Eylül University Medical School, Pathology, Izmir, Turkey

Background & Objectives: Endometrioid endometrial cancer (EEC) is classified in The Cancer Genome Atlas (TCGA) as p53 mutant, POLE mutant, MSI-H and no specific molecular profile (NSMP). However, the latter group still represents a heterogeneous group of cases and poses a challenge in terms of treatment planning and prognosis. In our study, we aimed to further characterize the molecular features of this group by dividing them into two groups according to survival status using TCGA data.
Methods: Cases (n=200) with a diagnosis of endometrioid carcinoma and mutation profile information in the Uterine Corpus Endometrial Carcinoma (TCGA, Firehose Legacy) dataset were used. Cases with p53, POLE, MLH-1, MLH-2, MSH-2, MSH-6, PMS-2 mutations and high tumour mutation burden (>10 mutations/per megabase) were excluded. Included cases were grouped according to survival status and compared for DNA mutations, copy number variations (CNV), mRNA and protein expression, and DNA methylation. P and $q < 0.05$ were considered significant.
Results: Among the 124 patients included in the study, 111 were alive (89.5%) while 13 were deceased (10.5%). The analysis identified 361 differentially expressed genes were detected (p and $q<0.05$). In terms of protein expression, CCNB1 exhibited expression in the ex group (p=1.196e-5, q=2.571e-3). In the comparison for DNA methylation, one gene (*OASL*, p=4.039e-5, q=0.0235) was more highly methylated in the surviving group while two genes (*GPR21*, p=5.32e-7, q=9.303e-4; *ALPK3*, p=9.434e-6, q=8.245e-3) were more highly methylated in the ex group. However, no significant difference was found in terms of mutation frequency and CNV ($p>0.05$).
Conclusion: We identified various molecular alterations in EECs that had a substantial impact on the prognosis in a molecularly heterogeneous group of NSMP patients. Consequently, experimental studies on these alterations hold great promise in terms of developing predictive markers that will affect the treatment plan of patients.

PS-17-004

Molecular determinants of invasion at the tumour-microenvironment interface of low-grade serous ovarian neoplasia

A. Zhang[1], R. Vallejos[2], A. Zhantuyakova[2], CB. Gilks[3], D. Huntsman[2], D. Cochrane[2]

[1]University of British Columbia, Pathology and Laboratory Medicine, Vancouver, Canada, [2]BC Cancer, Molecular Oncology, Vancouver, Canada, [3]Vancouver General Hospital, Pathology and Laboratory Medicine, Vancouver, Canada

Background & Objectives: Low-grade serous ovarian carcinomas (LGSCs) account for 5% of ovarian cancers and typically present with advanced stage disease that is resistant to therapy. LGSCs are thought to develop from serous borderline tumours, which are associated with much better outcomes. The molecular differences between LGSCs and serous borderline tumours that drive treatment resistance are poorly understood. We sought to understand the tumour and microenvironmental differences between LGSC and serous borderline tumour through single cell-resolution spatial transcriptomics.
Methods: We assembled a cohort of 20 LGSCs and 20 serous borderline tumours. Tissue microarrays were constructed from areas of invasive and borderline disease. Spatial transcriptomes for over 750,000 cells were performed using the 10X Genomics Xenium platform.
Results: LGSCs and serous borderline tumours show significant differences in cell type composition, tumour cell and stromal cell phenotypes. Compared to serous borderline tumours, LGSCs showed upregulation of c-MET and TGF-beta signalling and downregulation of hormone receptor pathways. Several invasion-associated genes showed spatially variable expression patterns with upregulation at the tumour-stromal interface in LGSCs but not in serous borderline tumours.
Conclusion: Low-grade serous carcinomas show spatially distinct patterns of tumour and stromal cell gene expression from serous borderline tumours. These differences may be exploitable through molecularly targeted therapies.

PS-17-005

Expression of PAX2, Beta-catenin and PTEN in 63 cases of atypical polypoid adenomyoma: association with recurrence and development of adenocarcinoma

A.E. Akın[1], D. Ateş[1], A.C. Güneş[2], H. Avcı[3], A. Usubütün[1]
[1]Hacettepe University, Pathology, Ankara, Turkey, [2]Hacettepe University, Obstetrics and Gynaecology, Ankara, Turkey, [3]Hacettepe University, Biostatistics, Ankara, Turkey

Background & Objectives: Atypical polypoid adenomyoma (APA) is a rare lesion involved in the differential diagnosis of endometrioid intraepithelial neoplasia (EIN) and endometrioid adenocarcinoma. This study aims to determine whether Beta-catenin nuclear positivity and PAX2/PTEN expression loss, which aid in EIN diagnosis, predict recurrence or adenocarcinoma development in APA and to assess MMR protein status.
Methods: A total of 63 biopsies from 41 patients meeting the WHO criteria for APA were included. These biopsies were classified as preserved or lost for PAX2, PTEN, MSH6, and PMS2, and as nuclear or membranous for beta-catenin. Immunohistochemistry results were statistically analysed for correlations with recurrence and development of adenocarcinoma.
Results: The median age was 36.4 years (range: 25–63). Recurrence occurred in 14 (34.1%) of 41 patients. The mean age of recurrent cases (33±5.35) was lower than non-recurrent cases (38.39±8.71) (p=0.035). Nuclear beta-catenin positivity, PAX2, and PTEN loss were more frequent in recurrent cases (80%, 53%, 60%) but not statistically significant (p=0.112, p>0.05, p>0.05). Similarly, nuclear beta-catenin positivity, PAX2, and PTEN loss were more common in adenocarcinoma cases (55.6%, 55.6%, 66.7%) but remained insignificant (p=0.62, p>0.35, p>0.82). Only one patient had MSH6 and MSH2 loss but did not develop adenocarcinoma or recurrence.
Conclusion: Loss of PAX2 and PTEN expression in APAs does not predict recurrence and adenocarcinoma development. Moreover, PAX2 and PTEN expression was preserved in nearly half of the cases, their diagnostic utility in APA is limited compared to EIN. They should also not be used to distinguish from EIN. Additionally, it was found that, although rare, MMR loss can occur in APA. Younger age at diagnosis was significantly associated with recurrence.

PS-17-006

Unraveling the impact of BRCA1/2 mutations and DNA Mismatch Repair protein expression on clinicopathological features in ovarian carcinomas

G. Kurt Çevik[1], F. Erdoğan[1], H. Tatli Doğan[1], T.D. Kökenek Ünal[1], D. Şener Dede[2], G. Uçar[2], S. Sekmek[2], G. Güleç Ceylan[3], P. Demir[4]
[1]Ankara Bilkent City Hospital, Medical Pathology, Ankara, Turkey, [2]Ankara Bilkent City Hospital, Medical Oncology, Ankara, Turkey, [3]Ankara Bilkent City Hospital, Medical Genetics, Ankara, Turkey, [4]Ankara Yildirim Beyazıt University, Faculty of Medicine, Biostatistics and Medical Informatics, Ankara, Turkey

Background & Objectives: Ovarian cancer remains the most lethal gynaecological malignancy. This study aims to investigate the prevalence of BRCA1/2 mutations and deficient DNA mismatch repair (dMMR) status in ovarian carcinoma and to evaluate their correlation with clinicopathological parameters.
Methods: This retrospective study included 132 patients diagnosed with ovarian carcinoma at our centre who were tested for BRCA1/2 mutations using Next-Generation Sequencing and for DNA MMR protein (MLH1, MSH2, MSH6, and PMS2) expression via immunohistochemistry. Clinicopathological and histopathological parameters (including solid, pseudoendometrioid, and transitional cell carcinoma-like(SET) pattern), poly(adenosinediphosphate–ribose) polymerase(PARP) inhibitors (PARP-i) therapy, progression-free survival (PFS), event-free survival (EFS), and overall survival (OS) analysis were assessed. Somatic and germline mutation detection were compared, and the associations of BRCA1/2 mutations and dMMR status with clinical outcomes were analysed.
Results: Somatic BRCA1/2 mutations were detected in 25.7% of cases, germline mutations in 20.9%, and overall (somatic or germline) mutations in 28%. Somatic mutations were detected in 8 cases without corresponding germline mutations, whereas 3 of the 5 cases deemed non-effective by somatic testing carried germline mutations. The concordance rate between somatic and germline testing was 87.6%. BRCA1/2 mutations were associated with significantly longer OS. Among patients treated with PARP-i, 71% had no recurrence, and the mean PFS was 21 months. OS was significantly longer in the PARP-i group*(p=0.005),* whereas the difference in EFS was not statistically significant*(p=0.473)*. The SET pattern was observed in 17.4% of cases, with a statistically significant association to BRCA1/2 mutations*(p=0.010)*. dMMR was observed in 7.6% of cases, without any statistically significant impact on clinical outcomes.
Conclusion: BRCA1/2 and dMMR status are critical for treatment strategies in ovarian cancer. Somatic or germline BRCA1/2 mutations, particularly when treated with PARP-i, lead to improved survival outcomes. Additionally, recognizing the presence of the SET pattern morphologically may provide insight into BRCA1/2 mutation status, potentially guiding prognosis and treatment decisions.

PS-17-007

Sex Cord Stromal Tumours of the ovary, a 24 years clinicopathological study in Farhat Hached University Hospital of Sousse. About 50 cases

D. Chiba[1], I. Bannour[2], C. Rjiba[2], B. Bannour[2], A. Benabdelkader[3], B. Sriha[3], M. Mokni[3]

[1]Avicenne Hospital, Pathology, Paris, France, [2]Farhat Hached Hospital, Gynaecology, Sousse, Tunisia, [3]Farhat Hached Hospital, Pathology, Sousse, Tunisia

Background & Objectives: Malignant SEX CORD STROMAL TUMORS OF THE OVARY (SCSTs) are a group of rare neoplasms. The importance of investigating these neoplasms stems from their rarity and heterogeneity and their limited data and treatment recommendations.
Purpose of the study: Characterize these rare tumours by analysing epidemiological features, clinical and paraclinical features, histological characteristics, treatment modalities, and survival rates. Identify the factors associated with the prognosis of these tumours and propose a management diagram tailored to the Tunisian context.
Methods: This was a descriptive and analytical monocentric observational study concerning female patients who were treated for SCSTs of the ovary, in the Department of Gynaecology-Obstetrics, at the Farhat Hached University Hospital from January 1999 to December 2023. The clinical, radiological and histological data were collected via patients' files and from the Centre cancer registry.
Results: A total of 50 patients were eligible for this study. The incidence of SCSTs was 0.1 per 100 000 per year. The mean age at diagnosis was 48,46 ± 19.92 years with extremes ranging from 6 to 86 years. The distribution differed by histological type. SLCTs occurring more frequently in the third decade of life while adult GCTs occurred mostly in the 6^{th} and 5^{th} decades of life. Ultrasound revealed a tumour in 97.90% of cases. Histologically, the mean tumour size was 13.20 cm. The most common histological subtype was Granulosa Cell tumours (GCTs) which account for 74% of cases and are divided into Adult Granulosa Cell tumours (AGCTs) (68%) and Juvenile Granulosa Cell tumours (JGCTs) (6%), the second ranked subtype was the Sertoli-Leydig cell tumour (SLCT) accounting for 26% of patients.
Conclusion: Malignant SCSTs, are rare tumours comprising different entities, the most common being GCTs and SLCTs. additional research is needed to establish a clear protocol for treatment especially in case of recurrence.

PS-17-008

Clinicopathological and molecular features of mesonephric-like adenocarcinoma of the ovary: a small series

C. Alves[1], J. Pires[2], S. Lérias[3], E. Ussene[4], M. Chorão[5], J. Ferreira[1,2], E. Oliva[6,7], A. Félix[1]
[1]Instituto Português de Oncologia, Serviço de Anatomia Patológica, Lisboa, Portugal, [2]NOVA Medical School, Lisboa, Portugal, [3]Fundação Champalimaud, Serviço de Anatomia Patológica, Lisboa, Portugal, [4]Hospital de Vila Franca de Xira, Serviço de Anatomia Patológica, Lisboa, Portugal, [5]Hospital Egas Moniz, Serviço de Anatomia Patológica, Lisboa, Portugal, [6]Massachusetts General Hospital, Department of Pathology, Boston, USA, [7]Harvard Medical School, Boston, USA

Background & Objectives: Mesonephric-like adenocarcinoma (MLA) is a rare ovarian tumour, and the correct diagnosis requires an extended immunohistochemical and molecular characterization. We evaluated the clinicopathological and molecular parameters of a small series of MLAs.
Methods: Four MLA cases were retrieved from our archives. Clinicopathological data was reviewed. H&E slides, immunohistochemistry (ER, PR, p53, PAX8, GATA3, TTF1, WT1) and Idylla TM Mutation Assay evaluation for KRAS/NRAS/BRAF were evaluated.
Results: Patients' median age was 67.5 years (53-94). Three patients had total hysterectomy with bilateral adnexectomy and omentectomy (3 pts), and unilateral adnexectomy (1 pts). All had complete cytoreduction. One patient had adjuvant chemotherapy. FIGO stage distribution was IA, IC1, IC2 and IIIB. Morphologically several patterns were identified: glandular (n=4), solid (n=2), cystic (n=2), papillary (n=1) and cords (n=1), and cells were predominantly atypical with elevated mitotic activity and pale chromatin. In three cases we detected admixture of different areas (mixed tumours), namely benign/borderline mucinous component, endometrioid carcinoma with focal transformation into carcinosarcoma and carcinosarcoma with chondroid differentiation associated with MLA. Additionally, adnexal endometriosis was found in two cases, and no mesonephric remnants were identified. The immunohistochemistry profile was: ER and PR - (n=4); p53+ve, wild-type (n=4); PAX-8+ve (n=4). GATA3+ve (n=3); TTF1+ve (n=4); WT1-ve (n=4). The molecular evaluation detected KRAS mutation[35G>A p.(Gly12Asp)] (n=3) and NRAS mutation [182A>G p.(Gln61Arg)] (n=1). The median follow up was 11 months (3,9 – 34,8). All patients are alive, two of them with clinical evidence of early disease relapse after primary treatment (stage IC1 and IIIB).
Conclusion: Our series confirms, despite the limited follow-up data, that MLAs are aggressive tumours, even in early stages of disease. The immunohistochemical profile and presence of other mullerian-derived components, in this series, support a mullerian origin of these tumours, with frequent KRAS mutations.

PS-17-009

HER2 assessment in endometrial serous carcinoma: comparative evaluation of scoring systems and diagnostic concordance in a multicentre Italian cohort

A. d'Amati[1,2], A. Santoro[1], G. Mastrosimini[3], F. Addante[1], G. Scaglione[1], N. Dalessandris[1], A. Pesci[3], G.F. Zannoni[1]
[1]Anatomic Pathology Unit, Fondazione Policlinico Universitario "A. Gemelli" IRCCS, Università Cattolica S. Cuore, Rome, Italy, [2]PhD Programme in Applied Neuroscience, Department of Translational Biomedicine and Neuroscience (DiBraiN), University of Bari "Aldo Moro", Bari, Italy, [3]Department of Pathology, Sacred Heart Hospital Don Calabria Negrar, Verona, Italy

Background & Objectives: Endometrial serous carcinoma (ESC) is a highly aggressive subtype of endometrial cancer, often diagnosed at advanced stages and associated with poor prognosis. A subset of ESCs (~15%) shows HER2 overexpression and/or *ERBB2*amplification, which may benefit from targeted anti-HER2 therapy. However, HER2 testing remains non-standardized in ESC. This study aimed to compare ASCO/CAP 2007, ASCO/CAP 2018, and an ESC-specific scoring system in terms of diagnostic concordance and clinical utility.
Methods: We retrospectively analysed 113 hysterectomy specimens diagnosed as ESC, mixed carcinoma with serous component, or carcinosarcoma, collected from two Italian institutions. HER2 immunohistochemistry (clone 4B5) was performed and scored according to all three systems. Equivocal and discordant cases underwent dual-colour dual-hapten brightfield in situ hybridization (DDISH) for *ERBB2*. Statistical analyses included kappa concordance and association with clinicopathological variables.
Results: HER2 positivity (IHC 3+ and/or *ERBB2* amplification) was detected in 17/113 cases (15%). ASCO/CAP 2018 identified the highest number of HER2-positive cases (13 scored as 3+), demonstrating greater sensitivity compared to ASCO/CAP 2007 and the ESC-specific system, which each identified 10 cases as 3+. Four cases showed scoring discordance, with ASCO/CAP 2018 correctly classifying them as HER2-positive based on ISH results. Overall concordance was excellent between ASCO/CAP 2007 and the ESC system ($\kappa = 0.98$), and moderate between ASCO/CAP 2018 and the other two ($\kappa \approx 0.71$). HER2 positivity correlated significantly with age >70 years ($p = 0.016$). HER2 intratumoral heterogeneity was present in 12% of cases.
Conclusion: ASCO/CAP 2018 guidelines demonstrated superior sensitivity in identifying HER2-positive ESCs, potentially expanding

therapeutic eligibility. However, the ESC-specific and ASCO/CAP 2007 systems remain more conservative and closely aligned with prior clinical trial data. A harmonized, ESC-adapted scoring strategy is essential to optimize HER2 testing and ensure accurate patient selection for targeted therapy.

PS-17-010

Endometriosis-associated ovarian carcinomas: histotypes and molecular profiling

C. Ravaioli[1,2], D. De Biase[3,4], G. Tallini[5,3], T. Maloberti[3], A. Costantini[1], A. De Gaetano[6], M. Grillini[1], A. De Leo[3,5]
[1]Pathology Unit, IRCCS Azienda Ospedaliero Universitaria di Bologna, Bologna, Italy, [2]Department of Biomedical and Neuromotor Sciences (DIBINEM), University of Bologna, Bologna, Italy, [3]Solid Tumour Molecular Pathology Laboratory, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, [4]Department of Pharmacy and Biotechnology (FaBit), University of Bologna, Bologna, Italy, [5]Department of Medical and Surgical Sciences (DIMEC), University of Bologna, Bologna, Italy, [6]Pathology Unit, IRCCS Azienda Ospedaliero Universitaria Di Bologna, Bologna, Italy

Background & Objectives: The Cancer Genome Atlas (TCGA) classifies endometrial carcinoma into four molecular subgroups: POLE (ultramutated), mismatch repair-deficient (MMRd, hypermutated), TP53-mutated (copy-number-high), and no specific molecular profile (NSMP, copy-number-low). While some studies have analysed the distribution of molecular subtypes in specific ovarian carcinoma histotypes, data on endometriosis-associated ovarian carcinomas (EAOCs) remain limited.
Methods: We examined a series of 39 consecutive ovarian carcinomas (OCs) arising in the context of endometriosis. Two pathologists independently reviewed all cases based on morphology and an immunohistochemical panel. IHC and next-generation sequencing (NGS) were used to assign surrogate molecular subtypes: POLE-mutated (POLE), mismatch repair-deficient (MMRd), TP53-mutated (p53abn), and NSMP. Clinical data, including age at diagnosis, FIGO stage, and follow-up, were collected.
Results: Our cohort included 20 (51.3%) low-grade endometrioid adenocarcinomas, 7 (18%) high-grade endometrioid adenocarcinomas, 8 (20.5%) clear cell carcinomas, and 4 (10.2%) mesonephric-like adenocarcinomas. Molecular classification identified 3 (7,7%) POLE OCs, 5 (12,8%) p53 abn, 2 (5,1%) MMRd, and 29 (74,4%) NSMP. The mean age at diagnosis was 56 years (range: 31–79). FIGO stage ranged from IA to IIIC, with the majority of cases classified as stage I (19 cases), stage II (13 cases), and stage III (7 cases). During a follow-up period ranging from 6 to 120 months, recurrence was observed in 8 cases, with 2 disease-related deaths. All recurrent cases belonged to the NSMP molecular subgroup, except for one case in the p53-mutated subgroup. Histologically, recurrent cases included 3 clear cell carcinomas, 2 mesonephric-like adenocarcinomas, 1 high-grade endometrioid adenocarcinoma, and 2 low-grade endometrioid adenocarcinomas with advanced-stage disease at diagnosis.
Conclusion: Endometriosis-associated OCs exhibit a higher prevalence of the NSMP molecular subtype compared to their endometrial counterparts, with low-grade endometrioid adenocarcinoma being the most represented histotype. Among NSMP tumours, FIGO stage at diagnosis and histotype remain the most reliable parameters for prognostic stratification.

PS-17-011

PD-L1 expression in high-grade serous ovarian carcinoma is associated to specific types of lymphocytic infiltrate and tumour segments

L. Jovanovic[1], A. Cirkovic[2], S. Milenkovic[1], S. Djuricic[3], B. Sosic-Jurjevic[4], T. Janjic[1], M. Jovic[5], R. Jankovic[2]
[1]University Clinical Centre of Serbia, Belgrade, Serbia, [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia, [3]Faculty of Medicine, University of Banja Luka, Banja Luka, Bosnia and Herzegovina, [4]Institute for Biological Research "Siniša Stanković", Belgrade, Serbia, [5]Military Medical Academy, Belgrade, Serbia

Background & Objectives: Research on ovarian cancer predominantly focuses on high-grade serous ovarian cancer (HGSOC). Patients with this aggressive form of ovarian cancer often exhibit resistance to therapy and have a generally poor prognosis. HGSOC suppresses the host's immune response by activating checkpoint mechanisms, such as programmed death protein 1 (PD-1) and its ligand, programmed death-ligand 1 (PD-L1). This interaction renders tumour cells resistant to effector lymphocytes. The infiltration of lymphocytes plays a crucial role in regulating PD-L1 expression.
Methods: This study involved 91 patients with HGSOC. Immunohistochemical analysis was conducted using the tissue microarray (TMA) technique, with correlations made between carcinoma segments and the localization of lymphocytic infiltrates. PD-L1 expression was scored as follows: negative (0), with no positive cells or only a single positive cell (<1%); low (1+), with fewer than 10% positive cells; moderate (2+), with 10-50% positive cells; and strong (3+), with more than 50% positive cells. The lymphocytic infiltrate was assessed on whole slides prior to TMA construction, comparing central and peripheral tumour regions, and its localization was correlated with PD-L1 expression on tumour cells.
Results: High levels of PD-L1 expression were more commonly found in the invasive regions of the tumour compared to the central parts ($p<0.001$). No significant correlation was observed between the peritumoral lymphocytic infiltrate and PD-L1 expression, regardless of the tumour segment. In contrast, intratumoral lymphocytic infiltration was more frequent (84.3%) in the central tumour regions and was associated with higher PD-L1 expression ($p=0.003$).
Conclusion: The most prominent PD-L1 expression was observed in the invasive regions of HGSOC. Only the central tumour regions showed significant PD-L1 expression associated with notable intratumoral lymphocytic infiltration. Our findings support the hypothesis that PD-L1 inhibitors could offer an effective therapeutic strategy for aggressive ovarian cancers like HGSOC, particularly in cases with prominent intratumoral lymphocytic infiltration.

PS-17-012

Utility of HOXB13 in differential diagnosis of female genital tract lesions with putative prostatic differentiation

L. Gerykova[1], J. Laco[1], H. Hornychova[1], K. Kamaradova[1,2], M. Trnkova[2], P. Dundr[3], R. Matej[4,5,3], J. Soukup[6,1,3]
[1]Charles University, Faculty of Medicine in Hradec Králové and University Hospital Hradec Králové, The Fingerland Department of Pathology, Hradec Kralove, Czech Republic, [2]Unilabs Pathology k.s., Prague, Czech Republic, [3]Charles University, First Faculty of Medicine and General University Hospital in Prague, Department of Pathology, Prague, Czech Republic, [4]Third Faculty of Medicine, Charles University, University Hospital Královské Vinohrady, Department of Pathology, Prague, Czech Republic, [5]Third Faculty of Medicine, Charles University, Thomayer University Hospital, Department of Pathology and Molecular Medicine, Prague, Czech Republic, [6]Military University Hospital Prague, Department of Pathology, Prague, Czech Republic

Background & Objectives: Female genital tract lesions with putative prostatic differentiation include tubulosquamous polyps (TSP), ectopic prostatic tissue (EPT), and adenoid basal cell carcinoma (ABC). HOXB13 is a transcription factor highly specific for the prostate, however its diagnostic utility in gynaecologic pathology has not been studied.

Methods: The cohort of 13 TSPs, 6 EPTs, 13 ABCs, and 8 adenoid basal hyperplasias (ABHs) was analysed for expression of prostatic markers HOXB13 and NKX3.1. Additional 18 HSILs, 10 squamous cell carcinomas (SCCs), 11 endocervical adenocarcinomas (EACs), and 5 poorly differentiated endometrial endometrioid carcinomas (ECs) were studied with HOXB13 and p16. The results were recorded as immunoreactive score (IRS).
Results: In benign lesions (TSPs, EPTs), HOXB13 and NKX3.1 was positive in 100% and 89.4%, respectively. No expression of HOXB13, NKX3.1, and p16 was observed in ABHs. In contrast, all ABCs showed diffuse p16 positivity. NKX3.1 was positive in 76.9% of ABCs (median IRS 2), while HOXB13 was positive in 100% ABCs (median IRS 8) and the extent of positivity differed significantly (p=0.0004). NKX3.1 stained preferentially glandular structures but not basaloid cells in majority of the cases. HOXB13 was regularly observed in basal zone of normal ectocervical epithelium and in a subset of HSILs (44.4% of all HSILs and in 87.5% of HSILs associated with ABC). HOXB13 was positive in 2 EACs and in 2 G3 EC (IRS≤2 in all 4 cases). Thus, any HOXB13 positivity in invasive carcinoma was 100% sensitive and 84.6% specific for the diagnosis of ABC. In contrast, NKX3.1 was only 76.9% sensitive for the diagnosis of ABC.
Conclusion: HOXB13 is a more robust and sensitive marker of ABC. All studied ABHs lacked p16 immunoreactivity as well as prostatic markers and this further support its unrelatedness to ABC.

PS-17-013
MTAP deficiency: a novel potential predictive marker in high-grade and undifferentiated uterine sarcomas
E. Radová[1], N. Hájková[1], J. Hojný[1], E. Krkavcová[1], J. Dvořák[1], I. Stružinská[1], M. Kendall Bártů[1], P. Dundr[1]

[1]First Faculty of Medicine Charles University and General University Hospital in Prague, Institute of Pathology, Prague, Czech Republic
Background & Objectives: Uterine sarcomas, including high-grade endometrial stromal sarcoma (HG-ESS) and undifferentiated uterine sarcoma (UUS), are aggressive tumours with limited treatment options. Methylthioadenosine phosphorylase (MTAP) deficiency, frequently associated with 9p21 deletions (CDKN2A/B), may serve as a predictive marker for targeted therapy or antifolate therapy in various cancers. In this study, we analysed MTAP at the DNA and protein levels in HG-ESS and UUS to identify potential therapeutic targets.
Methods: A cohort comprising 57 HG-ESS, 3 low-grade ESS with HG transformation, and 41 UUS underwent next-generation sequencing (NGS) using a DNA-targeted panel, which included *MTAP*, *CDKN2A/B*. Copy number variation (CNV) analysis focused on the *MTAP*, *CDKN2A/B* genes. Immunohistochemistry (IHC) was performed using the MTAP antibody clone RBT-MTAP (Bio SB).
Results: Homozygous deletion of the *MTAP* gene was observed in 2/41 (5%) UUS, 1/3 low-grade ESS with HG transformation, and 8/57 (14%) HG-ESS. Co-deletions of *CDKN2A* and *CDKN2B* were found in 9 of 11 MTAP-deleted tumours. The remaining two MTAP-deleted tumours exhibited either deletion of *CDKN2A* exon 1 or complete deletion of *CDKN2A* with intact *CDKN2B*. CNV analysis strongly correlated with IHC results. All MTAP-deleted samples had H-scores of 0 (except one), indicating no MTAP protein expression. *MTAP* non-deleted samples had a median IHC H-score of 160 (range 30–300, IQR=100–200).
Conclusion: We observed that 11% of HG-ESS/UUS tumours harbour MTAP deletion, providing the first comprehensive characterization of its frequency and occurrence in these rare, aggressive gynaecological tumour types. Our study suggests potential treatment strategies for MTAP-deficient tumours, including PRMT5 and MAT2A inhibition, as well as antifolate therapy. We demonstrated high concordance between MTAP IHC and CNV analysis. Further clinical validation is necessary to assess the therapeutic relevance of these approaches.

Supported by the Ministry of Health, Czech Republic (MH CZ DRO-VFN 64165), the European Regional Development Fund (BBMRI_CZ LM2023033), and Charles University (Project UNCE 24/MED/018).

PS-17-014
Should HER2 in uterine serous carcinomas be evaluated in biopsy or hysterectomy material?
Z. Bayramoglu[1], Y. Cakir[2,1], S. Kurt[3], H.T. Timur[3], B. Saatli[3]
[1]The Instıtutte of Health Sciences, Department of Molecular Pathology, Izmir, Turkey, [2]Dokuz Eylul University Faculty of Medicine, Pathology, Izmir, Turkey, [3]Dokuz Eylul University Faculty of Medicine, Department of Gynaecological Oncology, Izmir, Turkey

Background & Objectives: HER2 is an important prognostic and therapeutic target in uterine serous carcinoma. Our aim was to determine our HER2 rate in endometrial biopsy and hysterectomy materials in patients with uterine serous carcinoma and to determine the effect of sample differences on the results.
Methods: Endometrial biopsy and hysterectomy materials of 35 patients diagnosed with uterine serous carcinoma between 2021 and 2024 were included in the study. HER2 positivity by IHC and CISH was determined according to ASCO/CAP version 1.2.0.0 HER2 guidelines.
Results: In our biopsy materials, 5 of our 35 patients showed +3 reaction with immunohistochemical HER2. In 3 patients, +2 reaction with HER2 was observed and 2 of these patients were HER2 positive and 1 was negative by CISH method. HER2 positivity was seen in 7 of 35 patients in total. In hysterectomy material, 7 of 35 patients had +3 reaction with immunohistochemical HER2. In 4 patients, +2 reaction with HER2 was observed and 2 of these patients were HER2 positive and 2 of them were negative by CISH method. HER2 positivity was seen in 8 of 35 patients in total. When compared to both groups, 2 patients who were negative in biopsy material were HER2 positive in resection material.
Conclusion: There are no standardised protocols for the selection of the optimum sample type or algorithm for HER2 testing in endometrial serous carcinomas. We compared HER2 immunohistochemical scores, heterogeneity of HER2 expression, CISH results, and overall HER2 status between the 2 sample types. As a result, we actually found high concordance between biopsy materials and histrectomy materials.

PS-17-015
Riluzole inhibits ovarian cancer cell migration by altering extracellular matrix structure
C. Villa[1], E. Duranti[1], M. Cadamuro[1], M. Lavitrano[1]
[1]University of Milano-Bicocca, Department of Medicine and Surgery, Monza, Italy

Background & Objectives: The glutamate release inhibitor riluzole has been shown to slow the progression of amyotrophic lateral sclerosis, a rapidly progressive neurodegenerative condition. However, recent studies suggested that riluzole may also possess antitumor properties, but its effects on ovarian cancer remain unexplored.
Methods: The ovarian cancer cell lines OVCAR5 and OVCAR8 were treated with different concentrations of riluzole (10-1000 μM) for 48 hours. MTT and wound healing assays were performed to assess the effects of riluzole on cell viability and migration, respectively. Additionally, bulk RNA-Sequencing was performed in order to analyse the impact of riluzole on ovarian cancer cells transcriptome.
Results: Riluzole treatment (10–1000 μM) for 48 hours had no significant effect on cell viability in either OVCAR5 or OVCAR8 cells. Conversely, wound healing assays demonstrated a significant reduction in cell migration following riluzole treatment at 10 and 50 μM ($p < 0.05$). Migration rates of both cell lines decreased by more than 30% when compared to the untreated control groups. Transcriptomic

analysis revealed that riluzole significantly altered the expression of genes involved in extracellular matrix organization and structural integrity, suggesting a potential mechanism underlying its antimigratory effects.
Conclusion: Our preliminary findings indicated that riluzole has no effect on cell viability but can significantly slow migration capacity in both cell lines, probably through the modulation of extracellular matrix. These results suggest that riluzole may interfere with key pathways involved in tumour cell motility, offering new perspectives on its potential as an antimetastatic drug. However, a more extended research is required to further investigate the molecular targets of riluzole and its underlying antitumor mechanisms in ovarian cancer.

PS-17-016
Survival comparison analysis between Endocervical adenocarcinoma and Squamous cell carcinoma cervix with a special focus on HPV status
D. Jain[1], M. Wahidi[2], H. Jang[3], R. Jaroudi[2], D. Allison[4], N. Rakislova[5,6], T. Kiyokawa[7], S. Kim[3], R. Soslow[8], S. Stolnicu[9], R. Ali-Fehmi[2]
[1]Wayne State University, Detroit, USA, [2]University of Michigan, Ann Arbor, USA, [3]Karmanos Cancer Institute, Biostatistics and Bioinformatics Core, Detroit, USA, [4]Memorial Sloan Kettering Cancer Centre, New York, USA, [5]University of Barcelona, Barcelona, Spain, [6]IS Global, Barcelona, Spain, [7]Jikei University, Tokyo, Japan, [8]Cleveland Clinic, Ohio, USA, [9]University of Medicine, Pharmacy, Sciences and Technology, Targu Mures, Romania

Background & Objectives: Squamous cell carcinoma (SCC) accounts for 75% of all cervical cancers (CC), while endocervical adenocarcinoma (EAC) represents about 25%. Based on Human papillomavirus (HPV) status, WHO 2020 has classified both tumour types into HPV-associated (HPVA) and HPV-independent (HPVI). Our study examines the impact of HPV status and patient-specific characteristics on overall survival (OS) and recurrence-free survival (RFS) for SCC and EAC.
Methods: This multi-continental retrospective study analysed clinicopathologic data of 634 patients with microscopically confirmed CC (only SCC and EAC histology) across Asia, Europe, and North America. HPV status was determined using PCR or ISH for HR- and LR-HPV, using same platform. Descriptive analysis and Cox regression models produced.
Results: 533 (84.1%) patients were HPVA and 101 (15.9%) HPVI. 412 had SCC morphology (88.1%: HPVA; 11.9%: HPVI) and 222 had EAC differentiation (76.6%: HPVA; 23.4%: HPVI). Compared to EAC, patients with SCC were older (median age: 51 vs. 45 years; $P < 0.001$), had higher HPV ISH+ status (88.1% vs. 76.6%; $P < 0.001$), and higher rates of lymph-vascular invasion (LVI; 64.8% vs. 56.8%; $P = 0.004$). However, patients with EAC had higher metastasis rates in pelvic organs (13.5% vs. 2.4%; $P < 0.001$). In univariable analysis, patients with HPVI status; SCC; higher stage; older age; LVI+; regional/remote lymph node metastasis (RLNM); adjuvant treatment (AT) had worse OS or RFS than those with HPVA status; EAC; lower stage; young age; without LVI, RLNM, and AT (all $P \leq 0.007$). European patients had worse OS than North American patients; those with higher grade had worse RFS than lower grade (all $p<0.05$). In multivariable analysis, age, stage, LVI, and tumour type remained significant for OS, while tumour grade, LVI, and HPV status remained significant for RFS.
Conclusion: Study highlights significance of tumour type and HPV status in determining CC survival, underscoring need for personalized treatment strategies.

PS-17-017
Mismatch Repair Protein Status in Tubo-Ovarian High Grade Serous Carcinoma
S. Nofech Mozes[1,2], D. Bassiouny[2], E. Olkhov-Mitsel[1], F.-I. Lu[1,2], J. Mirkovic[1,2], A. Plotkin[2]
[1]Sunnybrook Health Sciences Centre, Precision Diagnostics and Therapeutics Program, Toronto, Canada, [2]University of Toronto, Laboratory Medicine and Pathobiology, Toronto, Canada

Background & Objectives: Testing of tumour biomarkers is rapidly evolving with expanding therapeutic indications. In ovarian carcinoma, Mismatch Repair Protein (MMR) immunohistochemistry (IHC) has mainly been performed to screen for Lynch Syndrome (LS) in non-high-grade serous carcinoma (HGSC) and, more recently, to select patients with advanced/metastatic disease for immunotherapy. This study assessed the prevalence of MMR deficiency (MMRd) in Tubo-ovarian HGSC (T-O HGSC) by IHC.
Methods: MMR status was assessed in full sections from sequential routine 33 T-O HGSCs from 2024 and a tissue microarray (TMA) of 416 T-O HGSCs (2000–2013) that had at least a cystectomy. Gynaecologic pathologists determined histologic typing and MMR IHC status. Cases with non-HGSC histology or prior/synchronous endometrial carcinoma were excluded. Cases with MMRd or equivocal TMA results were retested on full section. Stromal cell immunoreactivity was confirmed for adequacy. P53 was defined as abnormal (overexpressed (OE), null or cytoplasmic) or normal. ER and PR were considered positive if moderate to strong nuclear staining was present in ≥1% of tumour cells.
Results: Among 449 T-O HGSC patients, all 4 MMR proteins were intact in 32/33 routine cases and 412/413 TMA cases, totalling 444/446 (99.5%). PMS2 loss with intact MLH1/MSH2/MSH6 was detected in two cases. In these MMRd patients, hysterectomy and bilateral salpingo-oophorectomy revealed benign endometrium and no in situ carcinoma in fallopian tubes. P53 was abnormal/normal/NA in 424 (94.4%)/19 (4.2%)/6 (1.3%) cases. ER was positive/negative/NA in 389(86.7%)/51 (11.3%)/9 (2.0%). PR was positive/negative/NA in 125 (27.8%)/303 (67.5%)/21 (4.7%) cases.
Conclusion: MMR loss is rare (0.5%) in T-O HGSC that may represent sporadic T-O HGSC in LS patients. In health systems with finite operational budgets, MMR IHC may need to be reserved for patients with family or personal history suspicious of LS. Other biomarkers, such as tumour mutational burden, may be more appropriate to guide immunotherapy selection.

PS-17-018
Age-related alterations in inflammaging markers in the endometrial cell cultures
A. Drobintseva[1], I. Kvetnoy[1], R. Nasyrov[2], D. Ivanov[3]
[1]Saint Petersburg State Paediatric Medical University, Histology and Embryology named after A.G. Knorre, Saint Petersburg, Russia, [2]Saint Petersburg State Paediatric Medical University, The Prof. D.D. Lohov Department of Pathological Anatomy with Course of Forensic Medicine, Saint Petersburg, Russia, [3]Saint Petersburg State Paediatric Medical University, Department of Neonatology with Courses in Neurology and Obstetrics-Gynaecology, Saint Petersburg, Russia

Background & Objectives: The concept of "inflammaging," introduced by C. Franceschi in 2014, describes a chronic, low-grade inflammatory state that drives systemic aging. Chronic uterine inflammation promotes endometriosis and reduces fertility. The aim of the study is to identify new markers of inflammaging and compare the expression of these markers in the endometrium of women according to reproductive age.
Methods: Endometrial tissue samples were collected via pipelle biopsy during the secretory phase of the menstrual cycle and divided into two age groups: Group 1 (under 35 years, n=10) and Group 2 (over 35 years, n=10), each group was subdivided to control and inflammaging. Cell cultures were isolated using a standard protocol developed in our laboratory. UV-C at 254 nm was used to modulate genotoxic stress.

Results: Under genotoxic stress, IL-8 levels significantly increased in both young and older reproductive age groups compared to controls: 9-fold higher in women under 35 and 13-fold higher in women over 35. When modelling inflammaging increase in IL-1α expression was observed in both age groups compared to the control. IL-6 expression was higher in the inflammaging group compared to controls, but no significant differences were found between two age groups.
In the control group, SIRT-1 expression was significantly lower in the older reproductive age group compared to those under 35. Under genotoxic stress, SIRT-1 expression decreased significantly in both age groups (3.8-fold and 4.0-fold, respectively). Similarly, SIRT-6 expression decreased significantly with age in both control and stress-exposed groups.
Conclusion: The study revealed, for the first time, that levels of IL-8, SIRT1, and SIRT6 in endometrial cell cultures significantly decrease with the transition from young to older reproductive age. At the same time, the expression of IL-1a increased significantly with the age. The IL-6 levels in the endometrium did not depend from the age.

PS-17-019
The potential prognostic value of TROP2 and FOXC1 expression in uterine leiomyosarcomas: a study of 57 cases
T. Jones[1], M. DeBerry[1], M. Jones[1]
[1]University of Pittsburgh Medical Centre, Pathology Department, Pittsburgh, USA

Background & Objectives: Uterine leiomyosarcomas (uLMS) are malignant mesenchymal neoplasms which portend a poor prognosis with available treatments and a search for targetable therapy continues. Human trophoblast cell-surface marker (TROP2) has demonstrated increased expression and has been reported as an independent marker of poor survival in various cancers. Forkhead box C1 (FOXC1) is a transcription factor which has shown involvement in tumorigenesis in multiple neoplasms. To our knowledge, TROP2 and FOXC1 expression in uLMS has not yet been investigated.
Methods: The expression of TROP2 and FOXC1 was evaluated by immunohistochemistry in 57 uLMS. The reactivity of both markers was calculated as H-score = (1+ staining x % cells) + (2 + staining x % cells) +(3 + staining x % of cells) ranging from 1-300. Overall survival (OS) curves were obtained using the Kaplan-Meier method and comparisons were made with the log-rank test. Statistical significance was assumed at $p < 0.05$. Analysis was performed using IBM SPSS Statistics 29.0.2.0.
Results: TROP2 positivity was seen in 19% (11/57) of uLMS. The H-score ranged from 15 to 300 (mean: 130). FOXC1 reactivity was identified in 21% of cases (12/57). The H-score ranged from 10 to 230 (mean: 78). The mean survival times for TROP2-positive and FOXC1-positive tumours were lower than tumours that were negative for these markers (64.0 versus 103.5 months; 72.7 versus 109 months, respectively). The differences in OS were not statistically significant for expression of either marker (TROP2 p=0.862; FOXC1 p=0.515).
Conclusion: Although significant changes in OS with expression of TROP2 and FOXC1 were not identified, the average survival was shorter in TROP2 and FOXC1-positive tumours compared with negative cases in our small study. In light of recent trials of targeted therapy for TROP2 and FOXC1 in breast, gastrointestinal, and other cancers, further investigating the expression of these markers in uLMS would be beneficial.

PS-17-020
Placental pathology in maternal diabetes mellitus according to Amsterdam classification
J. Korolczuk[1], E. Poniedziałek-Czajkowska[2], I. Korolczuk[3], A. Korolczuk[4]
[1]University Hospital, Department of Pathomorphology, Cracow, Poland, [2]Medical University of Lublin, Department of Obstetrics and Perinatology, Lublin, Poland, [3]Medical University of Lublin, Chair and Department of Psychology, Lublin, Poland, [4]Medical University of Lublin, Department of Clinical Pathomorphology, Lublin, Poland

Background & Objectives: Gestational diabetes mellitus (GDM) is associated with increased risks of serious adverse outcomes: congenital anomaly, stillbirth, neonatal death, preterm delivery, large for gestational age infants and neonatal intensive care unit admission. Diabetes developing in early pregnancy affects mainly the structure of the placenta while its onset in late pregnancy disturbances mainly placental function. The aim of this study was the analysis of placental abnormalities in pregnant women with GDM and their association with the state of the foetus at birth.
Methods: 124 pregnant women with confirmed GDM and 80 non-diabetic patients were included in the study. Patients with preexisting diabetes and those with associated pathologic conditions (such as hypertension, autoimmunologic diseases) were excluded. Clinical data were obtained from medical files. Placenta was collected at the time of delivery. Macroscopic examination, sampling and microscopic examination were conducted according to guidelines of Amsterdam Placental Workshop Group Consensus.
Results: In both GDM groups majority of gestational diabetes was diagnosed in the second pregnancy. Most deliveries were in the third trimester. Gross findings included: increased placental weight, abnormal umbilical cord insertion and increased coiling. Foetal vascular malperfusions (FVM) dominated among microscopic findings being statistically significant. Impaired villous maturation: delayed villous maturation and distal villous hypoplasia were present.
Conclusion: Several abnormalities are reported in association with FVM, and these include a variety of foetal/neonatal pathologies. As FMV are reported in GDM, pathologic examination of the placenta by experienced histopathologist may direct the further management of the baby and mother.

PS-17-021
Detection of POLE mutations in endometrial carcinomas: bridging histopathology and deep learning algorithms
F. Alberto[1], F. Aguirre Neira[1], V. Escobedo Rodríguez[1], A. Reques Llanos[1], S. García Hernandez[1], R. Carreras Salas[1], D. Zamora Atenza[1], J.C. Ferreres Piñas[1], I. Costa Trachsel[1]
[1]Hospital Universitari Parc Taulí, Institut d'Investigació i Innovació Parc Taulí (I3PT), Universitat Autònoma de Barcelona, Pathology, Sabadell, Spain

Background & Objectives: Analysis of POLE mutations in endometrial carcinomas(ECs) is cost-limiting and not available worldwide. We have characterized histopathological features of the molecular classes of EC(POLEmut, MMRd, p53abn and NSMP), and performed a proof-of-concept analysis using deep learning(DL) classifier models to identify POLE mutation status from H&E images.
Methods: Anonymized whole H&E slides from 119 ECs of our institution, molecularly classified (51/42,86% NSMP, 34/28,57% MMRd, 23/19,33% p53abn, 11/9,24% POLEmut), were reviewed (glandular outlines, solid areas, squamous differentiation, atypia, giant cells, intratumoral lymphocytes, MELF, necrosis, lymphovascular invasion (ILV), atypical mitosis and aberrant differentiation) with histological diagnosis and molecular class prediction. Concurrently, we took pictures (20x) from a balanced distribution of 20 ECs per class (adding POLEmut from the public database) and created a dataset for POLEmut and POLEwt (wild type), applying supervised transfer learning using two DL free platforms (Google's Teachable Machine(TM) and Apple's Create ML(CML).
Results: Molecular groups exhibited histopathological heterogeneity, with significant distribution (p<0,05) for glands with smooth (96%NSMP/43%p53abn) or irregular outlines

(65%p53abn/24%NSMP), marked atypia (70%p53abn/16%NSMP), giant cells (57%p53abn/4%NSMP), necrosis (52%p53abn/8% NSMP), ILV (70%p53abn/27%NSMP), mitosis (70%p53abn/8%NSMP) and aberrant differentiation (27%POLEmut/2%NSMP/9%p53abn). The right histological diagnosis was reached in 82%, higher in p53abn (87%) and lower in POLEmut (73%). The molecular prediction was 50%, higher in p53abn (83%) and lower in POLEmut (18%) and MMRd (26%). Regarding DL platforms, TM achieved an overall accuracy of 0,95 (0,98 for POLEmut and 0,93 for POLEwt), with less than 10% of misclassifications. CML displayed less overall accuracy 0,88 (POLEmut:0.82 and POLEwt: 0,90) but several advantages such as ability to explore the misclassified images or many adjustable parameters.
Conclusion: ECs present histopathological features allowing a subtype diagnosis but insufficient to accurately predict molecular class. However, DL models exhibit potential usefulness and viability for POLEmut detection on H&E images that could serve as a selection approach for molecular analysis.

PS-17-022

Vulvar Squamous Cell Carcinomas (VSCC) with both immunohistochemical p16-overexpression and aberrant p53 immunostaining *"Double-Positive"* tumours molecularly belongs to HPV-independent *TP53*-mutated molecular subtype

L.-C. Prof. Horn[1], B. Gilks[2], G.G.R. Hiller[1], M. Stiller[1], L. Hoang[3], A.K. Hoehn[1]
[1]University Hospital of Leipzig, Institute of Pathology, Leipzig, Germany, [2]Vancouver General Hospital, Department of Pathology, Vancouver, Canada, [3]Vancouver General Hospital, University of British Columbia, Department of Pathology, Vancouver, Canada

Background & Objectives: There is increasing impact of molecular subclassification of vulvar squamous cell carcinomas (VSCC). The molecular approach subclassifies VSCC into tumours that arise secondary to high-risk human papillomavirus infection (HPV-associated, or HPVA) and those that arise independent of HPV (HPVI), defining three molecular subtypes of VSCC (HPVa, HPVi p53 abnormal, and HPVi p53 wild type). In the majority of cases, molecular subtyping belongs on immunohistochemical staining for p16 and p53 using pattern based analysis of staining results. VSCC representing both p16-overexpression and p53-aberrant staining cannot classified into molecular subtypes by immunohistochemistry alone.
Methods: Histopathological and immunohistochemical evaluation (p16, p53) as well as mutational analysis by next generation sequencing performed on HPV high-risk DNA negative (HPVI) VSCC.
Results: Seven cases were available with a mean age of 72.6 years of age (range 43 to 8 years). All cases represented block-like overexpression for p16 as well as aberrant p53-immunoepression (parabasal/diffuse overexpression, null staining, aberrant cytoplasmatic) within the keratinising and non-keratinising invasive tumour cell nests. All tumours were negative for HPV-DNA and showed pathogenic *TP53*-mutation on NGS-analysis. Two cases represented additional pathogenic mutation of *PIK3CA*.
Conclusion: VSCC representing both p16-overexpression and aberrant (mutation type) p53-immunostaining cannot be classified by immunohistochemistry alone. Mutational analysis represent *TP53*-mutation indicating that immunohistochemical "double-positive" VSCC belongs to HPVI-VSCC, p53 abnormal subtype.

PS-17-023

Correlation of DICER1 immunohistochemistry and mutational status in a large cohort of ovarian sex cord-stromal tumours

A. Šafanda[1], N. Hájková[1], Q.H. Bui[1], M. Flídrová[1], M. Kendall Bártů[1], R. Jakša[1], P. Dundr[1], K. Němejcová[1]
[1]Institute of Pathology, First Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czech Republic

Background & Objectives: *DICER1* is an essential gene involved in microRNA processing via RNA interference, and its mutations are associated with a wide range of neoplastic conditions, including ovarian sex cord-stromal tumours. We analysed a large cohort of these tumours, focusing on the correlation between molecular and immunohistochemical status, assessing the potential diagnostic value of DICER1 immunohistochemistry.
Methods: We examined and correlated 249 ovarian sex cord-stromal tumours, including 214 adult granulosa cell tumours (AGCT), 5 juvenile granulosa cell tumours (JGCT), and 30 Sertoli-Leydig cell tumours (SLCT). Immunohistochemistry (IHC) was performed on tissue microarrays and verified on whole tissue sections in equivocal cases. Molecular analysis was carried out using DNA-based next-generation sequencing (NGS). Additionally, RNA-based NGS was performed in all SLCT cases, all of which were eligible for expression profiling.
Results: Among AGCT, two cases harboured *DICER1* mutations - one with positive and one with negative IHC expression. Additionally, three *DICER1*-wildtype AGCT showed positive IHC staining. All five JGCT were *DICER1*-wildtype and IHC-negative. Among the 30 SLCT, 16 (53%) had *DICER1* mutations; of these, 15 (94%) demonstrated positive IHC expression. One SLCT with *DICER1* mutation was IHC-negative. Among the 14 *DICER1*-wildtype SLCT, one case (7%) showed IHC positivity, while the rest were negative.
Conclusion: Our study supports the potential utility of DICER1 IHC as a surrogate marker in SLCT. In contrast, no consistent correlation was observed in AGCT and JGCT. These findings indicate that IHC may serve as a practical and cost-effective alternative when molecular testing is not available; however, further validation is required to confirm these results.

Background & Objectives: Endometrial hyperplasia (EH) is recognized as a precursor to endometrial carcinoma, with classification into typical endometrial hyperplasia (TEH) and atypical endometrial hyperplasia (AEH) based on histopathological features. Accurate differentiation between these subtypes is essential for guiding clinical decision-making and stratifying patients at risk for malignant transformation. This study evaluates the expression of PTEN, PAX2, P53, Ki67, and beta-catenin as potential biomarkers to enhance diagnostic accuracy in differentiating typical from atypical endometrial hyperplasia, specifically within the context of the Bulgarian population and its associated risk factors.
Methods: A total of 150 endometrial biopsy specimens were analysed, divided into three groups**:** Group 1 (Control, n=50)**,**consisting of normal proliferative and secretory endometrium; Group 2 (TEH, n=50), with histologically confirmed typical endometrial hyperplasia and Group 3 (AEH, n=50), comprising cases with nuclear atypia. Immunohistochemistry (IHC) was performed on formalin-fixed paraffin-embedded (FFPE) tissue to evaluate the expression of PTEN, PAX2,

P53, Ki67, and beta-catenin. Biomarker expression was semi-quantified based on staining intensity and the percentage of positive cells.
Results: Loss of PTEN and PAX2 was observed in 72% of AEH cases, compared to only 8% in TEH . The Ki67 proliferation index was significantly higher in AEH. Aberrant P53 expression, including overexpression or complete loss, was found in 24% of AEH cases, whereas TEH exhibited wild-type expression. Additionally, beta-catenin nuclear accumulation was detected in 38% of AEH cases, while no nuclear staining was observed in TEH or normal endometrium.
Conclusion: Loss of PTEN and PAX2, increased Ki67, aberrant P53 expression, and beta-catenin nuclear accumulation are significantly associated with AEH and may serve as reliable biomarkers for distinguishing atypical from typical hyperplasia, enhancing early detection and risk stratification for endometrial carcinoma.

PS-17-025

Deciphering tumour heterogeneity of ARID1A expression in Endometrial Carcinomas using histogram based digital pathology

T. Rau[1,2], M. Simons[3], M.M. Anokhina[1], E. Vasella[2], F. Siegenthaler[4], S. Imboden[4], M.D. Mueller[4], M. Fix[1,3]
[1]Institute of Pathology, Heinrich-Heine-University and University Hospital, Düsseldorf, Germany, [2]Institute of Tissuemedicine and Pathology, University Bern, Bern, Switzerland, [3]Radboud University Medical Centre Nijmegen, Pathology, Nijmegen, The Netherlands, [4]University Hospital Inselspital Bern, Gynaecology and Obstetrics, Bern, Switzerland

Background & Objectives: Beyond accurate risk stratification in endometrial carcinomas (EC) by molecular classification further biomarkers like *ARID1A* mutation emerge as potential therapeutical targets. Compared NGS and digital pathology analysis seeks to assess the most reproducible approach to biomarker quantification, reducing interobserver variability. This study aims to tackle ARID1A expression patterns with respect to intratumoral heterogeneity in EC.
Methods: A total of 63 EC cases from the University Hospital Bern with known molecular status by TSO 500 sequencing were analysed for ARID1A expression using immunohistochemistry. Staining percentages and intensity were quantified using QuPath using intensity histograms as novel interpretation tool. Cases were classified as homogeneous or heterogeneous based on the presence of a bimodal intensity distribution.
Results: Among the 60 cases, 28 (46.6%) exhibited bimodal intensity histograms, indicating intratumoral heterogeneity in ARID1A expression with this novel approach. These cases showed distinct subpopulations with varying staining intensities, suggesting potential biological differences or subclones within tumours. The remaining 32 (53.3%) cases displayed a homogeneous expression pattern with n=14 (23.3%) showing a clear loss and n=18 (30%) retained staining. As expected, concordance between *ARID1A* mutational status was higher in homogenous than heterogenous cases.
Conclusion: QuPath successfully identified tumour heterogeneity in EC through intensity histogram analysis, demonstrating its potential as a tool for refining biomarker-driven risk stratification. The detection of bimodal expression patterns may provide additional insights into tumour biology with implications for NGS testing. Future studies should focus on standardizing digital pathology protocols and expanding analyses to other biomarkers to further enhance clinical applicability.

PS-17-026

Molecular profiling of endometrial precursor lesions according to the four molecular subtypes

T.T. Rau[1], M.M. Anokhina[1], V.M. Wildhagen[1], S.M. Sheikh[1], R. Bolotin[2], E. Ruckhaeberle[3], W. Meier[3], T. Fehm[3], Y. Güven[1]
[1]Institute of Pathology, Heinrich-Heine-University and University Hospital, Düsseldorf, Germany, [2]Clinic of Gynaecology and Obstetrics, EVK Mettmann, Mettmann, Germany, [3]Clinic of Gynaecology and Obstetrics, Heinrich-Heine-University and University Hospital, Düsseldorf, Germany

Background & Objectives: Endometrial cancer (EC) ranks as the second most prevalent gynaecological malignancy. The Cancer Genome Atlas (TCGA) has identified molecular subtypes that are essential for determining risk levels and guiding treatment choices. Current insights into the molecular changes in endometrial precursor lesions are still limited in existing research, primarily due to their infrequent occurrence in pathological records and the small sample sizes.
Methods: We conducted a comprehensive histopathological and molecular examination of so far 15 precursor lesions using immunohistochemistry (p53, MSH6, PAX2, PTEN, L1CAM, PMS2), and a targeted NGS panel (POLE, PTEN, TP53, CTNNB1, MLH1, MSH2, MSH6, PMS2) on laser-capture microdissected areas and in corresponding tumour areas and metaplastic lesions, if applicable.
Results: Out of these 15, one case was POLEmut, one MMRd, 10 NSMP and 3 cases P53abn, respectively. Of note, MMR protein loss was rarely found to occur even in ciliated metaplastic epithelia prior to obvious atypia. Additionally, we discovered pathogenic PTEN mutations in 7 atypia and 2 tumour samples.
Conclusion: Our results are consistent with emerging evidence that molecular subtypes arise early in the process of carcinogenesis. Furthermore, precursor lesions contain the complete range of molecular subtypes observed in endometrial carcinoma. The predominance of PTEN alterations and the rarity of POLE mutations in our cohort suggest distinct pathways for early tumour development, with implications for fertility-preserving management strategies in future research

PS-17-027

Epithelial-mesenchymal Transition (EMT) immunophenotype is more common in the prognostic poor $p16^{-ve}/p53^{abn}$ molecular subtype of vulvar squamous cell carcinoma

A.K. Höhn[1], C.E. Brambs[2], M. Mende[3], M. Höckel[4], C. Eckey[1], G.G.R. Hiller[1], L.-C. Horn[1]
[1]Institute of Pathology, Division of Breast Gynaecologic & Perinatal Pathology, Leipzig, Germany, [2]Luzerner Kantonsspital, Obstetrics and Gynaecology, Lucerne, Switzerland, [3]Institute of Medical Information, Statistics and Epidemiology, University of Leipzig, Leipzig, Germany, [4]University Hospital of Leipzig, Obstetrics and Gynaecology, Leipzig, Germany

Background & Objectives: Epithelial-mesenchymal transition (EMT) is associated with increased metastatic spread. Data on vulvar carcinoma are limited. Dissociative tumour growth and strong peritumoral stromal remodelling has been shown to be associated with epithelial-to-mesenchymal transition (EMT) in VSCC (Holthoff et al. 2016, Rofrigues et al. 2013). mounting evidence that EMT plays an essential role in lymphatic spread (Campo et al. 2015). Some of the most validated markers to identify cells undergoing EMT are vimentin, e-cadherin and cyclin D1.
Methods: Thirty-two squamous cell carcinoma of the vulva were evaluated for immunohistochemical expression of EMT-markers (vimentin, cyclin D1, e-cadherin) using immunoreactive score (IRS). Overall staining scores were compared to the molecular subtypes of vulval carcinoma, defining $p16^{+ve}/p53^{wt}$ and $p16^{-}ve/p53^{mut}$ VCX.
Results: Staining for vimentin and cyclin D1 was seen within tumour cells at the front of invasion in 100% and 84.4% of the tumours, respectively. The majority of cases (68.7%) showed negative or reduced staining for e-cadherin. $p16^{-}ve/p53^{abn}$ represented higher expression of the EMT markers vimentin (4.5 versus 0; p=0.03) and cyclin D1 (7 versus 5; p=0.87) without differences in e-cadherin (6 versus 3; p=1.0) when compared to $p16^{+ve}/p53^{wt}$ VCX.

Conclusion: The present study indicates an EMT-phenotype in p16^{-}ve/p53^{mut} VCX which may represent one driver for the prognostic poor outcome in that molecular type of VCX.

PS-17-028

Multi-parameter characterisation of disseminated tumour cells (DTCs) in patients with cervical carcinoma

A.K. Höhn[1], E. Brochwitz[2], L. Weydandt[2], N. Dornhöfer[2], K. Winter[3], B. Aktas[2], I. Nel[2]

[1]University Hospital Leipzig, Institute of Pathology, Division of Breast Gynaecologic & Perinatal Pathology, Leipzig, Germany, [2]University Hospital Leipzig, Department of Obstetrics & Gynaecology, Leipzig, Germany, [3]Institute of Anatomy, Medical Faculty, Leipzig, Germany

Background & Objectives: While disseminated tumour cells (DTCs) are associated with an unfavourable prognosis in breast cancer [Hartkopf et al. 2021], their significance in cervical carcinoma remains unclear. Current detection methods are based exclusively on the epithelial marker cytokeratin (CK) without any clear prognostic relevance [Fehm et al. 2014].

Methods: We analysed bone marrow aspirates from 43 patients with early or locally advanced cervical carcinoma. A two-stage multiparameter immunofluorescence (IF) staining method was developed to characterise the DTCs. This allowed the five different markers CK, vimentin, p16, PD-L1 and VEGF to be analysed on the same cell. Corresponding tumour tissue samples were stained against p16, VEGF and PD-L1 and compared with the expression in the DTCs.

Results: The DTC positive rate was 74% (32/43 patients). A total of 248 DTCs were found, with a median cell count of 7 DTCs (range: 1-17) per patient. Overall, 27% (68) of the cells were CK+, 85% (211) Vim+, 20% (49) VEGF+, 11% (27) PD-L1+ and 21% (53) p16+. We were able to identify 22 different DTC subpopulations. Vim+-only DTCs (54 %) were the most frequent, followed by CK+-only (12 %), the combination Vim+/VEGF+/p16+ (7 %), CK+/Vim+/VEGF+/p16+ (4 %) and CK+/Vim+ DTCs (4 %). Spearman rank correlation showed that the presence of Vim+ was significantly negatively correlated to the presence of CK+ on the same cell ($r = -0.529$, $p < 0.001$). In addition, the expression of p16+ on the DTCs correlated significantly positively with VEGF+ ($r = 0.631$, $p < 0.001$) and PD-L1+ ($r = 0.323$, $p < 0.001$). Comparison of the expression of VEGF, p16 and PD-L1 in tumour tissue vs. DTCs (n=28) revealed discordance rates between 43-64%.

Conclusion: The majority of DTCs were of the mesenchymal type (Vim+). The prognostic relevance of individual DTC phenotypes will be analysed in more detail by correlation with clinical data.

PS-17-029

Neuroendocrine marker and thyroglobulin expression in mesonephric and mesonephric-like carcinomas: implications for diagnosis

J. Mirkovic[1,2], E. Olkhov-Mitsel[1], L. Abdul-Karim[1,2], F.-I Lu[1,2], S. Nofech-Mozes[1,2], WG. McCluggage[3]

[1]Sunnybrook Health Sciences Centre, Division of Anatomic Pathology, Department of Laboratory Medicine and Molecular Diagnostics, Precision Diagnostics and Therapeutics Program, Toronto, Canada, [2]University of Toronto, Laboratory Medicine and Pathobiology, Toronto, Canada, [3]Belfast Health and Social Care Trust, Department of Pathology, Belfast, United Kingdom

Background & Objectives: This study examines the expression of neuroendocrine markers (chromogranin, synaptophysin, CD56, and INSM1) and thyroglobulin in ovarian and endometrial mesonephric-like adenocarcinoma (MLA) and cervical mesonephric carcinoma (MA). As these tumours share morphologic and immunohistochemical features with other gynaecologic carcinomas, understanding their immunoprofile is important to avoid diagnostic pitfalls.

Methods: The study cohort included 14 MLAs and 5 MAs from two institutions. Immunohistochemical staining (distribution and intensity) for chromogranin, synaptophysin, CD56, INSM1, and thyroglobulin was performed on whole-tissue sections.

Results: CD56 was the most frequently expressed neuroendocrine marker, detected in 14/18 (82.3%) cases, with up to 70% expression. Synaptophysin was positive in 8/19 (42.1%) cases with up to 30% expression. Chromogranin was positive in 5/19 (26.3%) cases, with staining up to 30%, while INSM1 was expressed in 4/18 (22.2%) cases, with positivity up to 20%. Thyroglobulin expression was more uncommon, identified in only 2/13 (15.4.%) cases (2% and 5% in ovarian MLAs).

Conclusion: Similar to other gynaecological adenocarcinomas, a subset of MLAs and MAs exhibit neuroendocrine marker expression, which should be recognized and not misinterpreted as evidence of a neuroendocrine neoplasm. Rare cases exhibit focal thyroglobulin positivity and this presents a diagnostic pitfall, especially in an ovarian neoplasm exhibiting TTF1 positivity (often positive in MLA) when the differential diagnosis may include malignant struma ovarii or metastatic thyroid carcinoma.

PS-17-030

PD-1 expression in the tumour microenvironment of endometrial cancer depending on MMR status

S. Vtorushin[1], A. Kalinchuk[2], A. Malsteva[3], L. Kolomiets[3], L. Tashireva[2]

[1]Cancer Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Department of General and Molecular Pathology, Tomsk, Russia, [2]Cancer Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Laboratory of Molecular Cancer Therapy, Tomsk, Russia, [3]Cancer Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Gynaecology Department, Tomsk, Russia

Background & Objectives: Endometrial cancer is a common malignancy of the female reproductive system affecting women globally. In recent years, the role of the tumour microenvironment in the development and progression of this disease has been actively studied. The aim of the study was to investigate the expression patterns of PD-1 on immune cells in the microenvironment of MMR-proficient and MMR-deficient endometrial cancers.

Methods: The study included 44 patients with endometrial cancer (34 – pMMR, 10 – dMMR). Immunohistochemical assessment of MMR status was performed on the Ventana BenchMark ULTRA platform using antibodies: MLH1, PMS2, MSH2, MSH6. Multiplex tyramide signal amplification immunofluorescence was used for tumour microenvironment phenotyping. This was performed using the BOND RXm automated stainer, primary antibodies against CD8, PD-1, CD20, CD163, FoxP3. The number of CD8+ cells, CD20+ cells, CD163+ macrophages, and FoxP3+ T-regulatory cells in the tumour stroma was quantified, along with PD-1 expression.

Results: In pMMR tumours, the predominant cell population was CD163+ macrophages, followed by CD8+ T cells, FoxP3+ T cells, and CD20+ B cells ($p=0.0001$). In dMMR tumours, the numbers of CD163+ , CD8+, and CD20+ cells did not differ, while FoxP3+ T cells were the least abundant ($p=0.0210$). PD-1 expression was equally rare and low in FoxP3+ T cells and CD163+ macrophages ($p=0.1820$, $p=0.3605$, respectively). The proportion of PD-1-expressing CD8+ T cells did not differ between MMR statuses ($p>0.05$). In dMMR endometrial cancer, there was a significant increase in PD-1-expressing CD20+ B cells compared to pMMR tumours ($p=0.0003$).

Conclusion: This study found that PD-1 expression occurs on all studied cell types in the tumour microenvironment. However, PD-1 expression on CD20+ B cells is more characteristic of MMR-deficient

tumours, which may be associated with a better response to immunotherapy. These results highlight the need for further research into the endometrial cancer microenvironment to personalize therapy and develop effective predictive biomarkers.

Funding: The study was supported by the Russian Science Foundation (grant # 20-75-10033-P)

PS-17-031

Integrative analysis of histopathological subtypes and PD-L1 status in high-grade serous ovarian carcinoma: correlations with clinicopathologic features and survival outcomes

M. Ayyıldız Mercan[1], T.D. Yalta[1], İ. Bayrakçı[2]
[1]Trakya University, Department of Pathology, Edirne, Turkey, [2]Trakya University, Department of Oncology, Edirne, Turkey

Background & Objectives: High-grade serous ovarian carcinoma(HGSOC) is divided into four gene expression-based subtypes. Murakami et al. created a new histopathological classification with each molecular subtype. We aimed to classify HGSOCs into histopathological subtypes and to compare the subtypes with PDL-1 status and clinicopathological prognostic parameters.
Methods: 158 cases between 2007-2021 were included in the study. Clinicopathologic findings were noted. Platinum-free interval(PFI), progression-free survival(PFS), and overall survival(OS) data were obtained from follow-up at the oncology clinic. The tumour was divided into four subtypes as mesenchymal(MT), immunoreactive(IR), solid proliferative(SP) and papilloglandular(PG) by (1)evaluating the infiltrative pattern in the desmoplastic stroma, (2)intratumoral and stromal lymphocyte count, (3)solid pattern and (4)cribriform glandular pattern. The cases were also named with a binary classification system as mesenchymal(MT) and non-mesenchymal(n-MT) subtype. Immunohistochemically, CD8/144B mouse monoclonal IgG1 and PD-L1 22C3 clone antibody kit were applied.
Results: 141 cases (34 MT,16 IR,33 SP,58 PG) were followed up at our centre. There was a significant difference between subtypes and PFI, with a higher number of MT cases in the group with PFI <6 months(p=0.012). There was no significant difference in PFS and OS among the four subtypes(p=0.100,p=0.094). In pairwise comparison analysis MT subtype had a statistically significant shorter PFS than SP subtype(p=0.022) and MT subtype had statistically shorter OS than SP and PG subtype(p=0.024,p=0.048). According to the binary histopathological classification, PFS(p=0.022) and OS(p=0.014) of the MT subtype(n=34) were significantly worse than the n-MT(n=107) subtype. A significant association was found between PD-L1 positivity and IR subtype(p=0.002).
Conclusion: Since molecular methods are difficult to access and costly, a histopathological classification that offers prognostic prediction and individualized treatment is valuable. The binary classification system (rather than four subtypes) may enhance reproducibility and improve prognostic prediction in HGSOC. This classification system and its association with PD-L1 status and IR subtype could facilitate personalized treatment strategies in future clinical practice.

Funding: This study has been supported by the 'Trakya University Scientific Research Projects Unit' under grant number: 2023/182

PS-17-032

Reclassification of endometrial carcinoma by the implementation of a 161-gene NGS panel

M. Gomez Dorronsoro[1], M.C. Caballero Martínez1,[1], A. Yagüe Hernando1[1], A. De Oliveira Gomes1,[1], L. Ruiz Estigarribia1[1], M.L. Alvarez Gigli[1], P. Fernández Seara[1], J.C. Muruzabal Torquemada[2], D. Guerrero Setas[3]
[1]Hospital Universitario de Navarra (HUN), Pathology, Pamplona, Spain, [2]Hospital Universitario de Navarra (HUN), Gynaecology, Pamplona, Spain, [3]Hospital Universitario de Navarra (HUN), Molecula Pathology Cancer Group, Navarrabiomed, Pamplona, Spain

Background & Objectives: Endometrial cancer (EC) comprises four TCGA-molecular prognostic groups, i.e. Polimerase-Ɛ (*POLE*)-mutant, mismatch-repair (MMR)-deficient, *TP53*-abnormal and "no specific molecular profile" (NSMP) EC. These groups are integrated into ESGO-ESTRO-ESP and WHO guidelines. The NSMP group is clinically heterogeneous and the detection of new molecular parameters is mandatory. Our objective is to evaluate this group by a Next-Generation-Sequencing (NGS) panel composed of 161 genes.
Methods: The group of study consists of endometrial biopsies from 77 women diagnosed of endometrioid, serous and clear cell EC. The patients were classified according to MMR and TP53 expression by IHC and the presence of POLE mutations by NGS in all the patients. Targeted DNA/RNA-based NGS was considered to identify single nucleotide variants (SNVs), insertions and deletions (indels), copy number variations (CNVs) and fusions using the 161-gene-panel *Oncomine™ Comprehensive.v3 (*OCAv3*), Chef-ready library panel (ThermoFisher Scientific*) with automatic workflow.
Results: We found five (6.5%), 20 (25.9%), 13 (16.9%) and 37 (48.1%) cases were of *POLE*-mutant, mismatch repair (MMR)-deficient, *TP53* abnormal and NSMP EC, respectively. Two cases (2.6%) were *MMR-deficient/TP53* abnormal. Two out of five POLE-mutant cases displayed PMS2 and MSH2 mutations detected only by NGS. In NSMP EC group, NGS helped to find nine cases (24.0%) with TP53 mutations that had not been not identified by IHC. Among the alterations detected in this group, we found PIK3CA mutations at exons 10 and 21 in 8 patients (21.6%) and 1 patient with KRAS p.Gly12Cys mutation (2.7%), actionable in other type of tumours.
Conclusion: NGS allows the detection of unexpected TP53 mutations and hence the reclassification of patients from NSMP EC group into TP53-mutant EC. It also makes possible to find additional gene variants of possible clinical value that have been proved to be of clinical value in other types of tumours, i.e. PIK3CA and KRAS G12C mutations.

PS-17-033

Endometrial cancer and mismatch repair deficiency: are we missing Lynch syndrome cases?

A.E. Akın[1], A. Oruç[1], T.A. Erdoğdu[2], C.D. Durmaz[2], D. Ateş[1], A. Usubütün[1]
[1]Hacettepe University, Pathology, Ankara, Turkey, [2]Hacettepe University, Medical Genetics, Ankara, Turkey

Background & Objectives: Lynch syndrome is a hereditary cancer syndrome linked to mismatch repair (MMR) gene defects. MMR deficiency occurs in approximately 30% of endometrial cancers. MLH1 loss can also occur due to hypermethylation. Patients with non-methylated MLH1 loss or MSH6/MSH2 loss should be screened for Lynch syndrome. This study evaluates the effectiveness of our institutional algorithm and clinical awareness.
Methods: We reviewed biopsy reports of 970 endometrial cancer patients (between 2020–2024), analysing immunohistochemical MMR status, MLH1 hypermethylation, and Lynch syndrome genetic evaluations.
Results: Among 970 patients, 244 (25.2%) had MMR deficiency, with a mean diagnosis age of 59.8 years (26–84). MLH1 expression was preserved in 44 cases, while 200 showed MLH1 and PMS2 loss. MLH1 methylation was assessed in 120 cases, revealing 14 (11.6%) non-methylated cases.
Of 58 expected referrals, only 22 patients (8 PMS2-MLH1 loss, 7 MSH2-MSH6 loss, 4 MSH6 loss, 2 PMS2 loss, 1 MSH6-PMS2-MSH2 loss) attended genetic counselling. Genetic results were unavailable

for 5 cases. Six tested negative, one had hypermethylated MLH1, and one was under investigation. A hereditary cancer-related mutation was identified in 9 patients.
Conclusion: Among 244 MMR-deficient cases, 200 had MLH1 loss, yet 80 (40%) were not tested for MLH1 hypermethylation. Of those tested, 14 (11.6%) were non-methylated. Despite identifying MMR-deficient patients and informing clinicians, awareness regarding MLH1 hypermethylation and hereditary cancer screening remains low. This study highlights the need for improved clinician awareness and patient education, particularly in developing countries, to ensure appropriate testing and genetic counselling. Social awareness initiatives may be crucial in increasing Lynch syndrome detection and protecting future generations.

PS-17-034
Clinical, morphological and age-related features of HSIL/LSIL and cervical cancer
A. Filin[1], V. Pozhidaeva[2], I. Sertakov[1], V. Danilenko[1], E. Chupandina[1], A. Bobrovskikh[1], M. Bobrovskikh[1], E. Verbitskaya[1], A. Goryacheva[1], E. Ulitina[1], D. Bugrimov[1], N. Tashmatova[3], K. Sakibaev[3]
[1]Voronezh State Medical University, Department of Pathological Anatomy, Voronezh, Russia, [2]Voronezh State Medical University, Department of Oncology, Voronezh, Russia, [3]Osh State University, Department of Anatomy, Histology and Normal Physiology, Osh, Kyrgyzstan

Background & Objectives: The annual increase in the number of cervical cancer (CC) cases shows the urgent need to step up diagnostic and preventive measures among women of different age groups. Currently, the morphogenesis of CC has not been fully studied, modern concepts are based on the viral theory of oncogenesis, that is, the sequence of changes from dysplasia to cancer. The aim of the work was to study the clinical and morphological features of dysplasia and CC in women of different age groups.
Methods: The conclusions of pathologists from the regional pathology bureau in patients with dysplasia and CC were studied. Age groups (by decades of life), the area of the tumour and the depth of invasion were assessed.
Results: The number of cases of dysplasia and CC increases with age, with CC being 10-15 years late (dysplasia peak 30-39 y.o., CC peak 40-49 y.o.). The incidence of HSIL was about 10 times higher than LSIL. In age groups over 50 years of age, there is a decrease in the incidence of dysplasia, despite the fact that CC rates are decreasing slightly. The average size of the cancer site and the depth of invasion were almost the same in all age groups. More often these are tumours up to 2 sq.cm in size, large sizes are rare. With increasing age, this feature persists, there is no shift towards increasing the size of the tumour or the depth of invasion in older age groups.
Conclusion: The peak incidence of LSIL/HSIL is observed in the 30-39-year-old group, CC - in the 40-49-year-old group. The lesion area and depth of invasion in CC do not show the expected increase with increasing age of patients, which indicates the non-linearity of cancer development, which makes it difficult to apply screening approaches.

PS-17-035
Pseudocarcinomatous epithelial hyperplasia of the fallopian tube: a comprehensive clinicopathological study of 31 cases
Y.A. Cho[1], C.K. Park[2], H.-S. Kim[1]
[1]Samsung Medical Centre, Department of Pathology and Translational Genomic, Seoul, Republic of Korea, [2]Seegene Medical Foundation, Pathology Centre, Seoul, Republic of Korea

Background & Objectives: The aim of this study was to investigate the clinicopathological features of pseudocarcinomatous epithelial hyperplasia (PCEH) of the fallopian tube. We provide a detailed description of the histological and immunophenotypic characteristics of tubal PCEH to help pathologists differentiate it from its mimickers, including high-grade serous tubal carcinoma (HGSC) and serous tubal intraepithelial carcinoma (STIC).
Methods: Between January 2019 and December 2023, we identified cases diagnosed as PCEH, HGSC, or STIC from the institutional database. Clinical information was collected through a review of electronic medical records. Immunostaining for CK7, p53, and Ki-67 was performed.
Results: Twelve patients with PCEH were included in the study. The ages of the patients ranged from 20 to 45 years, with six patients having a prior history of pelvic inflammatory disease. Histologically, PCEH demonstrated significant epithelial proliferation with papillary and cribriform architecture, nuclear stratification, crowding, and mild-to-moderate nuclear atypia. An intense inflammatory response was observed in all PCEH cases. Most cases lacked mitotic figures and showed a low Ki-67 labelling index, whereas both HGSC and STIC exhibited brisk mitotic activity and high Ki-67 labelling indices. In contrast to the aberrant p53 expression seen in HGSC and STIC, all PCEH cases exhibited a wild-type pattern of p53 immunostaining.
Conclusion: Due to its rarity, the correct diagnosis of PCEH can be challenging. Key diagnostic features, including the absence of high-grade nuclear atypia, low mitotic activity, and a wild-type p53 expression pattern, can help distinguish PCEH from other entities. These characteristics should be carefully considered to ensure accurate diagnosis and appropriate management for patients with PCEH.

PS-17-036
Reevaluation of the prognostic value of CRS in the context of homologous recombination deficiency and maintenance therapies
M.T. Dawid de Vera[1], B. Montero Balaguer[2], I. Rey Ferreira[3], M. Arnáez de la Cruz[4], S. Domingo del Pozo[4], V. Lago Leal[3]
[1]Health Research Institute Hospital La Fe, Pathology, Valencia, Spain, [2]University and Polytechnic La Fe Hospital, Pathology, Valencia, Spain, [3]Health Research Institute Hospital La Fe, Gynaecologic Oncology, Valencia, Spain, [4]University and Polytechnic La Fe Hospital, Gynaecologic Oncology, Valencia, Spain

Background & Objectives: Ovarian cancer is the fifth leading cause of mortality in women, with high-grade serous carcinoma (HGSC) being the most common subtype. When primary surgery is not feasible, neoadjuvant chemotherapy (NACT) followed by interval debulking surgery (IDS) is used, allowing for the evaluation of the chemotherapy response score (CRS).
Omental CRS is the gold standard due to its lower variability and prognostic value with two categories (CRS1/2 and CRS3) proposed for better clinical applicability, although its predictive value remains debated. Approximately 50% of HGSCs exhibit homologous recombination deficiency (HRD), increasing sensitivity to platinum-based chemotherapy. Also, maintenance therapies with bevacizumab (BVZ) or PARP inhibitors (iPARP) improve survival, potentially challenging the independent prognostic value of CRS.
This study aimed to assess the prognostic value of CRS and its relationship with HRD and maintenance therapies.
Methods: A retrospective study was conducted on patients with advanced HGSC undergoing IDS after NACT between 2009 and 2023. Clinical, surgical, and histopathological variables were analysed. A univariate analysis was performed, and progression-free survival (PFS) and overall survival (OS) were assessed using Kaplan-Meier curves and logistic regression.
Results: A total of 132 patients were included. Omental CRS3 was associated with HRD tumours ($p=0.048$) and adnexal CRS ($p<0.001$). Patients with omental CRS3 had higher PFS ($p=0.003$) and OS

(p=0.006). Adnexal CRS showed no prognostic differences. BVZ had no impact on PFS (p=0.8) or OS (p=0.2). Patients with HRD or treated with iPARP had improved PFS and OS, with iPARP use being the only independent prognostic factor.
Conclusion: Omental CRS is associated with better PFS and OS, unlike adnexal CRS. Patients with HRD exhibit better pathological response and prognosis. The use of iPARP is the only independent prognostic factor, questioning the prognostic value of CRS in patients receiving iPARP after IDS.

PS-17-037
Diagnostic significance of PD-L1 and HER2 expression in high-grade serous ovarian carcinoma: an immunohistochemical analysis
M. Kuprytė[1,2], U. Morkūnaitė[2], R. Malonytė[3], M. Masevičienė[3,2], S. Liutkauskienė[3], L. Poškienė[4,1]
[1]Hospital of Lithuanian University of Health Sciences Kauno Klinikos, Pathological Anatomy, Kaunas, Lithuania, [2]Lithuanian University of Health Sciences, Kaunas, Lithuania, [3]Hospital of Lithuanian University of Health Sciences Kauno Klinikos, Oncology and Haematology, Kaunas, Lithuania, [4]Lithuanian University of Health Sciences Kauno Klinikos, Pathological Anatomy, Kaunas, Lithuania

Background & Objectives: High-grade serous ovarian carcinoma (HGSOC) is the most common aggressive subtype of ovarian cancer, often diagnosed at advanced stage. PD-L1 and HER2 protein expression may have diagnostic, prognostic, and therapeutic relevance, yet their role remains unclear. Study objective is to evaluate features of protein expression of these microenvironmental markers.
Methods: Immunohistochemical reactions against PD-L1 (Dako 22C3 clone) and HER2 (SP3 clone) were performed for 97 selected high-grade serous ovarian carcinoma cases. TNM stage, patient's age, and presence of applied neoadjuvant chemotherapy were also investigated. Statistical analysis was applied (p<0.05).
Results: Mean age of patients was 64.36 (10.52) years old (y.o.) with predominant pT3c (52.1%, n=50), followed by 16.7% (n=16) in pT3b, 15.6% (n=15) in pT3a. Considering pN status, pN0 (78.1%, n=75) category was predominant among selected serous ovarian carcinoma cases. PD-L1 expression below 1% was identified in 11.3% cases (n = 11), while intermediate expression (1–49%) was observed in 12.4% cases (n = 12). HER2 1+ staining intensity was detected in 8.2% (n = 8), and strong 3+ expression was present in 4.1% cases (n = 4). Most selected cases were PD-L1-negative (76.3%, n=74) and HER2-negative (87.6%, n=85). Neoadjuvant chemotherapy was applied in 21.6% (n=21) selected cases. Younger patients were more likely to be confirmed with high-grade ovarian serous carcinoma spreading to the local lymph nodes (58.52 (9.35) y.o. vs 66.05 (10.35) y.o.; p=0.002).
Conclusion: This study highlights that the majority of high-grade serous ovarian carcinoma (HGSOC) cases lack significant PD-L1 and HER2 expression, suggesting limited utility of these markers as standalone therapeutic targets in most patients. However, a subset of cases did exhibit intermediate PD-L1 or strong HER2 expression, indicating potential relevance for personalized treatment in selected patients. Additionally, younger patients demonstrated a statistically significant association with lymph node involvement, suggesting a more aggressive disease pattern in this subgroup.

PS-17-038
The correlation of tumour-infiltrating lymphocytes and immune-inflammatory environment with progression-free survival in high-grade serous ovarian carcinoma
S. Miceska[1,2], C. Grašič Kuhar[2,3], S. Frković Grazio[4], E. Škof[2,3], V. Kloboves Prevodnik[1,5]
[1]Institute of Oncology Ljubljana, Department of Cytopathology, Ljubljana, Slovenia, [2]University of Ljubljana, Faculty of Medicine, Faculty of Medicine, Slovenia, [3]Institute of Oncology Ljubljana, Department of Medical Oncology, Ljubljana, Slovenia, [4]University Medical Centre, Department of Pathology, Division of Gynaecology, Ljubljana, Slovenia, [5]University of Maribor, Department of Pathology, Maribor, Slovenia

Background & Objectives: High-grade serous ovarian carcinoma (HGSC) is the most lethal gynaecological malignancy, with limited improvement in survival over recent years and an urgent need for novel prognostic markers. Tumour-infiltrating lymphocytes (TILs) and systemic immune-inflammatory environment have shown potential prognostic value, but their roles and interplay remain poorly understood due to limited and sometimes contradictory evidence. Our objective was to assess TILs and inflammatory scores in HGSC and investigate their association with progression-free survival (PFS).
Methods: Forty-six patients with primary HGSC were included in the study. Intratumoral and stromal CD3+ and CD8+ TILs (iTILs and sTILs) were manually evaluated by immunohistochemistry, following the recommendations of the International Immuno-Oncology Biomarkers Working Group. The systemic immune-inflammation index (SII) and the pan-immune-inflammation value (PIV) were calculated using complete blood-count data obtained at the time of diagnosis. ROC curve analysis was performed to determine optimal cut-off values for categorizing patients into low and high groups for TILs and immune-inflammatory scores, which were then correlated with PFS.
Results: CD3+ and CD8+ sTILs were present with median percentages of 13.67% and 8.50%, with optimal cut-offs of 12.9% and 5.66%, respectively. The median levels of iTILs were below 1.67%. The median values for SII and PIV were 1,466.27 and 919.98, with cut-offs of 912.45 and 423.92, respectively. CD8+ sTILs (p=0.015) and PIV (p=0.018) were significantly associated with PFS, while CD3+ sTILs and SII did not reach significance. Notably, higher CD8+ levels were linked to worse PFS, possibly indicating functional exhaustion. No direct correlation was observed between CD8+ sTILs and either SII or PIV.
Conclusion: CD8+ sTILs and PIV emerged as significant prognostic markers for PFS in primary HGSC. Their independent predictive value underscores the importance of local and systemic immune responses in disease progression; however, larger patient cohorts and multicentric studies are needed to validate and strengthen these findings.

PS-17-040
Uterine inflammatory myofibroblastic tumour: clinicopathological and molecular study emphasizing p16 absence and CDKN2A deletion association with aggressiveness
G. Pereira[1], I. Silvestre[2], D. Doutel[1], S. Mata[1], V. Carneiro[3], M.d.C. Martins[4], A. Félix[1,2], J. Ferreira[1]
[1]Instituto Português de Oncologia de Lisboa Francisco Gentil, Pathology, Lisbon, Portugal, [2]Nova Medical School, Lisbon, Portugal, [3]Hospital do Divino Espírito Santo, Pathology, Ponta Delgada, Portugal, [4]Instituto Português de Oncologia de Lisboa Francisco Gentil, Unidade de Investigação em Patobiologia Molecular (UIPM), Lisbon, Portugal

Background & Objectives: Uterine inflammatory myofibroblastic tumour (IMT) is a rare mesenchymal neoplasm with frequent 'leiomyoma-like' morphology associated with *ALK* gene rearrangement. Clinical outcome is uncertain, but *CDKN2A* deletion and genome complexity have been shown to be prognostic relevant. We aim to evaluate clinicopathological and molecular features of a small series of uterine IMT.
Methods: Four cases of uterine IMT were diagnosed between 2020-2025 in our archives. Clinicopathological data was reviewed. p16

and p53 IHC were performed as well as FISH for *ALK* and *CDNK2A* and CGH.
Results: Patients were aged 53-75 years old (mean age:65 years). One case presented with extrauterine disease. During a mean follow-up of 14.3 months, none of the cases recurred. Tumours' mean size was 12.2 cm. 3/4 cases (75%) showed expansive borders. An exclusive compact, leiomyoma-like, pattern was present in 2/4 of cases with the remainder showing a myxoid pattern (ranging from 60-90%). A diffuse and severe lymphoplasmacytic infiltration was present in 3/4 of cases. Ischemic-type necrosis was present in 3/4 of cases and 2/4 had moderate/severe atypia. Mitotic mean count was 2/10HPF. Based on the risk stratification score, 1 case was classified as high-risk and 3 as intermediate-risk. All cases were ALK IHC positive (diffuse or multifocal) and smooth muscle actin and desmin expression ranged from multifocal to diffuse in all cases; caldesmon was negative in one case. All cases were wild-type p53. 3/4 cases had *ALK* gene rearrangement by FISH. Only the tumour with extrauterine disease had p16 expression in <1% of cells and *CDKN2A* deletion. P16 was patchy in the remaining tumours and no *CDKN2A* deletions were found. A complex profile was found by CGH in 3 cases.
Conclusion: Some IMTs can have an exclusive 'leiomyoma-like' morphology. ALK IHC staining may not correlate with *ALK* fusions, especially using FISH. P16 IHC and *CDKN2A* deletion may be prognostic useful.

PS-17-041
PD-L1 testing in HPV-related cervical cancer: simplifying pembrolizumab access
M. Al Nasir[1], G. Akiki[2], A. Rajaram[1], S. Diwan[3], S. Ghandurah[1], M.Z. Bouyadjera Bachir[4], A. Hodgson[5], B. Tessier-Cloutier[1]
[1]McGill University Health Centre, Department of Pathology, Montreal, Canada, [2]McGill University, Department of Pathology, Montreal, Canada, [3]McGill University, Faculty of Medicine, Montreal, Canada, [4]Université de Montréal, Faculté de Pharmacie, Quebec, Canada, [5]University Health Network, Laboratory Medicine Program, Toronto, Canada

Background & Objectives: Pembrolizumab treatment for recurrent/metastatic cervical cancer requires PD-L1 testing, which can add cost, risk misinterpretation, and delay treatment. Given the low positivity threshold in cervical carcinomas, this study examines PD-L1 expression across the spectrum of cervical neoplasia.
Methods: In a series of cervical carcinomas, PD-L1 immunohistochemical (IHC) expression was assessed using the PD-L1 IHC 22C3 pharmDx assay. Positivity was defined as a combined positive score (CPS) ≥1. The subgroups included: HPV-associated squamous cell carcinoma (HPVa-SCC), HPV-independent squamous cell carcinoma (HPVi-SCC), HPV-associated non-SCC (HPVa-nonSCC), and HPV-independent non-SCC (HPVi-nonSCC). PD-L1 expression rates were compared across subgroups using chi-squared test and Student's t-test.
Results: The cohort included 54 HPVa-SCC, one HPVi-SCC, 15 HPVa-nonSCC (including 11 endocervical adenocarcinoma, three mixed endocervical adenocarcinomas with neuroendocrine carcinoma component, and one pure neuroendocrine carcinoma), and six HPVi-nonSCC (including two gastric type adenocarcinomas, three endocervical adenocarcinoma NOS, and one adenosquamous carcinoma). All HPVa-SCC carcinomas (n=54) and HPVi-SCC (n=1) were PD-L1 positive, while three PD-L1 negative cases were identified among the HPVa-nonSCC (1/15) and HPVi-nonSCC (2/6). The rate of PD-L1 positivity was significantly higher in HPVa-SCC when compared to the other subgroups combined ($p<0.01$). The average PD-L1 CPS in HPVa-SCC (CPS 40) was higher than the other subgroups combined (CPS 24), though this difference was not statistically significant ($p>0.05$).
Conclusion: These findings support reconsidering PD-L1 testing requirements for pembrolizumab eligibility in cervical cancer. Although the small number of HPVa-nonSCC cases limits conclusions for this group, the absence of PD-L1-negative HPVa-SCC — which accounts for most cervical cancers — suggests routine testing in this subset may be unnecessary. PD-L1 testing remains informative for HPV-independent tumours, especially given their low case numbers.

PS-17-043
Ectopic adipogenesis in uterine scar and its relation to Placenta accreta spectrum
N. Tikhonova[1], V. Aleksankina[1], T. Fokina[1], A. Milovanov[1], N. Nizyaeva[1], Z. Gioeva[1], L. Mikhaleva[1]
[1]Petrovsky National Research Centre of Surgery, Moscow, Russia

Background & Objectives: Placenta accreta spectrum (PAS) is a severe complication of pregnancy and believed to associate with uterine scar after caesarean section (CS). The uterine scar is a necessary but not enough factor for PAS. During histopathological observation we often find adipocyte clusters in accreta area. We have suggested that adipocytes in scars may affect the development of PAS.
Methods: Histological and immunohistochemical study of uterine samples obtained during abdominal delivery was performed. The study included women without a previous CS (group 1, n=10), with a scar in the uterine wall without complicated (group 2, n=23) and with complicated by PAS (group 3, n=22).
Results: No adipocytes were found in group 1. In group 2, clusters of adipocytes were found in 83% of cases and only in the scar zone: in serosa 40%, in the perivascular zone 28%, among muscle bundles 15%. In the 3rd group the thinned uterine wall was detected in 68% and adipocyte component in 86% of cases. Adipocytes was observed in serosa (56%), in the perivascular zone (25%) and among muscle bundles (6%). No adipocytic component was found in the uterine wall outside the scar tissue and from women without previous CS. The number of adipocyte clusters in PAS group was greater than in group 2 ($p < 0.05$). In the uterine wall outside the adipocyte clusters, a decrease in CD68 cells was detected in the groups with a scar compared to the control group ($p < 0.05$). In the zones of adipocyte clusters were revealed a decrease in CD68 cells but an increase in CD163 and CD206 in the PAS group compared to group 2.
Conclusion: Adipocyte clusters in caesarean scar indicated the disturbance of cell interactions. Differences in CD206 and CD163 cells in adipocyte clusters between groups may be indirect evidence that uterine adipocytes affect the development of PAS.

Funding: The work was carried out within the framework of FSBSI "Petrovsky National Research Centre of Surgery", 119991 Moscow, Russia, No. 123030700105-0 (FURG-2023-0046)

PS-17-044
The role of adipose tissue in the healing of rat uterine wall after a full-thickness surgical incision
N. Tikhonova[1], V. Alexankina[1], A. Elchaninov[1], L. Mikhaleva[1]
[1]Petrovsky National Research Centre of Surgery, Moscow, Russia

Background & Objectives: Data about the role of components of adipose tissue in the repair of damaged uterine walls are limited, although a number of authors claim that cell-based drugs from adipose tissue have a positive effect on the repair of damaged uterine walls in laboratory rodents. The aim of the study was to evaluate the adipocyte components in the uterine wall of rats in healing after a full-thickness surgical incision.
Methods: The study was on 40 female Sprague Dawley rats. The animals were subjected to a full-thickness longitudinal incision in the wall of the right uterine horn, with the left one serving as an intact control.

We carried out morphological examinations of the uterine walls daily in 5 animals from day 1 to 7 and on day 15. The sections from paraffin blocks were stained with haematoxylin and eosin and Mallory's trichrome staining. Immunohistochemistry detected FABP4+ adipocytes and CD68+ macrophages.T
Results: The period of the most active interaction of adipose tissue with the damaged horn to last from day 3 to 15 and coincide with the macrophage activation in the healing zone. The intact left uterine horn was not involved in the interaction processes with the mesenteric adipose tissue. From day 3FABP4+ cells in the uterine wall of the operated horn formed groups, creating rounded nest-like structures. Clusters of FABP4+ cells were localized in the healing zone, near the suture material, and in the perimetrium near the mesentery attachment sites. There were no FABP4+ cells in the left intact horn.
Conclusion: We characterized the morphological interaction of adipose tissue with the damaged uterine wall during the first two weeks after a full-thickness surgical incision of the rat uterine horn. The results of the study indicate that adipocytes take an active part in the healing after a surgical incision of the rat uterine wall at the earliest stages

Funding: The work was carried out within the framework of FSBSI "Petrovsky National Research Centre of Surgery", 119991 Moscow, Russia, No. 123030700105-0 (FURG-2023-0046)

Undifferentiated small round cell sarcomas of soft tissue: insights from WHO updates and a five-case clinical experience

S.-P. Simion[1], M. Chincesan[2,3], L. Banias[4], G.B. Molnár[5], E. Horváth[6]
[1]County Clinical Hospital of Targu Mures, Department of Pathology, Targu Mures, Romania, [2]"George Emil Palade" University of Medicine, Pharmacy, Science and Technology of Targu Mures, Targu Mures, Romania, [3]County Emergency Clinical Hospital of Târgu Mures, Department of Paediatrics, Targu Mures, Romania, [4]"George Emil Palade" University of Medicine, Pharmacy, Science, and Technology of Targu Mures, Department of Pathology, Targu Mures, Romania, [5]"George Emil Palade" University of Medicine, Pharmacy, Science, and Technology of Targu Mures, Department of Biochemistry and the Chemistry of Environmental Factors, Targu Mures, Romania, [6]"George Emil Palade" University of Medicine, Department of Pathology, Targu Mures, Romania

Background & Objectives: The extraskeletal undifferentiated small round cell sarcomas (URCS) are an extremely rare, heterogeneous group of soft tissue tumours that usually affect young adults but have been reported from 2 months to 81 years of age with a slight male predominance. The WHO classification recognizes four main subtypes (Ewing sarcoma, EWSR1-non-ETS fusion round cell sarcoma, CIC rearranged sarcoma, and BCOR-altered sarcoma) with different behaviour and clinical course. Because of overlapping features, these invasive neoplasms have a high misdiagnosis rate. Molecular testing is often required for accurate diagnosis.
Methods: From January 2023 to date, five soft tissue URCS have been diagnosed in our laboratory: three Ewing sarcomas, one CIC-rearranged sarcoma, and one BCOR-altered sarcoma. Patient ages ranged from 3 to 25 years, with three females and two males. All cases underwent comprehensive histopathologic and immunohistochemical examination, and molecular testing was performed in three tumours to further evaluate specific genetic alterations.
Results: Involved tumour sites included the shoulder, axillary, chest wall, and pelvic-abdominal and laterocervical soft tissues. All three cases diagnosed as Ewing sarcoma showed classic morphology with strong CD99 and vimentin positivity; two of them were also confirmed by molecular testing (presence of EWSR1:FLI1 fusion). The suspected CIC rearrangement sarcoma showed WT1, myogenin and vimentin expression but was negative for CD99 and desmin. The BCOR-altered sarcoma also showed strong CD99 and vimentin positivity, and FISH analysis supported a diagnosis consistent with BCOR-ITD-associated undifferentiated round cell sarcoma. In terms of clinical outcome, four patients received treatment and remain in follow-up, while the suspected CIC rearrangement patient declined evaluation and was transferred to another centre.
Conclusion: Immunoh ntial for the diagnosis of small round cell soft tissue sarcoma, and molecular genetic testing clarifies equivocal cases. A multimodal approach (integration of clinical, radiologic, histopathologic, and molecular data) improves diagnostic accuracy and increases the chance of survival.

PS-18-002
Functional screens unravelling neddylation as a therapeutic vulnerability in soft tissue sarcoma

Y. Chen[1,2], L. Planas-Paz[1], A. Mendieta Pliego[1,2], S. Kollar[1], C. Pauli[1,3]
[1]University Hospital Zurich, Department of Pathology and Molecular Pathology, Zurich, Switzerland, [2]University of Zurich, Faculty of Science, Zurich, Switzerland, [3]University of Zurich, Medical Faculty, Zurich, Switzerland

Background & Objectives: Soft Tissue Sarcomas (STS) are a heterogeneous group of mesenchymal tumours with more than 70 histological subtypes. Standard treatments for the majority of STS have been limited to surgery, radiation and chemotherapy for decades without significant advances, causing poor patient prognosis. Despite recent advances in genomic landscape profiling, there is no existing targeted therapy for complex karyotype STS due to a lack of recurrent genomic aberration and high genomic instability. Moreover, the lack of well characterized patient-derived cell models (sacro-sphere models) has impeded therapeutic development. We aim to discover novel therapeutic targets with patient-derived STS models.
Methods: We firstly establish a biobank of well-characterized patient-derived STS cell models, then we perform whole genome CRISPR screens and medium-throughput drug screens with *ex vivo* cell models to uncover new targets.
Results: Through a comprehensive whole-genome CRISPR screen and medium-throughput drug screens, we have uncovered the significance of protein homeostasis regulation, especially neddylation in soft tissue sarcoma pathogenesis. Building upon our existing findings and literature, we hypothesize that STS subtypes exhibiting high genomic instability, especially with a homologous recombination deficiency (HRD), are more susceptible to proteomic stress induced cell death. More specifically, we have discovered that neddylation inhibitor MLN4924 and TAS4464, but not other protein homeostasis disruptors including proteasome, ubiquitination, heat shock protein and chaperone inhibitors, displayed differential potency towards STS that harbour HRD, possibly by activating Unfolded Protein Response (UPR) induced cell death as previously reported. We have thus investigated the cell death mechanism upon MLN4924 inhibition, with focuses on DNA damage, cell cycle arrest and UPR -induced cell death. We also found impaired cell proliferation upon CRISPR KO of key UPR genes. We are validating our results by patient-derived xenografts.
Conclusion: Our research has discovered neddylation inhibition as a therapeutic vulnerability in STS with HRD, which can potentially stratify patients and improve clinical outcome.

PS-18-003
The pivotal role of platelets in metastasis of osteosarcoma

J. Ichikawa[1], R. Tatsuno[1], T. Kawasaki[2], M. Wako[1], T. Hagino[3], S. Ochiai[3], H. Haro[1]
[1]University of Yamanashi, Orthopaedic Surgery, Chuo, Japan, [2]Saitama Medical University International Medical Centre, Pathology, Hidaka,

Japan, [3]National Hospital Organization (NHO) Kofu National Hospital, Orthopaedic Surgery, Kofu, Japan

Background & Objectives: Treatment outcomes for osteosarcoma have improved with chemotherapy and surgery, although prognosis has stagnated for over 20 years. Recent studies have highlighted the role of the tumour microenvironment and coagulation system, particularly thrombin, in tumour growth and metastasis. Platelets activated by thrombin shield tumours from stress and immune attacks while promoting survival and proliferation during metastasis. This study investigated how platelets interact with osteosarcoma to explore their therapeutic applications.
Methods: Osteosarcoma cell lines (MG63 and 143B) were transfected with green fluorescent protein (GFP), washed human platelets were prepared from healthy volunteers, and a platelet aggregation assay was used to observe interactions. Immunofluorescence was quantified and *in vivo* experiments used BALB/c-nu/nu mice. Statistical differences were determined using Student's t-test ($p<0.05$).
Results: Platelets aggregated in high lung metastatic 143B-GFP and low metastatic MG63-GFP cells. Two-hours post-tail vein injection of 143B-GFP and MG63-GFP cells, there was no significant difference between the two cell types. However, 48 h post-injection, there were no MG63-GFP cells and significantly more 143B-GFP cells, suggesting that extravasation occurred only in highly metastatic 143B cells. In addition, a thrombocytopenia model induced with GP1b antibodies showed no difference between IgG and GP1b antibodies, 2 h post-intravenous tail injection of 143B-GFP cells. However, 48 h later, cells with GP1b antibodies were significantly reduced compared to cells with IgG antibodies, suggesting that platelets regulate extravasation. Finally, *in vivo* experiments, GP1b antibody revealed a drastic reduction in the number of microcolonies in lungs.
Conclusion: This study highlights that platelets play a key role in metastasis of osteosarcoma. Tumour platelet aggregation, which is observed in osteosarcoma, promotes metastasis. Thrombocytopenia inhibits extravasation in metastatic cells, suggesting that anti-platelet agents (e.g., aspirin and P2Y12 inhibitors) could be viable therapies. Investigating platelet-releasing cytokines and tumour podoplanin-platelet CLEC-2 interactions may inspire diagnostic and therapeutic advances.

PS-18-005
Protein expression of Glypican-3 in soft tissue sarcomas is associated with poor prognosis regardless tumour subtypes
H. Song[1], U. Jo[1], F.E. Escorcia[2], J.-Y. Chung[2], J.S. Song[1]
[1]Asan Medical Centre, Pathology, Seoul, Republic of Korea, [2]National Institutes of Health, Molecular Imaging Branch, Centre for Cancer Research, Bethesda, USA

Background & Objectives: Glypican-3 (GPC3) is a glycoprotein of the glypican family that is overexpressed on the cell surface of hepatocellular carcinoma. It is a promising biomarker for liver cancer diagnosis and an emerging candidate for novel molecular target therapies. In contrast, the role of GPC3 in soft tissue sarcoma has not been well established. In this study, we observed the expression of GPC3 in various soft tissue sarcomas and evaluated its clinical significance using immunohistochemistry (IHC).
Methods: A tissue microarray (TMA) was constructed using 249 cases of soft tissue sarcoma collected from 2000 to 2015 at a single institute, the Asan Medical Centre. IHC with TMAs and methylation-specific PCR were performed, and clinicopathologic parameters were analysed.
Results: Malignant peripheral nerve sheath tumour (51.4%) most commonly exhibited positive GPC-3 expression, followed by myxoid liposarcoma (44.7%) and alveolar rhabdomyosarcoma (42.1%). To investigate the pathogenesis underlying the varying GPC-3 expression across subtypes, methylation-specific PCR was performed; however, most sarcomas exhibited an unmethylated status with no significant differences between subtypes. Additionally, no clinicopathologic correlation was observed except for age ($p = 0.01$). GPC-3 overexpression was associated with poor prognosis, regardless of sarcoma subtype ($p = 0.005$, log-rank test).
Conclusion: GPC3 protein expression varied among sarcoma subtypes, suggesting that selective anti-GPC3 therapeutic strategies should be applied based on tumour subtype. Moreover, GPC3 protein expression is a prognostic marker for poor survival.

PS-18-006
Clinicopathological spectrum of intimal sarcomas: diagnostic challenges and molecular insights
A.E. Akın[1], O. Kurtulan[1], D. Ateş[1], S. Önder[1], K. Kösemehmetoğlu[1]
[1]Hacettepe University, Pathology, Ankara, Turkey

Background & Objectives: Intimal sarcoma is a rare and aggressive tumour. Recently, two molecular signatures have been defined: "Copy number variation-high" involving Wnt/beta-catenin pathway and microsatellite instability-high-like with mismatch repair (MMR) protein loss. This study aims to evaluate the clinicopathological features of intimal sarcomas and assess MMR protein status and beta-catenin expression.
Methods: We reviewed 16 biopsies from 11 patients. Immunohistochemistry for MLH1, MSH6, PMS2, and beta-catenin was performed on available tissue samples or unstained slides.
Results: Of 11 patients, 3 were male, and 8 (73%) were female, with a mean age of 50 years (22–75). Six tumours were in the pulmonary artery, four in the heart, and one in both. Six had a history of pulmonary thromboembolism. The mean tumour size in 8 cases was 7.1 cm (3–10 cm). Morphologically, all had a myxoid and/or collagenized stroma. Necrosis was present in 3 cases (27%). Inflammatory cells were interspersed in 7 cases. Three cases showed prominent vascularity, and 4 had smooth muscle differentiation. Adipocytic differentiation or lipoblast-like cells were seen in 5 cases. Two distinct tumour morphologies coexisted in 3 cases. *MDM2* was amplified in all 7 FISH-tested tumours and MDM2 immunoexpression was present in 3 additional tumours. PMS2, MSH6, and MLH1 expressions were retained, and beta-catenin was negative in all tested cases. Tumours were positive for SMA (5/11), CD34 (1/10), CAM5.2 (2/8), EMA (1/2), and negative for AE1/AE3 (0/4). Eight patients died due to the disease, while three remained alive for 5, 8, and 72 months.
Conclusion: Intimal sarcomas exhibit highly variable morphologies across a wide age range. The presence of lipoblast-like cells, mature adipocytes, hemangiopericytic vascular pattern, smooth muscle differentiation, and epithelial marker positivity can complicate diagnosis in biopsies. *MDM2* was amplified in all cases tested by FISH. We were unable to show MMR deficiency or beta-catenin overexpression, immunohistochemically.

PS-18-007
Clinicopathological and molecular characterization of benign vascular lesions in adults display reproducible phenotypic-genotypic correlations and represents a valuable diagnostic surrogate
A. Kalmykova[1], R. Stöhr[2], A. Agaimy[2]
[1]Pathology Laboratory EPL, Kyiv, Ukraine, [2]Comprehensive Cancer Centre (CCC) Erlangen-EMN, Institute of Pathology, University Hospital, Friedrich-Alexander University Erlangen-Nürnberg (FAU), Erlangen, Germany

Background & Objectives: Cutaneous and visceral benign vascular lesions in adults are heterogeneous, some of them can mimic malignant entities. Their molecular features remain underinvestigated due to their benign nature and the lack of comprehensive studies.
Methods: 64 benign vascular lesions from 64 patients exhibiting a wide range of anatomic distributions were included. The lesions included

anastomosing haemangioma (AH), capillary-venous malformations (CVM), fibro-adipose vascular anomalies (FAVA), epithelioid haemangioma (EH), intramuscular angiomatosis, Kaposiform lymphatic malformation (KLM), lobular capillary haemangioma (LCH), lipo-venous malformation, sinusoidal capillary haemangioma (SCH), as well as lesions with mixed patterns. Patients were 25 females and 39 males; all but three were adults (mean age 48yo, range: 3 to 83). All lesions have been submitted for second opinion. Molecular testing was performed on FFPE tumour DNA using custom small NGS panels that include the relevant genes (GNA11, GNAQ, PIK3CA, PTEN, RAF/RAS).

Results: GNA11 and GNAQ were the most frequently mutated genes in AH (20 of 27 cases, independent of the anatomic site). These mutations were also identified in mixed lesions that contained an AH-like component. Some of them also exhibited a second mutation in PIK3CA and rarely FANCF gene.

RAS pathway mutations (KRAS, NRAS, and MAP2K1) were most commonly found in LCH.

Alterations in the PIK3CA were frequently observed in CVM.

The least frequent mutations, PTEN and IDH1, were detected in FAVA and SCH, respectively. A wildtype status was observed across nearly all lesions with the highest frequency detected in venous malformations and LCH.

Conclusion: This study provides a detailed molecular analysis of benign vascular tumours, shedding light on their genetic landscape and the potential relevance of specific mutations in their pathogenesis. Many of these alterations represent valuable surrogate diagnostic tools on limited biopsies from unusually located lesions such as those in the breast or the retroperitoneum where well differentiated angiosarcoma is a consideration.

PS-18-009

Rare primary breast sarcomas: a case series from a tertiary cancer

S.A. Saraf[1], I. Makker[2], S. Agrawal[3], M. Tripathi[4], A. Kapoor[5], P. Giridhar[6], Z. Chowdhury[2]

[1]V. G. Background & Objectives: Primary breast sarcomas account for <1% of all breast cancer cases, typically affecting patients aged >55 years. They are difficult to differentiate from other types of breast cancer based on the clinical and imaging results and are associated with a poor prognosis. It is important to recognize them owing to differences in treatment options. We here present a series of four cases of primary breast sarcomas. The purpose of presenting this case series is to familiarize the pathologist with these rare entities as they clinically mimic epithelial malignancy of the breast but are heterogeneous and follow a different clinical course and treatment protocol.

Methods: A collection of four rare breast mesenchymal tumours is presented. The cases were worked up extensively with ancillary testing and the diagnosis was rendered.

Results: A total of four cases were identified. All cases were females with age group of presentation being 14-71 years with the mean age being 44 years. The tumour size ranged from 1.5-20 cms. A diagnosis of malignant peripheral nerve sheath tumour was rendered in one case, one was diagnosed as chondrosarcoma, one as osteosarcoma, and the last as rhabdomyosarcoma. A diverse panel of immunohistochemistry markers was used to reach the final diagnosis, including but not limited to SMA, desmin, CD34, S-100, H3k27me3, myogenin, myoD1, and SATB2 amongst others. The most common differential in all these cases was a malignant phyllodes tumour.

Conclusion: This case series describes unique cases of primary breast sarcomas. Histology plays a pivotal role in the diagnosis of these tumours along with an immunohistochemical panel that is valuable in excluding phyllodes tumours and differentiating amongst the various sarcomas. In these cases, immunohistochemistry was a major contributor in diagnosis. This study supports and builds upon global data on rare breast neoplasms, while offering valuable regional insights.

Immunohistochemical profiling of mismatch repair deficiency in advanced prostate cancer: a retrospective analysis

I. Traila[1,2], D. Herman[2], D. Anderco[2], M. Iacob[2], A. Dema[1,2], V. Dema[3,4]

[1]"Victor Babes" University of Medicine and Pharmacy, Microscopic Morphology-Anatomic Pathology, ANAPATMOL Research Centre, Timisoara, Romania, [2]"Pius Brînzeu" County Clinical Emergency Hospital, Pathology, Timisoara, Romania, [3]"Victor Babes" University of Medicine and Pharmacy, Dept XV, Discipline of Urology, Timisoara, Romania, [4]"Pius Brînzeu" County Clinical Emergency Hospital, Urology, Timisoara, Romania

Background & Objectives: Mismatch repair (MMR) deficiency has been reported in prostatic cancer with a low prevalence, ranging from 0.4% to 3.5%, and is commonly associated with advanced tumour stages. The study aims to investigate the prevalence of MMR deficiency in high-grade prostatic acinar adenocarcinoma (PAA) using IHC analysis.

Methods: For this study, 26 cases of PAA with high Gleason scores (≥8) with available data on PSA levels and metastatic status were selected. Formalin-fixed, paraffin-embedded specimens, including prostatic biopsies, prostatectomies, and TUR-P samples, were evaluated by immunohistochemistry (IHC) to assess the expression of mismatch repair proteins (MLH1, PMS2, MSH2, and MSH6).

Results: Our analysis included 26 specimens, comprising 18 prostatic biopsies, three prostatectomies, and 5 TUR-P samples. Serum PSA levels ranged from 6.7 to 3090 ng/ml. Distant metastases were identified in 61.54% of cases (16 samples). All cases were evaluated by IHC for MMR protein expression, revealing an MMR deficiency rate of 23.08% (6 cases). Among the deficient cases, one showed isolated loss of MLH1 expression, two exhibited isolated loss of MSH6, and three demonstrated concurrent loss of MSH2 and MSH6. We performed a logistic regression analysis to evaluate whether PSA levels and the presence of metastases were associated with MMR status. The resulting p-value was ≈ 1.00, indicating no statistically significant correlation between the variables analysed. In this cohort, MMR status does not appear to be predicted by serum PSA levels or the metastatic status.

Conclusion: This study highlights a notable prevalence of MMR deficiency in advanced prostate cancer (poorly differentiated and high stage). Serum PSA levels and metastatic status showed no significant association with MMR status, suggesting the need to explore alternative indicators for identifying and testing cases potentially eligible for checkpoint inhibitor therapies.

PS-19-002

Liquid biopsy-based comprehensive genomic profiling in advanced prostate cancer

I. Adamik[1], H. Engi[1], E. Tóth[1], Z. Melegh[1]

[1]National Institute of Oncology, Department of Surgical and Molecular Pathology, Budapest, Hungary

Background & Objectives: Comprehensive genomic profiling (CGP) from liquid biopsy is an emerging method, and allows the assessment of hundreds of genes and genome-wide signatures in a minimally invasive manner. In metastatic prostate cancer, liquid biopsy is often the only feasible method for tumour sampling. Bone, a frequent metastatic site, is not only difficult to sample but the decalcification process also degrades the DNA. In other cases, the condition of the patient may not be suitable for invasive procedures.
Methods: Fourteen patients (aged 45-76) with advanced prostate cancer were selected as unsuitable candidates for tissue-based CGP. Cell-free DNA (cfDNA) was extracted from the patients' plasma. Trusight Oncology 500 ctDNA next generation sequencing panel test was performed, which assesses homologous recombination repair (HRR) gene mutations and genome-wide signatures, such as tumour mutational burden (TMB) and microsatellite instability. A clonal hematopoietic origin of the mutations was excluded.
Results: HRR gene mutation was found in 21% (3 out of 14) of the cases. No BRCA1 or BRCA2 mutation was identified. Other HRR gene mutation was detected in 3 cases (CHEK2, RAD51B with CDK12, and ATM). No microsatellite instability was detected in our cohort. Five patients had a tumour with high TMB (>10 mutations/Megabase).
Conclusion: HRR mutation was detected at a similar incidence reported in primary tumours, but with the notable lack of BRCA mutation. This might be due to the relatively small size of our cohort. The significance of blood TMB (bTMB) is still not well established. Recent studies suggest that TMB and bTMB correlate, but a new cut-off (probably higher than 10 mutations/Megabase) needs to be validated to predict response to immune checkpoint inhibitor. Liquid biopsy-based CGP can be an exceptionally helpful tool for identifying targetable genomic alterations, especially in cases with tissue sampling difficulties. However, further investigations are needed to predict therapeutic responses.

PS-19-003

Evaluation of incidence and histopathological findings of soft tissue sarcomas in genitourinary tract

H.M. Turhan[1], S. Kabul[1]
[1]Bursa Uludag University, Medical Pathology, Bursa, Turkey

Background & Objectives: This study aims to assess the clinicopathological features and prognostic factors affecting survival in patients diagnosed with genitourinary sarcomas at our institution.
Methods: Patients diagnosed with primary genitourinary soft tissue sarcomas between 2014–2025 were retrospectively reviewed from our hospital's pathology archive. Sarcomas of female genital tract and retroperitoneal origin were excluded. Thirty-eight patients with clinical follow-up were included. Demographic, histopathological, and clinical data (age, sex, histologic type, tumour size, necrosis, mitotic count, primary organ, metastasis, surgical margins, and follow-up duration) were collected through literature review. Data were analysed using IBM SPSS Statistics 27 with appropriate statistical methods.
Results: The cohort included 28 males and 10 females, with 17 paediatric and 21 adult patients. The mean overall survival was 41.1 months. The kidney was the most common tumour site (42.1%), followed by the bladder (28.9%), testis/paratesticular region (23.7%), and prostate (5.2%).Rhabdomyosarcoma was the most frequent histological subtype (26.3%), followed by leiomyosarcoma (23.7%) and clear cell sarcoma (15.8%).High mitotic activity (≥20 mitoses/10 HPF) was observed in 47.4% of cases, and tumour necrosis in 78.9%. At diagnosis, systemic metastases were present in 42.1% of patients, and surgical margin positivity in 28.9%. By the end of follow-up, 55.2% of patients were alive. Tumour location significantly influenced survival (p=0.016), with kidney tumours showing the longest and prostate tumours the shortest survival. Survival also differed significantly by tumour type (p<0.001), with clear cell sarcoma having the longest and malignant peripheral nerve sheath tumours the shortest survival. Absence of metastasis at diagnosis was linked to longer survival (p=0.003).Positive surgical margins were associated with shorter survival (p=0.041).No significant association with survival was found for mitotic activity (p=0.382), tumour necrosis (p=0.077), age (p=0.069), or tumour size (p=0.754).
Conclusion: Tumour type and location, metastasis at diagnosis, and margin status are key prognostic factors for survival in genitourinary sarcomas. Recognizing these factors can guide clinical decision-making and patient management.

PS-19-004

Prognosis and tumour grading in bladder urothelial carcinomas with intratumoral grade heterogeneity

K. Doğan[1], G.V. Alkan[2,3], M. Türk Alkan[4], E. Önder[2]
[1]Karadeniz Eregli State Hospital, Pathology, Zonguldak, Turkey, [2]Ankara Etlik City Hospital, Pathology, Ankara, Turkey, [3]Kahramanmaraş State Hospital, Pathology, Kahramanmaraş, Turkey, [4]Ordu University Training and Research Hospital, Pathology, Ordu, Turkey

Background & Objectives: Grade heterogeneity is one of the most debated issues in grading urothelial carcinomas. According to the 2021 World Health Organization (WHO) classification, approximately one-third of urothelial carcinomas exhibit grade heterogeneity, and a minimum of 5% high-grade component is currently required for a tumour to be classified as high-grade. However, it is also emphasized that further studies are needed to determine this threshold. In this study, we aimed to investigate the prognostic significance of the high-grade component in urothelial carcinomas exhibiting grade heterogeneity and to determine a cut-off value for the high-grade proportion based on survival data.
Methods: In this retrospective study, 180 cases of non–muscle-invasive urothelial carcinoma diagnosed via transurethral resection of bladder tumours (TURBT) between January 2019 and August 2022 were included. All cases demonstrated grade heterogeneity. The presence of lamina propria invasion, percentage of high-grade tumour, recurrence, and overall survival were evaluated.
Results: Recurrence was observed in 26.67% of the cases, and the two-year survival rate was 73.33%. Statistical analysis revealed no significant association between recurrence and the proportion of high-grade tumours. However, a significant decrease in survival was observed with increasing proportions of high-grade components. Receiver operating characteristic (ROC) curve analysis identified a cut-off value of 27.5% for the high-grade tumour component in relation to overall survival.
Conclusion: Our study demonstrated a strong association between the proportion of high-grade components and survival in non–muscle-invasive urothelial carcinomas. Considering our findings and existing literature, our results suggest that a threshold higher than 5% may be more appropriate for classifying tumours as high-grade. Large-scale, multi-centre studies are warranted to validate and refine these findings.

PS-19-007

Tumour budding in urothelial carcinoma, single institution study of 84 cases

A. Bdioui[1,2], A. Mahmoudi[3], R. Bader[2], Z. El Euch[2], S. Hmissa[2], N. Missaoui[1]
[1]Sousse Medical School, Research Laboratory Oncogenesis and Tumoral Progression LR21ES03, Sousse, Tunisia, [2]Sahloul Hospital, Pathology, Sousse, Tunisia, [3]Farhat Hached Hospital, Pathology, Sousse, Tunisia

Background & Objectives: In Tunisia, Urothelial carcinoma is the most common genitourinary cancer in men and the second most common cancer. Approximately 20-30% of patients with newly diagnosed bladder cancer have muscle-invasive disease. Despite advances in management, predicting outcome remains a challenge due to the limitations of classical prognostic factors. Identification of novel markers, such as tumour budding (TB), may represent a promising advance.
The aim of this study was to investigate tumour budding in muscle-infiltrating urothelial carcinoma of the bladder and to analyse its prognostic significance.
Methods: We performed an analytical study including cases of muscle-invading bladder urothelial carcinoma. Tumour budding was assessed using the hot spot method, according to the recommendations of the International Tumour Budding Conference Consensus in 2016.
Results: Our study included 84 cases. The sex ratio was estimated at 11. The majority of tumours were high grade. Carcinoma in situ lesions was seen in 32.1% of cases. Vascular emboli were identified in 63 cases, lymphatic emboli in 68% and peri-nervous invasion in 58.3% of tumours. Tumours were classified as pT4a in 40.5% of cases. The presence of lymph node metastases was noted in 28.6% of cases.
Tumour budding was observed in 41.7% of cases: it was grade I: in 9.5% of cases, grade II: in 16.7% of cases, grade III: in 15.5% of cases. There was a correlation between TB and the type of invasion, the degree of parietal infiltration, the presence of vascular emboli, the presence of lymphatic emboli, the presence of peri-nervous involvement (p=0.012) and the presence of carcinoma in situ. There was no correlation with epidemiological data, tumour size, grade, histological variants or overall survival.
Conclusion: These results highlight the potential role of TB as a prognostic marker in muscle-infiltrating bladder cancer and pave the way for its use as an additional tool in patient sratification.

PS-19-009

Reporting practices in post radiation prostate biopsies among genitourinary pathologists

N.-N.J. Nguyen[1], A. Lopez Beltran[2], D. Berney[3], L. Cheng[4], K. Collins[5], E. Compérat[6], L. Egevad[7], S. Fine[8], N. Greenland[9], A. Hartmann[10], K. Iczkowski[11], S. Mohanty[12], G. Quiroga-Garza[13], M.R. Raspollini[14], A. Sangoi[15], S. Satturwar[16], R. Shah[17], S. Shen[18], S. Smith[19], G.J. van Leenders[20], M. van Montfoort[21], S. Wobker[22], T. van der Kwast[23], M. Downes[1]

Background & Objectives: Despite the widespread use of radiation therapy (RT) in prostatic adenocarcinoma, no formal, international pathology reporting guidelines exist, with only two prior studies (1987[1], 2009[2]) providing recommendations on how to assess these cases. We surveyed genitourinary (GU) pathologists to determine their reporting practice in post-RT prostate biopsies.
Methods: A 14-question survey was circulated to GU pathologists to understand annual reporting volumes, grading approach, use of immunohistochemistry (IHC) and reporting of morphologic features in the context of prior RT. Representative images of post-RT prostatic carcinomas (n=3) were included.
Results: 21/28 GU pathologists completed the survey. Annually, 24% report <10 post-RT biopsies, 57% assess 10-50 cases, and 19% see >50. Pathologists reporting ≥10 cases/annum are more likely to comment on radiation effect vs those who see <10 (86% vs 20%, p=0.055). 24% do not report Gleason score/grade group (GS/GG) if there is known prior radiation while 71% report GS/GG if radiation effect is present in background benign tissue but absent in cancer. Regarding the 3 examples of post-RT cancer included in the survey, the proportion of pathologists who said they would grade was 19%, 57% and 86%, respectively. Overall 67% comment on the degree of radiation change, including 63% of those who report GS/GG and 80% of those who do not report GS/GG. 52% always note the presence of intraductal/cribriform carcinoma, 33% note only if they provide GS/GG, and 14% never report in post-RT biopsies. 62% routinely use IHC to identify residual cancer including all who do not provide GS/GG. With respect to awareness of reporting guidelines, 58% believed there are none, and 14% were unsure.
Conclusion: There is widespread variability in reporting practice in post-RT prostate biopsies amongst GU pathologists, with variable use of IHC, reporting of intraductal/cribriform carcinoma, and GS/GG assignment. Formal, evidence-based guidelines would help standardizing reporting practice.

PS-19-010

Assessment of c-kit expression in neuroendocrine carcinomas of the genitourinary tract: an exploratory study

N.-N.J. Nguyen[1], E. Slodkowska[1], K. Khan[1], R. Kerbel[1], L. Chen[1], M. Downes[1]
[1]Sunnybrook Health Sciences Centre, University of Toronto, Toronto, Canada

Background & Objectives: De novo neuroendocrine carcinomas (NEC) of the genitourinary (GU) tract are relatively rare but increased frequency is noted in prostate cancers treated with androgen deprivation therapy. Therapeutic options are limited. C-kit (CD117) is upregulated in treatment-emergent NEC of prostate mediated via FOXA1/A2. Phase-1 clinical trials assessing c-kit antibody-drug conjugates (ADC) in NEC of multiple tumour sites have started. Our objective was to explore the pattern and frequency of c-kit expression in a real world cohort of NEC from the GU tract.
Methods: High grade NEC of prostate and bladder were identified through search of the laboratory information system. Gleason score 10/10 acinar prostatic adenocarcinomas, and high grade, muscle invasive urothelial carcinomas (MIBC) were used as controls. All were stained with CD117 antibody (DAKO, 1/400 dilution, run on Ventana Benchmark Ultra platform). Each case was assessed using H-scores (range 0-300), calculated as follows: (3 x percentage of cells with strong staining) + (2 x percentage of cells with moderate staining) + (1 x percentage of cells with weak staining).
Results: Twenty-four GU NEC were identified: 10 NEC of prostatic origin (6 de novo) and 14 NEC of bladder origin. Thirty-eight controls (18 Gleason score 10/10 prostate and 20 MIBC) were used. Expression of cytoplasmic CD117 was seen in 13/24 (54%) NEC, including 7/10 prostate cases and 6/14 bladder cases. H-scores ranged from 10 to 270. All control cases (n=38) were negative for CD117 (p< 0.0001).

Conclusion: Pharmacologic inhibition of c-kit represents a novel therapeutic target in high NEC of the GU tract. Prostate derived NEC displayed higher frequency of CD117 expression than urothelial NEC. Additional larger series should be explored to fully evaluate the frequency, patterns of expression and clinico-pathological correlates for determining future clinical utility of c-kit ADC.

PS-19-011

Expression profiles and translational relevance of transcriptional regulators of neuroendocrine differentiation in castration-resistant prostate cancer

G. Vocino Trucco[1], G. Farinea[2], F. Napoli[2], E. Bollito[1], S. Novello[2], C. Buttigliero[2], M. Volante[2]
[1]San Luigi University Hospital, Pathology Unit, Orbassano, Turin, Italy, [2]San Luigi University Hospital, Department of Oncology, Orbassano, Turin, Italy

Background & Objectives: The acquisition of a neuroendocrine phenotype by prostate cancer cells is a known mechanism leading to castration resistance, defining the so-called "treatment-related neuroendocrine prostatic carcinomas (t-NEPCs)". While the molecular drivers of t-NEPCs remain unclear, marked epigenetic differences between t-NEPCs and non-neuroendocrine castration-resistant prostate cancers suggest a role for transcriptional reprogramming. This study aimed to investigate the expression patterns of transcription factors associated with neuroendocrine differentiation in patients with castration-resistant prostate cancer, exploring their association with the development of a neuroendocrine phenotype, pathological features, and clinical outcomes, including responses to androgen deprivation therapy (ADT) and survival.
Methods: Eighty-three prostate cancer tissue samples from patients subsequently treated with first line ADT, and later with androgen receptor pathway inhibitors (ARPI) were retrieved. Gene expression of transcriptional regulators mediating neuroendocrine differentiation (*ASCL1*, *DLL3*, *NEUROD1*, *MYCL1*, *INSM1*, *NOTCH1*, *YAP1* and *POU2F3*) were assessed using real-time PCR. Additionally, the immunohistochemical (IHC) expression of synaptophysin and chromogranin A was evaluated.
Results: Unsupervised hierarchical analysis revealed three primary transcriptional classes significantly correlated with neuroendocrine phenotype. In particular, *ASCL1* was significantly associated with *CHGA* gene expression and with positive chromogranin A and synaptophysin IHC. In terms of clinical outcomes, low *DLL3* and *POU2F3* expression, and high *MYCL1* expression, were associated with disease progression during ARPI treatment. High *CHGA* expression was associated with poor disease-free survival during both ADT and ARPI treatments. Moreover, high *ASCL1* expression correlated with shorter time-to-progression interval and overall survival during ARPI treatment.
Conclusion: Our study revealed heterogeneous expression patterns of transcriptional regulators of neuroendocrine differentiation in prostate cancer patients admitted to ADT. Moreover, it provides the first evidence of the role of *ASCL1* as a prognostic parameter in prostate cancer patients undergoing ARPI.

PS-19-012

DNA methylation profiling of urological cancers identifies novel cancer-specific and pan-cancer biomarkers, and reveals differentially activated pathways for therapeutic targeting

J. Lobo[1], V. Constâncio[2], A. Gomez[3], J. Ramalho-Carvalho[2], I. Carneiro[1], R. Freitas[4], M. Esteller[5], R. Henrique[1], C. Jerónimo[2]
[1]Portuguese Oncology Institute of Porto (IPO Porto), Pathology, Porto, Portugal, [2]Portuguese Oncology Institute of Porto (IPO Porto), Cancer Biology and Epigenetics Group, Porto, Portugal, [3]University of Vic - Central University of Catalonia (UVic-UCC), Biosciences, Barcelona, Spain, [4]Portuguese Oncology Institute of Porto (IPO Porto), Urology, Porto, Portugal, [5]Josep Carreras Leukemia Research Institute (IJC), Cancer Epigenetics Group, Barcelona, Spain

Background & Objectives: DNA methylation profiling holds promise for biomarker discovery and therapeutic targeting with hypomethylating epidrugs. This study aimed to investigate the DNA methylation landscape of prostate, bladder and kidney cancer (PCa, BlCa, KCa), integrating findings with The Cancer Genome Atlas (TCGA) datasets to identify both shared and cancer-specific DNA methylation signatures with functional relevance.
Methods: DNA methylation profiles of 72 fresh-frozen tissues were histologically characterized, underwent DNA extraction and were analysed using the HumanMethylation450 BeadChip methylation array (Illumina). These included 25 PCa (acinar adenocarcinoma), 5 normal prostatic tissues (transurethral ressections, without HGPIN), 14 BlCa (urothelial carcinomas), 5 normal bladder urothelium (from cystoprostatectomies not harbouring urothelial neoplasia), 17 KCa (all clear cell RCC), and 6 normal kidney cortical tissue (from nephroureterectomies not harbouring renal cortical neoplasia). Unsupervised clustering and principal component analysis was performed. Differentially methylated CpG sites were identified, and then further analysed using the TCGA datasets [RNAseq and DNA methylation (450k)] to evaluate their impact on gene expression. Gene ontology (GO) analysis was performed to identify affected biological pathways.
Results: DNA methylation profiles distinguished tissue types, and also normal from cancer tissues within each tissue type. BlCa and KCa showed predominant genome-wide hypomethylation (suggesting genomic instability), whereas PCa was characterized by predominant promoter hypermethylation. Hypermethylation-associated gene silencing in PCa and BlCa affected genes involved in DNA repair, oxidative stress regulation, epithelial-mesenchymal transition (EMT), and immune evasion. Cancer-specific analyses revealed that PCa hypermethylation predominantly impacted metabolic and detoxification pathways, whereas in BlCa, it affected genes regulating cell fate and tissue organization.
Conclusion: This study provides new insights into the epigenetic heterogeneity of urological cancers. The identification of both shared and cancer-specific methylation patterns highlights their potential as biomarkers for early detection, disease monitoring and therapeutic targeting.

PS-19-013

Prognostic value of androgen receptor and androgen receptor splice variant-7 in prostatic adenocarcinoma

I.D. Caruntu[1], S.E. Giusca[1], M.B. Chifu[1], B. Gafton[2], C. Terinte[3], I. Prutianu[4]
[1]University of Medicine and Pharmacy "Grigore T. Popa", Department of Morphofunctional Sciences I, Iasi, Romania, [2]University of Medicine and Pharmacy "Grigore T. Popa", Department of Medicine III, Iasi, Romania, [3]Regional Institute of Oncology, Department of Pathology, Iasi, Romania, [4]Neolife Medical Centre, Department of Oncology, Iasi, Romania

Background & Objectives: Current research on prostate cancer focuses on the role of the androgen receptor (AR) and its variants in hormone sensitivity and resistance. Our study analyzes AR and androgen receptor splice variant-7 (AR-V7) heterogeneity, emphasizing their relationship with clinico-pathological parameters that influence tumour behaviour.
Methods: The study group comprised 86 cases of prostatic adenocarcinoma (pADK). Clinico-pathological characteristics - including age, PSA value, histological type, Gleason score, ISUP prognostic grading group, clinical/pathological staging, progression-free survival (PFS), and overall survival (OS) - were extracted from medical records. AR

and AR-V7 expression were assessed immunohistochemically. Relationships between AR and AR-V7 immunoprofiles (positive versus negative) and clinico-pathological parameters were statistically analysed.
Results: AR immunoexpression was positive in 72 cases (92.31%) and negative in 6 cases (7.69%), while AR-V7 immunopositivity was identified in only 10 out of 78 cases (12.82%). Statistical analysis of classical clinico-pathological factors and AR immunoexpression showed significant differences concerning clinical stage at diagnosis, PSA value, ISUP prognostic grading group, tumour localization in both prostate lobes, and histological type. AR-V7 immunoexpression showed a statistically significant correlation only with clinical stage at diagnosis and extensive tumour localization in both prostate lobes. Kaplan-Meier curves and Cox regression analysis indicated no statistically significant differences in OS or PFS based on AR and AR-V7 positivity or negativity.
Conclusion: The mechanisms underlying hormone sensitivity and resistance in pADK are not yet fully understood. Studies investigating AR as a prognostic factor report heterogeneous and contradictory results due to major differences in cohort structures and immunoexpression assessment methods. Our results suggest that although AR status significantly correlates with several clinico-pathological parameters, it does not influence tumour progression. The AR-V7 profile, consistent with data reported in the literature, supports its potential role in the development of antiandrogen treatment resistance in pADK patients.

Background & Objectives: Mucinous tubular and spindle cell carcinoma (MTSCC) is a rare subtype of renal cell carcinoma and considered a low-grade neoplasm. Limited data exists regarding its clinical course, prognostic factors, defining histopathological and immunohistochemical features. This study aims to provide a comprehensive evaluation of the clinicopathological and immunohistochemical features of MTSCC through a multicentre retrospective series, explore potential diagnostic markers via tissue microarray analysis.
Methods: A total of 71 MTSCC cases were retrospectively collected from 17 institutions; patient demographics, pathological findings including tumour size, pT stage, nuclear grade, the presence of high-grade or sarcomatoid phenotype, necrosis, metastasis, were reviewed. A panel of marker expression including CK7, CK20, PAX8, RCC, AMACR, PanCK, EMA, CD10, 34βE12, other HMWK and vimentin were evaluated. 20 out of 71 cases also underwent tissue microarray analysis with immunostaining for keratin 7, CD10, AMACR, VSTM2A and YAP1. The extent and intensity of staining semi-quantitatively assessed by 2 pathologists. Results were correlated with morphological and clinical parameters.
Results: The cohort included 47 females and 24 males, with a mean age of 60 years. Mean tumour size was 58.8 mm. Most tumours were pT1 (52.1%) and grade 2 (60.6%). High-grade features were present in 16.9%, sarcomatoid differentiation in 9.8%, tumour necrosis in 7%, metastasis in 8.5% of the cases. CK7, AMACR, PAX8 were among the 3 consistently positive markers in almost all cases (consecutively, 100%, 100% and 92.3%). CD10 and RCC expressions were variable (76.9% and 61.5%). Tissue microarray confirmed high AMACR, YAP1 and CK7 expression (consecutively 95%, 95% and 75%), and weak but common VSTM2A expression (75%). CD10 was mostly negative, some cases show weak-heterogeneous staining.
Conclusion: This study represents one of the largest series of MTSCC; aims to support the diagnostic immunoprofile of MTSCC, potentially identifying novel markers (VSTM2A, YAP1) that may help differential diagnosis.

PS-19-015

Mutational profile of invasive penile squamous cell carcinoma

M. Ermakov[1], M. Seles[2], U. Bele[2], S. Ahyai[2], S. Regauer[1], K. Kashofer[1]
[1]Medical University of Graz, Diagnostic and Research Institute of Pathology, Graz, Austria, [2]Medical University of Graz, Department of Urology, Graz, Austria

Background & Objectives: Penile squamous cell carcinoma (SCC) are rare cancers that arise after transforming human papillomavirus (HPV) infection or independent of HPV. Limited knowledge about genetic alterations comes from studies of mainly small cohorts of typically mixed aetiology.
Methods: Invasive penile SCC of 133 patients from a single institution in a low-incidence country, hot spots of 50 cancer-relevant genes were analysed with targeted next-generation sequencing.
Results: 64/133 SCC were classified as HPV-induced with 20/64 (31%) carrying somatic mutations. 69/133 SCC arose independent of HPV with 61/69 (88%) featuring somatic mutations. *PIK3CA*, *FGFR3 and FBXW7* mutations occurred in both groups in similar numbers as seen in other human cancers. Mutations in *TP53* (41/69; 59%) and *CDKN2A* (30/69; 43%) with a co-occurrence in 25/69 (36%) and *HRAS* (12/69; 17%) occurred exclusively in HPV-independent SCC. Multiple genes mutations occurred in 9/64 (14%) HPV-induced SCC versus 42/69 (61%) HPV-independent SCC (Chi square; $p< 0.001$). More than one mutation per gene (multi hits) were characteristic for HPV-independent SCC (14/69; 20%) compared to 3/64 (5%) HPV-induced SCC (Chi square; $p<0.001$). The total number of mutations was significantly higher in HPV-independent (136 mutations) than in HPV-induced penile SCC (38 mutations; Welsh test; $p<0.001$). No differences were identified with age or tumour stage of the primary SCC in neither etiologic group suggesting that acquisition of driver gene mutations are early events after invasion.
Conclusion: There are characteristic differences in mutational landscapes for the two aetiologies. While genetic mutations in tumour suppressor genes drive HPV-independent penile carcinogenesis, oncogenic action of E6 and E7 substitute for mutations in HPV-induced SCC.

Only a subgroup of patients with advanced mutated HPV-positive SCC may be candidates for targeted therapy and clinical trials, while HPV-independent SCC with tumour suppressor gene mutations remain a therapeutic challenge.

PS-19-016

Genomic copy number variations in human papillomavirus (HPV) – induced and HPV – independent penile cancer

M. Ermakov[1], S. Regauer[1], K. Kashofer[1]
[1]Medical University of Graz, Diagnostic and Research Institute of Pathology, Graz, Austria

Background & Objectives: Penile squamous cell cancer (SCC) is a rare disease that arise via two major pathways: human papillomavirus (HPV) - induced and HPV - independent. Genomic copy number variations (CNV) are observed in many cancer types, however, their role in penile carcinogenesis remain to be poorly understood. In this study, we examined CNV changes in a cohort of 122 invasive penile SCC from a single low-incidence country.
Methods: DNA was extracted from micro-dissected tumour tissues and analysed for the presence of HPV genotype-specific DNA using the LCD-Array (CHIPRON) and for CNV by shallow WGS (Agilent SureSelect). Immunohistochemical overexpression of p16INK4A served as a surrogate marker for a transforming HPV infection. A segmentation algorithm was used to identify CNV segments associated with gains (CN>2) and losses (CN<2). Statistical analysis was performed using R.
Results: The overall fraction of genome alterations - documented as percentage of genome with CN changes - did not differ significantly between 63/122 (52%) HPV-induced SCC (median: 42.6%) and 59/122 (48%) HPV-independent SCC (median: 45.2%). The most common shared alterations included gains on 1q (HPV-induced: 51%, HPV-independent: 36%) and 3q (HPV-induced: 56%, HPV-independent: 52%), and losses of 19q (HPV-induced: 37%, HPV-independent: 40%). Although HPV-independent SCC featured more losses of 19p (53% vs. 32%) and 21q (25% vs. 9%), these differences were not significant Significant differences ($p<0.05$) in HPV-independent SCC were observed for gains of 8q (69% vs. 32%), 7p (43% vs 21%) and 7q (31% vs 11%). Losses of 11p (HPV-induced: 27%, HPV-independent: 7%) and 11q (HPV-induced: 19%, HPV-independent: 2%) were characteristic of HPV-induced SCC.
Conclusion: Our results demonstrate recurrent CNV patterns in penile SCC with overlapping and distinct alterations with respect to HPV status. The data suggest involvement of both stochastic genomic instability and pathway-specific mechanisms in the development of HPV-induced and HPV-independent tumours.

PS-19-017

Heterogeneity of PSMA expression in lymph node metastases of prostate adenocarcinoma and correlation with PSMA imaging

F. Kirner[1], T. Metzler[1], I. Rauscher[2], C. Mogler[1], M. Remke[1]
[1]Institute of General Pathology and Pathological Anatomy of the Technical University of Munich, Munich, Germany, [2]MRI (München rechts der Isar) Technical University Munich, Munich, Germany

Background & Objectives: Prostate-specific membrane antigen (PSMA) is a widely used target molecule in the treatment and imaging of prostate cancer. PSMA-PET offers good specificity in the detection of lymph node metastases. However, literature reports vary in terms of sensitivity, ranging from 40 to 85 %. Our previous studies showed a clear intra- and intertumoral heterogeneity of PSMA expression in primary prostate cancer. To test whether the limited sensitivity of PSMA-PET-CT is due to heterogeneous
PSMA expression also in lymph node metastases, we investigated PSMA expression in lymph node metastases by immunohistochemistry in correlation with PSMA-based imaging (PSMA-PET-CT).
Methods: 216 lymph node metastases from 92 patients were included. PSMA expression was determined for lymphnode metastases and primary tumours by PSMA immunohistochemistry (Abcam, 1:50) followed by semiquantitative (immunoreactive score) and semiautomatic evaluation (QuPath). These values were correlated with histomorphological and imaging parameters.
Results: Preoperative PSMA-PET-CT showed a sensitivity of 63 % in relation to the individual lymph node metastases. False positive results (4%) were due to PSMA-expression in germinal centres of reactive lymph nodes. In addition to size, overall DAB intensity, but not membranous staining alone, differed significantly between detected and undetected lymph node metastases.
Consistent with our previous studies, we found PSMA negative areas in 28% of all primary prostate
cancers, but only 2% of patients presented with partially or completely PSMA negative lymph node
metastases. Unlike in primary prostate cancer, PSMA expression was homogeneous within metastases of the same patient.
Conclusion: Low PSMA expression is a key factor for false negative results in PSMA-PET-CT, and any PSMA staining (cytoplasmic and membranous) seems to be relevant for PSMA-PET-CT detection.
Unlike primary prostate cancer, lymph node metastases from the same patient showed uniform staining patterns underlining the clonal nature of lymph node metastases.

PS-19-018

International validation of glass slide-based and digital grading of renal cell carcinoma: reproducibility study and need for standardization

J. Westerdorf[1], A. Pryalukhin[2], M.-L. Eich[3], A. Quaas[1], N. Gaisa[4], T. Bismar[5], J. Felipe Lima[5], I. Fahoum[6], H. Pham[7], H. Reis[8], M. Tretiakova[9], Y. Tolkach[1]
[1]University Hospital Cologne, Institute of General Pathology and Pathologic Anatomy, Cologne, Germany, [2]University Hospital Wiener Neustadt, Institute of Pathology and Molecular Pathology, Vienna, Austria, [3]Charité Berlin, Institute of Pathology, Berlin, Germany, [4]University Hospital Ulm, Institute of Pathology, Ulm, Germany, [5]University of Calgary, Department of Biochemistry & Molecular Biology, Calgary, Canada, [6]Tel-Aviv Sourasky Medical Centre, Department of Pathology, Tel-Aviv, Israel, [7]Bach Mai Hospital, Department of Pathology, Hanoi, Vietnam, [8]University Hospital Frankfurt, Dr. Senckenberg Institute of Pathologie, Frankfurt, Germany, [9]University of Washington, Department of Laboratory Medicine & Pathology, Seattle, USA

Background & Objectives: The WHO-recommended grading system for clear cell (ccRCC) and papillary renal cell carcinoma (pRCC) was introduced in 2012 and is based on nucleolar prominence (G1-G3) and additional histological features (G4). While its prognostic relevance has been validated in glass-slide microscopy (GSM), its applicability to digital pathology (DP) remains underexplored. This study aimed to assess the reproducibility of grading across DP and GSM modalities.
Methods: A total of 197 ccRCC and 139 pRCC cases from Cologne University Hospital (UKK) and University Hospital Wiener Neustadt (WNS) (collected from 2012-2022) were digitized and independently graded on GSM and DP by 9 international genitourinary pathologists using the WHO system. A washout period of $\geq$ 3 weeks was implemented between modalities. Interrater variability was assessed using pairwise weighted Cohen's kappa. For each case, a majority vote (MV; highest frequency grade, defaulting to the higher grade in ties) and a consensus grading (CG; $\geq$50% agreement, when available) were calculated.
Results: In ccRCC cohorts, interobserver agreement on GSM ranged from 0.25–0.81 vs MV and 0.34–0.83 vs CG. For DP, this range was 0.27–0.85 (MV) and 0.29–0.84 (CG). In pRCC cohorts, interobserver

agreement on GSM ranged from 0.39–0.65 vs MV and 0.54–0.82 vs CG. For DP this range was 0.26–0.63 (MV) and 0.24–0.82 (CG). There were significant variations in intrarater agreement (DP vs GSM for single pathologists): 0.47–0.90 for ccRCC and 0.32–0.74 for pRCC. Observed trends were overgrading using DP and differences in G4 feature interpretation.
Conclusion: WHO grading showed moderate interrater agreement across modalities, with better reproducibility in ccRCC. Digital grading did not consistently replicate GSM and tended to higher grades, emphasizing the need for RCC grading standardization.

PS-19-019
Gene expression profiling in prostate cancer: a bioinformatics approach to prognostic stratification
J.S. Marrero Afonso[1]
[1]Hospital Universitario Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain

Background & Objectives: Prostate cancer is a highly prevalent disease and transcriptomic analysis has emerged as a valuable tool for its molecular characterization. This study performed a differential gene expression analysis in prostatic acinar adenocarcinoma to identify biological pathways associated with tumour progression.
Methods: RNA-seq data from the PRJNA237581 project, including 103 FFPE tissue samples from multiple institutions, were analysed. RNA extraction followed quality control steps, library were prepared using Illumina HiSeq2000. Data processing included quality assessment (FASTQC software), trimming (TrimGalore), and alignment to the human genome GRCh38.p14 (HISAT2). Read quantification was performed with HTSeq-count, followed by differential expression analysis in RStudio (edgeR). Genes with an FDR < 0.05 and a logFC|1| were considered significant. Functional enrichment was assessed using Gene Ontology (GO) analysis.
Results: A total of 265 differentially expressed genes were identified, with 65% downregulated in high-grade tumours (Gleason 8–10). These genes were primarily associated with urological development (p-value: 1.74e-05) and cellular adhesion pathways (p-value: 0.00018), including NET1 (logFC = 2.92; FDR = 0.013), reflecting the transition from well-formed tubular structures to the dedifferentiated morphologies. Increased glycolysis and methylglyoxal biosynthesis, linked to NF-kB activation and bone metastases, were also observed (*p*-value: 0.005). In contrast, upregulated pathways included: cell cycle regulation (*p*-value: 8.73e-05), DNA structure maintenance, and histone methylation-mediated epigenetic modifications (*p*-value: 7.1e-05). Additionally, the enrichment of neurogenesis-related pathways (*p*-value: 0.00012), for example N4BP3 (logFC = 2.6; FDR = 0.0033), suggests a role for stromal interactions in disease progression. Regulatory molecules, such lncRNA LIPT2-AS1 (logFC=-2,44; FDR=9,54e-04), which is associated with PD-L1 expression, were found to be upregulated in high-grade tumours and could represent a surrogate marker of good prognosis.
Conclusion: The pathogenesis of prostate cancer is highly complex, involving interrelated molecular mechanisms that can be deciphered using bioinformatics tools. Our findings highlight related biological pathways and provide insights for personalized patient management.

PS-19-020
B72.3 serves as a new diagnostic marker for testicular leydig cell tumour
J. Zhao[1], W. Mi[2], V. Nair[3], Q. Ding[2]
[1]University of Texas MD Anderson Cancer Centre, Department of Anatomical Pathology, Houston, USA, [2]University of Texas MD Anderson Cancer Centre, Houston, USA, [3]Indiana University Health and School of Medicine, Department of Pathology and Laboratory Medicine, Indianapolis, USA

Background & Objectives: As two most common sex cord-stromal tumours in testis, Leydig cell tumour (LCT) and Sertoli cell tumour (SCT) may show overlapping morphological features and immunoprofile, causing diagnostic difficulty. Differential diagnosis of these two tumours is mainly based on histological features, and there is no reliable diagnostic marker to distinguish them. B72.3 is a widely used immunohistochemistry antibody which recognizes tumour-associated glycoprotein 72 (TAG-72) expressed in a broad range of normal and tumour tissues. Incidentally, we found that B72.3 can specifically stain Leydig cells, but not Sertoli cells, in testis. We hypothesize that B72.3 may serve as a new diagnostic marker for testicular LCT.
Methods: We retrospectively identified patients with testicular LCT or SCT in the MD Anderson Cancer Centre and University of Indiana from 2012 to 2022. The histological slides were reviewed by two genitourinary pathologists to confirm the diagnoses. The tissue-embedded paraffin blocks were retrieved and recut for B72.3 immunostain, which were evaluated independently by two pathologists.
Results: We identified 47 patients with average age of 47 year old (range 1-77), who were diagnosed with testicular LCT (organ confined, n=28), testicular SCT (organ confined, n=10), metastatic LCT (n=7), and metastatic SCT (n=2). B72.3 immunostain was performed in 17 testicular LCTs (12 primary and 5 metastases) and 7 testicular SCTs (6 primary and 1 metastasis). 10 of 17 (59%) LCTs showed focal to diffuse positive staining of B72.3, among which 9 of 12 (75%) primary tumours are positive while only 1 of 5 (20%) metastatic tumours is positive. By contrast, all 7 testicular SCTs were negative for B72.3.
Conclusion: Our study suggests that B72.3 is a new diagnostic marker for testicular LCT, and it can help us differentiate testicular LCT from SCT in challenging cases. In addition, high-grade testicular and metastatic LCTs tend to lose the B72.3 expression.

Funding: University of Texas MD Anderson Cancer Centre (To Dr. Jianping Zhao) and Andrew Sabin Family Fellowship (to Dr. Qingqing Ding)

PS-19-021
Navigating diagnostic complexity: AI improves pathologist accuracy and agreement in identification of intraductal carcinoma of the prostate and cribriform growth patterns
F. Maclean[1], A. De Souza[2], C. Petrucco[2], M. Peratikos[3]
[1]Douglass Hanly Moir Pathology, Anatomical Pathology, Sydney, Australia, [2]Franklin.ai, Sydney, Australia, [3]Biostatistics and Data Science, LLC, Nashville, USA

Background & Objectives: Both ISUP and GUPS in 2019 recognised the importance of reporting the presence of intraductal carcinoma (IDC-P) and cribriform architecture in prostate core biopsies (PCB). The presence of these patterns is correlated with a higher risk of biochemical recurrence. However, the agreement between pathologists for both of these entities is suboptimal. Recent consensus meetings held by ISUP and GUPS have attempted to further refine the diagnostic criteria for IDC-P, highlighting the importance of identification This study evaluates our AI model's ability to assist pathologists in detecting these features, enhancing consistency.
Methods: We performed a clinical validation study to evaluate our AI model's ability to augment pathologists' performance identifying the presence of IDC-P and cribriform architecture on PCB specimens using ground truth data as the benchmark. Classification performance was measured using Area Under the Curve (AUC). Reader agreement on classification of clinical findings was assessed using the Intraclass

Correlation Coefficient (ICC). A two-way random effects model measured absolute agreement.
Results: AI-assisted pathologists demonstrated superior diagnostic performance. For Acinar Gleason pattern 4 carcinoma with cribriform architecture, AI-assisted pathologists achieved an AUC of 0.870 compared to 0.866 unassisted. For IDC-P, AI assistance resulted in an AUC of 0.840 versus 0.785 unassisted. Interobserver agreement also improved with AI assistance. The ICC for cribriform architecture agreement improved from 0.704 to 0.730 while IDC-P increased from 0.566 to 0.634. These findings highlight both enhanced diagnostic accuracy and increased agreement among pathologists when utilising AI assistance.
Conclusion: We demonstrate that AI-assisted pathologists achieve superior diagnostic accuracy and consistency identifying both IDC-P and cribriform architectures. Patients with IDC-P are ineligible for active surveillance (AS), and the presence of cribriform growth would dissuade some urologists from AS. Thus, increased accuracy and agreement in diagnosing these architectures may impact treatment pathways.

PS-19-022
Digital PCR analysis of FGFR3 aberrations: fast, multiplex, and reliable
M. Parzinger[1], S. Ruetz[1], K. Tran[2], K. Sollweck[3], H. Bartsch[4]
[1]Gemeinschaftspraxis für Pathologie Traunstein, Molecular Pathology, Traunstein, Germany, [2]Kliniken Südostbayern AG, Oncology, Traunstein, Germany, [3]Thermo Fisher Scientific GmbH, Thermo Fisher Scientific, Darmstadt, Germany, [4]Gemeinschaftspraxis für Pathologie Traunstein, Molecular and Clinical Pathology, Traunstein, Germany

Background & Objectives: Genetic aberrations, including point mutations and fusion oncogenes of fibroblast growth factor receptor 3 (*FGFR3*) are known drivers of tumour initiation, progression and resistance, and established biomarkers for targeted therapies such as erdafitinib in urothelial carcinoma. While sequencing can detect *FGFR3* mutations, digital PCR (dPCR) offers a more affordable alternative with a simplified workflow and rapid turnaround time, suitable for repeated testing or resistance monitoring. We aimed to develop a testing method for detection of the 5 most common FGFR3 mutations and fusions using multiplex dPCR testing and validated its performance on samples collected from urothelial carcinoma cases.
Methods: We designed assays for research use only to detect 8 most common *FGFR3* genetic alterations including 5 point mutations (R248C, S249C, G370C, Y373C, G380R) and 3 fusions (FGFR3-TACC3 (E17;E11), FGFR3-TACC3 (E17;E10), FGFR3-BAIAP2L1 (E17;E2)) in a total of 4 multiplex reactions. Each reaction contained 2 primer/probe pairs for mutant and wild-type alleles, labeled with FAM, VIC, ABY, or CY5 fluorophores. Digital PCR was performed on Absolute Q instrument (Thermo Fisher Scientific). Analytical performance of the assays was assessed using engineered plasmids containing mutant and wild-type FGFR3 sequences, with varying allele frequencies (AF). Additionally, urothelial cancer research samples and synthetic samples provided through a ring trial were tested.
Results: The tested assays demonstrated 100% sensitivity in reference material for the respective mutations. FGFR3 genetic aberrations could be detected at AF of 0.1%. In total 5 samples provided through a ring trial were analysed with 100% correct results.
Conclusion: Digital PCR on Absolute Q instrument offers a rapid and highly accurate technique for *FGFR3* genetic aberrations detection for cancer research. The method is particularly suitable for analysing liquid biopsy material including urine and blood as well as formalin-fixed, paraffin-embedded tissue samples, as it demonstrates high analytical sensitivity and specificity in identifying mutational variants with low allele frequencies.

PS-19-023
The role of cancer-associated macrophages within the tumour microenvironment of bladder cancers
I. Sycheva[1], N. Oleynikova[1]
[1]Lomonosov Moscow State University (MSU), Faculty of Medicine, Moscow, Russia

Background & Objectives: New surgical methods (minimally invasive techniques and organ-preserving orientations) for treating bladder cancer (BC) have identified new ways to target the tumour environment, including tumour/caner-associated macrophages (TAM/CAM). This group of cells is heterogeneous: m1-CAM is inflammatory and antiangiogenic, m2-CAM provides a tissue remodelling function. M2-CAM is activated in hypoxic areas of tumour tissue and promotes proliferation of peritumoral capillaries. BC is divided into muscle-invasive (MIBC), muscle-non-invasive (MNIBC) and non-invasive categories, according to invasion level.
Methods: Immunohistochemistry was performed on material from 27 BCG-treated patients (1) and 40 non-treated patients (2). A study used the markers CD68 for common macrophages and CD163 for M2-CAM. The evaluation was done quantitatively, determining the mean by counting cells in 10 high-power fields (x400, HPF).
Results: Group (1) found CD163+CAM infiltration in MIBC (pT2) to be 9-fold higher than in pT1 and CD163+CAM infiltration in pT1 to be 4-fold higher than in non-invasive BC (pTa).A 2-fold increase in CAM infiltration was noted in recurrent low-grade MIBC cases from group (1) compared to the primary tumour. In recurrent group (1) with reduced stage compared to the primary, there was a 2.3-fold decrease in CD68+CAM stromal infiltration.
In group (2), CD163+CAM infiltration was 4-fold higher in high grade MIBC cases (>pT1) compared to high grade MIBC carcinomas. The results suggest that higher CAM of MIBC is linked to poorer outcomes. These findings suggest that CAM's role in regulating the immune response within urothelial carcinoma is confirmed.
Conclusion: This study shows that CAM can stimulate tumour growth and metastasis. More investigation is needed. Finding specific CAM antigens (type m2) and looking at how they link to clinical data in larger samples can update tests for diagnosing and genetic markers of urothelial carcinomas. This should be done using minimally invasive laboratory techniques.

PS-19-024
Cancer-associated fibroblasts and clinical and morphological features of prostate cancer
I. Sycheva[1], O. Nesterova[2], N. Oleynikova[1], M. Varentsov[2], I. Zhestkov[1], A. Strigunov[2], A. Kamalov[2]
[1]Lomonosov Moscow State University (MSU), Faculty of Medicine, Moscow, Russia, [2]Lomonosov Moscow State University (MSU), Moscow Scientific Educational Institute (MSEI) Oncourology Clinic, Moscow, Russia

Background & Objectives: Tumour microenvironment can modulate the tumour behaviour. One of the components of the tumour microenvironment is cancer-associated fibroblasts (CAFs). Fibroblast activation protein (FAP) and platelet-derived growth factor receptors α and β (PDGFR α and β) can be used as markers of CAFs. Objective: to evaluate the association between the clinical and morphological features of prostate cancer and CAFs markers, FAP and PDGFR α+β.
Methods: The study used surgical material obtained from 34 patients with prostate cancer. The surgical material was stained with FAP and PDGFRa+β. The relationship between these markers and features of prostate cancer was analysed using the RStudio.
Results: A higher Gleason grade was noted in the presence of FAP: in 81.3% of cases, prostate cancer was classified as 4+3=7 and higher,

while in the absence of FAP, only 33.3% (p=0.014). Patients with FAP were significantly more likely to have lymphatic invasion, which was detected in 43.8% of cases, while in the absence of FAP it was detected only in 5.6% (p=0.015). In the presence of FAP, patients were more likely to have lymph nodes involvement (31.2% and 5.6%), however, this parameter had a borderline significance (p=0.078). With moderate/high PDGFRa+β expression, a higher Gleason grade was noted: in 80.0% of cases, prostate cancer was classified as 4+3=7 and higher, while with no/weak PDGFRa+β expression, only 36.8% (p=0.030). In patients with moderate/high PDGFRa+β expression, there was a more frequent probability of involvement of lymph nodes and more likely to have lesions according to MRI at the borderline significance (p=0.097 and p=0.063, respectively).
Conclusion: The presence and severity of expression of stromal CAFs markers are associated with unfavourable clinical and morphological features of prostate cancer, in particular, with a higher Gleason grade, more frequent lesions on MRI and the presence of invasion into the lymphatic vessels.

PS-19-026
Spatial transcriptomic analysis of hormone-naïve prostate cancer and matched lymph node metastases to identify predictors of lymph node invasion
G. Wasinger[1], A. Oszwald[1], R. Sheibani-Tezerji[1], O. Cussenot[2], E. Compérat[1], G. Egger[1]
[1]Medical University of Vienna, Department of Pathology, Vienna, Austria, [2]Medical University of Vienna, Department of Urology, Vienna, Austria

Background & Objectives: Pelvic lymph node dissection (PLND) during radical prostatectomy (RPE) for primary prostate cancer (PCa) is currently guided by clinical risk assessments and nomograms, but its therapeutic benefit remains unclear. Many patients undergo PLND without confirmed lymph node (LN) metastasis, highlighting the need for a more precise molecular predictor. PCa's inherent heterogeneity complicates this effort. This study investigates spatial transcriptional changes associated with metastatic progression.
Methods: Using the GeoMx® Digital Spatial Profiler platform (NanoString, WA, USA), we analysed 299 regions of interest (ROIs) of formalin-fixed paraffin-embedded tissue microarrays of 50 PCa patients (34 metastasizing, 16 non-metastasizing). These ROIs included unifocal and multifocal primary tumour foci (n=172), matched LN metastasis (n=34) and non-cancerous prostate epithelium (n=92).
Data analysis, conducted using R Bioconductor, involved unsupervised analysis to identify patterns and relationships in gene expression levels across different inter- and intratumoral ROIs of tumour foci and metastases. Differential gene expression (DGE) analysis identified potential genes and signatures linked to LN invasion.
Results: Principal component analysis revealed significant inter- and intratumoral heterogeneity. In multifocal PCa, unsupervised hierarchical clustering using Euclidean distance enabled the identification of the likely seeding focus by comparing gene expression patterns of individual foci with matched metastatic samples. In certain patients, this allowed for the detection of potential seeding cells, providing insights into mechanisms of LN invasion. Together, this provides a novel approach to identify genes and gene signatures responsible for LN invasion in PCa, which might be used as biomarkers or future therapeutic targets.
Conclusion: Spatial transcriptomics highlights PCa's heterogeneity and the complexity of predicting LN involvement using molecular markers. Unsupervised analysis enables identification of likely seeding foci and cells, offering a novel approach to identify genes linked to LN invasion. Future efforts will focus on refining predictive models to improve LN metastasis assessment, potentially reducing unnecessary PLND and its associated risks.

PS-19-027
Detection of germ cell neoplasia in situ in testicular biopsy for male infertility: a 15-year retrospective study with OCT3/4 immunohistochemistry reflex testing
R. Choiniere[1], W.PA. Boellaard[2], G.J.L.H. van Leenders[1]
[1]Erasmus MC Cancer Institute, University Medical Centre, Department of Pathology, Rotterdam, The Netherlands, [2]Erasmus MC Cancer Institute, University Medical Centre, Department of Urology, Rotterdam, The Netherlands

Background & Objectives: Testicular biopsy is a useful diagnostic tool in the management of unexplained male infertility and azoospermia. As this procedure is often performed in patients with risk factors for testicular malignancy such as cryptorchidism, atrophy, testicular microlithiasis/masses or a history of malignancy, much care should be taken to detect germ cell neoplasia in situ (GCNIS) in this higher risk population.
In this long-spanned retrospective series, we focus on the detection of GCNIS with the uniform use of OCT3/4 immunohistochemistry in our academic institution.
Methods: Through a search of our pathology medical system, we included all men who underwent testicular biopsy for infertility, including cases with a simultaneous contralateral orchidectomy between 2010 and 2025. The detection of GCNIS was performed through histology and the reflex use of OCT3/4 immunohistochemistry for all patients.
Results: A total of 2,085 testicular biopsy cases met the inclusion criteria, of which 47 (2.3%) resulted in a diagnosis of GCNIS and/or seminoma. Of these, half of the cases were not clinically suspected (1.2%), meaning the patient was not known/suspected for a testicular tumour in either testis or did not show a testicular mass on ultrasound. For these 26 men, 6 (23.1%) had normal spermatogenesis in the involved testis. In all cases, OCT3/4 immunohistochemistry was positive in GCNIS. In the 21 clinically suspicious cases of biopsy with simultaneous contralateral orchidectomy or ipsilateral testicular mass, there was a high risk of diagnosing malignancy (38.9%).
Conclusion: We confirmed the prevalence of non-clinically suspected GCNIS on testicular infertility biopsy (1.2%) which was, in most cases, associated with impaired spermatogenesis. We argue that although GCNIS was indeed diagnosed in 0.29% of cases without clinical suspicion and with normal spermatic maturation, the use of OCT3/4 might be more appropriate if reserved for histologically and/or clinically suggestive cases.

PS-19-028
SPINK1 and ERG in prostate cancer: their role in renal function and chronic kidney disease progression

[1]"Grigore T. Popa" University of Medicine and Pharmacy, Department of Morphofunctional Sciences I, Iași, Romania, [2]Neolife Medical Clinic, Department of Oncology, Iași, Romania, [3]"Grigore T. Popa" University of Medicine and Pharmacy, Department of Medicine III, Iași, Romania

Background & Objectives: SPINK1 and ERG are molecular markers in prostate cancer, often considered mutually exclusive. Their co-expression may impact renal function. This study explores the relationship between SPINK1, ERG expression, and renal impairment in patients with prostate cancer and chronic kidney disease (CKD).
Methods: We analysed 72 prostate cancer patients with CKD undergoing radical prostatectomy. Tumour samples were assessed for SPINK1 and ERG expression using immunohistochemistry. Renal function parameters, including preoperative and postoperative creatinine levels and CKD stages, were recorded. Patients were stratified into

four groups based on SPINK1 and ERG status. Correlations between molecular expression, renal function, and disease progression were statistically analysed.
Results: ERG+/SPINK1+ subgroup had the highest postoperative creatinine levels and CKD progression rates ($p = 0.02$). In contrast, ERG+/SPINK1− patients showed significantly better renal outcomes. ERG−/SPINK1+ patients exhibited distinct renal impairment patterns, suggesting SPINK1-driven CKD progression. The ERG−/SPINK1− group had moderate renal outcomes, indicating ERG absence alone does not drive dysfunction. SPINK1 expression correlated with worse renal function, while ERG presence appeared protective. Patients with SPINK1+/ERG+ tumours had higher rates of post-surgical renal decline than other subgroups. Additionally, SPINK1+ tumours were associated with increased proteinuria, linking SPINK1 to renal injury. The combination of SPINK1 and ERG expression patterns may serve as a prognostic biomarker for cancer progression and renal outcomes, highlighting the importance of molecular profiling in clinical decision-making and treatment.
Conclusion: SPINK1 and ERG co-expression defines an aggressive prostate cancer subset with an increased renal burden. SPINK1 may contribute to CKD progression, while ERG alone appears neutral. Patients with SPINK1+/ERG+ tumours exhibited worse renal function, suggesting a synergistic effect. These findings challenge the assumption of mutual exclusivity between SPINK1 and ERG. Molecular profiling could improve risk stratification and treatment selection. Targeted therapies addressing SPINK1+/ERG+ interactions may enhance oncologic outcomes and also mitigate renal dysfunction, improving overall patient management.

PS-19-029
Can we foresee grade and stage progression in mixed low- and high-grade non-invasive papillary urothelial carcinomas?
B. Karabulut[1], O. Dağ[2], K. Kösemehmetoğlu[3], G. Güner Gebeş[3]
[1]Etimesgut Sehit Sait Erturk State Hospital, Pathology Laboratory, Ankara, Turkey, [2]Hacettepe University, Department of Biostatistics, Ankara, Turkey, [3]Hacettepe University, Department of Pathology, Ankara, Turkey

Background & Objectives: Non-invasive papillary urothelial carcinoma (NIPUC) is currently graded in a 2-tier system, and some cases have mixed low- and high-grade morphology. This study aims to evaluate detailed morphological features of mixed NIPUC and determine the impact of histopathologic features on grade and stage progression.
Methods: A total of 106 primary and follow-up bladder specimens (range 2-13) of 28 patients with a diagnosis of mixed NIPUC were retrieved. Pathological parameters were specified as the volume of biopsy, percentages of 2-tier (low-high) and 4-tier (Grade 1-4) grades, hot-spot mitotic count and location of mitotic activity, discohesiveness, and the presence of whirling. Outcome measures were the grade trend (decline or incline) and stage progression.
Results: The mean age was 65 (range 35-81), and all patients, except for two, were male. Ten patients had a previous biopsy showing pure low-grade NIPUC. Half of the patients had more than 5% high-grade areas, with a mean of 16% (range 1-80); therefore, they were classified as high-grade according to the 2-tier grading system. The mean distributions of grades (G1 to G4) were 42%, 42%, 15%, and 1%, respectively. The mean mitotic count was 20/10BBA (range 2-86). Tumours with more than 80% grade 1 histology did not exhibit an upward trend in grade. Stage progression was observed in tumours with a total percentage of grade 3 and grade 4 (high-grade) areas exceeding 5% (p=0,031). There was no correlation between mitotic activity, discohesiveness, or the presence of whirling and either the grade trend or stage progression. Grade trend was correlated with stage progression (p=0,012).
Conclusion: Mixed NIPUC has variable clinical outcomes that depend on the amount of grade 1 areas (>80%) suggesting a non-inclining grade trend in follow-up biopsies and the presence of >5% high-grade (grade 3 and 4) morphology estimating a stage progression.

PS-19-030
Tertiary lymphoid structures in bladder cancer - current concept based on our epidemiology, histology and immunohistochemical studies
M. Gulinac[1,2], T. Velikova[2], D. Dikov[3]
[1]Medical University of Plovdiv, Department of General and Clinical Pathology, Plovdiv, Bulgaria, [2]Medical Faculty, Sofia University St. Kliment Ohridski, Sofia, Bulgaria, [3]Grand Hospital de l'Este Francilien, Medical Faculty, Department of General and Clinical Pathology, Jossigny, France

Background & Objectives: Bladder carcinomas (BC) are common malignancies of the urinary tract in developed countries, but the role of immune responses, especially tertiary lymphoid structures (TLS), remains underexplored. TLS are organized tumour-infiltrating lymphocytic structures that play a key role in modulating the cancer immunologic response, offering potential strategies for cancer immunotherapy. To evaluate the presence and characteristics of TLS in BC, comparing TLS in non-invasive and muscle-invasive carcinomas of varying malignancy grades, and analysing their immunohistochemical profile.
Methods: We retrospectively analysed urothelial bladder carcinoma cases from 2016–2020, including 104 cases (42 low-grade, 62 high-grade). Immunohistochemical staining for CD31, CD34, CD3, CD20, CD21, S100, C-kit, smooth muscle actin (SMA), and PD-L1 was performed.
Results: TLS were categorized into 4 groups /grades. Approximately 42/104 (40.4%) of TLS in BC was 2nd grade. Also, grade 2 TLS were detected mostly in muscle invasive BC (pT2) with 21/104(44.7%) and high-grade (HG) BC with 27/104 (43.5%). An association between the stage of BC and the presence of TLS in its stroma estimated by Pearson correlation coefficients (p=0.021) was observed. Lack of PD-L1 expression in TLS was found in a larger number of the studied cases (51/104 (70.8%)) and only in 21/104 (29.2%) were positive expression. Of these, most of described cases with positive expression for PD-L1 were TLS, grade 3 (62.5%). Positive PD-L1 expression in association with PD-L1 show significant correlation, estimated by Pearson (p=0.005).
Conclusion: Patients with high-grade/moderately and/or poorly differentiated/ BC, in the early stage of invasion (pT1 and pT2) have a moderate stromal reaction (grade 2), but with weak or absent PD-L1 expression. Therefore, in these patients the positive expression is due to a greater percentage of tumour cells, and not to tumour-associated lymphoid cells, respectively, PD-L1 expression will be found in invasive HG BC with grade 3 TLS.

PS-19-032
Novel AI-assisted algorithm for prostate cancer detection and grading - preliminary findings
M. Maniewski[1,2], J. Borowczak[3], I. Wasiak[4], P. Krajewski[5], J. Kwiecień[5], J. Durślewicz[1,6], P. Giedziun[5], A. Bartczak[7,8], Ł. Szylberg[2,1,4]

Skłodowska-Curie National Institute of Oncology – National Research Institute, Krakow Branch, Kraków, Poland

Background & Objectives: The Gleason grading system remains the primary tool for prostate cancer diagnosis, but its high intra- and inter-observer variability can impact patients. In light of advancements in artificial intelligence facilitating automated analysis, we developed an algorithm for Gleason pattern detection in prostate biopsy cores. This investigation presents preliminary findings derived from the analysis.
Methods: We analysed a cohort of 274 digitized slides, each encompassing 1–2 biopsy cores: 58 with BPL, 60 in grade group 1, 25 in grade group 2, 31 in grade group 3, 57 in grade group 4, and 43 in grade group 5. All samples underwent processing utilizing the Gleason Classification 4.0 (v4.05) algorithmic tool. Two independent pathologists reviewed and rated the results on a 1–5 quality scale.
Results: Among 274 cases, 158 were concordant. Optimal assessment was achieved in 81 cases (29.6%). In 116 cases, algorithm-based adjustments were deemed unacceptable. The highest concordance was in the 4+4 (43/56) and BPL (43/58) groups, while the 5+4 (14/15) and 4+5 (17/28) groups had the highest discordance. The algorithm achieved 97.7% sensitivity and 72.4% specificity for cancer detection at a 4.68% tumour cell cutoff (AUC 0.985 [95% CI 0.949–0.990]).
Conclusion: The algorithm demonstrated high sensitivity in detecting cancer cells. However, its accuracy in determining the Gleason score of a specimen requires further improvement.

Funding: Implementation of the Project co-financed by the National Centre for Research and Development (NCBR) within the framework of the Operational Programme Smart Growth 2014-2020, 1/1.1.1/2020 Fast Track 1_2020, entitled: "Advanced diagnostics of prostate cancer using machine learning methods and deep learning"

PS-19-033

Prognostic significance of EZH2 immunohistochemical expression in urothelial bladder cancer

S. Stojnev[1], A. Ristic Petrovic[1], I. Conic[2], I. Petkovic[2], M. Krstic[1], L. Jankovic Velickovic[1]
[1]University Clinical Centre Nis, Department of Pathology, Nis, Serbia, [2]University Clinical Centre Nis, Department of Oncology, Nis, Serbia

Background & Objectives: Urothelial bladder cancer (UBC) is a common malignancy with a high impact on the healthcare system. The EZH2 transcriptional repressor plays a crucial role in the oncogenesis of bladder cancer. This research aimed to investigate the expression profile of EZH2 in UBC, analyse the correlation with clinicopathological features, and assess the possible prognostic significance of EZH2 expression.
Methods: Immunohistochemical analysis of EZH2 expression comprised 647 cases of UBC, including 201 non-invasive pTa tumours, 296 superficially invasive UBC with infiltration of lamina propria, and 150 muscle-invasive bladder tumours. The median follow-up of the patients was 60 months. Tissue samples embedded in tissue microarrays were analysed immunohistochemically for EZH2 expression. Expression status was correlated with clinicopathological and follow-up data.
Results: High nuclear expression of EZH2 was found in 38.9% of the tumours. High EZH2 was more frequently observed in older patients ($p<0.001$) but showed no significant association with gender or smoking status of the patients. The expression of EZH2 was strongly associated with high tumour grade and advanced stage ($p<0.001$, respectively). Moreover, there was a direct correlation between EZH2 expression and the finding of carcinoma in situ in the surrounding bladder mucosa and divergent differentiation ($p<0.001$, respectively). High EZH2 was a significant indicator of cancer specific mortality ($p<0.001$). In survival analysis, high EZH2 expression was strongly associated with shorter overall survival of the patients ($p<0.001$). Patients with EZH2 high tumours had a 24 month shorter median survival than patients with EZH2 low tumours.
Conclusion: The expression of the epigenetic silencer EZH2 may play a significant role in predicting UBC prognosis. EZH2 is an indicator of aggressive tumour behaviour and adverse prognosis in UBC. The assessment of EZH2 immunohistochemical expression may serve as a promising complementary diagnostic tool in selecting patients who require closer follow-up and has a promising role in targeted anticancer therapy.

PS-19-034

Detection of microplastics in urothelial carcinomas with varying degrees of dysplasia

K. Mikus Kuracinova[1], M. Bollova[1], J. Pavol[1]
[1]Institute of Pathological Anatomy, Faculty of Medicine, Comenius University in Bratislava and University Hospital Bratislava, Bratislava, Slovakia

Background & Objectives: Microplastics, defined as plastic particles smaller than 7 μm, are persistent environmental pollutants that have been detected in food, drinking water, and biological systems. Given their widespread presence, concerns have emerged regarding their potential impact on human health. This study investigates whether microplastics are present in urinary bladder carcinomas and explores their possible involvement in tumorigenesis. We hypothesize that microplastics consumed through food and water may be excreted via the urogenital tract and, if retained, could contribute to pathological processes.
Methods: This study employs a novel approach to detect microplastics in formalin-fixed, paraffin-embedded tissue samples from patients with low-grade and high-grade papillary urothelial carcinoma. Tissue samples were deparaffinized and stained using Nile Red in dimethyl sulfoxide (DMSO), a technique optimized for microplastic visualization. Fluorescence microscopy was then used to identify microplastic particles, specifically those smaller than 7 μm, based on their characteristic fluorescence signal.
Results: Microplastics were detected in urothelial cells, the submucosa, and within blood vessels. Their presence was observed diffusely throughout the tumour tissue.
Conclusion: The detection of microplastics in urothelial carcinoma tissue raises important questions regarding their potential role in carcinogenesis. While our findings do not establish a causal relationship, they underscore the need for further studies to investigate possible correlations and underlying mechanisms by which microplastics may influence tumour development.

Confocal microscopy as a real time diagnostic tool in the Cambridge kidney one-stop mass investigation clinic. An evaluation of 54 patients

A. Warren[1,2], A. Malaviya[1], S. Appukutty[1], A. Silva[1], E. Cresci[1], C. Re[3,4], J.P. Blackmur[3,4], T. Kuusk[3,4], T.J. Mitchell[3,4], J. Armitage[4], A.C. Riddick[4], L. Starling[4], H. Fox[4], V.T. Nair[4], S. Norman[4], C. Gilby[5], T. Barrett[6], R. Bakewell[6], T. See[6], N. Hilliard[6], N. Shaida[6], G.D. Stewart[3,4]
[1]Cambridge University Hospitals NHS Foundation Trust, Cambridge Biomedical Campus, Department of Histopathology, Cambridge, United Kingdom, [2]University of Cambridge, Cambridge Biomedical Campus, Department of Pathology, Cambridge, United Kingdom, [3]University of Cambridge, Cambridge Biomedical Campus, Department of Surgery, Cambridge, United Kingdom, [4]Cambridge University Hospitals NHS Foundation Trust, Department of Urology,

Cambridge, United Kingdom, [5]Cambridge University Hospitals NHS Foundation Trust, Cambridge Biomedical Campus, Cancer Directorate, Cambridge, United Kingdom, [6]Cambridge University Hospitals NHS Foundation Trust, Cambridge Biomedical Campus, Department of Radiology, Cambridge, United Kingdom

Background & Objectives: Ex-vivo confocal microscopy (CFM) is an emerging diagnostic tool for real time histological assessment of fresh tissue. Urologists are increasingly reliant on percutaneous renal tumour biopsies (RTB) for informed management decisions. However, the yield varies, with 10-20% being non-diagnostic. Here we present a study of the use of CFM for the assessment of RTB in the setting of a one-stop clinic enabling same day treatment planning with patients. The primary objective is evaluating biopsy adequacy and diagnostic accuracy for tumour type using CFM and assessing its feasibility in a one-stop clinic.
Methods: The Cambridge kidney One-Stop Mass investigation Clinic (CkOSMIC) was established in January 2024. RTB performed under ultrasound guidance were examined using the VivaScope 2500. The specimens were then processed through conventional histopathology. Concordance between CFM and routine histological assessment was evaluated.
Results: 54 patients underwent RTB from January 2024 to March 2025 under the CkOSMIC pathway. A rapid assessment was provided whilst the patient was in the Ultrasound suite. The median time/IQR from specimen-receipt to result was 22min/18-24.5min with CFM. 9(16.6%) patients had non-diagnostic biopsies, 4 underwent immediate repeat biopsies with provision of same day results. 5(10%) cases were designated as renal neoplasms on CFM; however, tumour typing was deferred to conventional histopathology. Of the 45 cases where a provisional diagnosis was possible on CFM, there was 93% concordance for type of renal tumour. Clear cell renal cell carcinoma was the predominant tumour type (62%); 26% oncocytic tumours were identified and 12% were assessed to be other renal lesions. There were 3(5.5%) discordant cases for tumour type, with none resulting in a benign-malignant discrepancy.
Conclusion: The high concordance rates between conventional histopathology and CFM indicate that this is an accurate and reliable tool for instant histopathological evaluation and can be used safely in the setting of a one-stop kidney cancer clinic.

PS-19-036
Cracking CROCC gene in chromophobe renal cell carcinoma with sarcomatoid dedifferentiation
M. Brunelli[1], S. Gobbo[1], A. Caliò[1], P. Colombo[2], R. Franco[3], M.R. Raspollini[4], M. Colecchia[5], G. Martignoni[1,6]
[1]University of Verona, Department of Diagnostic and Public Health, Verona, Italy, [2]IRCCS Humanitas Research Hospital, Department of Pathology, Milano, Italy, [3]Università degli Studi della Campania "Luigi Vanvitelli", Dipartimento di Salute Mentale, Fisica e Medicina Preventiva, Napoli, Italy, [4]University Hospital Careggi, Firenze, Italy, [5]IRCCS San Raffaele Hospital, Milano, Italy, [6]Ospedale P. Pederzoli, Pathology Unit, Peschiera del Garda (VR), Italy

Background & Objectives: Sarcomatoid dedifferentiation in chromophobe renal cell carcinoma (RCCs) does represent an adverse morphological feature, as being marker of poor prognostication. Little is known about the genomic pathway causing dedifferentiation and clinical poor outcomes.
Methods: We aimed to investigate the genomic dataset focusing on chromosomal instability from public repository, and on hot spot genes involved in the errors of the mitotic machinery. Immunohistochemistry as CROCC (Ciliary Rootlet Coiled-Coil, Rootletin) and other related biomarkers were tested from the dataset; FISH (chr 1p36) was also performed as surrogate of the hot spot pathways.
Results: Genomic public dataset mapped 122 hot spot genes, with the CROCC gene pathway involved in the correction of centrosome segregation errors. The CROCC gene was altered in 15/21 (71%) of the sarcomatoid dedifferentiated chromophobe RCCs; FISH analysis revealed loss of the 1p36 gene locus in 13/15 (86%) CROCC+ cases and in 3/6 (50%) of CROCC- cases. All findings were observed in both sarcomatoid and epithelial components of chromophobe RCCs. P53 was observed in 13/21 (62%) of cases. Parvalbumin and S100A1 were expressed in the epithelial components of all cases.
Conclusion: Altered (crack) CROCC gene is a key altered pathway involved in the genomic instability of dedifferentiated chromophobe RCCs. The crack of the CROCC gene is observable also in the epithelial component of chromophobe RCCs. Overall altered genes reveal the mechanism of low tolerance to gross mitotic errors and promoting tetraploidization. Interfering with the CROCC gene in near-diploid chromophobe cancer cells may disrupts mitotic spindle architecture, and causes altered DNA segregation errors, resulting in a highly aggressive features. Cure of the CROCC gene, after restoration in a metastatic cellular model harbouring 1p36.13 deletion, may reduce the risk of metastases. Overall, we shed light to the genomic instability of dedifferentiated chromophobe RCCs, with using CAR-T cell pioneering treatments.

PS-19-038
Impact of whole tissue submission on lymph node yield in pelvic lymph node dissections for radical prostatectomy: a retrospective study
N. Kruseman[1], N. Mayer[1]
[1]Cork University Hospital, Cork, Ireland

Background & Objectives: Pelvic lymph node dissection (PLND) is central to prostate cancer staging, yet no consensus exists on optimal specimen submission. The recently revised RCPath dataset shows a poor correlation between nodal size and metastasis, with smaller, impalpable nodes often positive. Notably, the diameter of the largest metastatic deposit is more predictive of cancer-specific survival than the number of positive nodes. Although whole tissue submission may increase node yield, its clinical value remains uncertain. This study examined whether whole tissue submission impacts lymph node yield and pathological staging in routine diagnostic practice.
Methods: 514 radical prostatectomies were performed at Cork University Hospital between 2019–2023. Of these, 183 cases included separate lymph node specimens, and 172/183 (94%) had all tissue submitted for processing. Pathology reports were reviewed for node yield, staging, and deposit size.
Results: The average lymph node yield was 18.4 (median 18, range 0–59), comprising 10.1 palpable and 8.2 non-palpable nodes. On average, 7.2 extra blocks yielded 1.1 non-palpable nodes per block. Of 183 cases, 130 were N0, 28 Nx (13 with no nodes), and 25 N1. N1 cases had an average of 25 nodes (median 24), with 2 positive nodes on average and a mean deposit size of 4 mm. All N1 cases had bilateral sampling; three were N1(mi) and four lacked deposit size data.
Conclusion: Whole tissue submission increased total lymph node yield by capturing additional non-palpable nodes. However, the yield per extra block was low, averaging only 1.1 non-palpable nodes per block. The RCPath dataset provides no definitive guidance on expected lymph node yield or on whether full embedding of PLND specimens is required. In this context, routine full embedding may not represent an efficient use of laboratory resources. These findings underscore the need for standardised, evidence-based protocols that balance diagnostic thoroughness with practical resource management in PLND processing.

PS-19-039

Morphologic, molecular and therapeutic effects of the epigenetic drug panobinostat in AVPC PDX models: advancing treatment strategies for aggressive prostate cancer

E. Kontogianni[1], K. Mesiakaris[1], R. Soundararajan[2], M. Estecio[3], P. Stepherd[4], J. Dong[5], C. Logothetis[5], S. Logotheti[1], V. Tzelepi[1]
[1]University of Patras, Medical School, Pathology, Patras, Greece, [2]The University of Texas MD Anderson Cancer Centre, Translational Molecular Pathology, Houston, USA, [3]The University of Texas MD Anderson Cancer Centre, Epigenetics and Molecular Carcinogenesis, Houston, USA, [4]The University of Texas MD Anderson Cancer Centre, Genitourinary Medical Oncology, Houston, USA, [5]The University of Texas MD Anderson Cancer Centre, Department of Genitourinary Medical Oncology, Houston, USA

Background & Objectives: Aggressive variants of prostate cancer (AVPC) represent an androgen-indifferent state characterized by distinct morphologic, genetic and epigenetic characteristics. The MDA PCa 144-4 (AR-negative large cell neuroendocrine carcinoma) and MDA PCa 177-B (AR-negative adenocarcinoma with a basal phenotype) are patient-derived xenograft (PDX) models, initially developed at MD Anderson Cancer Centre and now maintained at the University of Patras. These models provide a robust system for studying AVPC. In this study we utilized these models to investigate the effect of an epigenetic modulator in prostate cancer.
Methods: C.B.-17 SCID male mice (~5 weeks old) underwent subcutaneous implantation of patient-derived tumours. Intraperitoneal drug administration began when tumour volume reached ~250 mm^3. Panobinostat (20 mg/kg), a histone deacetylase inhibitor, was administered and its effects were compared to those of the chemotherapeutic drug Carboplatin (40mg/kg). Control groups received solvent solutions. Following treatment, tumour tissues were harvested for morphological and molecular (i.e. immunohistochemistry for key epigenetic biomarkers) analyses. Statistical significance was set to $p<0.05$ for all comparisons.
Results: Carboplatin treatment led to a decrease in tumour size, while panobinostat slowed tumour growth compared to placebo therapy ($p<0.05$ and $p<0.001$, respectively). Therapy did not alter cell morphology or the expression of standard markers (i.e. AR, PSA, chromogranin, synaptophysin). Analyses of the epigenetic markers are pending.
Conclusion: Our findings highlight the therapeutic potential of epigenetic modulators as a novel strategy for treating aggressive prostate cancer. Future studies will evaluate the efficacy of panobinostat in combination with standard therapies across an expanded cohort of PDX models.

PS-19-040

Prognostic tissue markers for clear cell renal cell carcinoma tumour-stroma interaction: influence on TNM staging criteria

A.M. Cimpean[1], A.A. Cosma[1], M.M. Pasca Fenesan[1], E. Melnic[2]
[1]Victor Babes University of Medicine and Pharmacy, Microscopic Morphology/Histology, Timisoara, Romania, [2]Nicolae Testemitanu State University of Medicine and Pharmacy, Department of Pathology, Chisinau, Moldova, Republic of

Background & Objectives: New biomarkers with prognostic impact are needed to explore for clear cell renal cell carcinoma (cc-RCC) due to its quick ability to develop resistance to therapy. We aim to study the impact of Chloride Intracellular Channel Protein 1(CLIC1) expression in tumour and stromal compartments on TNM staging parameters from cc-RCC cases presenting tertiary lymphoid structures (TLSs) in their stroma, compared to cc-RCC cases lacking TLSs.
Methods: CLIC1 immunohistochemistry was conducted on 60 cc RCC tissue biopsies, followed by an evaluation of CLIC1 expression in both tumour and stromal compartments, with particular emphasis on the expression patterns of tumour cells (nuclear-N, cytoplasmic-C, membrane-M, or combined), as well as its expression in the vascular endothelium of stromal vessels and TLSs. The existence and quantity of TLS were precisely evaluated for each case, aiding in the delineation of two cc-RCC subgroups. Microscopic evaluation was then incorporated into the comparative examination of the heterogeneity in TNM staging parameters for TLS-positive versus TLS-negative cc-RCC cases.
Results: The presence of TLS was mostly linked to the CLIC1-CM pattern in tumour cells. The CLIC1-CM pattern exhibited a robust correlation with the quantity of CLIC1 positive stromal vasculature (CLIC1-MVD, $p=0.026$), as well as with T ($p=0.028$) and M ($p=0.031$). CLIC1-expressing cc-RCC with an NC pattern in tumour cells contains TLSs that significantly affect the G ($p=0.026$) and M parameters ($p=0.025$), but no relationships were seen with CLIC1-MVD. The cc-RCC subgroup devoid of TLSs exhibited nuclear expression of CLIC1 in tumour cells. The distinctive significant correlation identified for the negative subgroup of TLSs was between N and M ($p=0.028$).
Conclusion: TLSs presence, CLIC1 tumour positivity and stromal vessels strongly influence TNM staging parameters highly dependent by CLIC1 expression patterns.CLIC1 CM and M pattern seems to favour metastasis but also stromal vascularization while TLS presence may be considering a worse prognostic marker.

Background & Objectives: Gastric hyperplastic polyps (GHPs) frequently arise in a background of chronic gastritis/gastropathy. They may harbour foci of dysplasia (1–20%) and, less commonly, adenocarcinoma (~2%), particularly in larger lesions. We aimed to explore clinicopathological features and immunophenotype of GHPs with dysplasia/adenocarcinoma.
Methods: The full series included 782 GHPs ≥10mm, resected endoscopically across eight Portuguese tertiary centres (2013-2024). Patients with hereditary polyposis syndromes were excluded.

Neoplastic transformation was observed in 33 polyps (4.2%); from these, 18 cases underwent central histopathological review and are reported here. Immunohistochemistry for gastric and intestinal differentiation (MUC5AC, MUC6, MUC2, CDX2) was performed.
Results: Most neoplastic GHPs were body-located (11/18, 61.1%), with a median size of 25mm (range:12-50mm). Features of mucosal prolapse were observed in eight cases, including one hamartomatous inverted polyp. Low-grade dysplasia (LGD), high-grade dysplasia (HGD) and adenocarcinoma (ADC) were found in 10 (55.6%), eight (44.4%) and six (33.3%) cases, respectively. Dysplasia extent correlated with grade and malignant transformation: focal (<10%) in seven cases (all LGD); multifocal (10–50%) in eight (LGD:n=3, HGD:n=5, ADC:n=3); diffuse (>90%) in three (all HGD+ADC). Morphological subtyping of dysplasia showed pure gastric or intestinal morphology in 11 cases (61.1%), associated with lower risk of progression (LGD:n=9/11,81.8%; HDG:n=2/11,18.2%; ADC:n=0/11,0%), whereas coexistence of gastric and intestinal morphology (seven cases, 38.9%) was associated with higher risk of malignancy (LGD:n=1/7,14.3%; HDG:n=6/7,85.7%; ADC:n=6/7,85.7%). Preliminary subtyping of eight cases by immunohistochemistry showed hybrid immunophenotype in the majority of cases (6/8,75%), encompassing LGD and HGD/ADC. All ADC showed tubular/papillary morphology (intestinal subtype by Laurén) and were low-grade.
Conclusion: The extent of dysplastic involvement - especially when diffuse - as well as the coexistence of gastric and intestinal differentiation, suggesting unstable phenotype, are key predictors of malignant transformation in GHPs. Preliminary data suggest that morphological subtyping may be more informative than immunophenotype for risk stratification.

PS-20-002
How did COVID-19 pandemic influence clinico-pathological characteristics of colorectal-cancer?
K. Dovžan[1], I. Hussein[1], T. Špes[1], Ž. Ledinek[1,2], T. Bujas[2], V. Kloboves Prevodnik[1,3]
[1]Faculty of Medicine, University of Maribor, Maribor, Slovenia, [2]University Medical Centre Maribor, Department of Pathology, Maribor, Slovenia, [3]Institute of Oncology Ljubljana, Department of Cytopathology, Ljubljana, Slovenia

Background & Objectives: Colorectal cancer (CRC) is a major global health concern, with early detection and timely treatment playing a crucial role in patient outcomes. The COVID-19 pandemic significantly disrupted healthcare services, potentially causing delayed CRC diagnosis and thus affecting treatment and prognosis of those patients.
Methods: In our retrospective analysis we examined clinico-pathological data of 694 patients who underwent surgery for CRC and whose surgical specimens were diagnosed at the Department of Pathology, University Medical Centre Maribor from January 2018 to January 2023. We compared demographic data, histopathological characteristics of tumours, tumour stage and treatment in two groups of patients, one diagnosed in pre-COVID-19 period and the other during the COVID-19 pandemics.
Results: Out of 694 patients included in the study, 406 (58,5 %) were labelled as pre-COVID-19 and 288 (41,5 %) cases as during COVID-19. The pre-COVID-19 group of patients had lower tumour grade χ^2 (1, N = 661) = 20.47, $p < 0.001$ and tumour stage (U = 49,325, Z = -2.712, $p < 0.05$) at the time of diagnosis compared to patients, diagnosed during COVID-19 pandemic. Additionally, in the pre-COVID19 group the number of cases diagnosed in national screening program was slightly higher than in COVID-19 group, however the difference was not significant. Similar trend was observed for the need to perform emergency surgery due to disease-related complications e.g. perforation or ileus, which was slightly higher during COVID-19 pandemic. Other histopathological and clinical data also did not significantly differ between the groups.
Conclusion: COVID-19 pandemic significantly impacted tumour grade and tumour stage of CRC at the time of diagnosis. Accessibility to screening program was also negatively affected by the pandemic and slightly more patients needed emergency surgery due to disease-related complications. Our findings thus underscore the importance of maintaining of cancer screening programs and treatment of cancer patients during healthcare crisis.

PS-20-003
Unraveling the immunopathology of celiac disease: a correlation between Marsh stage progression and IgA deposits
R.-G. Ionescu[1], I. Tudor[1], R.-M. Busca[1], D.M. Marinoiu[1], A.-I. Cibotariu[1], R. Neagu[1], L. Stanciu[1], V. Marin[1], S.-A. Zurac[1,2], A. Bordea[1], C. Popp[1]
[1]Colentina University Hospital, Pathology, Bucharest, Romania, [2]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background & Objectives: This study aims to elucidate the relationship between the histopathological severity of celiac disease, as classified by the Marsh grading system, and the distribution of IgA deposits within the intestinal mucosa. Given the pivotal role of IgA in mucosal immunity, uncovering its progressive depletion in correlation with tissue damage could provide novel insights into pathophysiology.
Methods: Duodenal biopsy specimens from patients with active celiac disease were systematically evaluated through histopathological and immunohistochemical analyses. The samples were categorized according to the Marsh classification and IgA deposits were quantified using a visual analogue scale. Statistical models were employed to assess the association between increasing Marsh scores and IgA depletion.
Results: A striking inverse correlation was observed between Marsh grade severity and IgA deposition. Patients with extensive mucosal damage (Marsh 3) exhibited a profound reduction in IgA deposits compared to those with milder histopathological alterations (Marsh 1-2). For patients diagnosed with Marsh 2, 3a and 3b there were similar findings regarding IgA deposits. The most pronounced depletion was noted in cases with complete villous atrophy, highlighting a progressive impairment of mucosal immune defense mechanisms.
Conclusion: These findings underscore a direct link between escalating histological severity in celiac disease and a concomitant reduction in IgA deposits, suggesting that extensive mucosal destruction may compromise the integrity of local immune responses. This novel insight into the interplay between histopathological damage and mucosal immunity could pave the way for refined therapeutic interventions aimed at preserving mucosal defense mechanisms in severe celiac disease.

PS-20-004
Expression of HER2 in primary colorectal carcinomas
S. Kanoun[1], I. Helal[1], F. Khanchel[1], N. Khedhiri[2], E. Ben Brahim[1], R. Jouini[1], A. Chadli Debbiche[1]
[1]Habib Thameur University Hospital, Department of Pathology, Tunis, Tunisia, [2]Habib Thameur University Hospital, Department of General Surgery, Tunis, Tunisia

Background & Objectives: HER2 expression represents a potential theranostic marker in cancers like breast and gastric cancer, but its role in colorectal cancer (CRC) remains unclear, with reported rates varying widely.

This study assesses HER2 immunohistochemical expression in primary CRC across all stages in Tunisian patients to determine its prevalence in this population.
Methods: This retrospective study included all CRC patients diagnosed on surgical resection specimens at Habib Thameur Hospital over 3 years. HER2 status was assessed by immunohistochemistry using the Tissue MicroArray (TMA) technique, following esophagogastric cancer standardized criteria.
Results: The study included 104 CRC patients with a mean age of 61 years and a male-to-female ratio of 1.36. Tumours were predominantly located in the descending colon (52.9%). Disease staging revealed a majority of stage II cases (44.2%), followed by stage III (29.8%), stage IV (14.4%) and stage I (11.6%).
HER2 expression analysis revealed three distinct groups: the vast majority of cases (98%, $n = 102$) were HER2-negative (scores 0/1+). No equivocal cases (score 2+) were identified, and only one tumour (0.96%) exhibited HER2 overexpression (score 3+). The sole HER2 positive case (score 3+) was classified as pT2N0M0 with low histological grade and exhibited microsatellite instability (MSI-high status). Notably, 13 cases (12.5%) showed isolated cytoplasmic staining without membranous HER2 expression.
Conclusion: Our study found lower rates of HER2 overexpression in Tunisian CRC patients compared to other populations. These findings suggest the need for larger, multicente rstudies to clarify HER2's clinical role in CRC within our region. Notably, frequent cytoplasmic HER2 staining warrants further investigation into its biological and clinical relevance.

PS-20-005
Ten-year retrospective analysis of gastric biopsies: focus indefinite for dysplasia cases
G. Nogueira Fontinha[1,2], V. Almeida[1,2]
[1]ULS Coimbra, Pathology, Coimbra, Portugal, [2]University of Coimbra, Faculty of Medicine, Coimbra, Portugal

Background & Objectives: Gastric epithelial dysplasia is a known precursor of gastric carcinoma, yet its diagnosis — particularly in indefinite cases — remains challenging. This study aimed to evaluate the prevalence and outcomes of gastric dysplasia over a 10-year period, with special emphasis on the clinical-pathological evolution of cases initially diagnosed as "indefinite for dysplasia."
Methods: A retrospective review of gastric biopsies performed between 2013 and 2023 was conducted. Polipectomies, secondary neoplastic involvement and neoplasia of gastroesophageal anastomosis were excluded. For counting purposes multiple biopsies of a patient performed on a single moment were counted as 1. A total of 11553 gastric biopsies were analysed. Only the most severe diagnosis per biopsy was considered.
Results: Out of 11553 gastric biopsies 589 (5.1%) were carcinomas, 40 (0.3%) high-grade dysplasia (HGD), 137 (1.2%) low-grade dysplasia (LGD) and 22 (0.2%) were indefinite for dysplasia (ID). Patients with ID were mostly male (15/22) with mean age of 71.3 (range 43-91). 90% of ID biopsies were targeted at an endoscopic lesion. All cases were associated with some degree of inflammation.
Eleven (50%) patients underwent follow-up (FU) biopsies (mean interval: 5.8 month, range 1–24), 5 of which multiple re-biopsies. 4/11 (36.4%) had abnormal findings: 1 LGD, 2 adenocarcinomas diagnosed at first re-biopsy (both within 2 months) and the remaining patient an intestinal-type adenoma at 8 month and adenocarcinoma at 2 years re-evaluation. 7/11 (63.6%) had normal findings on re-biopsy, including the 2 cases without endoscopic lesion.
Conclusion: Gastric dysplasia in biopsies is infrequent, but presents a significant risk of malignant progression. Cases diagnosed as "indefinite for dysplasia" show heterogeneous outcomes. Close surveillance and prompt re-biopsy are essential, particularly when endoscopic lesions are present.

PS-20-006
Establishment and application of the Operative Link on Gastric Low-grade Dysplasia assessment (OLGLD) system based on biopsy specimens
R. Gao[1]
[1]Fuzhou University Affiliated Provincial Hospital, Pathology, Fuzhou, China

Background & Objectives: For patients with low-grade dysplasia (LGD) detected through biopsy, identifying factors related to endoscopic treatment is crucial.We established an operative link on gastric low-grade dysplasia assessment (OLGLD) system to predict the progressive risk of LGD in biopsy specimens, in order to propose new follow-up or treatment strategies for patients with LGD.
Methods: The OLGLD system was established based on whether goblet cells were present in LGD glands, the degree of LGD involvement (including horizontal and vertical involvement) and whether LGD glands involved margins in the first biopsy specimens of 527 patients with LGD, and was set different scores based on the incidence of advanced neoplasia in second biopsy or endoscopic resection specimens.
Results: According to the OLGLD system, there were significant differences in the incidence of advanced neoplasia for different indicator scores, total scores, or risk scores, and high-risk patients were identified through risk scores. For visible LGD lesions with clear margins, although the OLGLD system identified high-risk patients, there was no significant difference in the incidence of advanced neoplasia in lesions with $\geq$ 1cm in size, lesions with medium to high-risk scores and lesions with $\geq$ 1cm in size and lesions with medium to high-risk scores. The incidence and the risk of advanced neoplasia in patients with visible and unclear marginal LGD lesions of OLGLD high-risk scores were higher than that in patients with visible and unclear marginal LGD lesions. For invisible lesions, although no patients had advanced neoplasia during follow-up, and the OLGLD scores were mainly low-risk scores, the probability of re-detecting LGD for medium-risk-score lesions was significantly higher than that for low-risk-score lesions.
Conclusion: Although gastric mucosal biopsy through endoscopy showed LGD lesions, the OLGLD system was beneficial for screening high-risk patients.

PS-20-007
Clinical insights about the diagnoses of colonic high-grade neuroendocrine tumours and neuroendocrine carcinomas
M. Gonzalez[1], Y. Rong[2]
[1]Temple University Hospital / Lewis Katz School of Medicine, Pathology Department, Philadelphia, USA, [2]Temple University Hospital / Lewis Katz School of Medicine, Department of Pathology, Philadelphia, USA

Background & Objectives: In the recent WHO classification of Neuroendocrine neoplasms (NENs), neuroendocrine carcinomas (NECs) were separated from the category of neuroendocrine tumours (NETs) based on behaviour, morphology, molecular findings, treatment, and prognosis.
Occasionally, grade I/II NETs (GI/GII) can show progression to a GIII-NET, demonstrated by morphology, necrosis, or an increase in the Ki67-proliferative index. NECs lack (*MEN1/DAXX/ATRX)* mutations identified in GIII-NETs, harbour *TP53* and *RB1* mutations.
Methods: A 6-year retrospective review of cases diagnosed as colonic NETs and NECs was performed as a quality assurance project to determine if the diagnoses of GII/GIII-NETs was based on

morphology or KI67-proliferative index or mitoses. Our electronic medical record system retrieved the cases using a natural language search for "colon neuroendocrine" from 01/2019 to 01/2025.
The reports and slides of the GII-NETs, GIII-NETs and NECs were reviewed. Data regarding these biopsies (site, morphology, mitotic rate, Ki67-proliferative index) was recorded.
Results: One hundred nineteen specimens (NET:119/NEC:6) were identified. The details of these diagnoses and analyses are shown in Figure 1.
Figure 1
Conclusion: The most common NENs of the colon are rectal GI-NETs. Colonic NECs are rare. SCC is the most common type. The most common diagnostic pitfall was dismissing the morphology of SCC due to low KI67-indexes (30-40%), and/or mitotic rates. Patient A's had recurrent GIII-NETs but there were foci with SCC-morphology that showed loss of RB1/TP53 expression suggesting a rare progression to SCC.Morphology and no Ki67-proliferative index or mitoses is what distinguish NECs from GII or GIII-NETs. Other differentials should always be excluded, such as poorly-differentiated carcinomas with neuroendocrine features, metastatic NECs. The underlying molecular alteration of NET's progression to SCC still needs to be understood. Clinical and radiological correlation, stains (Rb, p53, INSM1) or NGS studies help in the differential diagnosis of challenging cases, and guide the clinical team toward an appropriate treatment.

PS-20-008
Evaluation of the demographical and histomorphological features and turnaround times of Bowel Cancer Screening Programme biopsies in a district general hospital in the UK – an audit
E. Gun[1], N. Alsanjari[1], P. Ozua[1]
[1]Basildon University Hospital, Mid and South Essex NHS Foundation Trust, Histopathology, Basildon, United Kingdom

Background & Objectives: The NHS Bowel Cancer Screening Programme (BCSP) is a UK-wide initiative aimed at early detection of bowel cancer to reduce mortality rates, offered to individuals aged 50 or above. The BCSP sets specific standards for pathologists reporting these biopsies. This audit aimed to evaluate the demographic profile of patients undergoing BCSP, the histomorphological features of detected lesions, the turnaround times (TATs) of BCSP biopsies compared to national standards, and to identify areas of excellence and opportunities for improvement.
Methods: An electronic search of the local histopathology reports from the hospital database was performed to identify the BCSP cases between January 2023 and January 2024. Reports were reviewed regarding age, gender, locations, number of polyps, diagnoses, and TATs.
Results: A total of 686 patients and 1851 specimens were identified. There were 424 males (61,8%) and 254 females (38,2%) with an average age of 66. Multiple specimens were received in 62,9%. The majority of specimens were localised in the rectosigmoid colon, followed by the transverse colon. The most common type of lesion was adenomatous polyps, with a total of 1205 lesions, constituting 67% of all lesions. Of these, 55% were tubular adenomas, 11% were tubulovillous adenomas, and <1% were villous adenomas. The high-grade dysplasia (HGD) rate in adenomatous polyps was 2,8%. Serrated lesions constituted 25% of all lesions, and all other diagnoses were detected in <10%. The average TAT was 3,18 (1,05-13,7) days.
Conclusion: The distribution of diagnoses aligns well with national BCSP data and demonstrates compliance with the national standards with excellent TATs, meeting patient management needs effectively. There is a slight underdiagnosis in HGD rates compared to the expected benchmark. To conclude, strengthening training and quality assurance measures to improve HGD detection should be performed while maintaining high standards in cancer reporting and TATs.

PS-20-009
Tumour and cytotoxic T cell proliferation patterns in colorectal cancer
M. Kastinen[1], J. Härkönen[2,3], P. Sirniö[1], H. Elomaa[4], H. Karjalainen[1], V.K. Äijälä[1], V.V. Tapiainen[1], M. Ahtiainen[5], J. Böhm[2], A. Tuomisto[1], M.J. Mäkinen[1], J.P. Väyrynen[1]
[1]Oulu University Hospital, and University of Oulu, Translational Medicine Research Unit, Medical Research Centre Oulu, Oulu, Finland, [2]Hospital Nova of Central Finland, Well Being Services County of Central Finland, Department of Pathology, Jyväskylä, Finland, [3]A.I. Virtanen Institute for Molecular Sciences, University of Eastern Finland, Faculty of Health Sciences, Kuopio, Finland, [4]University of Helsinki, Research Program in Systems Oncology, Helsinki, Finland, [5]Hospital Nova of Central Finland, Well Being Services County of Central Finland, Central Finland Biobank, Jyväskylä, Finland

Background & Objectives: Tumour cell proliferation is a prognostic tool in many cancers, but in colorectal cancer (CRC) results have been conflicting. Recently, intratumoral T cell proliferation has been associated with longer survival, but the mechanisms are complex and poorly understood. Our aim was to thoroughly evaluate the role of proliferation in tumour and CD8+ T cells in CRC.
Methods: We performed multiplex immunohistochemistry for MKI67 (Ki-67), CD8, and CK on two large CRC cohorts (N=1839). Additionally, we utilized Single-cell RNA sequencing data (N=62) to more characterize molecular features and signalling pathways of proliferating and non-proliferating cells.
Results: Tumour cell proliferation associated with improved cancer-specific survival (multivariable HR for high vs. low 0.60, 95%CI 0.43-0.83 in the larger cohort), downregulation of epithelial mesenchymal transition, and upregulation of MYC signalling. Higher proliferation correlated with an anti-tumorigenic microenvironment, marked by high densities of T cells, M1-like macrophages, and mature monocytic cells, and low densities of M2-like macrophages and immature monocytic cells (all $p<0.05$). Amongst immune cells, proliferating CD8+ T cells showed high expression of effector molecules such as GZMB and IFNG and were more strongly associated with favourable outcome than non-proliferating CD8+ T cells (multivariable HR for high vs. low 0.49, 95%CI 0.35-0.70 in the larger cohort). Spatial analysis revealed that proliferating CD8+ T cells were located 47% closer to tumour cells than non-proliferating CD8+ T cells, and the prognostic significance for both subsets was comparable when evaluating their proximity to tumour cells.
Conclusion: Cancer cell proliferation in CRC is associated with improved survival. Proliferating CD8+ T cells emerged as a stronger prognostic marker than non-proliferating CD8+ T cells, though this difference diminishes with closer spatial proximity to tumour cells. These results highlight the complex relationships between proliferation dynamics and the immune landscape in CRC.

Funding: This study was funded by Cancer Foundation Finland (59-5619 and 69-7354 to JPV), Finnish Medical Foundation (6021 to JPV; 6259 to MK), Oulu Medical Research Foundation (to MK), Cancer Society of Northern Finland (to MK), Sigrid Jusélius Foundation (230229 to JPV), and Finnish State Research Funding (to MJM and JPV). Is there a relationship between synchronous CD47/SIRPα and PD-L1 expression in advanced colon adenocarcinoma?
Z. Urun[1], Y. Baş[1], N. Koç[2], E. Rençber[3], B. Yılmaz[1], S.F. Acar[1], H.H. Keser Şahin[1], E.G. Alkurt[4], İ. Karadağ[5], M. Kendirci[4]
[1]Hitit University Faculty of Medicine, Department of Pathology, Çorum, Turkey, [2]University of Health Sciences Haydarpasa Numune

Training and Research Hospital, Department of Pathology, İstanbul, Turkey, [3]Hitit University Faculty of Medicine, Department of Public Health, Çorum, Turkey, [4]Hitit University Faculty of Medicine, Department of General Surgery, Çorum, Turkey, [5]Hitit University Faculty of Medicine, Department of Oncology, Çorum, Turkey

Background & Objectives: This study aims to determine the synchronous expression of CD47/SIRPα and PD-L1 in colon adenocarcinoma and to investigate their effects on clinicopathological factors and prognosis.
Methods: Immunohistochemical synchronous expression of CD47 (D3O7P), SIRPα (D6I3M) and PD-L1 (22C3) and their association with clinicopathological factors were examined in formalin-fixed paraffin-embedded specimens of 106 primary colon adenocarcinomas. CD47 and SIRPα was scored as 0% (score 0), 1-10% (1 point), 10-50% (2 points) and >50% (3 points) in tumour cells. Combined positive score (CPS) was used for PD-L1.
Results: There was a statistically significant positive relationship between pT3 and pT4 and PD-L1 and CD47 tumour cell expressions. CD47 expression was found to be ≥1% in all clinical stage 4 ($p<0.001$) and metastatic patients ($p<0.001$). 76.9% of pT4 patients had CD47 expression ($p=0.006$). CD47 was negative in 67.3% of patients with tumour budding score 1 ($p<0.001$). CD47 staining above 1% was detected in 76.5% of the patients with lymphovascular invasion ($p<0.001$). CD47 was positive in 34 (87.2%) of 39 (36.8%) patients with PD-L1 CPS ≥ 1% ($p<0.001$). While the mortality risk of patients with CD47 staining intensity ratio of 1-10% and 11-50% was 1.4 times higher than that of patients with <1%, the mortality risk was 3.89 times higher in patients with >50%, indicating that these results were a poor prognostic factor ($p<0.001$). There was a statistically significant difference between survival rates with CD47 staining intensity >50% ($p=0.003$).
Conclusion: It was understood that synchronous expression could occur in different cells of the same tumour. If the CD47 expression rate is high, it can be thought that it indicates the patients' possible clinical stage and pT elevation, N, and M. Additionally, proving synchronous expression associations will enable us to better understand their roles in colon adenocancer, how they affect the tumour microenvironment, and how to manage their immunotherapeutic targets.

Funding: Hitit University Scientific Research Projects Coordination, Çorum, Türkiye

PS-20-011
Metastatic renal cell carcinoma in the gastrointestinal tract, an easily missed entity
W. Cao[1]
[1]Brown University Health, Department of Pathology, Providence, USA

Background & Objectives: Renal cell carcinoma (RCC) usually metastasizes to lung, bone, liver, and brain. Metastasis of RCC to the gastrointestinal (GI) tract is rare. In this study, we analysed the metastatic RCCs in the GI tract.
Methods: We queried our records for metastatic RCCs in the GI tract from 1990 to 2024. Twenty cases were included. We analysed RCC types, metastatic locations, and the duration of metastasis after renal resection.
Results: Fifteen males and five females were included with an average age of 67 (ranging from 47 to 83). Sixteen cases were clear cell RCC (80%), three were chromophobe RCC (15%) and one was unclassified RCC (5%). Sixteen cases had nephrectomy in our institute. The GI metastatic incidence of RCC was 0.8% (16/2019). The metastatic sites were stomach (9/20, 45%), duodenum (7/20, 35%), and colorectum (4/20, 20%). The average duration of metastasis after nephrectomy was 80±16 months. As we expected, the lower pathological stages (pT1 and pT2) took much longer time (164±32 months, N=5) to metastasize than the higher pathological stages (pT3 and pT4, 62±13 months, N=11, $p<0.01$). Interestingly, two out of seven duodenal metastatic RCC were misdiagnosed as granulation tissue at the first diagnosis. The misdiagnosis rate of duodenal metastatic RCC was 29% (2/7). One out of nine gastric metastatic RCC was misdiagnosed as poorly differentiated gastric adenocarcinoma. The misdiagnosis rate of gastric metastatic RCC was 11% (1/9). All these three misdiagnosed cases were clear cell RCC.
Conclusion: Metastatic RCC in the gastrointestinal tract was rare (0.8%). The most common metastatic RCC was clear cell RCC (80%), and the most common locations were stomach and duodenum. The misdiagnosis rate in the duodenum and stomach was high (29% and 11%). When metastatic RCC is suspected in the duodenum and stomach, immunohistochemical stains should be performed to rule out metastatic RCC.

PS-20-012
PRMT5 regulates the proliferation of colorectal cancer by influencing NK cells
Z. Nie[1], Y. Guo[1], Z. Chang[2], J. Chang[2]
[1]Xi'an Daxing Hospital affiliated to Yan'an University, Department of Pathology, Xi'an, China, [2]Ministry of Education, School of Medicine, Northwest University, b. Key Laboratory of Resource Biology and Biotechnology in Western China, Xi'an Shaanxi, China

Background & Objectives: Colorectal cancer patients still exhibit immunotherapy resistance. Protein arginine methyltransferase 5 (PRMT5) and natural killer (NK) cells play important roles in tumorigenesis and immune escape by mediating the symmetrical dimethylation of arginine between histone and nonhistone proteins. However, whether PRMT5 regulates NK cell phenotypic plasticity and functional polarization remains unknown.
Methods: Multiple immunofluorescence staining of PRMT5, CD16, CD56, IL-1R8 and TIGIT was performed on samples from a total of 180 patients with CRC. NK92 cells overexpressing PRMT5 were constructed via lentiviral transduction and cocultured with CRC cells. The cytotoxicity of NK cells against tumour cells was detected. CRC cells were cocultured with PRMT5 inhibitor NK cells, and the proliferation of NK cells was detected. The expression of CD16, CD56, PRMT5, TIGIT and IL-1R8 was detected by flow cytometry. The effect of NK cells on the proliferation of CRC cells was detected by establishing a tumour-bearing mouse model with PRMT5 overexpression or PRMT5 inhibition.
Results: The change in the NK cell phenotype that occurs in the immune microenvironment of bowel cancer is closely related to the high expression of PRMT5 in the interstitium of bowel cancer patients. We found that PRMT5 is critical for peripheral NK cell maintenance. PRMT5 overexpression significantly reduced the cytotoxicity of NK cells. After the inhibition of PRMT5, the ability of NK cells to secrete cytokines was weakened, and the cytotoxicity was significantly enhanced. NK92 cells killed colorectal cancer cells, and overexpression of PRMT5 inhibited this effect and promoted CRC cell proliferation. The cytotoxicity of NK-92 cells supplemented with PRMT5 inhibitors was reduced, and the growth of colorectal cancer tumours was significantly inhibited.
Conclusion: PRMT5-silenced NK cells were still beneficial for the treatment of CRC with an immunodeficient microenvironment.PRMT5 is a potential therapeutic target for NK cells in colorectal cancer.

Exploring the relationship between histologic features and genomic profiles in gastric cancer

H.J. Oh[1], C. Kim[1], M. Kang[2], H.S. Lee[3], H.Y. Na[1], J.W. Kim[2], J.-W. Kim[2], S. Lee[4], K.-W. Lee[2]

[1]Seoul National University Bundang Hospital, Department of Pathology, Seongnam, Republic of Korea, [2]Seoul National University Bundang Hospital, Department of Internal Medicine, Seongnam, Republic of Korea, [3]Seoul National University Hospital, Department of Pathology, Seoul, Republic of Korea, [4]Seoul National University Bundang Hospital, Department of Pathology and Translational Medicine, Seongnam, Republic of Korea

Background & Objectives: Gastric cancer remains the fourth leading cause of cancer-related death. In stage IV disease, treatment decisions are guided by biomarkers such as C-erbB2, PD-L1, microsatellite instability, EBV, Claudin 18.2. However, these markers do not always accurately predict treatment response. Recent studies highlight the role of stromal components, including cancer-associated fibroblasts and tumour-infiltrating lymphocytes, in modulating drug sensitivity, though their genomic associations are not well defined. Advances in artificial intelligence-based digital pathology have enabled prognosis prediction and histology–genomic correlation in various cancers, but such integrative analyses are limited in gastric cancer. This study aims to explore the relationship between histologic features and genomic profiles to support therapeutic decision-making.
Methods: We analysed 405 patients with metastatic or recurrent gastric cancer who underwent next-generation sequencing (NGS) at Seoul National University Bundang Hospital from January 2020 to December 2023. Patients were subgrouped based on histologic type (e.g., tubular adenocarcinoma, poorly cohesive carcinoma, signet ring cell carcinoma, and others) and stromal reactions (lymphocytic infiltration, desmoplasia). Clinicopathological and molecular data were collected. Differences in NGS results among subgroups were evaluated, and associations between genetic mutations and clinicopathological or molecular features were analysed.
Results: TP53 mutation was the most common genetic alteration in all histologic subtypes except signet ring cell carcinoma, in which CDH1 mutation was predominant. BRCA2 mutations were frequently observed in the mixed adenocarcinoma (intestinal type dominant) subgroup, while KRAS mutations were common in the mucinous adenocarcinoma subgroup. Among desmoplasia subgroups, the highest-grade group showed a significantly higher frequency of CDH1 mutations compared to others.
Conclusion: This study demonstrates a correlation between histologic subtypes, genomic alterations, and clinicopathologic features in gastric cancer. Integrating histologic and molecular profiles may help predict patient prognosis and response to therapy, providing a foundation for more personalized treatment approaches.

Barrett's e-learning module leads to significant improvement of pathologists' assessment of oesophageal Barrett's biopsies with(out) dysplasia

M. van der Wel[1,2], A. Ooms[3], S. Meijer[1], on behalf of the Dutch Oesophageal Pathology Panel

[1]Amsterdam UMC, Pathology, Amsterdam, The Netherlands, [2]Isala Klinieken, Pathology, Zwolle, The Netherlands, [3]Pathan BV, Pathology, Rotterdam, The Netherlands

Background & Objectives: Assessment of Barrett's oesophagus (BE) biopsies is associated with significant interobserver variability. In the Netherlands we established an expert panel consisting of 15 quantitatively trained gastro-oesophageal (GE) expert pathologists, available for Dutch colleagues for consultation purposes but not readily accessible elsewhere. Using this panels' expertise, we built an e-learning module with which we investigated whether this module significantly improves diagnostic consensus within a large pathologist cohort.
Methods: The e-learning module consisted of an online platform containing 25 biopsy test cases (H&E and p53-slide) covering the BE diagnostic spectrum (11 non-dysplastic BE, 2 indefinite-for-dysplasia, 8 low-grade dysplasia, 4 high-grade dysplasia), followed by an evidence-based theoretical section, after which the same re-randomized 25 cases were re-assessed. All cases were selected from the expert panels' archives, with consensus of at least 75% of panel members ("gold-standard diagnosis"). Demographics of participants were recorded and concordance with the gold standard, as well as Cohen's Kappa, were calculated for pre- and postmodule results.
Results: 192 pathologists (including residents) enrolled and 124 participants finished the module (65%), 40% of which were general pathologists, 33% residents and 27% GE-pathologists. 65% of assessors had less than 10 years' experience assessing BE biopsies. Mean concordance with gold standard diagnosis was 81% pre-module and 85% post-module (p=0,0000) for dysplasia, corresponding to mean Cohen's kappa of 0,64 and 0,71 (p=0,0000). Both general pathologists and residents showed significant improvement of their BE biopsy assessment after working through the module. GE-pathologist also showed some improvement, albeit not significant.
Conclusion: This Barrett's e-learning module, built with the expertise of an expert pathology panel, leads to significant improvement of pathologists' assessment of BE biopsies. This implies that this module could be helpful in areas in which expert consultation is not readily available, in order to improve inter- and intrapathologist variability.

PS-20-015

Diagnostic variability in assessment of Barrett's oesophagus biopsies: creating awareness through laboratory-specific feedback reports

M. van der Wel[1,2], A. Ooms[3], S. Meijer[1], on behalf of the Dutch Oesophageal Pathology Panel

[1]Amsterdam UMC, Pathology, Amsterdam, The Netherlands, [2]Isala Klinieken, Pathology, Zwolle, The Netherlands, [3]Pathan BV, Pathology, Rotterdam, The Netherlands

Background & Objectives: Assessment of Barrett's oesophagus (BE-) biopsies is associated with significant inter- and intra-laboratory diagnostic variability, notably leading to overdiagnosing of dysplasia and therefore higher disease burden and health care costs. The aim of this study was to improve accuracy and decrease diagnostic variability on pathologist- and laboratory level. On pathologist-level, an e-learning was offered. On laboratory-level, feedback reports were sent out, benchmarking the individual laboratory against other Dutch laboratories. This abstract focusses on the laboratory-level results.
Methods: All protocolled reports of oesophageal BE-biopsies ± neoplasia were retrieved from the national pathology database for two six-month time periods, with the e-learning offered in between. Biopsies were classified according to the Vienna classification. For the two time periods, mean % grading per diagnostic category was calculated. An overall deviation score (ODS), representing the sum of deviations from the grade-specific overall proportions, was calculated to compare the absolute deviation for all grades at once. Case-mix correction was performed by multivariate logistic regression analyses, providing laboratory-specific ORs for non-dysplastic BE (NDBE) versus dysplastic BE. Individual laboratories received feedback reports where they were benchmarked against all other Dutch laboratories.
Results: After feedback and the offered e-learning module, no significant decrease in neoplastic diagnoses was reported on a national level

after case-mix correction (p=0,12). On individual laboratory level, 1/10 laboratories showed a significant decrease in neoplastic diagnoses (p=0,001). Comparing two time periods without case-mix correction, there is a trend towards less neoplastic diagnoses. Mean grading was 68% NDBE, 5% indefinite-for-dysplasia, 10% low-grade dysplasia (LGD), 3% high-grade dysplasia, 13% (suspected) carcinoma. ODS showed 45% versus 53% of laboratories falling within 95% confidence interval (CI) for the two time periods.
Conclusion: After laboratory-specific feedback and the e-learning, a trend towards more NDBE and less LGD diagnoses was observed. However, diagnostic grading behaviour of BE-biopsies didn't change significantly on laboratory- nor national level.

PS-20-016
Predictive value of superficial spreading feature for lymph node metastasis in T1b oesophageal squamous cell carcinoma and its implication for endoscopic resection
M.S. Roh[1], J.Y. Lee[2]
[1]Dong-A University College of Medicine, Pathology, Busan, Republic of Korea, [2]Dong-A University College of Medicine, Internal Medicine, Busan, Republic of Korea

Background & Objectives: Recently, endoscopic resection (ER) can be considered as the standard for care for selected T1b oesophageal squamous cell carcinoma (ESCC). It is well established that lymph node metastasis (LNM) is a key prognostic factor for T1b ESCC. Therefore, ER of T1b ESCC is suitable for lesions that have no or low risk of LNM. However, endoscopic findings for prediction of LNM are limited. Little is known about the significance of superficial spreading (SS) feature extending along the long axis of the oesophagus. This study aimed to evaluate the predictive value of SS feature for LNM and its implication for ER.
Methods: The study included 78 patients with T1b ESCC who had undergone esophagectomy with LN dissection. The incidence of LNM was compared according to SS length. We evaluated possible predictive SS length for LNM using the receiver operating characteristic (ROC) curve. We also evaluated the relationship between SS feature and other clinicopathological findings.
Results: The prevalence of LNM was 34.6% (27/78) and SS length was distributed from 1.2 cm to 10.9 cm. SS length was significantly correlated with LNM ($p = 0.043$) and marginally associated with depth of submucosal invasion ($p = 0.066$). However, SS length was not correlated with other clinicopathological findings. When we established the cutoff value for SS length (3.1 cm) by ROC curve, SS (≥3.1 cm) types tended to increase the risk of LNM than non-SS (<3.1 cm) types, but not significantly ($p = 0.057$).
Conclusion: Our data suggest that SS feature of T1b ESCC is a potentially useful marker for predicting LNM, although SS feature failed to demonstrate definitive evidence of significance. Based on these results, SS feature could be employed to decision-making by endoscopists with regard to which patients should best undergo ER. Further elucidation is needed to determine the significance before implementation into clinical practice.

PS-20-017
IgG4-related esophagitis – new kid on the block?
H. Henzinger[1], A. Aigelsreiter[1], M. Pollheimer[1], I. Milosevic[1], C. Langner[1]
[1]Diagnostic & Research Institute of Pathology, Medical University of Graz, Graz, Austria

Background & Objectives: IgG4-related esophagitis is a rare manifestation of IgG4-related disease and therefore not well recognized among pathologists. We hereby present six cases of IgG4-related esophagitis diagnosed at our institution between 2019 and 2025.
Methods: The institutional database was searched for all cases of IgG4-related esophagitis and the respective slides were reviewed. Diagnosis was validated in six cases (5 biopsies, 1 oesophageal resection) and correlated with clinical data.
Results: Three of the patients were female, three were male with a mean age of 61 years (range 54-74). Most patients had reflux symptoms (epigastric pain and/or regurgitation; 5/6) and dysphagia (4/6). In one case, the whole oesophagus was involved, while in the other 5/6 the lesions were confined to the distal third. Ulcerations were present in 100%, oesophageal stenosis in 50% of cases. None of the patients had any suspected or confirmed involvement of IgG4-related disease in another organ and only one had elevated serum IgG4 levels. In all cases, multiple rounds of biopsies were undertaken until diagnosis was made (mean 4, range 2-9), with the time to diagnosis ranging from 3 months to 18 years. Histologically, plasma cell dominant inflammation was present in all cases, with a range of 50 to >100 IgG4 positive plasma cells per HPF and an IgG4/IgG ratio of 30-95%. Follow-up was available for three patients, all of whom had clinical and histological remission after treatment with topical budesonide (3/3). However, 2/3 developed candidal esophagitis under therapy, and disease recurred in both patients after termination of steroid treatment.
Conclusion: IgG4-related esophagitis responds very well to corticosteroids but is easily overlooked in histology, in particular when tissue is only superficially sampled. With this case series, we want to highlight the importance of IgG4 immunohistochemistry in ulcerative esophagitis with plasma cell-predominant inflammatory infiltrate.

PS-20-018
Clinicopathological characterisation of Epstein–Barr virus-associated gastric cancer: a single-institution Polish study
A. Chrzan[1,2], E. Sarnowska[3], M. Suska-Węgier[1,2], A. Grabuś[2], N. Rusetska[3], J. Siedlecki[4], A. Mróz[2]
[1]Institute of Mother and Child, Department of Pathomorpology, Warsaw, Poland, [2]Maria Sklodowska-Curie National Research Institute of Oncology, Department of Cancer Pathomorphology, Warsaw, Poland, [3]Maria Sklodowska-Curie National Research Institute of Oncology, Laboratory of Experimental Immunotherapy, Warsaw, Poland, [4]Maria Sklodowska-Curie National Research Institute of Oncology, Department of Molecular and Translational Oncology, Warsaw, Poland

Background & Objectives: Epstein–Barr virus-associated gastric cancer (EBVaGC) is one of the four molecular subtypes of GC according to The Cancer Genome Atlas project. There is still a significant gap in understanding its clinicopathological features in geographical regions other than Asia. This study aimed to provide a characterisation of patients with EBVaGC based on postoperative material from the National Research Institute of Oncology in Warsaw, Poland.
Methods: A total of 262 cases with primary GC, who underwent gastrectomy between 2008 and 2018, were included. The tumour staging was assessed according to the 8th edition of the TNM classification. The morphology was evaluated using the Laurén and the 5th edition of the WHO classification. EBV was detected by chromogenic in situ hybridization with the INFORM EBER Probe. Stromal tumour-infiltrating lymphocytes (sTILs) were examined by a semi-quantitative method described by International Immuno-Oncology Biomarker Working Group (IIOBWG). All statistical analyses were conducted using R4.1.1 (R Core Team, 2021) package.
Results: EBER positivity was present in 12.21% of GC. Significant differences were noted in gender ($p<0.001$), age ($p=0.018$), tumour size ($p=0.039$), location ($p=0.003$), and morphological type ($p<0.001$). EBVaGC exhibited a negative association with the presence of mucous lakes ($p=0.004$), signet ring cells ($p=0.005$), tertiary lymphoid structures ($p=0.031$). EBVaGC was characterized by significantly more abundant sTILs within both the central tumour area and the invasive margin ($p<0.001$). No significant differences between EBVaGC and

EBV negative GC (EBVnGC) were found in terms of neuroinvasion, angioinvasion, and (y)pT, (y)pN, (y)pM parameters.
Conclusion: Findings suggest that Poland may excel in prevalence of EBVaGC compared to other countries. Patients with EBVaGC revealed significant clinicopathological differences from those with EBVnGC. The WHO classification proved to be more useful for morphologically categorising EBVaGC compared to Laurén's classification. It was shown that sTILs measured by the IIOBWG method are significantly more abundant in EBVaGC than in EBVnGC.

Funding: The work was co-financed by a donation from Roche company for the purchase of the INFORM EBER probe – donation number 54/D/7/8/2016

PS-20-020

Prognostic and immunological significance of stromal maturity and proportion in colorectal cancer

V.V. Tapiainen[1], P. Sirniö[1], H. Elomaa[2], H. Karjalainen[1], V.K. Äijälä[1], M. Kastinen[1], M. Ahtiainen[3], J. Böhm[4], A. Tuomisto[1], M.J. Mäkinen[1], J.P. Väyrynen[1]
[1]University of Oulu, Translational Medicine Research Unit, Medical Research Centre Oulu, Oulu, Finland, [2]University of Helsinki, Research Program in Systems Oncology, Helsinki, Finland, [3]Hospital Nova of Central Finland, Well Being Services County of Central Finland, Central Finland Biobank, Jyväskylä, Finland, [4]Hospital Nova of Central Finland, Well Being Services County of Central Finland, Department of Pathology, Jyväskylä, Finland

Background & Objectives: Tumour-stroma ratio (TSR) and desmoplastic reaction (DR) classification are prognostic factors potentially linked with the composition of the tumour microenvironment. This study examines the prognostic and immunological significance of TSR, DR classification, and their combined assessment in colorectal cancer.
Methods: TSR and DR classification were evaluated using H&E-stained slides in two colorectal cancer cohorts (N=1,876). We introduced a three-tiered Stroma Maturity and Proportion Score (SMAPS), based on the presence of high (>50%) TSR in the tumour centre and myxoid stroma (immature DR classification) at the invasive margin. Computational assessment of Alcian Blue staining (pH 2.5) intensity was used to quantify myxoid stroma. Multiplex immunohistochemistry, combined with digital image analysis, was utilized to study immune cell densities associated with SMAPS, TSR, DR classification and Alcian blue intensity.
Results: In the study cohort (N=1,100), both TSR (HR for stroma-high vs. stroma-low: 1.49, 95%CI: 1.15-1.93; P=0.003) and DR classification (HR for immature vs. mature DR: 1.84, 95%CI: 1.39-2.45; P<0.0001) were independent prognostic factors for cancer-specific survival. SMAPS demonstrated stronger prognostic value (HR for high vs. low SMAPS: 2.01, 95%CI: 1.47-2.75; P<0.0001) compared to TSR and DR classification alone. Stroma-high TSR, immature DR, and high SMAPS were associated with lower densities of $CD3^+$ T cells, $CD20^+CD79A^+$ B cells, M1-like macrophages, $CD66b^+$ granulocytes in both the tumour centre and invasive margin (P<0.05 for all). Alcian blue staining was associated with the immature DR group identified on H&E-stained slides and showed similar immune cell associations. Validation cohort (N=776) confirmed the independent prognostic significance of SMAPS.
Conclusion: SMAPS is a promising prognostic tool that integrates stromal maturity at the invasive margin and stromal proportion in the tumour centre, both being associated here with an immunosuppressive microenvironment characterized by lower densities of antitumorigenic immune cells.

PS-20-021

Axial margin sampling in colorectal cancer bowel resections – is it necessary?

L. Goh[1], C.Z.X. Chua[2], J.C.-Y. Ngu[3], L.M. Wang[4]
[1]Changi General Hospital, Anatomical Pathology, Singapore, Singapore, [2]Singapore General Hospital, Anatomical Pathology, Division of Pathology, Singapore, Singapore, [3]Changi General Hospital, General Surgery, Singapore, Singapore, [4]Parkway Laboratory Services, Singapore, Singapore

Background & Objectives: Adequacy of excision is an important prognostic factor in pathological examination of colorectal cancer resection specimens. Some studies advocate that sampling of axial margins is unnecessary if they are macroscopically clear. Criteria for retrospective margin sampling recommended by the Royal College of Pathologists are tumours showing aggressive morphological features such as signet ring cell morphology, extensive lymphovascular invasion and exceptionally infiltrative growth patterns. This study reviews the prevalence of axial margin involvement and associated tumour characteristics to determine whether and when sampling is necessary.
Methods: A search of the pathology department database at a single tertiary centre was performed for colorectal adenocarcinoma resection cases received over a 6 year period (January 2017 to December 2023). These were reviewed for tumour characteristics (TNM stage, lymphovascular invasion, perineural invasion) and margin status.
Results: 1015 colorectal adenocarcinoma resection cases (835 colonic & 180 rectal) were identified, of which 58(5.7%; 45 colonic, 13 rectal) had only circumferential (radial) margin involvement, and four (0.4%; 2 colonic, 2 rectal) had both circumferential and axial margin involvement. None had involved axial margin(s) without concurrent radial margin involvement. Tumour was macroscopically more than 3 cm from an involved axial margin in three (2 colonic, 1 rectal) cases. All were moderately differentiated, and showed serosal involvement, lymphovascular and perineural invasion and extensive nodal disease.
Conclusion: Axial margin involvement in colorectal resections is uncommon (<1%), which supports selective sampling of axial margins for carcinoma with high-risk features when tumour is macroscopically more than 3 cm away. The high-risk features identified in our study were circumferential margin involvement with simultaneous serosal involvement, lymphovascular invasion, perineural invasion, and extensive nodal disease. Poor differentiation such as signet ring cell morphology did not appear to be associated with axial margin involvement.

PS-20-022

Histological signature for risk stratification of lymph node metastasis in early-stage colorectal cancer (pT1)

E. Musulen[1,2], N. Arenós[2], N. Camacho[2], K. Sáez de Gordoa[3], M. Daca[4], P. Cano[5], M. Pellisé[4], M.T. Fernández-Figueras[1], D. Gil[5], M. Cuatrecasas[3]
[1]Hospital Universitari General de Catalunya-Grupo Quiron, Pathology Department, Sant Cugat del Vallès, Spain, [2]Institut de Recerca contra la Leucèmia Josep Carreras, Grup d'Epigenètica del Càncer, Badalona, Spain, [3]Hospital Clínic, Pathology Department, Barcelona, Spain, [4]Hospital Clínic, Gastroenterology Department, Barcelona, Spain, [5]Centre de Visió per Computació (CVC), Universitat Autònoma (UAB), Computer Science Department, Cerdanyola del Vallès, Spain

Background & Objectives: In pT1 colorectal cancer (CRC), there are no specific histopathological features that accurately predict lymph

node metastasis (LNM) to guide treatment after endoscopic resection. The aim of this study was to define a histological signature by combining various morphological parameters to predict regional LNM.
Methods: A total of 223 pT1 CRC cases from 223 patients (94 women and 129 men) were selected, 89 of whom had LNM at diagnosis. The parameters analysed included tumour grade differentiation (GTD), angiolymphatic invasion (ALI), perineural invasion (PI), tumour budding (TB), poorly differentiated clusters (PDC), vertical resection margin (VRM), and submucosal invasion (ISM). A univariate significance test was first performed to assess each parameter's relationship with LNM. Then, GTD, ALI, PDC, VRM, and ISM were analysed together in a multivariate analysis, considering all possible variable combinations into four risk categories: Very High Risk (VHR), Moderate High Risk (MHR), Moderate Low Risk (MLR), and Very Low Risk (VLR).
Results: The univariate analysis revealed that GTD, ALI, TB, PDC, and ISM had a statistically significant association with LNM, but each variable alone predicted less than 60% of LNM cases. When combining these parameters into risk groups the analysis showed a better predictive power (87% vs. 59.6%) compared to single variables. Statistically significant differences were found between metastasis proportions across the risk groups (VHR: $p<0.001$, MHR: $p<0.01$, MLR: $p=0.05$, and VLR: $p<0.01$). However, when the most favourable value combination was used, 10% of patients with LNM were missed (false negatives).
Conclusion: The combination of multiple high-risk parameters demonstrated better predictive power than individual markers alone and provided a four-group risk classification based on metastasis proportions. However, to avoid false negatives cases new technologies are needed to identify biomarkers in pT1 CRC that can better stratify the risk of LNM.

Gastric cancer whole-genome sequencing identifies peculiar mutational profile in Northeast Brazil

E. Neves[1], V. Costa Filho[2], F. Mesquita[3], A. Farias[4], L. Albuquerque[2], M. Noronha[2], R. Montenegro[3], J.P. Santos[5], C. Hirth[6], S.H. Rabenhorst[2]
[1]Hospital Infantil Albert Sabin, Pathology, Fortaleza, Brazil, [2]Universidade Federal do Ceará, Pathology and Forensic Medicine, Fortaleza, Brazil, [3]Universidade Federal do Ceará, Drug Research and Development Centre, Fortaleza, Brazil, [4]Universidade Federal do Ceará, Department of Physiology and Pharmacology, Fortaleza, Brazil, [5]Universidade Federal do Rio Grande do Norte, Núcleo Integrador de Pesquisa e Inovação, Natal, Brazil, [6]Instituto do Câncer do Ceará, Pathology, Fortaleza, Brazil

Background & Objectives: Gastric cancer (GC) is a heterogeneous disease. Next-Generation Sequencing (NGS) has improved our understanding, but the molecular classifications currently proposed are based on European and Asian patients, such as the TCGA network and the ACRG, respectively. Thus, the aim of this study was to evaluate the most commonly mutated genes in GC samples from Brazil and compare it to the TCGA database.
Methods: Exome sequencing of 62 patients from Northeast Brazil was performed using the Illumina NextSeq 1000 platform. The exome library was prepared using SureSelect All Exon V8. Copy number alterations were identified using PURPLE. For somatic variant analysis, raw sequencing data were processed using the nf-core/sarek 3.4.2 pipeline. Reads were aligned to the GRCh38 reference genome using BWA-MEM, followed by duplicate marking and base quality score recalibration (BQSR) with GATK. Somatic variant calling was performed using a combination of tools integrated into the pipeline, including Mutect2, Strelka2, and Lancet, ensuring high sensitivity and specificity.
Results: We identified 10 top-mutated genes (*TTN, MUC4, EPPK1, PKD1, MUC12, MUC19, ZBED3, MUC5AC, MUC16* and *DST*, respectively). Comparing to TCGA network, most of these genes presented a divergent mutational profile. Mutations in *TTN* was observed in 82% of our sample comparing to 51% of TCGA. Likewise, *MUC16, MUC4, EPPK1, PDK1* and *MUC12* were much more commonly mutated in our population (45%, 81%, 58%, 56% and 50%, respectively, compared to 31%, 6%, 5%, 7% and 0% in the TCGA database, respectively). On the other hand, commonly mutated genes in the TCGA, such as *TP53* and *ARID1* (46% and 27%, respectively), were rarely abnormal in our sample (11% and 15%, respectively).
Conclusion: This data suggests that the GC mutational profile in Northeast Brazil is unique, with some important divergence from the TCGA network, and highlights that a broader global evaluation would contribute to a better understanding of GC.

PS-20-024

Comparison of PD-L1 assays in oesophageal squamous cell carcinoma

H. Song[1], J.-S. Jeong[1], U. Jo[1], Y.S. Park[1], J.S. Song[1]
[1]Asan Medical Centre, Pathology, Seoul, Republic of Korea

Background & Objectives: Oesophageal squamous cell carcinoma (ESCC) comprises 84% of oesophageal cancers, with poor prognosis due to late diagnosis and limited treatment. Immunotherapy targeting programmed death-1 (PD-1) and programmed death-ligand 1 (PD-L1) has demonstrated improved survival outcomes, yet variability in PD-L1 testing platforms and scoring methods presents challenges. This study aims to evaluate the concordance between PD-L1 immunohistochemistry (IHC) assays, specifically 22C3 and 28-8, in ESCC using tumour proportion score (TPS) and combined positive score (CPS) methodologies to address inconsistencies in testing approaches.
Methods: PD-L1 expression in 200 ESCC cases at Asan Medical Centre was assessed using whole-slide sections from biopsy or surgical resection specimens. Two standardized PD-L1 assays (Dako 22C3 pharmDx and Dako 28-8 pharmDx) were evaluated following manufacturer protocols. Staining was independently scored by two pathologists using TPS with $\geq$1%, $\geq$10% and $\geq$50% cut-offs, and CPS with $\geq$1%, $\geq$10% and $\geq$50% cut-offs.
Results: Both assays showed similar distributions at lower cutoffs. At CPS $\geq$50%, positivity was higher with 28-8 (31%) than 22C3 (23%). Similarly, at TPS $\geq$50%, 28-8 showed more positive cases (24%) than 22C3 (18%), indicating potential differences in assay sensitivity at higher PD-L1 expression levels. Concordance on a continuous scale among the assays was good for CPS [intraclass correlation coefficient (ICC) range 0.76–0.85] and TPS (ICC range 0.78–0.87). Stratification by variable cut-offs demonstrated moderate to good agreement between the two assays, as analysed by Gwet's AC1. No statistically significant correlations between PD-L1 expression and clinicopatholoic parameters were identified. Non-significant trends emerged for tumour differentiation status with 22C3 (TPS, $p = 0.054$) and survival outcomes with 28-8 (TPS, $p = 0.073$), indicating potential biological associations requiring validation in expanded datasets.
Conclusion: Notable concordance was found among 22C3 and 28-8 assays, suggesting their potential interchangeability in selecting patients with ESCC for immune checkpoint inhibitor.

PS-20-025

Spatial transcriptomics reveal lineage complexity of gastric incomplete intestinal metaplasia and its association with gastric cancers

H. Kim[1], E. Park[2], B. Jang[2,3]
[1]Jeju National University College of Medicine, Department of Convergence Biomedical Science, Jeju, Republic of Korea, [2]Jeju National

University College of Medicine, Department of Pathology, Jeju, Republic of Korea, [3]Jeju National University Hospital, Pathology, Jeju, Republic of Korea

Background & Objectives: Incomplete intestinal metaplasia (Inc IM) is a precancerous lesion associated with an increased risk of gastric cancers (GCs); however, its molecular characteristics remain inadequately defined. This study aimed to elucidate the unique molecular phenotype and lineage complexity of Inc IM.
Methods: We utilized single-cell resolution spatial transcriptomics (Xenium) on gastric tissue samples—including normal mucosa, various IM subtypes, and GCs—using a customized panel of 294 organ-specific genes for enhanced cellular characterization. Pure organoid lines derived from human gastric tissues representing normal mucosa, complete IM (Com IM), and Inc IM were generated. Single cell RNA sequencing (scRNA seq) was performed to assess in vitro differentiation with Bone Morphogenic Protein (BMP) treatment.
Results: Inc IM exhibits mixed lineage features with distinct populations expressing both gastric and intestinal markers, whereas Com IM closely resembles small intestine architecture. A minute gland consisted of Inc IM cell clusters, representing very early Inc IM was identified in chronic gastritis, showing the upregulation of intestinal markers (e.g., DMBT1 and REG4) alongside downregulation of gastric markers. Interestingly, mixed gastric and intestinal phenotype was observed in both surface differentiated cells and stem/progenitor cells in Inc IM. When assessing the cell types in GCs, Inc IM cell clusters were more frequently associated with GC, particularly in MSS/TP53– and MSS/TP53+ molecular subtypes, underscoring its potential origin in gastric carcinogenesis. The BMP-induced expression changes in organoid models recapitulated in vivo observations, validating their utility for studying gastric metaplasia.
Conclusion: We demonstrated unique molecular phenotype and lineage complexity of Inc IM, emphasizing its significance as a precancerous lesion in gastric tissues. Our IM organoid lines lay the groundwork for future investigations into the epigenetic and transcriptional dynamics of metaplastic changes, highlighting the critical role of Inc IM in GC development.

Background & Objectives: Colorectal carcinoma (CRC) diagnosed at stage pT1 presents a unique challenge in pathological evaluation, which is crucial for guiding treatment and determining patient's prognosis. This study aimed to assess the interobserver variability in the histopathological evaluation of pT1 CRC.
Methods: This retrospective multicentric cohort study included 2,208 pT1 CRC patients diagnosed at 33 tertiary hospitals between 2007 and 2018 (EpiT1 consortium). A task force comprising 20 experienced pathologists conducted the histopathological evaluation using digitalized haematoxylin-eosin (HE) slides. A pilot study was performed with 10 cases, and after a consensus meeting 70 new cases were assessed (concordance study). We used percentage agreement and Gwet's AC1 for categorical variables, and intraclass correlation coefficient (ICC) for continuous variables.
Results: In the pilot study, histological grade, perineural invasion (PNI), and lymphovascular invasion (LVI) demonstrated 100% agreement, with moderate to good concordance for tumour budding (TB), poorly differentiated clusters (PDC), and margin assessment. The concordance study showed high agreement (≥90%) on histological grade, TB, PDC, PNI and LVI. Submucosal invasion depth showed excellent reliability in the concordance study (ICC=0.97). Lower concordance was observed on tumour infiltrating lymphocytes (TILs) and status of muscularis mucosae. Notably, the agreement of PDC was higher than for TB on both sub-studies.
Conclusion: Our results emphasize the need for standardization in evaluating pT1 CRC. Defining the evaluation criteria of pT1 histological features can improve the concordance among pathologists for most features. Moreover, the addition of PDC assessment in pT1 CRC diagnostic guidelines could help to improve the accuracy of risk stratification and reliably predict prognosis.

PS-20-027

Comparison of three different Claudin18.2 IHC assays in gastric and gastroesophageal junction (G/GEJ) cancer

H.L. Kristoffersen[1], R. Røge[1], C. Papior Carstensen[1], S. Nielsen[1]
[1]NordiQC, Department of Pathology, Aalborg University Hospital, Aalborg, Denmark

Background & Objectives: Immunohistochemistry (IHC) for Claudin18.2 (CLDN18.2) is a novel biomarker for treatment with zolbetuximab in gastric and gastroesophageal junction (G/GEJ) cancer. The aim of the study was to compare the staining patterns of two different CLDN18.2 IHC assays on the Dako Omnis platform with the approved VENTANA CLDN18 (43-14A) RxDx Assay, as not all diagnostic pathology laboratories have access to a Ventana BenchMark staining platform required for the approved IHC assay.
Methods: Optimized staining protocols for two different commercially available concentrated antibodies for CLDN18.2 were initially

developed on the Dako Omnis platform using TMAs comprising various normal tissues and G/GEJ cancers. Subsequently, each antibody was validated on TMAs comprising 67 G/GEJ cancers and 39 other neoplasias. To evaluate the accuracy, all neoplasias were also stained using the approved VENTANA CLDN18 (43-14A) RxDx Assay.
Results: The two optimized IHC assays provided comparable levels of diagnostic sensitivity and specificity to the approved assay with an overall diagnostic accuracy of 97% and 98,5% in G/GEJ cancers using a cut-off ≥75% of tumour cells demonstrating moderate-to-strong membranous staining. In the 39 tested non-G/GEJ cancers, only 1 (of 2) pancreas adenocarcinoma and 1 large cell neuroendocrine carcinoma showed positive staining reaction.
Conclusion: The two tested CLDN18.2 antibodies and the approved assay exhibited comparable staining patterns in both normal and neoplastic tissues. However, implementing CLDN18.2 IHC as predictive marker requires a rigorous optimization and validation process to ensure appropriate diagnostic accuracy of the assay. This study indicates that CLDN18.2 testing can be done on alternative IHC platforms, which is important for laboratories without access to the approved assay and platform from Ventana. This pilot study included 67 G/GEJ cancers (22 % positive). Further studies on larger cohort of G/GEJ cancers are needed to confirm our findings.

PS-20-028

The relationship between the expression of cancer-associated fibroblast markers and T-killers with characteristics of colorectal cancer

I. Sycheva[1], E. Makasheva[1], N. Oleynikova[1]
[1]Lomonosov Moscow State University (MSU), Faculty of Medicine, Moscow, Russia

Background & Objectives: Cancer-associated fibroblasts (CAFs) represent a heterogeneous group of cells in the tumour stroma that regulate tumour progression, and metastasis. This implies that CAFs hold significant prognostic and clinical importance for tumours of various localizations, including colorectal cancer.
Methods: Immunohistochemical analysis was performed on samples from 56 patients with colorectal cancer using antibodies against FAP and CD-8 to identify correlations with tumour stage, morphological characteristics, overall survival, and recurrence-free survival. The assessment was conducted based on quantitative parameters (area, percentage) of FAP and CD-8.
Results: A negative correlation was observed between the number of lymphocytes and perineural invasion (968 [488; 1748] vs. 548 [430; 607], $p = 0.019$). A negative correlation was also found between the number of lymphocytes and metastatic involvement of lymph nodes: patients with N1 had significantly less tissue infiltration compared to N0 (449.5 [253.25; 594.75] vs. 892.5 [560.25; 1691.75], $p = 0.013$). No correlation was found between the quantitative values of FAP and CD-8 lymphocytes with vascular invasion, gender, age, tumour localization, TNM staging, or Grade.
Conclusion: The influence of CAFs on tumour progression and invasiveness is a relatively new concept in medicine. Currently, there are conflicting data on whether this group of cells contributes to a more aggressive course of colorectal cancer. In our study, no association was found between the number of CAFs and the degree of lymphocyte infiltration in tumours or other clinical-demographic characteristics of patients. At the same time, a strong inverse correlation between tumour lymphocyte infiltration and perineural invasion, as well as the tumour`s tendency to metastasize was observed as expected. This area requires further research.

PS-20-029

Clinicopathological evaluation of oesophageal endoscopic resection (ER) specimens in a UK tertiary care centre

K. Pai[1], F. Khizer[1], K. Kalyanasundaram[1], V. Jayaram[1], S. Rajkumar[2]
[1]Royal Stoke University Hospital, Cellular Pathology, Stoke on Trent, United Kingdom, [2]Royal Stoke University Hospital, Gastroenterology, Stoke on Trent, United Kingdom

Background & Objectives: Endoscopic resection (ER), including endoscopic submucosal dissection (ESD) and endoscopic mucosal resection (EMR), is an established treatment for early oesophageal cancer, particularly in Eastern countries. While its use in the UK remains limited, ER is a preferred approach for early-stage disease in tertiary care centres. This study evaluates the histopathological features and clinical outcomes of oesophageal cancers treated with ER at our institution, assessing adherence to the Royal College of Pathologists (RCPath) dataset and European Society of Gastrointestinal Endoscopy (ESGE) guidelines.
Methods: We retrospectively analysed 40 consecutive oesophageal ER specimens (24 ESD, 16 EMR) from patients with oesophageal malignancies (26 intramucosal, 14 submucosal) over an eight-month period (January–August 2024). Pathological parameters included tumour morphology, differentiation grade, dysplasia, lymphovascular and perineural invasion, depth of invasion, staging, and margin status. Follow-up data included endoscopic surveillance (n=14), endoscopic biopsies (n=14), and multidisciplinary team (MDT) outcomes. Poor prognostic factors were defined as poor differentiation, depth of invasion, positive margins on ESD, and metastasis on imaging.
Results: A male predominance (n=35) with a mean age of 73 years was observed. Among submucosal cancers (n=14), six were adenocarcinomas and four were squamous cell carcinomas. Poor prognostic features were identified in six cases (15%), including poor differentiation, lymphovascular invasion, submucosal invasion (pT1b), tumour budding, tubulo-infiltrative histology, and positive margins. All six had positive deep margins, and four required additional treatment.
Conclusion: Our findings support ESGE guidelines regarding high-risk pathological features necessitating further therapy in oesophageal cancer. All cases met RCPath dataset parameters, reinforcing the role of ER in early-stage disease management.

PS-20-030

Heterogeneous mismatch repair protein expression in gastric cancer: prevalence and clinicopathological implications

E. Porubayeva[1], A. Zakharkina[1], D. Kalinin[2], N. Danilova[1]
[1]Lomonosov Moscow State University, Moscow, Russia, [2]A.V. Vishnevsky National Medical Research Centre of Surgery, Moscow, Russia

Background & Objectives: Heterogeneous mismatch repair (hMMR) status, noted in colorectal and endometrial cancers, remains underexplored in gastric cancer (GC). This study investigates hMMR prevalence in GC and its clinicopathological correlates, aiming to elucidate its role in tumour progression and potential implications for immunotherapy responsiveness.
Methods: We analysed surgical specimens from 159 GC patients (2010–2018) without neoadjuvant therapy. Immunohistochemistry targeted MMR proteins (MSH2 [79H11], MSH6 [EP49], MLH1 [ES05], PMS2 [EP51]). hMMR was defined as ≥20% unstained areas amid strongly stained regions, classified per Joost et al. (modified) as intraglandular, clonal, or mixed patterns. MMR status was correlated with sex, age, tumour site, macroscopic type, size, histologic subtype, differentiation grade, vascular invasion, TNM stage, and clinical stage. Statistical analysis used χ^2 or Fisher's exact tests in Statistica 12.5.192.7 ($p<0.05$).
Results: hMMR was observed in 37/159 cases (23.3%), MMR-proficient in 104 (65.4%), and MMR-deficient in 12 (7.6%). Among MMR-deficient cases, 6 (3.8%) exhibited hMMR of retained markers (MMR-deficient/hMMR). Dual-marker heterogeneity, predominantly MLH1/PMS2 (n=17), was common. hMMR was enriched in

papillary vs. discohesive subtypes (p=0.031), while MMR-proficient tumours prevailed in the latter. Both hMMR and MMR-deficient/hMMR statuses were linked to intestinal subtype (p=0.006, p=0.036) and well-differentiated tumours (p<0.05, p=0.014). hMMR predominated in macroscopic types 3–4 vs. MMR-deficient/hMMR (p<0.001). No significant correlations emerged with sex, age, or tumour size.
Conclusion: hMMR affects 23.3% of GC cases, often involving MLH1/PMS2, and correlates with papillary and intestinal subtypes, well-differentiated tumours, and advanced macroscopic types, suggesting clonal evolution with implications for prognosis and immunotherapy.

PS-20-031
Favorable immunohistochemical prognostic factors for gastric cancer
E. Porubayeva[1], D. Kalinin[2], T. Sotnikova[3], N. Danilova[1]
[1]Lomonosov Moscow State University, Moscow, Russia, [2]A.V. Vishnevsky National Medical Research Centre of Surgery, Moscow, Russia, [3]I.V. Davydovsky City Clinical Hospital, Moscow, Russia

Background & Objectives: Gastric cancer remains a leading cause of cancer-related mortality globally, characterized by high incidence and heterogeneous outcomes necessitating reliable prognostic markers. This study aims to identify independent immunohistochemical (IHC) predictors of survival in gastric cancer patients untreated with immunotherapy, using the Cox proportional hazards model to assess intrinsic tumour biology.
Methods: We evaluated 310 patients with gastric cancer who underwent surgical resection as primary treatment, without prior or subsequent immunotherapy. Tumours were histologically classified per Lauren: 119 intestinal, 114 intermediate, and 77 diffuse. A panel of 21 IHC markers—including mismatch repair proteins (MSH2, MSH6, MLH1, PMS2), PD-L1 (SP142 clone), E-cadherin, β-catenin, and others (e.g., HER2, p53)—was analysed alongside Epstein-Barr virus (EBER) small RNA expression. Clinicopathological variables (age, sex, TNM stage, Lauren type) were correlated with survival outcomes using Cox regression analysis.
Results: Male gender was associated with a 2.02-fold higher mortality risk (p<0.001), each additional year of age increased risk by 1.02-fold (p=0.02), N-stage (lymph node metastasis) by 1.61-fold (p<0.001), and M-stage (distant metastasis) by 2.52-fold (p<0.001); other clinicopathological traits were non-significant (p>0.05). Notably, MMR-negative status reduced mortality risk twofold (p=0.05), possibly due to increased tumour immunogenicity from elevated mutation burden. PD-L1 positivity (SP142) lowered mortality risk 4.35-fold (p=0.005), potentially by modulating immune suppression in the tumour microenvironment. In contrast, aberrant E-cadherin (p=0.019) and β-catenin (p=0.001) expression emerged as adverse prognostic factors, likely linked to Wnt pathway activation driving tumour aggressiveness. These findings highlight novel prognostic roles in untreated patients.
Conclusion: Among gastric cancer patients not receiving immunotherapy, positive PD-L1 (SP142) and negative MMR status independently predict significantly better survival outcomes, whereas aberrant E-cadherin and β-catenin expression indicate poorer prognosis. These insights enhance risk stratification and suggest new avenues for personalized therapeutic strategies in future research.

PS-20-032
Prognostic significance of tumour-infiltrating lymphocytes in gastric carcinoma
N. Abdessayed[1], S. Frini[1], Z. Nfikha[1], S. Yacoub[1], M. Mokni[1]
[1]Farhat Hached University Hospital, Pathology, Sousse, Tunisia

Background & Objectives: Tumour-infiltrating lymphocytes (TILs) are a crucial component of the tumour microenvironment that reflects the host's antitumor immune response. They have been investigated as a prognostic factor in several cancers. This study aimed to assess the prognostic value of TILs in gastric carcinoma (GC).
Methods: The study included all patients diagnosed with GC who underwent surgical treatment without prior chemotherapy over nine years. TILs were assessed by two pathologists following the recommendations of the International TIL Working Group (ITWG), and inter-rater reliability was evaluated. Cases were stratified based on TIL density using the median, 75th percentile, and ITWG thresholds as cut-off points.
Results: A total of 98 patients were included in the study. The mean overall survival (OS) was 44.1 ± 5.3 months, with a median OS of 24.7 ± 5.1 months. The mean relapse-free survival (RFS) was 45.8 ± 6.1 months, with a median RFS of 25.8 ± 7.2 months. Using the median as a cut-off point, 34 GCs were classified as low TILs (<10%), while 64 were classified as high TILs (>10%). TIL density was significantly correlated with the histological subtype and TNM stage ($p < 0.05$). In univariate analysis, TILs were significantly associated with OS and RFS. Low TIL density was linked to poor survival, whereas high TIL density was associated with a better prognosis (mean OS: 22.6 months for low TILs vs. 51.7 months for high TILs; $p < 0.001$ / mean RFS: 25.4 months for low TILs vs. 52.8 months for high TILs; $p = 0.006$). In multivariate analysis, TILs, the presence of metastases, and lymph node involvement (pN+) were independent prognostic factors for OS, while only TILs and pN+ were independent prognostic factors for RFS.
Conclusion: These findings suggest that TILs may serve as an independent prognostic factor for OS and RFS in GC.

PS-20-033
Evaluation of current and future theranostic biomarkers in gastric cancers
N. Roberto[1], A. Regnier[1], F. Marguet[1,2], J.-C. Sabourin[1,2]
[1]Department of Pathology, Rouen University Hospital, Rouen, France, [2]INSERM 1245, Normandy University, Rouen, France

Background & Objectives: Gastric carcinoma (GC) is one of the leading causes of cancer-related mortality worldwide. Identifying relevant biomarkers is crucial. The aim of this study was to evaluate the 5 known theranostic biomarkers in surgical specimens of GC, and to compare 2 of them, Claudin18 and FGFR2b, with their respective preoperative biopsy.
Methods: This retrospective study included a cohort of 46 patients with GC. Five biomarkers were analysed: Claudin18, FGFR2b, HER2, PD-L1 and mismatch repair deficiency (dMMR). Positive expression was defined as: a score of 2 to 3+ in ≥75% of tumour cells for Claudin18, a score of 2 to 3+ in ≥10% of tumour cells for FGFR2b, a score of 3+ or 2+ with gene amplification in ≥10% of tumour cells for HER2, a combined positive score of >10% for PD-L1, and loss of expression of MLH1/PMS2 or MSH2/MSH6 proteins for dMMR.
For Claudin18 and FGFR2b, preoperative biopsies were compared with their respective surgical specimen.
Results: Forty-six GC surgical specimens were analysed, corresponding to 30 men and 16 women, with a mean age of 68 years (range 35-90).
Biomarkers were positive in 16 cases for Claudin18 (37%), in 8 cases for FGFR2b (19%), in 8 cases for PD-L1 (19%), in 7 cases for HER2 (16%), and in 4 cases for dMMR (9%). When comparing surgical specimens to biopsies, discordant results were found in 6 cases for Claudin18 and in 4 cases for FGFR2b. Biomarker overlap is presented in a Venn diagram.
Conclusion: This is, to our knowledge, the first description of the 5 known theranostic biomarkers in gastric carcinomas. The overlap between the 5 GC biomarkers was low, allowing a clear therapeutic strategy. The discordances observed with Claudin18 and FGFR2b between surgical specimens and biopsies were likely due to tumour

heterogeneity, emphasizing the importance of multiple biopsy sampling for histological diagnosis and biomarker assessment.

PS-20-034

Phosphohistone H3 expression in gastroenteropancreatic neuroendocrine tumours

J. Kini[1], A. Sharma[1], G. Kini[1], E. Edwin[1], P. K Suresh[1], P. Vivekananda[1]
[1]Kasturba Medical College Mangalore, Manipal Academy of Higher Education, Karnataka, Manipal, India, Pathology, Mangalore, India

Background & Objectives: Neuroendocrine neoplasms (NENs) primarily originate in gastroenteropancreatic system and are classified by 2022 WHO classification into well differentiated neuroendocrine tumours (NETs), poorly differentiated carcinoma(NECs) and mixed neuroendocrine- non-neuroendocrine neoplasms(MiNENs) based on histopathological differentiation, mitotic index and Ki-67 proliferation index. Phosphohistone H3 (PHH3), a mitotic marker crucial for tumour grading is well studied in other malignancies but its prognostic value in GEP-NENs is still under evaluation. This study aims at evaluating the expression of PHH3 in gastroenteropancreatic neuroendocrine neoplasms (GEP-NENs).
Methods: A retrospective study was performed on all patients diagnosed as GEP-NENs from January 2016 to December 2023 in the Department of Pathology, Kasturba Medical College, Mangalore. Immunohistochemistry with PPH3 and Ki-67 was done on available paraffin blocks according to standard staining protocols.
Results: 72 cases of GEP-NENs with patients age range between 13-88 years (mean 55.8 years) and a slight male predominance(1.18:1) were evaluated. Duodenum was the most common site (41.7%) followed by stomach (15.3%). Most tumours were well differentiated NETs (82%), and predominantly grade1 (59.7%). PHH3 had higher predictive accuracy (76.4%) than Ki-67(72.2%) for mitotic activity and showed a strong correlation with necrosis (p value-<0.001), reinforcing its utility in identifying aggressive tumours. Discrepancies between the two markers were particularly observed in high grade cases, where Ki-67 indices were disproportionately higher than PHH3. The findings underscore PHH3 as a valuable adjunct to Ki-67 for accurate tumour grading and prognostication of GEP-NENs, with ROC analysis further confirming its diagnostic strength (AUC=0.829, $p<0.001$). No significant associations were found between PHH3 and lymph node status, lymphovascular or perineural invasion.
Conclusion: PHH3 outperformed ki-67 as a precise proliferation marker in GEP-NENs, offering stronger correlation with aggressive features like necrosis. While Ki-67 remains valuable for overall proliferation, PHH3 specificity may help prevent over grading particularly in high grade neuroendocrine tumours.

PS-20-036

Tumour-infiltrating immune cells are more abundant in lung metastases from colorectal cancer than in paired primary tumours and their prognostic value depends on adjuvant chemotherapy

D.S. Kuznyecov[1,2], C. Siesing[1,3], H. Vidarsdottir[4], P. Jönsson[5], J. Eberhard[1,3], H. Brunnström[2,4], K. Leandersson[6], K. Jirström[1,2]
[1]Division of Oncology and Therapeutic Pathology Lund University, Department of Clinical Sciences, Lund, Sweden, [2]Skåne University Hospital, Department of Clinical Genetics, Pathology and Molecular Diagnostics, Lund, Sweden, [3]Skåne University Hospital, Department of Haematology, Oncology and Radiation Physics, Lund, Sweden, [4]Division of Pathology Lund University, Department of Clinical Sciences, Lund, Sweden, [5]Division of Thoracic Surgery Lund University, Department of Clinical Sciences Lund, Lund, Sweden, [6]Cancer Immunology Lund University, Department of Translational Medicine, Malmö, Sweden

Background & Objectives: The immune microenvironment plays a crucial role in the progression of colorectal cancer (CRC), but its variation across primary tumours and metastatic sites remains incompletely understood. In this study, we compared the composition and prognostic significance of the immune microenvironment in lung metastases, paired primary tumours, and liver metastases from a retrospective cohort of patients with metastatic CRC (mCRC) who underwent pulmonary metastasectomy.
Methods: A total of 216 mCRC patients treated at a single Swedish institution were included. Immunohistochemistry was applied to evaluate CD3+, CD8+, CD20+, FoxP3+, and PD-L1+ immune cells, as well as tertiary lymphoid-like structures (TLLSs), on tissue microarrays constructed from lung metastases, paired primary tumours, and liver metastases.
Results: Lung metastases exhibited significantly higher infiltration of all immune cell subsets compared to both primary tumours and liver metastases. FoxP3+ cell density was lower in liver metastases than in primary tumours. Immune cell infiltration in lung metastases was largely unaffected by neoadjuvant chemotherapy, except for lower FoxP3+ cell infiltration in treated cases. None of the immune markers bore prognostic significance in the overall analysis. However, high infiltration of FoxP3+, CD20+, and PD-L1+ immune cells, and the presence of TLLSs in lung metastases, was associated with improved overall survival in patients receiving adjuvant chemotherapy, with a significant prognostic treatment interaction. None of the immune markers were prognostic in primary tumours or liver metastases.
Conclusion: These findings underscore a distinct, more immunologically active immune microenvironment in CRC lung metastases compared to primary tumours and liver metastases, that suggestedly also predicts response to adjuvant chemotherapy. Immune profiling of lung metastases may thus pave the way for improved personalized treatment of these patients.

PS-20-037

A comparative analysis of microsatellite instability and mismatch repair protein deficiency in colorectal carcinoma cases with a review of diagnostic challenges

A. Rai[1], S.A. Barodawala[1], K. Chadha[1], M. Banerjee[1], M. Chanekar[1], R. Jatale[1]
[1]Global Reference Laboratory, Metropolis Healthcare Limited, Histopathology, Mumbai, India

Background & Objectives: Microsatellite instability (MSI) and mismatch repair (MMR) deficiency are important prognostic as well as predictive biomarkers in colorectal cancer (CRC). The DNA MMR system recognizes short insertions, deletions, and single base mismatches during DNA replication and recombination. Deficiency in MMR proteins, leads to frameshift mutations in microsatellite repeats and microsatellite instability (MSI). This analysis delves into the concordance between MSI and MMR protein expression in CRC, highlighting diagnostic challenges and proposing solutions to enhance diagnostic accuracy.
Methods: Between January 2018 to January 2024, a comprehensive study was conducted involving 522 colorectal carcinoma (CRC) cases analysed for mismatch repair (MMR) protein expression using immunohistochemistry (IHC), and 640 CRC cases assessed for microsatellite instability (MSI) through polymerase chain reaction (PCR) targeting frameshift mutations. A subsequent comparison followed to evaluate the concordance and the diagnostic difficulties were reviewed.
Results: In our study, mismatch repair (MMR) deficiency was identified in 20.31% (106/522) of colorectal carcinoma (CRC) cases with the loss of PMS2 being most prevalent (72.64%), followed by MLH1 loss (59.43%), MSH6 (24.53%), and MSH2 (19.81%). Microsatellite instability (MSI) testing revealed 27.19% (174/640) cases as unstable, with BAT21 marker demonstrating highest instability

(86.78%), followed by BAT26 (83.91%), NR21 (81.03%), NR27 (79.89%), and NR24 (76.44%). High MSI (MSI-H) was observed in 3.45% cases, while low MSI (MSI-L) was seen in 1.15%. Concordance between MMR and MSI showed an 88.82% agreement. In addition, we evaluated the challenges pathologists encounter when assessing MMR and MSI status such as pre-analytic variables, interpretative pitfalls, and reporting complexities.
Conclusion: Accurate assessment of MSI and MMR protein status is pivotal in the management of colorectal carcinoma, influencing both prognostic evaluations and therapeutic decisions. Our study demonstrated a high concordance between the two tests. However, to further enhance diagnostic precision and improve patient outcome, we recommend standardization of testing protocols and continuous quality control.

PS-20-038

Aberrant occludin and claudin-1 expression in intestinal mucosa associates with inflammatory bowel disease activity and response to biologic therapy

V. Bravou[1], E. Tsounis[2], C. Geramoutsou[1], P. Bosgana[1], I. Aggeletopoulou[2], P. Pastras[2], T. Lourida[2], G. Theocharis[2], G. Diamantopoulou[2], V. Zolota[3], S. Assimakopoulos[4], K. Thomopoulos[2], C. Triantos[2]
[1]Medical School, University of Patras, Department of Anatomy-Histology-Embryology, Patras, Greece, [2]University Hospital of Patras, Division of Gastroenterology, Department of Internal Medicine, Patras, Greece, [3]Medical School, University of Patras, Department of Pathology, Patras, Greece, [4]Medical School, University of Patras, Division of Infectious Diseases, Department of Internal Medicine, Patras, Greece

Background & Objectives: Tight junction (TJs) proteins, occludin and claudin-1 are essential for gut barrier homeostasis. We aimed to assess the expression of occludin and claudin-1 in the intestinal mucosa of patients with inflammatory bowel disease (IBD) in relation to clinical parameters and disease outcomes.
Methods: A total of 189 IBD patients were enrolled in the study (male: 59%, age: 45.5±18 years), including 92 with Crohn's disease (CD) and 97 with ulcerative colitis (UC), as well as 61 healthy controls (HC). Follow-up biopsies (>6 months) were available for 100 patients. Clinical, laboratory, histology, and endoscopic data were retrieved for all patients with available colonic or ileal biopsies. The expression of TJ proteins occludin and claudin-1 was assessed by immunohistochemistry (IHC) (H-score).
Results: Patients with active CD (CDAI>150) demonstrated increased cytoplasmic occludin expression in both the crypts (72.9±63.8 vs. 42.4±37; p=0.033) and surface epithelium (75.7±50.6 vs. 52±46.2; p=0.01), and higher cytoplasmic claudin-1 levels in the crypts (70.2±63.6 vs. 43±43.6; p=0.02), compared to HC, where both proteins showed mainly membranous localization. Patients with active UC (Mayo Score>6) showed increased cytoplasmic occludin expression in the crypts (58.3±43.1 vs. 42.4±37; 0.049) and the surface epithelium (78.7±57.8 vs. 52±46.2; p=0.009) compared to HC. Occludin expression in the crypts correlated with systemic inflammation markers, including CRP (r=0.4; p=0.001) and PLT (r=0.23; p=0.023), disease activity indices such as CDAI in CD (r=0.33; p=0.003) and the Mayo Score in UC (r=0.42; p<0.001) and histologic activity, as assessed by the Nancy index (r=0.21; p=0.008). In follow-up biopsies, patients receiving biologic therapy experienced a greater reduction in crypt cytoplasmic occludin levels versus biologic-naïve patients (-39.3±73.8 vs. -9.2±43.8; p=0.038).
Conclusion: Aberrant expression of claudin-1 and occludin in active IBD supports an important role of the intestinal barrier's dysfunction in the disease.

PS-20-039

Significance of tumour-infiltrating lymphocytes and macrophages before and after neoadjuvant chemo-radiotherapy for rectal cancer

M. Gulubova[1], M.M. Ignatova[2], K. Ivanova[1], A. Klisarova[3], E. Encheva[3], G. Minkov[4]
[1]Trakia University, Medical Faculty, General and Clinical Pathology, Stara Zagora, Bulgaria, [2]Complex Oncology Centre, General and Clinical Pathology, Stara Zagora, Bulgaria, [3]Medical University, Radiology and Nuclear Medicine, Varna, Bulgaria, [4]Trakia University, Medical Faculty, Surgery, Stara Zagora, Bulgaria

Background & Objectives: In rectal cancers TNM classification is of major importance but gives limited prognostic information and no prediction on the benefit of a chosen therapy.
In the present study we provide evidence that the type, the density, and the location of immune cells within tumour strongly influence the evolution of the tumour and the effect of neoadjuvant chemo-radiotherapy for the patients.
Rectal cancer is one of the most common gastrointestinal cancers. Neoadjuvant chemo-radiotherapy (nCRT) followed by surgery has been accepted to be standard treatment procedure for locally advanced rectal cancer (LARC). Furthermore, the anti-tumour immune response contributes to the response of nCRT.
Methods: We aimed to investigate the participation of T lymphocytes subsets (CD8, FoxP3, IL-17, RORγt) and type 1 macrophages ($CD163^+$) in the characterization of tumour microenvironment (TME) before and after nCRT in 22 patients with LARC.
Results: Density of $CD8^+$ TILs in the invasive front (IF) (41.61±4.43 v.s 74.98±60.27) and in tumour stroma (TS) (30.91±2.04 v.s 66.71±56.19) has been found to be increased after nCRT compared to the same locations in pre-therapy biopsies. The FoxP3 Tregs decreased in number in IF and TS (31.40±3.07 v.s 29.76±27.83 and 29.45±38.33 v.s 21.37±21.53, respectively) in post-nCRT treatment biopsies. The number of $CD163^+$ macrophages, IL-17^+ cells and RORγt^+ cells has been increased in post-nCRT treatment samples.
Statistically significant difference is found in the number of $CD8^+$TILs in the IF in post-nCRT as compared to the probes before nCRT (p=0.001, $\chi 2$=2.87).
Conclusion: The current study suggests that local antitumor immunity could be enhanced by increased numbers of $CD8^+$ and $CD163^+$ immune cells after nCRT. Concerning other T helper cells such as IL-17 (RORγt) and FoxP3, their numbers are modulated in the TME probably by nCRT and other factors such as intestinal microflora and the intestinal immunosuppressive milleu.

PS-20-041

Assessing FABP4 and CD36 expression in gastrointestinal cancer cell lines co-cultured with mature adipocytes in context with SARIFA

E.-M. Allmendinger[1], L. Siebenhüter[1], N. Reitsam[2], D. Neufeldt[3], J. Waidhauser[3], B. Märkl[4]
[1]University Hospital Augsburg, General Pathology and Molecular Diagnostics, Augsburg, Germany, [2]Medical Faculty, University of Augsburg, General Pathology and Molecular Diagnostics, Augsburg, Germany, [3]Medical Faculty, University of Augsburg, Haematology and Oncology, Augsburg, Germany, [4]General Pathology and Molecular Diagnostics, Medical Faculty, University of Augsburg, Augsburg, Germany

Background & Objectives: The histological biomarker SARIFA (Stroma AReactive Invasion Front Areas), recently introduced by our group, marks regions where tumour cells directly interact with

adipocytes without intervening connective tissue. Easily identifiable, SARIFA holds strong prognostic potential for guiding gastrointestinal cancer (GIC) therapy. Lipid metabolism in tumour cells is key in this context, as tumour-adipocyte interactions at the invasion front correlate with altered fat metabolism protein expression, including elevated FABP4 and CD36. Our research examines how the SARIFA microenvironment both drives and responds to these metabolic shifts.
Methods: We analysed RNA expression in GIC cell lines co-cultured with adipocytes. Preadipocytes, isolated from patient tissue, were seeded and differentiated for 14 days, confirmed by lipid droplet formation. GIC cell lines (HCT116, COLO205, 23132/87) were then seeded into transwell inserts. Co-culturing continued over 15 days with media changes and passaging of GIC cell lines every 72 hours. Cells were collected at each passage and at four post-co-culture time points for analysis.
Results: Co-culturing GIC cell lines with mature adipocytes led to altered FABP4 and CD36 expression levels, which became evident after three days of co-culture. Over a prolonged 15-day co-cultivation period, FABP4 expression exhibited fluctuations ranging from 2- to 5-fold, depending on the cell line and time point. In contrast, CD36 expression steadily increased over time, reaching 6- to 20-fold upregulation, with expression peaks varying across cell lines. All cell lines lost their overexpression one to two passages post-co-culture. Findings were reproducible across experiments.
Conclusion: Using a simplified in vitro SARIFA model, we showed that mature adipocytes influence FABP4 and CD36 expression in nearby cancer cells, significantly increasing CD36 levels over time. These findings support the idea that direct adipocyte contact activates lipid metabolism in tumour cells. Further adjustments are needed for FABP4 experiments.

Funding: BZKF

PS-20-042
Transfer of SARIFA-status of colorectal cancer into metastases
L. Rentschler[1,2], K. Krieger[1,2], D. Vlasenko[3,2], J. Waidhauser[4,2], B. Märkl[1,2]
[1]University of Augsburg - Medical Faculty, Pathology, Augsburg, Germany, [2]Bavarian Cancer Research Centre (BZKF), Augsburg, Germany, [3]University of Augsburg - Medical Faculty, General and Visceral Surgery, Augsburg, Germany, [4]University of Augsburg - Medical Faculty, Haematology and Oncology, Augsburg, Germany

Background & Objectives: SARIFA (Stroma AReative Invasion Front Areas) has recently emerged as an independent negative prognostic H&E-based biomarker for colorectal carcinomas. SARIFA is primarily characterized by direct tumour adipocyte interaction without intervening collagenous stromal reaction. It has not yet been shown whether the SARIFA-status of colorectal cancer exhibited at the primary tumour site is carried to metastatic sites.
Methods: So far 16 cases of patients with colorectal carcinomas and at least one metastasis in a site containing fatty tissue were identified from the archive of the pathology department of the University Augsburg. Metastatic sites included peritoneal or intraabdominal metastases in 15 cases and 1 case with a pleural metastasis. SARIFA-status of the primary tumour site and the metastasis was determined and compared on all available H&E-stained tumour slides. Fisher exact test was used for hypothesis testing.
Results: Among the 16 cases, 12 exhibited SARIFA at the primary tumour site of which 10 also showed SARIFA-positive metastases, with 2 cases remaining negative for SARIFA at the metastatic site. All 4 cases with SARIFA-negative primary tumours were also negative at the secondary site. This shows that the SARIFA-status of the primary tumour site and metastatic sites is highly significantly correlated (P=.008).
Conclusion: The apparent transfer of the SARIFA-status between different tumour sites suggests that the presence of SARIFA is determined by a tumour-host interaction that is not necessarily site specific. Further studies on larger collectives should be conducted to confirm this finding and to determine the specific tumour or microenvironment characteristics leading to this phenomenon.

PS-20-043
Histopathological study of endoscopic biopsies of upper gastrointestinal tract in children with inflammatory bowel disease
J. Jevtić[1], A. Ensari[2], H. Kahraman[2], M. Đuknić[1], M. Duka[1], N. Gardinovački[1], L. Simić[1], N. Ristić[3], I. Milovanovich[3], M. Radusinović[3], N. Popovac[3], I. Đorđić[3], R. Janković[1]
[1]Institute of Pathology, University of Belgrade, Faculty of Medicine, Belgrade, Serbia, [2]Ankara University, Faculty of Medicine, Pathology, Ankara, Turkey, [3]University Children's Hospital, Gastroenterology, Hepatology and GI Endoscopy, Belgrade, Serbia

Background & Objectives: Changes in the upper gastrointestinal tract (UGI) are observed in both Crohn's disease (CD) and ulcerative colitis (UC). This study aims to identify UGI histological characteristics that effectively distinguish CD from UC.
Methods: A cross-sectional study was conducted on 67 paediatric patients diagnosed with IBD (43 with CD and 24 with UC) from 2020 to 2024. Histopathological analysis of UGI biopsies assessed FAG (lymphohistiocytic infiltrate with neutrophils around foveolae or glands), FEG (lymphohistiocytic infiltrate without neutrophils), IELosis, dyskeratosis, and the presence and distribution of eosinophils and neutrophils, comparing these features between groups.
Results: FAG was detected in 45,9% of CD patients, significantly higher than the 5,3% observed in UC (p=0,022). Additionally, CD patients exhibited a greater presence of neutrophils within the epithelial structures of the antrum, both in the wall and lumen (p=0,012). Contrarily, the presence of FEG showed no significant differences between CD (43,2%) and UC (42,1%), but the presence of lymphocytes within the epithelial structures of the antrum was significantly more common in CD (p=0,001). Notably, the presence of neutrophils within the duodenal crypt epithelium (p=0,006) and lamina propria eosinophils (p=0,033), as well as oesophageal dyskeratosis (p=0,03) and oesophageal intraepithelial lymphocytes (LyE) (p=0,019), were more frequently observed in CD patients.
Conclusion: The study underscores the importance of defining FAG and FEG, highlighting that the presence of FAG in the gastric antrum primarily suggests CD. Furthermore, it emphasizes the significance of inflammatory cell distribution (lymphocytes, neutrophils) within the epithelial structures of the oesophagus, stomach, and duodenum, often indicative of CD rather than UC.

PS-20-044
Implications of the tumour immune microenvironment of advanced Epstein-Barr virus-associated gastric cancer for immunotherapy response
Y. Cho[1], S. Ahn[1], K.-M. Kim[1]
[1]Samsung Medical Centre, Department of Pathology and Translational Genomics, Seoul, Republic of Korea

Background & Objectives: Although evidence suggests that some Epstein-Barr Virus-associated gastric cancer (EBVaGC) patients may benefit from immunotherapy, the effectiveness of anti-PD-1 antibody as a biomarker in EBVaGC remains controversial. We aimed to comprehensively analyse the immune microenvironment of advanced EBVaGC and its association with the response to immunotherapy.
Methods: With multiplex immunohistochemistry staining, the expression of immune markers (PD-L1, LAG3, FoxP3, CD8, CD4, PanCK, CK+/PD-L1+, CD8+/PD-L1+, LAG3+/CD8+, CD4+/

FOXP3+) was evaluated retrospectively in tumour sections from 12 cases of advanced EBVaGC patients who were treated with immunotherapy. Computational image analysis was used to quantify the density of each markers within the tumour and stromal region.
Results: Higher PD-L1+, CK+/PD-L1+ levels in the tumour region were significantly associated with better response to immunotherapy (P=0.04545 and 0.03788). Higher CD4+, CD8+/PD-L1+, CD4+/FoxP3+ levels in the stromal region were significantly associated with better response (P=0.04798, 0.04545, and 0.0101), whereas higher LAG3+ levels in the stromal region was significantly associated with worse response (P=0.01894). Within combined regions of the tumour and adjacent stroma, higher PD-L1+, CD4+, CD8+/PD-L1+, CD4+/FoxP3+ levels were significantly associated with better response (P=0.04798, 0.04798, 0.02904, and 0.005051). For LAG3, lower expression levels in total region was significantly associated with better response (P=0.01894).
Conclusion: This study highlights several immune markers other than PD-L1 as potential biomarkers in predicting the response to immunotherapy in EBVaGC. Future studies are required to confirm their potential to predict tumour responses to immune therapy.

PS-20-046
Claudin 18.2 expression as a biomarker in gastric cancer: clinicopathological correlations and therapeutic implications
M.A. Bani[1,2], T.N. Nguyen[1], C. Smolenschi[3], S. Cosconea[3], L. Benhaim[4], A. Boileve[3,2], R. Barbe[5], R. Soufan[1], M. Charlot[1], S. Vignaud[1], S. Pitterboth[1], A. Hollebecque[3], M. Ducreux[3,2], P. Dartigues[1]
[1]Gustave Roussy Cancer Campus, Medical Biology and Pathology Department, Pathology Laboratory, Villejuif, France, [2]Paris-Saclay University, Villejuif, France, [3]Gustave Roussy Cancer Campus, Department of Digestive Oncology, Gustave Roussy Cancer Centre, Villejuif, France, [4]Gustave Roussy Cancer Campus, Department of Surgical Oncology, Gustave Roussy Cancer Centre, Villejuif, France, [5]Gustave Roussy Cancer Campus, Department of Medical Imaging, Villejuif, France

Background & Objectives: Gastric cancer (GC) continues to pose a significant clinical challenge due to its high mortality and limited targeted therapies. Claudin 18.2 (CLDN18.2), a protein primarily expressed in gastric epithelium, has emerged as a promising biomarker and therapeutic target. This study investigated CLDN18.2 expression in GC and gastroesophageal junction (GEJ), assessing its clinicopathological associations and prognostic significance to better understand its potential therapeutic relevance.
Methods: An observational cohort analysis of 112 patients with GC/GEJ diagnosed between 2013 and 2024. CLDN18.2 expression was evaluated via immunohistochemistry, with positivity determined by membranous staining intensity and percentage of stained tumour cells. Cases were considered positive if they had ≥75% positive tumour cells with moderate and high intensity. We also assessed H-SCORE for these cases. Statistical associations were explored between CLDN18.2 expression and clinicopathological features including specimen type, tumour site, stage, histological subtypes (Lauren and WHO), molecular markers (HER2, PD-L1, MMR status, Epstein-Barr virus [EBER]), and clinical outcomes.
Results: CLDN18.2 positivity was significantly associated with metastatic specimens compared to primary tumours (29.41% vs. 6.41%; OR=0.16; CI[0.051–0.53]; p=0.002) and advanced TNM stage IV disease (p=0.046). A significant correlation was found between CLDN18.2 expression and EBER positivity (23.53% positive vs. 0% negative; p=0.002). Median tumour size was smaller in CLDN18.2-positive tumours (30 mm vs. 42.5 mm), though not statistically significant (p=0.156). No significant correlations emerged between CLDN18.2 expression and HER2 amplification, mismatch repair deficiency, or PD-L1 scores (TPS and CPS). Survival analyses showed no statistically significant differences in recurrence-free or overall survival between CLDN18.2-positive and negative groups.
Conclusion: CLDN18.2 expression is notably associated with metastatic disease and advanced GC/GEJ stages, highlighting its potential as a therapeutic target. Its strong association with EBER positivity suggests biological specificity that may guide treatment selection. Despite lacking a direct prognostic impact, these findings emphasize CLDN18.2's therapeutic promise, advocating further investigations.

PS-20-047
Quantitative image analysis of tumour-infiltrating lymphocytes in rectal cancer: preliminary data on therapeutic response prediction
L. Ruiz Estigarribia[1], I. Fernández de los Reyes[1], A. Panizo Santos[1], I. Caseda[2], I. Labiano[2], A.E. Huerta[2], A. Lecumberri[2], E. Mata[3,2], J. Suarez[4], R. Vera[3]
[1]Hospital Universitario de Navarra, Department of Pathology, Pamplona, Spain, [2]Oncobiona Group, Navarrabiomed-Instituto de Investigación Sanitaria de Navarra (IdiSNA), Pamplona, Spain, [3]Hospital Universitario de Navarra, Department of Medical Oncology, Pamplona, Spain, [4]Hospital Universitario de Navarra, Department of Surgery, Pamplona, Spain

Background & Objectives: Locally advanced rectal cancer (LARC) is routinely treated with neoadjuvant therapy (NAT), followed by surgery. However, responses to NAT are heterogeneous. The "watch-and-wait" strategy, aims to preserve organ in good responders, but requires reliable biomarkers to predict treatment response. Tumour-infiltrating lymphocytes (TILs) reflect the host immune response and have been linked to a more favourable tumour microenvironment. Objective quantification of TILs in pretreatment biopsies may help stratify patients and guide clinical decisions.
Methods: Clinical and pathological data were collected from patients diagnosed with LARC and treated with NAT. Pretreatment biopsies were immunohistochemically stained for CD3, CD4, CD8, and CD15. Slides were scanned and analysed using the QuPath software. The density of positive immune cells was automatically quantified (cells/mm²) in the manually selected hotspot areas. Pathological response was evaluated using the Mandard Tumour Regression Grade (TRG) system. Six patients (3 women and 3 men) with LARC who received NAT were included in this preliminary study. Five patients underwent surgical resection with TRG 3, and one with TRG 4. Descriptive statistics and one-way ANOVA were used to compare the mean cell densities between TRG groups. Due to the limited sample size, the results were interpreted as exploratory.
Results: Preliminary analysis revealed inter-individual variability in the densities of CD3+, CD4+, and CD8+ cells, with no statistically significant differences observed between TRG groups. In contrast, CD15+ cell density was higher in TRG4 compared to TRG3, both in hotspot and global areas, with a trend toward statistical significance in the global analysis *($p = 0.060$).*
Conclusion: Preliminary data suggest that a high density of CD15+ cells may be associated with an immunosuppressive tumour microenvironment and a poorer response to neoadjuvant therapy. Further analysis is in progress to explore the role of TILs as key modulators of treatment response.

PS-20-048
Clinicopathological features and prognostic implications of High-grade Appendiceal Mucinous Neoplasm (HAMN): a multicentre study
E. Paşaoğlu[1], N. Dursun[2], M. Gulluoglu[3], M. Büyük[3], M. Cin[4], B. Yilmaz Ozguven[2], T.B. Ozcan[1], D. Canoglu[5], E. Akay[6], G. Harman Kamali[7], N. Berker[3], H. Karatay[2]

[1]Health Sciences University Bagcılar Education and Research Hospital, Pathology, Istanbul, Turkey, [2]Health Sciences University Basaksehir Cam and Sakura City Hospital, Pathology, Istanbul, Turkey, [3]Istanbul University Istanbul Faculty of Medicine, Pathology, Istanbul, Turkey, [4]Health Sciences University Istanbul Education and Research Hospital, Pathology, Istanbul, Turkey, [5]Health Sciences University Kartal Dr Lutfi Kırdar City Hospital, Pathology, Istanbul, Turkey, [6]Health Sciences University Kayseri Faculty of Medicine Kayseri City Hospital, Pathology, Istanbul, Turkey, [7]Health Sciences University Prof Dr Cemil Tascıoglu City Hospital, Pathology, Istanbul, Turkey

Background & Objectives: High-Grade Appendiceal Mucinous Neoplasm (HAMN) is a term, introduced in 2016 to describe tumours exhibiting pushing-type invasion similar to low-grade appendiceal mucinous neoplasms (LAMNs), but possessing high-grade cytological features. Data regarding the behaviour of these rare tumours is quite limited. This multicentre study aims to investigate the clinicopathological features and behaviour of HAMNs, the impact of focal high-grade features on prognosis.
Methods: Slides from cases diagnosed as HAMN or LAMN with focal high-grade atypia in seven centres were reviewed by an experienced gastrointestinal pathologist. Thirty-four cases met inclusion criteria. Clinical details and follow-up data were collected from hospital records.
Results: The mean age was 57 years, female-to-male ratio was 1.83. Diffuse appendiceal enlargement occurred in 25 cases. High-grade features were focal (≤10%) in 10 and extensive(>75%) in 15 cases. The most frequent architectural pattern was micropapillary, which is not observed in LAMNs, followed by undulating, villous, cribriform, flat patterns. Serosal perforation was observed in 18 cases; 9 had periappendicular acellular mucin, and other 9 had cellular mucin. Three cases of the latter had grade 2(G2) and six had grade 1(G1) pseudomyxoma peritonei (PMP), while six cases presented with peritoneal acellular mucin. No tumours confined to the appendix recurred. PMP developed in one patient during follow-up. Among the two cases with 10% high-grade histological features, one was associated with PMP-G2, and one with PMP-G1. Among nine patients who presented with PMP, one died of disease, one died due to postoperative complications, and four were alive with disease at last follow-up.
Conclusion: HAMNs appear to have a stage-dependent behaviour similar to LAMNs. Prognosis is good in cases limited to appendix. However, when they spread to the peritoneum, may produce PMP-G2, which can be associated with worse prognosis. Cases showing focal high-grade histology also should be reported as HAMN due to potential association with PMP-G2.

PS-20-049

Molecular profiling of RAS and BRAF mutations in colorectal carcinoma: a comparative study between pT1-pT3 and pT4 stages

G. Sahraoui[1], R. Aouadi[1], H. Douik[1], A. Khemir[1], N. Hammadi[1], R. Doghri[1], L. Charfi[1], K. Mrad[1]
[1]Pathology Department, Salah Azaiez Institute, Tunis, Tunisia

Background & Objectives: Colorectal carcinoma (CRC) is the third most prevalent cancer and the second leading cause of cancer-related deaths worldwide. Molecular alterations play a critical role in tumour behaviour and therapeutic strategies. Mutations in RAS (KRAS, NRAS) and BRAF genes have been widely studied for their prognostic and predictive implications. Although these mutations have been thoroughly investigated in CRC, their variation in prevalence and distribution across different tumour stages is not well established. This study aims to analyse and compare the molecular profiles of RAS and BRAF mutations in different TNM stages of CRC.
Methods: This is a retrospective study including cases of CRC referred to our department for molecular testing of KRAS, NRAS and BRAF genes. Tumours were classified into two groups based on TNM staging: pT1-pT3 group and pT4 group. Molecular analysis was performed using polymerase chain reaction (PCR) and sequencing techniques.
Results: Our study included 496 cases. The mean age of patients was 59 years. Mutations in KRAS gene were detected in 243 cases (49%) while NRAS and BRAF mutations were detected in 20 cases (4%) each. A single case (0.1%) exhibited a dual NRAS and BRAF mutation. There was a significant association between pT4 stage and higher prevalence of KRAS G12A, NRAS codon 61, and BRAF V600E mutations (p=0.046).
Conclusion: Our findings suggest a significant association between tumour stage and specific molecular alterations in CRC. The higher prevalence of KRAS and BRAF mutations in advanced-stage tumours indicates their potential involvement in tumour proliferation and disease progression.

PS-20-051

B7-H3 expression in gastric cancer and its correlation with CD8+ T cell infiltration

D. Ulase[1], H.-M. Behrens[1], C. Röcken[1]
[1]Christian-Albrechts-University Kiel and University Medical Centre Schleswig-Holstein, Campus Kiel, Department of Pathology, Kiel, Germany

Background & Objectives: The majority of patients diagnosed with gastric cancer (GC) present at advanced stage. Immunotherapy has changed the management of GC, however its efficacy is limited, associated with severe side effects and significant costs. There is a high demand for new biomarkers. B7-H3 (CD276), an immune checkpoint molecule with both immune and non-immune functions, is currently investigated as a potential therapeutic target. Data on expression in GC are limited. We aimed to investigate B7-H3 expression patterns in a large therapy-naive cohort of GC.
Methods: Formalin-fixed, paraffin-embedded whole tissue sections (n=354) were analysed using immunohistochemistry. The level of B7-H3 intensity was divided into B7-H3-low (0-1) and -high (2-3) groups, correlated with clinicopathological variables, and overall survival (OS). Density of CD8+ cells was assessed using whole slide digital imaging. To address the spatial distribution of CD8+ cells, ratios between tumour centre and invasive margin were calculated.
Results: High B7-H3 expression was observed in tumour stroma (51.7%) and parenchyma (12.7%). High stromal B7-H3 expression was associated with sex (p<0.001), tumour localization (p=0.001), Lauren phenotype (p<0.001), HER2-status (p=0.001) and CD8-ratio (p<0.001). Significant differences between median CD8-ratios were observed (1.21, B7-H3-low vs. 0.62, B7-H3 high, p<0.001). No significant differences in OS could be demonstrated between cases with low and high stromal expression, or low *vs.* high median CD8-ratios. Parenchymal B7-H3 expression correlated with Lauren phenotype (p<0.001), pN-status (p=0.007), HER2-status (p=0.001) and OS (p=0.009). When subdivided by sex, the prognostic effect was seen only in females (17.1 months, B7-H3 low *vs.* 3.3 months, B7-H3 high, p<0.001).
Conclusion: B7-H3 is overexpressed in GC, making it a promising target for immunotherapy. An association between B7-H3 stromal expression and spatial distribution of CD8+ cells was observed, suggesting the potential role of B7-H3 in tumour microenvironment (TME). Further studies are needed to investigate the impact of sexual dimorphism in TME and immunotherapy-strategies of GC.

PS-20-052

Surgery for Crohn's disease: histopathological predictors of recurrence at the proximal resection margin

H. Maaroufi[1], F. Khanchel[1], I. Helal[1], S. Riahi[2], R. Hedhili[1], E. Ben Brahim[1], M. Sabbeh[2], R. Jouini[1], A. Chadli[1]
[1]Habib Thameur Hospital, Department of Pathology, Tunis, Tunisia, [2]Habib Thameur Hospital, Department of Surgery, Tunis, Tunisia

Background & Objectives: Surgical intervention is required in 80% of Crohn's disease patients during their lifetime. Patient and disease-related factors have been established as potential risk factors for post-operative recurrence (POR). However, the role of microscopic inflammation at the resection margins as a predictor of POR remains unclear. The aim of this study was to assess the predictive value of histological parameters at the proximal ileocecal resection margin for disease recurrence.
Methods: A retrospective study on patients undergoing ileocecal resection for Crohn's disease between 2000 and 2020 was conducted. Pathology reports were reviewed, and slides pertaining to proximal surgical margins were reexamined. Histological findings were correlated to endoscopic, clinical and surgical recurrence.
Results: In total, 70 patients were identified with a median follow-up of 10.7 years. Thirty-three patients developed endoscopic recurrence within the first year. Clinical and surgical recurrence were observed in 35 and 9 cases respectively. Histological examination of the proximal margin found cryptitis and neutrophils in chorion in 10% and 25.7% of cases respectively. Myenteric and submucosal plexitis were found in 47% and 20% of cases respectively. Granulomas were found in 10% of cases. The Kaplan Meier analysis identified that the presence of myenteric and submucosal plexitis at the proximal resection margin was associated with shorter time to surgical recurrence (p=0.007, 0.046, respectively).
Conclusion: Submucosal and myenteric plexitis at the proximal ileal resection margin after ileocecal resection identifies a patient group at high risk for an earlier second surgical intervention. These patients have a different and more aggressive natural history of disease. Therefore, pathological evaluation of plexitis at the proximal resection margin should be implemented in the current pathological practice after ileocaecal resection for Crohn's disease.

PS-20-053

Usage of modifying phrases in pathology reports on gastric dysplasia: can we improve diagnostic accuracy by expressing the degree of certainty?

A. Krasnova[1], E. Abrosimova[2], V. Vikentyeva[1], A. Kononov[1], S. Mozgovoi[1], A. Shimanskaya[1]
[1]Omsk State Medical University, Pathology, Omsk, Russia, [2]Omsk State Agrarian University, Foreign Languages, Omsk, Russia

Background & Objectives: The biopsy report, based on biopsy findings, is a complex form of communication that incorporates standardization, objectivity, and accuracy while also reflecting the pathologist's professional expertise. Modifiers indicating the degree of certainty are essential for clarity, as endoscopic biopsy results for stomach mucosal dysplasia often lack precision, leading to uncertainty in grading. This inherent limitation underscores the challenge of providing a clear and reliable diagnosis in clinical practice.
Methods: A list of 16 frequently used words and phrases, formulated after analysing more than 800 biopsy pathology reports, included terms like "not reliably determined," "doubtful signs," "suggestive of," "similar to," "cannot be excluded," "suspicious in," "similar to," "typical picture," "probable," "the most probable," "most consistent," and "reliably determined," which help to convey uncertainty and variability in diagnostic conclusions.
Results: The study utilized a simple questionnaire to evaluate the confidence levels of 12 specialized pathologists and 28 clinicians across various specialties using a 10-point ranked scale (0 - absence to 10 - 100% presence). The research identified significant variability in confidence/validity scores for each phrase, with "reliably determined" scoring 3 and "similar to..." scoring 7. This chaotic, inconsistent use of heterogeneous terms and modifiers significantly disrupts professional communication between pathologists and clinicians, leading to potential misunderstandings and inaccuracies in diagnostic conclusions. This high variability in how uncertainty is perceived and expressed poses a significant challenge in ensuring clear and consistent diagnostic reporting.
Conclusion: To improve this situation, the study proposed several solutions, including strictly limiting the use of these terms in separate sections of the report, creating a standardized list of modifying phrases, introducing algorithmic interpretations, transitioning to a more formalized synopsis format with minimal variability, and incorporating quantitative parameters to reflect certainty levels. These measures aim to enhance clarity, reduce uncertainty, and improve the reliability of diagnostic communication in biopsy reports.

Spleen and lymph node morphology in CLL/SLL: a comparison between histology and scanning electron microscopy

A. Canino[1], T. Congiu[1], F. Angotzi[2], L. Nonnis[1], R. Murru[1], R. Ambu[1], M. Piras[1], C. Gerosa[1], L. Pilloni[1], D. Fanni[1]
[1]University of Cagliari, Department of Medical Sciences and Public Health, Cagliari, Italy, [2]University of Padova, Haematology Unit, Padova, Italy

Background & Objectives: Chronic lymphocytic leukaemia/small lymphocytic lymphoma (CLL/SLL) is a type of B-cell lymphoma characterized by small, mature B cells that affect the peripheral blood, bone marrow, lymph nodes, and spleen, often resulting in splenomegaly. The infiltration of the white pulp is particularly prominent, leading to a loss of distinction between red and white pulp.
Methods: We examined a spleen from a 51-year-old patient diagnosed with CLL/SLL (weight: 2400 g; dimensions: 27×17×12 cm). Histological analysis included haematoxylin-eosin staining, along with an immunohistochemical panel for lymphomas. Additionally, samples from the spleen and hilar lymph nodes were prepared and analysed using a Zeiss 600 scanning electron microscope (SEM) to evaluate ultrastructural changes.
Results: Histological analysis revealed a diffuse proliferation of small lymphoid cells with scant cytoplasm and small nuclei, interspersed with medium-sized cells featuring dispersed chromatin and small nucleoli. These cells expressed markers including CD20, CD79a, PAX5, BCL2, CD5, and CD23. SEM demonstrated neoplastic infiltration that disrupted the splenic stroma and compromised the normal connective framework. The remaining stroma appeared as thin fibrous strands trapped among irregularly shaped neoplastic cells, forming a dense mass that completely altered the spleen's architecture. In the metastatic lymph node, the tumour cells created an even denser mass that replaced the entire tissue. The remaining connective structures were barely recognizable, and the neoplastic cells appeared more cohesively packed together.
Conclusion: Ultrastructural evaluation is a valuable approach to studying lymphoma morphology. SEM, in particular, reveals structural details that may not be visible with light or transmission electron microscopy. The combination of SEM and histological analysis

provides new insights into the infiltration patterns of CLL/SLL within the spleen and lymph nodes. Notably, SEM highlights differences in the three-dimensional organization of neoplastic cells in the spleen compared to metastatic lymph nodes, as well as their distinct interactions with connective tissue.

PS-21-002

The detection of ultrastructural features on electron microscope images of renal samples using deep learning

L. Nezamuldeen[1], W. Mal[2], R. A. Al Zahrani[3], S. Jambi[4], M.S. Jafri[5]
[1]King Abdulaziz University, King Fahd Medical Research Centre, The Vaccines and Immunotherapy Unit, Jeddah, Saudi Arabia, [2]King Abdulaziz University, Faculty of Applied Medical Sciences, Department of Medical Laboratory Sciences, Jeddah, Saudi Arabia, [3]King Abdulaziz University, Faculty of Medicine, Department of Pathology, Jeddah, Saudi Arabia, [4]King Abdulaziz University, Faculty of Computing and Information Technology, Department of Information Systems, Jeddah, Saudi Arabia, [5]George Mason University, School of Systems Biology, Fairfax, USA

Background & Objectives: Chronic kidney disease (CKD) affects over 10% of the global population, with diagnosis relying heavily on the analysis of renal biopsy images, including transmission electron microscopy (TEM). Manual analysis is time-consuming and prone to interobserver variability. This study leverages YOLOv8-OBB deep learning models to automate the detection of six ultrastructural features in renal biopsies—glomerular basement membrane (GBM), mesangial folds, deposits, normal podocytes, podocytopathy, and subepithelial deposits—to reduce diagnostic variability and enhance efficiency.
Methods: We developed five YOLOv8-OBB-based models with different training strategies: a "From Scratch" model, a pretrained model, and models with grayscale channel enhancements (GSch), additional feature extraction layers (4FExL), or both. An ensemble method combining predictions from these models was also tested. The dataset included 607 TEM images, augmented to 1652 images using grayscale conversion and brightness adjustments, annotated for six features. Model performance was evaluated using mAP@0.5, mAP@0.5-0.95, and F1-scores.
Results: Pretrained models consistently outperformed the "From Scratch" approach, with mAP@0.5 scores ranging from 0.927 to 0.936 vs. 0.877. The Pretrained+GSch+4FExL model excelled in detecting small features (confidence scores ≥30% for GBM, podocytopathy, and mesangium deposits). The ensemble method achieved high confidence thresholds (>60% for mesangial deposits, >70% for mesangial folds, and > 80% for podocytopathy, > 50% for normal podocytes, and >30% for GBM), demonstrating robust and consistent detection across features and reducing false positives by 15–20%.
Conclusion: Pretrained YOLOv8-OBB models, enhanced with grayscale and feature extraction, significantly improve ultrastructural feature detection in renal biopsies. The ensemble method boosts accuracy, streamlining pathology workflows. A web application, *RENAL AI*, was developed for diagnostics. Future work will expand feature regions, incorporate segmentation methods, and integrate detected features with patient history and blood work (e.g., proteinuria, serum creatinine) for precise disease classification (e.g., membranous nephropathy, lupus nephritis), enhancing clinical decision-making in nephrology.

PS-21-003

Mitochondria-ER Contact Sites (MERCS) in Human Glioblastoma Stem-like Cells and Differentiated Glioblastoma Cells

G. Arismendi Morillo[1]
[1]University of Deusto, Faculty of Health Sciences, Bilbao, Spain

Background & Objectives: Understanding the characterization of Mitochondria-ER Contac Sites (MERCS) in Glioblastoma Cells, could be important for the therapeutical approach.
Methods: MERCS ultrastructure of Glioblastoma Stem-like Cells (GSC) and Differentiated Glioblastoma Cells (DGC) in surgical specimens from human astrocytic neoplasms were studied.
Results: MERCS in Glioblastoma like-Stem Cells (GSC) are scarce. In Differentiated Glioblatoma Cells (DGC) are numerous.
Conclusion: Two remarkable cell types were observed with respect to MERCS: GSC or "MERCS deficient cells" and DGC or "MERCS rich cells". Conspicuous contrast in MERCS amount between GSC and DGC could be represent a differential metabolic phenotype. Therefore, an effective therapy seems to be a metabolic-multifaceted strategy.

Historical evolution of pathology autopsy in 1923–1970: experience of local Lithuanian pathology centre

M. Kuprytė[1,2], V. Matutytė[2], V. Šarauskas[3], V. Martinkutė[3], L. Poškienė[2,3]
[1]Lithuanian University of Health Sciences Kauno Klinikos, Pathological Anatomy, Kaunas, Lithuania, [2]Lithuanian University of Health Sciences, Kaunas, Lithuania, [3]Hospital of Lithuanian University of Health Sciences Kauno Klinikos, Pathological Anatomy, Kaunas, Lithuania

Background & Objectives: Extensive study of a pathology autopsy data trends in different historical periods reflects a validated historical data on evolution of clinical medicine in different regions, also assisting in standardizing the control of disease frequency evaluation. Study objective is to determine trends of autopsies in 1923 – 1970 of local Lithuanian pathology centre.
Methods: Archival documents of pathology autopsy of 2128 patients who died in 1923-1925, 1930, 1935, 1940, 1945, 1950, 1960, and 1970 in local Lithuanian pathology centre were selected. Data parameters of age, sex, and main disease diagnosed after pathology autopsy were collected from archival protocols. Descriptive statistics and $\chi 2$ test were applied ($p<0.05$). Bioethical committee approval no. BEC-MF-342.
Results: Rate of adult pathology autopsies was 88.1% in 1923-1925, 82.9% in 1930, 88.7% in 1935, 71.1% in 1940, 88.7% in 1945, 45.6% in 1950, 62.4% in 1960, and 79.1% in 1970. Average patient's age of selected cases increased from 35.6 years old in 1923-1925 up to 57.4 years old in 1970. More than 60% of pathology autopsies were performed for men in 1923-1925, whereas 55.4% of selected cases were men autopsies in 1970. Infectious diseases were predominant in 1923-1925 (22.3%), which continued to decrease up to 4.9% in 1970 ($p<0.05$). Neoplasia were diagnosed in 16.5% cases in 1923-1925, and increased up to 35.4% in 1970 ($p<0.05$). Rate of cardiovascular diseases was 14.7% in 1923-1925 and increased up to 30.2% in 1970 ($p<0.05$).
Conclusion: Significant trends of pathology autopsy of local Lithuanian pathology centre in 1923-1970 was characterized in the study. Rates of adult pathology autopsy, changes in patient's age and sex, as well as main disease reflects the impact of historical events on sociodemographic and clinical medicine trends, emphasizing the role of pathology autopsy as an effective tool to monitor accurate and timely status of clinical medicine situation in local region.

PS-22-002

History of pathology in Tunisia: a tribute to the country's pioneering pathologists

A. Bdioui[1,2], Z. El Euch[1], S. Sakly[1], R. Bader[1], S. Mestiri[1], S. Hmissa[1]
[1]Sahloul Hospital, Pathology, Sousse, Tunisia, [2]Sousse Medical School, Research Laboratory Oncogenesis and Tumoral Progression LR21ES03, Sousse, Tunisia

Background & Objectives: The history of pathology can be traced back to the earliest application of the scientific method to medicine.

Rudolf Virchow is generally recognised as the father of microscopic pathology. In Tunisia, the history of pathology is relatively recent, beginning shortly after independence.
Methods: In that context, we carried out a bibliographical research on the country's first pathologists.
Results: Professor Amor Chadli was the first Tunisian pathologist to head the Institut Pasteur in Tunis from 1963 to 1988, and was also the founding Dean of the first Tunisian medical school. He was appointed Head of the Pathology department at Pasteur Institut in Tunis, the only Tunisian department i until 1972. In 1963, During his tenure, the Pasteur Institute of Tunis played its part in the country's health progress, the training of managers and biomedical research. In 1985, Professor Amor Chadli obtained a revision of the status of the scientific staff of the Tunisian Pasteur Institute and builb the first molecular biology department.
Among the pioneers in pathology, we also cite Professor Chedly Bouzakoura, as the first pathologist in Tunisia central region, dean of Sousse medical school and director of Regional Public Health Department under his leadership, pathology as well health sector has achieved prodigious success.
The list is long, but unfortunately we can't be exhaustive, we cite also Dr. Mouhamed Moncef Zitouna, former head of pathology department of Rabta hospital, in Tunis, who is a distinguished as academic author and researcher His extensive body of work spans various features of pathology. We cite also Pr Sarra Ben jilani as the first female pathologist in Tunisia, and head of Charles Nicolles hospital in Tunis.
Conclusion: To these inescapable icons, we are grateful. This tribute is a recognition and gratitude for the exemplary career of the doctors and their colossal work of leadership.

PS-22-003
Pathology Museum's conjoined twins collection from Institute of Anatomical and Molecular Pathology, Faculty of Medicine of the University of Coimbra
A. Lai[1], M. Viseu[2], G. Fontinha[2,1], R. Silva[2], A. Alarcão[2,3], A.F. Ladeirinha[2,3], J. Pimentel[2,1], V. Almeida[2,1], M.R. Silva[2,3], T. Ferreira[2], L. Carvalho[2,3,1], V. Sousa[2,3,1], R. Gouveia[2]
[1]Unidade Local de Saúde de Coimbra - Hospitais da Universidade de Coimbra, Serviço de Anatomia Patológica, Coimbra, Portugal, [2]Institute of Anatomical and Molecular Pathology, Faculty of Medicine of the University of Coimbra, Coimbra, Portugal, [3]CIMAGO – Research Centre for Environment, Genetics and Oncobiology, Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background & Objectives: Conjoined twins incidence is approximately 1 per 200,000 births, but is probably underestimated, representing one of the rarest forms of congenital anomalies. This type of anomalies can emerge in case of monochorionic-monoamniotic pregnancies and are characterized by fused twins, with at least 9 different types described in literature. Despite the most common accepted theory for its aetiology is partial fission or secondary fusion, not plainly explain every possible conjunction.
It is in this scenario that the Pathology Museums shows its important role of preserving these infrequent specimens.
Methods: We have documented the specimens preserved in Pathology Museum from Institute of Anatomical and Molecular Pathology, Faculty of Medicine of the University of Coimbra, through macroscopic evaluation and description of type of fusion, associated external malformations and estimated gestational age.
Results: The present collection comprise 10 specimens: 4 cephalopagus (joined from head to umbilicus), 5 thoraco-omphalopagus (joined thorax and abdomen) and 1 craniopagus (cranium fusion). We only identified leporine lip as another congenital malformation present in 1 twin of the craniopagus case, and in both twins in one of the thoraco-omphalopagus cases.
All cases were acquired during the 20th century and the estimated gestational age ranges from 25th to 31st weeks.
Conclusion: Pathology Museums plays an important role in preserving rare specimens and rare pathologies as happen in this type of congenital malformation. They provide current pathologists and other interested audience an opportunity to see and study this cases.

PS-22-004
The specimens of syphilitic aortitis of the Pathology Collection of the University of Turin
L. Ferrari[1], S. Micalizio[2], M. Ginepro[3], G. Orlando[2], E.R. Ghergu[3], F. Alchera[3], F. Zampieri[4], M. Papotti[2]
[1]Cardinal Massaia Hospital, Division of Pathology, Asti, Italy, [2]University of Turin, Department of Oncology, Turin, Italy, [3]University of Turin, Department of Chemistry, Turin, Italy, [4]University of Padua, Unit of History of Medicine, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Padua, Italy

Background & Objectives: There are 9 specimens of syphilitic aortitis among the 395 wet specimens of the Pathology Collection of the University of Turin which derives from the Royal Pathology Museum of University of Turin dating back to the XIX and XX century. This pathology condition was the study field of Professor Pio Foà and his successor Ferruccio Vanzetti. During the conservation intervention of the Pathology Collection the preservative liquids of these specimens have been sampled to check for the presence of mercury and arsenic. These substances are related to possible drug treatment. One case of syphilitic aortitis collected by Professor Foà was histologically sampled to evaluate the morphology.
Methods: The analysis of the heavy metals is carried out after mineralization (ICP-OES) on a sample of the preservative liquid of each specimen. All the specimens have original labels on the jar and this allows to know when they date back. Haematoxylin-Eosin, histochemical staining for elastic fibres and immunohistochemical staining Vimentin and Factor VIII were performed.
Results: The presence of arsenic and mercury correlates with their time, in view of the spread of Salvarsan since 1910. The absence of significant arsenic content in the era prior to the spread of Salvarsan shows that these values are attributable to the drug treatment. This is confirmed by the fact that no known fixative had arsenic in its composition. Histochemical and immunohistochemical stains show endarteritis obliterans and the formation of capillaries.
Conclusion: The study of some wet specimens belonging to the Pathology Collection of the University of Turin shows their historical and paleopathological value once again. Chemical analyses show that this value is not limited to the specimens but extends to the preservative liquid. The histological analysis supports the potential of studying historical wet specimens with modern techniques.

PS-22-005
Fluid toxicity of ancient wet specimens: a safe proposal for the Pathology Collection of Turin
L. Ferrari[1], S. Micalizio[2], M. Ginepro[3], G. Orlando[2], E.R. Ghergu[3], F. Alchera[3], M. Papotti[2]
[1]Cardinal Massaia Hospital, Division of Pathology, Asti, Italy, [2]University of Turin, Department of Oncology, Turin, Italy, [3]University of Turin, Department of Chemistry, Turin, Italy

Background & Objectives: The wet specimens from ancient museum pathological collections are kept in liquids whose composition is often unknown. However, they may also contain formalin for filling operations due to evaporation of the original liquid over time. Formalin is known to be carcinogenic, therefore it is necessary to safeguard the safety of the exposure environment of the specimens. The historical Pathology Collection of the University of Turin includes 395 wet

specimens. During the recent conservation intervention, it was made safe by a sealed closure of the jars.
Methods: Formalin content was tested in a small sample of the original fluids of 49 wet specimens with the kit Specroquant ®. Their jars were then sealed using rosin lute or vaseline and the presence of formaldehyde in the room was tested using an environmental tester
Results: 47 specimens contain 0.2-2.5% free formaldehyde, due to subsequent refills and not to the initial fixation procedure. Just 2 specimens dating back to the 1930s contains 3.5-4.5% free formaldehyde, due to the fixation procedure. This data is consistent with the time of preparation of the oldest wet specimens of the Pathology Collection between 1898 and 1923. It also shows that the traditional set-up continued at University of Turin even in subsequent years up to the 1930s. Environmental tests for formaldehyde in the ambient air of the exhibition room did not detect any formaldehyde.
Conclusion: Despite the scant presence of formalin, the closure of the jars prevents the spread of volatiles in the environment. The museum collection is therefore safe for the exhibition visitors.

PS-23-001
Advanced technology for efficient tuberculosis, NTM, and drug resistance detection using Genes2Me OnePCR and Rapi-Q platforms

N. Erande[1], B.S. Gurjar[1], N. Kumar[1], R. Dongerdiye[1]
[1]Genes2Me Pvt Ltd. India, R&D, Gurugram, India

Background & Objectives: Tuberculosis (TB) remains a major global health challenge, further complicated by drug-resistant TB (DR-TB) and the need to differentiate it from non-tuberculous mycobacteria (NTM). The **Genes2Me OnePCR POCT** and **Rapi-Q platforms** offer a **SAMPLE IN-RESULT OUT** solution for rapid TB, NTM, and drug resistance detection, targeting **RIF-1 to RIF-4**, **katG (codon 315)**, and **inhA (C-15T)** mutations. This study aims to evaluate their performance and compare it with the MIGIT and CBNAAT **MTB/RIF assay**.
Methods: Clinical samples, including sputum, culture, and other pulmonary specimens, were processed using a proprietary **Inactivation & Liquefaction (IL) buffer**, which breaks down the mucin matrix, reduces viscosity, and releases trapped bacteria for efficient nucleic acid extraction. The **OnePCR POCT platform** is a compact, automated system designed for point-of-care use, delivering results in **100 minutes**. It employs a **four-tube assay** for TB detection, NTM differentiation, and drug resistance analysis, making it ideal for decentralized diagnostic settings. In parallel, the **Rapi-Q platform** offers a high-throughput solution combined with the **Rapi-X16 extraction unit**, processing up to **16 samples simultaneously**.
Results: When tested with **100 MGIT-positive** and **100 MGIT-negative** clinical samples, the assays demonstrated an overall **clinical sensitivity of 95-96%** across MTB, MTB-NTM, and TB-MDR targets, outperforming the **Cepheid Xpert MTB/RIF assay** in multiple external centres. The platforms exhibited **specificity of 97-98%**, effectively distinguishing MTB from NTM and accurately identifying drug-resistant strains. The analytical performance showed a **Limit of Detection (LOD) of 50-70 rfu/mL** for both wild-type MTB and NTM strains, and 100rfu/ml for MDR with no cross-reactivity observed with common pathogens or interference from substances such as **human genomic DNA, tobacco**, or tuberculosis drugs.
Conclusion: The **Genes2Me OnePCR POCT and Rapi-Q platforms** provide a **rapid, accurate, and reliable** solution for TB diagnosis, NTM differentiation, and drug resistance detection.

PS-23-002
Visceral leishmaniasis in bone marrow biopsies: analysis of four tertiary hospitals

R.I. Alvarado Cuenca[1], G. Cancho Galán[1], A. Gaafar[1], C. Valentí Ponsa[1], S. Montes-Moreno[2], J. Gómez Román[2], T. Zudaire Fuertes[3], J.S. Castillo Malla[4], L. Aguirrezabal Marcotegui[1], I. Fernández de la Prieta[1], P. Calvo Torio[1], M. Catbaños Bueno[1], N. Arbide del Río[1]
[1]Basurto University Hospital, Pathology, Bilbao, Spain, [2]Marqués de Valdecilla University Hospital, Pathology, Santander, Spain, [3]San Pedro University Hospital, Pathology, Logroño, Spain, [4]Miguel Servet University Hospital, Pathology, Zaragoza, Spain

Background & Objectives: Leishmaniasis is a disease caused by Leishmania spp., primarily affecting bone marrow, liver, and spleen, particularly in immunosuppressed patients. Histopathology, histochemical techniques and immunochemistry, including Giemsa and CD1a staining, play a crucial role in diagnosis. This study aims to analyse clinical presentation, diagnostic findings, and outcome of bone marrow involvement in visceral leishmaniasis.
Methods: We conducted a retrospective descriptive study across four tertiary hospitals in Spain, analysing nine cases diagnosed between 2014 and 2024. Clinical characteristics, diagnostic methods, risk factors, and complications have been assessed.
Results: The median age of patients was 49 years (r: 35-70), with a predominance of males (89%). Most patients were from Spain (78%), followed by Portugal (22%) and Georgia (11%), all residing in Spain at the time of diagnosis.
Histological examination revealed amastigotes within histiocytes dispersed in the bone marrow in all cases, without granuloma formation. Giemsa staining was positive in 89% of cases, PAS in 22%, and CD1a expression was detected in 67%.
HIV infection was the most common risk factor (67%), followed by intravenous drug use (56%), hepatitis C (33%), alcohol consumption (22%), and hepatitis B (11%). Clinically, most patients had no recent travel history, but hepatomegaly and splenomegaly were frequently observed. Complications included membranoproliferative glomerulonephritis (22%) and one fatal case (11%).
Conclusion: Haematoxylin H-E, staining is the most useful technique for evaluating bone marrow samples, while Giemsa remains the most effective histochemical method for diagnosing visceral leishmaniasis, particularly in immunosuppressed patients. CD1a serves as a valuable complementary marker. Although PAS has a lower positivity rate, it can still provide additional diagnostic support.
The presence of severe clinical complications, such as glomerulonephritis and mortality, underscores the potentially fatal course of the disease in immunosuppressed individuals. Additionally, common manifestations like hepatomegaly and splenomegaly reinforce clinical suspicion and highlight the need for comprehensive patient evaluation.

PS-23-003
Trends in hydatidiform mole incidence during the pandemic: should we worry?

D. Burlacu[1], A. Burlacu[1], L. Chira[1], I. Jung[1], T. Mezei[1]
[1]University of Medicine and Pharmacy, Science and Technology George Emil Palade, Pathology, Targu-Mures, Romania

Background & Objectives: Whether partial or complete, hydatidiform moles (HM) are pre-malignant gestational trophoblastic diseases represented by trophoblastic over-proliferation without normal foetal development. Adverse pregnancy outcome, especially HM pathogenesis was theorized to be related to the hostile inflammatory environment characteristic to viral pandemics, as COVID-19 pandemic was. This study aimed to determine whether an increase in HM incidence trend could be observed during the pandemic.

Methods: An observational analitical study was conducted. The total number and percentage we reffered to was of the pregnant women registered on the Obstetrics Department of the Emergency Clinical County Hospital of Targu-Mures, who gave birth or suffered a misscariage between January 2019-December 2023. We decided upon this study period considering two years prior to and two years after 2021, the highest pandemic peak-year in Romania. Medical disorders of pregnancy were included, with emphasis on HM. HM were diagnosed only on histopathological examination without performing any molecular tests.
Results: Of a total 8155 registered-pregnancies, 62 (0.76%) were HM diagnosis. The annual incidence rate of registry-identified HM has increased from 0.72% 12-50 years-old patients in 2019 to 1.24% in 2023. Partial HM had higher incidence rate between 2019-2023 (0.39%, 0.11%, 0.43%, 0.86% and 0.83%) with a total incidence of 0.51%. HM was associated with extreme maternal age (=< 18 years-old (20.96%) and >=35 years-old patients (29.02%), p<0.0001). The highest HM incidence rate was seen among nulliparous women (58.06%, p=0.0607). The mean gestational age of the embryo at the time of diagnosis was 9 gestational weeks. Endometritis (74.19%) and abundant vaginal bleeding (38.70%) were associated (p<0.0001).
Conclusion: In crisis periods, such as COVID-19 pandemic was, nulliparous women are more susceptible to a HM diagnosis given the associated poorer inflammatory function, suggesting a possible causative association of COVID-19. Further studies and comparison with non-pandemic data are necessary to get more insight into this relation.

PS-23-004

Human papillomavirus's influence on proteasome-mediated immune stimulation in cervical and oropharyngeal cancer

V. Malone[1], P. Tewari[2], B. Mohamed[2], C. Martin[2], J. O'Leary[1]
[1]Trinity College Dublin, Discipline of Histopathology, School of Medicine, Dublin, Ireland, [2]Trinity College Dublin, Molecular Pathology Laboratory, Dublin, Ireland

Background & Objectives: The proteasome is an essential cellular component which degrades and recycles proteins. One of its key functions is to generate antigenic peptides for presentation via MHC Class-I. In virally-infected or transformed cells, antigens derived from viral or tumour-associated proteins can activate cytotoxic T-lymphocytes. Stimulated by IFNy and TNFα, the proteasome undergoes a conformational change in which some of its subunits are replaced by 'immunosubunits', creating a more diverse array of antigenic peptides to incite an immune response.
Proteasomal function is tightly regulated. PSME4 is a negative regulator of proteasome/immunoproteasome activity. PSME4 depletion enhances antigen presentation, while the ratio of PSME4 to immunosubunit PSMB10 correlates with immunotherapeutic response.
This project aims to evaluate the impact of HPV infection on proteasomal and immunoproteasomal expression.
Methods: SiHa (cervical, HPV16+), C33a (cervical, HPV-), SCC154 (oropharyngeal, HPV16+) and SCC4 (oropharyngeal, HPV-) cell lines were grown following standard cell culture procedures. The expression of PSME4 and PSMB10 was evaluated in HPV+ and HPV- cervical and oropharyngeal cancer cell lines by Western blot. Immunofluorescence for PSME4 was performed on SiHa and C33a cell lines to evaluate protein intracellular localisation.
Results: *Western blot:* Strong PSME4 in all cell lines, with increased expression in C33a and SCC4 (both HPV-). Increased PSMB10 (immunosubunit) expression in C33a and SCC4 compared to HPV+ cell lines (SiHa and SCC154).
PSME4 Immunofluorescence: Intense staining of SiHa, with preferential nuclear localisation. Strong staining of C33a cells in both nuclear and cytoplasmic compartments.
Conclusion: Our understanding of HPV's ability to alter proteasomal function as a mechanism of immune escape is limited. These results suggest that HPV alters the expression and localisation of regulatory subunit PSME4 and reduces expression of immunosubunit PSMB10. This may contribute to viral and tumour immune escape in HPV infected cells, and may serve as a potential target for future immunomodulatory therapies.

PS-25 Poster Session Other Topics

PS-25-001

Rising workload and diagnostic complexity in histopathology and the impact on turnaround times in Ireland

G. Galambosi[1], Á. Mitchell[2], A. Treacy[3], N. Swan[4]
[1]St James's Hospital, Histopathology, Dublin, Ireland, [2]Royal College of Physicians of Ireland, Dublin, Ireland, [3]Mater Misericordiae University Hospital, Histopathology, Dublin, Ireland, [4]St Vincent's University Hospital, Histopathology, Dublin, Ireland

Background & Objectives: The Irish National Histopathology Quality Improvement (NHQI) Programme collects data in the form of procedure codes (P codes), quality codes (Q codes) and metrics regarding workload, turnaround times and other key quality indicators (KQIs) relating to histology, cytology and autopsy cases. The Programme recommends turnaround time (TAT) targets of 5-10 days depending on specimen type.
Methods: A review of national histopathology data (January 2013–December 2023) examined workload in 28-33 laboratories which included the number of cases, specimens, special stains, immunohistochemical stains, and TAT figures. Statistical analysis was performed using SPSS Statistics, utilizing linear regression, compound annual growth rate and Pearson correlation analysis. Statistical significance was set at $p < 0.05$.
Results: Over the 11-year period from 2013 to 2023, case numbers increased by 34.4% (420,790 to 565,669). The average specimen number per case increased from 1.6 to 1.8 ($R^2 = 0.977$, $p<0.01$), and the average block numbers per case increased from 2.7 to 2.9 ($R^2 = 0.709$, $p<0.01$), reflecting a significantly increased workload per case.
Cases requiring immunohistochemical (IHC) stains increased by 123% (43,865 to 97,593). Additionally, the total number of IHC stains performed rose by 102.7% (285,660 to 579,035). The compound annual growth rate (CAGR) of IHC stain number (7.3%) significantly outpaced that of total cases (3.0%).
The percentage of cases meeting TAT targets declined from 78.4% in 2015 to 56.4% in 2023. A significant negative correlation was observed between TAT compliance and specimen numbers ($r = -0.872$, $p = 0.002$).
Conclusion: This review of the NHQI Programme data highlights a significant increase in workload, with a shift towards more complex diagnostic work reflected in the doubling of IHC use over 11 years. The burden of increasing workload and case complexity is having a significant negative impact on TATs.

PS-25-002

Reticulin framework changes in poorly differentiated carcinoma metastases compared to large-cell lymphomas

A. Coman[1], L.-F. Dragostin[1], R.-G. Ionescu[1], L. Sticlaru[1], M. Bușcă[1], C. Popp[1], C. Dumitru[1], S. Zurac[2,1]
[1]Colentina University Hospital, Department of Pathology, Bucharest, Romania, [2]"Carol Davila" University of Medicine and Pharmacy, Department of Pathology, Bucharest, Romania

Background & Objectives: Reticulin fibres are responsible for maintaining the functional integrity of tissues and also have a role in the

patterns of invasion seen in various neoplasms. The aim of this study is to evaluate the changes that occur to reticulin fibres in poorly differentiated carcinoma metastases to lymph nodes and large-cell lymphomas, in order to identify shortcuts for immunohistochemical diagnosis.
Methods: We included, in a retrospective study, 13 patients with lymph node metastases from poorly differentiated carcinomas of the gastrointestinal tract, 11 patients with lymph node metastases from poorly differentiated breast carcinomas and 10 patients with large-cell lymphomas. Reticulin framework patterns were assessed with Gomori silver reticulin stain and the density of the reticulin fibres was calculated as the ratio of total fiber area to overall tissue area using the Fiji image analysis software.
Results: In the case of poorly differentiated carcinomas, the reticulin fibres were long, dense, thick and were distributed around islets of cells with a lot of branches, while in lymphomas the fibres were shorter, thinner and had an uneven distribution with numerous scattered fragments. The density of the reticulin framework had a mean value of 6.1% in lymphomas, while the values for poorly differentiated carcinoma metastases were very close at 10.5% for gastrointestinal metastases and 10.6% for breast metastases.
Conclusion: In the era of expensive immunohistochemistry, using the Gomori silver reticulin stain can prove to be useful as a first step in distinguishing between poorly differentiated carcinomas and large-cell lymphomas. Routine histologic evaluation using this stain can aid further immunohistochemical studies to be better targeted.

PS-25-005
Real-time FFPE NSCLC block stability using PD-L1 IHC 22C3 pharmDx
C. Roach[1], J. Musser[1], S. Tabuena-Frolli[2], S. Hund[1], K. Kulangara[1]
[1]Agilent Technologies, Companion Diagnostics, R&D, Carpinteria, USA, [2]Agilent Technologies, Biostatistics, R&D, Carpinteria, USA

Background & Objectives: PD-L1 IHC 22C3 pharmDx is intended for use in a qualitative immunohistochemical (IHC) assay to detect PD-L1 expression in formalin-fixed, paraffin-embedded (FFPE) human specimens routinely processed for diagnostic evaluation. Guidelines for use of FFPE blocks vary, with limited data to support their extended shelf life.
A real-time stability study on non-small cell lung cancer (NSCLC) blocks was performed to assess if the age of the blocks, stored over time, impacted PD-L1 expression.
Methods: NSCLC specimens were used to evaluate PD-L1 expression in FFPE blocks aged over time. A cohort of 188 NSCLC blocks were commercially procured and populated to include the full dynamic range of PD-L1 expression. In addition, an enrichment of near-cutoff specimens for both TPS 1% and 50% cutoffs were included. All specimens were prepared as FFPE blocks, properly stored in the dark at room temperature until time of sectioning. PD-L1 IHC 22C3 pharmDx (SK006) staining was performed at Time 0, 3 years and 5 years. PD-L1 expression was assessed for any changes in TPS over time compared to the initial Time 0 staining.
Results: A concordance correlation coefficient (CCC) with 95% CI was calculated to be 0.954 (0.938, 0.966) demonstrating strong alignment in TPS between staining results at Time 0 versus 5 years. The diagnostic agreement for TPS 1% and TPS 50% cutoffs both generated overall agreement 95% percentile bootstrap CI lower-bound values >90%. Our results showed no significant change in PD-L1 expression in sections from aged FFPE NSCLC blocks stored in the dark at ambient conditions over time, supporting a shelf life of at least 5 years.
Conclusion: NSCLC FFPE tissue blocks may be stored at ambient temperature for at least 5 years, where the PD-L1 antigen is well preserved and stable for evaluation with PD-L1 IHC 22C3 pharmDx.

PS-25-006
Centers for experimental animal pathology occupy a small but valuable niche in translational medicine – time for a change?
T. Poth[1,2], P. Schirmacher[1]
[1]Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany, [2]Center for Model System and Comparative Pathology, Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany

Background & Objectives: Since CRISPR/Cas9 systems can be easily used to establish new genetically engineered mouse models, application of these models to explore predictive and therapeutic topics for human diseases is rising. Centers for comparative histopathology bridges the veterinary and human pathology fields and can combine optimally the technical, research, and diagnostic expertise for phenotyping, evaluation and interpretation of complex animal models in the context of human pathology to reach meaningful study results.
Methods: In 2016, the *Centre for Model System and Comparative Pathology (CMCP)* was established at the Institute of Pathology of the University Hospital Heidelberg to cover the demand for tissue processing and expertise in comparative pathology. Besides the *Comparative Experimental Pathology (CEP)* in Munich, the CMCP is the second centre in Germany pursuing such an integrative propose. An overview of the experience gained in handling of more than 450 animal projects with more than 40.000 processed tissue specimens is given.
Results: Centers for experimental animal pathology as the CMCP enable optimal tissue processing of large sample cohorts. They offer a broad spectrum of standard and specialized tissue-based technologies including tailored immunohistochemistry and animal model evaluation, phenotyping and scoring. The expertise in veterinary pathology allows detection of species-specific background lesions and individual spontaneous lesions to avoid misinterpretations. By providing essential prerequisites for high-quality, reproducible and sustainable research in the translational medicine, the requirements for publications in top-class professional journals were ideally fulfilled.
Conclusion: The importance of animal models reflecting human diseases will increase in future but the need for high-quality animal tissue processing and animal model evaluation cannot be met by single facilities in a niche position. To cover the existing gap and the expectable rising demand in the German and European translational research landscape, further facilities for experimental animal pathology that are integrated in the human pathology environment should be established.

PS-25-007
Pilot evaluation of a formalin recycling system in pathology: efficacy, environmental impact, and cost-benefit analysis of a sustainable alternative to single-use fixatives
R. Vergara[1], S. Amintas[2,3], D. Cazalis[1], M. De Prigounoff[1], N. Bernard[4], B. Le Bail[1], G. Belleannée[1], A. Rullier[1]

[1]CHU de Bordeaux, Pathology, Bordeaux, France, [2]CHU de Bordeaux, Molecular Pathology, Bordeaux, France, [3]Bordeaux Institut of Oncology, INSERM 1312, Université de Bordeaux, Bordeaux, France, [4]CHU de Bordeaux, Internal Medicine, Bordeaux, France
Background & Objectives: Climate emergency requires healthcare decarbonization. In Pathology laboratories, formalin, widely used for tissue fixation, is a single-use harmful reagent. We previously showed that reusing "nearly new" formalin from biopsies (season 1) reduces consumption without compromising quality and security (doi:10.1016/j.pathol.2024.12.639). This study aimed to i) test a formalin recycler for soiled formalin, ii) evaluate its impact on annual consumption alone (season 2) and combined with previous measures (season 1+2), and iii) quantify the environmental impact of this reduction.

Methods: We selected soiled formalin following manufacturer's guidelines using an in-house colour chart. A gravity-based recycler with activated carbon filter was used (doi:10.1093/ajcp/aqac062). Recycled formalin was tested for pH and formaldehyde concentration, and validated through the entire specimen pathway including immunohistochemical and molecular analyses. Formalin consumption was compared before and after recycler implementation and against 2021 reference. Environmental impact (CO_2 equivalent emissions (CO_2eq), human toxicity, and freshwater ecotoxicity) was assessed using ADEME and Ecoinvent v3 databases.
Results: Recycled formalin met all quality standards with no abnormalities detected in specimen analyses. Implementation in the second half of 2024 reduced consumption by 25% compared to 2023 (same period). Overall strategy (season 1+2) reduced formalin consumption by 54% compared to 2021 (4081 versus 1889 liters), resulting in 5 tons of CO_2eq avoided, €12,500 saved, and reduced human and aquatic toxicities (242.5 and 152.5 kg 1,4DBeq respectively). The laboratory also gained operational autonomy.
Conclusion: Pathology laboratories can effectively mitigate their environmental impact by reducing formalin consumption through recycling strategies, representing a valuable opportunity until more sustainable fixation alternatives are developed.

PS-25-008
Rapid tissue sectioning system for real-time histopathological diagnosis
A. Kowalewski[1,2], D. Marciniak[3]
[1]Bydgoszcz University of Science and Technology, Faculty of Medicine, Bydgoszcz, Poland, [2]Oncology Centre Prof. Franciszek Łukaszczyk Memorial Hospital, Department of Tumour Pathology, Bydgoszcz, Poland, [3]Bydgoszcz University of Science and Technology, Department of Manufacturing Techniques, Faculty of Mechanical Engineering, Bydgoszcz, Poland

Background & Objectives: Traditional histopathological techniques such as paraffin-based microtomy and frozen sectioning present significant drawbacks, including long processing times and the generation of artifacts like ice crystals. The objective of this work is to develop a novel device that enables the production of ultra-thin tissue sections (3–5 μm) rapidly, without paraffin embedding or freezing, thereby facilitating rapid histopathological diagnosis.
Methods: The system employs a perforated tissue stabilization plate integrated with a vacuum mechanism to securely fix the tissue, eliminating distortions during cutting. A synchronized movement mechanism aligns the tissue with a microscope slide that features a low-friction, cooled surface (0–4 °C). A rotary cutting blade with adjustable thickness control enables precise sectioning, after which the tissue slice is automatically transferred onto an adhesive-coated slide. Immediate fixation and staining protocols are applied to the section, which can then be directly integrated with a digital slide scanner for real-time analysis.
Results: The system is expected to consistently produce high-quality tissue sections with adjustable thickness between 3 and 5 μm. The integrated process minimizes preparation time and eliminates the freezing artifacts commonly seen in traditional methods. Furthermore, its compatibility with digital tissue scanners supports imaging analysis, potentially accelerating diagnostic workflows.
Conclusion: This tissue sectioning system offers an alternative to existing histopathological methods by delivering rapid, artifact-free tissue sections. Its potential integration with digital imaging technologies underscores its value as a tool for enhancing diagnostic efficiency and accuracy, particularly in time-critical scenarios.

PS-25-009
Influence of preprocessing of stimulated Raman scattering images on the performance of deep neural networks for detecting cancer tissue
A. Weber[1,2], K. Enderle-Ammour[1], K.-M. Schröder[1], M.C. Metzger[3], L.S. Brandenburg[3], J. Beck[4,5], J. Straehle[4,5], D. Steybe[3,4,6], M. Hassan[7], S. Schmid[7], B. Ohm[7], M. Werner[1,8], B. Passlick[7], R. Schmelzeisen[3,4], U.-T. Le[7], P. Bronsert[1,8,9]
[1]Institute for Surgical Pathology, Medical Centre, University of Freiburg, Faculty of Medicine, Freiburg, Germany, [2]University of Freiburg, Faculty of Biology, Freiburg, Germany, [3]Department of Oral and Maxillofacial Surgery, Medical Centre, University of Freiburg, Freiburg, Germany, [4]Center for Advanced Surgical Tissue Analysis (CAST), University of Freiburg, Freiburg, Germany, [5]Department of Neurosurgery, Medical Centre, University of Freiburg, Freiburg, Germany, [6]Department of Oral, Maxillofacial Surgery and Facial Plastic Surgery, University Hospital, LMU Munich, Munich, Germany, [7]Department of Thoracic Surgery, Medical Centre, University of Freiburg, Faculty of Medicine, Freiburg, Germany, [8]Tumorbank Comprehensive Cancer Centre Freiburg, Medical Centre, University of Freiburg, Freiburg, Germany, [9]Core Facility for Histopathology and Digital Pathology, Medical Centre, University of Freiburg, Freiburg, Germany

Background & Objectives: Stimulated Raman scattering (SRS) microscopy enables intraoperative visualization of histological features similar to haematoxylin and eosin staining, known as stimulated Raman histology (SRH). Deep learning (DL) has become a powerful tool in automated cancer diagnostics. However, SRS image preprocessing remains crucial, affecting model performance and reliability. This study explores how various preprocessing methods impact six neural network architectures—VGG19, ResNet50, InceptionResNetV2, Xception, ConvNeXt, and Vision Transformer—in classifying tumoral and non-tumoral tissue in SRS and SRH images of oral squamous cell carcinoma (OSCC) and non-small cell lung carcinoma (NSCLC).
Methods: A dataset of 542 SRS and SRH images (pixel size: 467 nm), annotated by pathologists, was divided into 48,175 tiles. Five preprocessing methods were applied to SRS images: complex manipulation, histogram matching, histogram equalization, Gaussian blurring, and scaling to [0,1]. Each model was trained five times for 40 epochs. Metrics included balanced accuracy, precision, recall, F1-score, and AUC. Class activation and attention maps highlighted predictive image features.
Results: SRH images achieved the highest balanced accuracy (0.87), followed by scaled SRS images (0.85). Preprocessing techniques with higher complexity tended to produce lower accuracy and greater variability. Simple pixel scaling yielded the most consistent results. While class activation maps identified regions relevant to model predictions, their alignment with biologically meaningful structures varied across architectures. Vision Transformers appeared to focus on cytoplasmic and membrane areas for accurate classification, whereas convolutional neural networks (CNNs) showed less consistent patterns of attention.
Conclusion: Preprocessing strategies markedly affect the accuracy and robustness of deep learning models applied to SRS data. Among the tested methods, simple scaling of pixel values to [0,1] provided more stable performance compared to more complex preprocessing. Although overall classification accuracy was high, linking DL predictions to biologically interpretable features remains a significant challenge.

PS-25-010

An on-line training and education portal for HER2-low interpretation in breast cancer: an initiative from the International Quality Network for Pathology

A. Dodson[1], S. Parry[1], F. Fenizia[2], A. Schønau[3], A. Shaaban[4]
[1]UK National External Quality Assessment Scheme for Immunocytochemistry and In-Situ Hybridisation, London, United Kingdom, [2]International Quality Network for Pathology, Luxembourg, Luxembourg, [3]PathoPulse ApS, Søborg, Denmark, [4]University of Birmingham, Department of Cancer and Genomic Sciences, Birmingham, United Kingdom

Background & Objectives: Trastuzumab deruxtecan is a treatment for metastatic breast cancer over expressing HER2 protein at a low-level (HER2-low).
Evidence shows that pathologists have difficulty in reproducibly assessing HER2-low, potentially leading to a negative impact on patient treatment outcomes.
The International Quality Network for Pathology (IQNPath) established an on-line training portal using a uniquely validated set of HER2-stained clinical cases.
The aims of the project were to:

- Provide an educational resource for the assessment of HER2-low cases
- Document the competence of portal users
- Gather information about demographics of the testing community.

Methods: A free-to-access portal was established using PathoGate platform software (PathoPulse ApS. Denmark). It went 'live' in November 2024. The cases used had previously been scored independently by 16 expert pathologists.
After registration users completed a questionnaire which gathered information about job role and relevant experience. Participants assessed a training set of 10 WSIs (matched H&E and HER2 stained) followed by one of two randomly allocated 20-case test sets.
Cohen's Weighted Kappa (CWK) statistics were generated for each participant using the consensus scores of the expert panel (SPSS, IBM, USA).
Results: In the 5-month period reported here, 132 users registered. Most were consultant pathologists (92, 63.0%), with the next largest group being biomedical scientists (24,16.4%).
Overall, 39 (26.7%) registrants had received HER2-low training; 45 (30.8%) reported HER2-low cases regularly (≥ 1 per week).
Of all those who registered, 115 (87.1%) completed the training set, and of these 61 assessed of one of the test sets.
The median CWK (range) for Test Set 1 users was 0.64 (0.29 - 0.88), for Test Set 2 it was 0.60 (0.41 - 0.75). In comparison results for the expert panel were 0.71 (0.41-0.85).
Conclusion: The portal was successfully established and was well-utilised. The CWK statistic indicated median agreement with the expert consensus that was moderate to substantial.

PS-25-011

Meeting the future: creation of multicolored, three-dimensionally printed organ models for gross examination training in Surgical Pathology residency

P. Kousidis[1], I. Sidiropoulos[1], S.A. Androniadou[1], F. Valanika[1], S. Tsiopoulos[1], O.I. Rantis[1], M. Bakatsianou[1], I.M. Tsoutsouras[2], G. Panselinas[1], A. Nikolaidou[1]
[1]"Theageneio" Anticancer Hospital, Pathology, Thessaloniki, Greece, [2]"Theageneio" Anticancer Hospital, Cytopathology, Thessaloniki, Greece

Background & Objectives: Currently, gross examination is performed worldwide by Pathologists and/or grossing personnel. Training for this very important aspect of pathologic examination can potentially be enhanced by the creation of models of excision specimens. Multicolored three-dimensional (3D) printing can further aid in the understanding of different anatomic structures and borders within the models and further elevate their learning potential.
Methods: A 3D-printed model of a radical nephrectomy specimen was created. A patient's computed tomography scan of the abdomen and pelvis was analysed for the production of a 100%-scale anatomic model. A tumour-like shape was added to the initial design, in order to simulate a renal tumour. The final model was 3D printed using low-hardness thermoplastic polyurethane material. Subsequently, copies of the model were independently dissected by seven Pathology Residents. The final results, in adequacy of sampling, correct margin evaluation and measurements of margin distances was evaluated. Two different Consultant Pathologists evaluated the sections macroscopically, independently and blinded with regard to each Resident. The Residents were provided with appropriate feedback and were tested on a model with a different location of the lesion and re-evaluated. Furthermore, the Residents and the Consultant Pathologists completed a survey on the potential benefits in their training through practice on similar models.
Results: The results of the evaluation of the Resident Pathologists showed adequate sampling of different areas and margins and low divergence from margin distances as set on the designed model, with improvement on re-evaluation. The ease of use of the models was rated positively. The estimated cost of production for each model was low.
Conclusion: The potential of the application of these techniques in the training of future Pathologists is highly promising. Our study builds on previously published literature and provides a framework that can be applied independently to enhance gross examination training.

PS-25-012

Advancing archival and precision retrieval in a pathology lab while securing tissue samples

P. Aguirre[1], A. Goitia[1], A. Gayoso[1], I. Ruiz[1]
[1]Hospital Universitario Donostia, Pathology Department, San Sebastian/Donostia, Spain

Background & Objectives: Donostia University Hospital's histology lab processes 350,000 slides and 230,000 blocks annually. Manual archiving was labour-intensive with high sample loss risk. The Pathology Department sought automation to improve traceability, reduce labour, and streamline sample management.
Methods: The Pathology Department conducted an observational study on 08.05.2024 with the implementation of two systems: one for automated scanning, registering, and sorting blocks, and another for slides. With these systems laboratory technicians don't need to sort samples sequentially. For retrieval, the systems quickly direct lab staff to the precise location of a sample and provides detailed information about its chain-of-custody.
Results: Adoption of the new systems decreased staff-needed hours. From 120 hours per month to archive and retrieve blocks in April 2024, to 60 hours in January 2025 (a decrease of 50%). For slides, the decrease was 66,6% (from 90 hours to 30 hours in the same period).
Even though the department suffered an increase in volume of samples processed during the study period, the hospital staff saved 4.415 hours annually in tissue sample management. This time gained by automating their workflow, has enabled the hospital to reassign 2.5 FTE positions

to aid in other areas that support patient care. The workflow of archiving samples became more efficient and eliminated errors.
Conclusion: The implementation of these systems revolutionized tissue sample storage and retrieval, significantly enhancing patient care and safety. Faster, more precise access to blocks and slides allows for faster diagnosis, enabling earlier treatment. Additionally, these advancements have improved laboratory workflow, reducing stress and minimizing the risk of sample loss. Staff benefit from increased efficiency and job satisfaction, fostering a more productive work environment. Ultimately, these innovations streamline operations while ensuring better outcomes for both patients and laboratory professionals.

PS-25-013
Sirolimus-coated balloons for the ureteral strictures. Could it be an efficient alternative to paclitaxel?
D. Koumoundourou[1], V. Tatanis[2], A. Peteinaris[2], T. Spinos[2], P. Kallidonis[2], V. Bravou[1], E. Liatsikos[2]
[1]University Hospital of Patras, Rio, Pathology, Patras, Greece, [2]University Hospital of Patras, Rio, Urology, Patras, Greece

Background & Objectives: Ureteral strictures, consisting of narrowing of the ureter, may lead to obstructed urine drainage and potential renal damage. Their management is challenging due to the intricate anatomy and need for precise treatment. Drug-coated balloons, using mainly paclitaxel, offer localized drug delivery to enhance stricture resolution and minimize recurrence. This study aimed to evaluate the distribution and effect of sirolimus within the ureter using sirolimus-coated balloons (SCB).
Methods: Two female porcine models (four ureters) were used, while artificial strictures were induced with a laser at the vesicoureteral junction. Afterward, ureteral balloons were applied, comparing specimens of no-sirolimus balloon ureter at zero time and SCBs ureters at zero time, 4 hours, and 8 hours. The main endpoints were the detection of sirolimus within the ureteral layers and its effect on regional inflammation. An evaluation of the intensity of inflammation followed, aiming to identify differences in lymphocytic infiltration between those into which everolimus had been injected and those that had not received the drug. The suppression of the inflammatory response—and consequently the effect of the drug—was indirectly assessed through the detection of Cyclin D1 expression and p27 protein."
Results: Everolimus reduced the inflammatory response as well as Cyclin D1 expression. p27 did not show significant differences in expression. However, the number of samples was insufficient to yield statistically significant results.
Conclusion: The use of sirolimus on drug-coated ureteral balloons seems to constitute a feasible alternative to paclitaxel, as it may be distributed within the ureteral layers and reduce the regional inflammation. The conduction of further experimental and clinical studies may empower the safety and effectiveness of the SCBs.

PS-25-014
Leverage complete sample traceability, from accessioning to archiving, to improve laboratory workflow and save time
A. Vidal[1], C. Millan de Prado[1], L. Gargallo Pérez[1], S. Gómez Canaleta[1], M.S. Costa Aguado[1], N. Urpí Carrasco[1], D. Moreno León[1]
[1]Bellvitge University Hospital-IDIBELL, Pathology, L'Hospitalet de Llobregat-Barcelona, Spain

Background & Objectives: With an annual volume of 150,000 paraffin blocks and 288,000 slides, the pathology department of a university hospital was spending more than 4,002 man-hours per year on sample management and was looking for a more efficient and safer workflow.
Methods: The department conducted an observational study with the implementation of three new systems (December 2022, January 2024 and April 2024). The first will automate pre- and post-processing scanning to ensure correct sample processing. The second and third systems automate the sorting, archiving and precise retrieval of tissue blocks and slides. The systems can also be integrated with the hospital's LIS, improving the complete chain of custody.
Results: In pre-processing, the new system eliminates the need to manually scan cassettes one by one, which took 350 hours per year before automated pre-processing, compared to 130 hours with the new system (57% less). The implementation of the pre-processing system saved 220 hours per year.
The implementation of the new block and slide tracking and archiving systems also resulted in a reduction in the time associated with archiving/re-archiving blocks and slides. From 320 hours per month to 150 hours per month, or 3,840 hours to 1,800 hours per year, saving an additional 2040 hours.
In addition, the three systems together eliminated 5 manual touch points.
Conclusion: Implementing these three systems has improved the entire laboratory workflow, from sample receipt to archiving and retrieval. The complete chain of custody increases patient safety by eliminating the manual touch points that contribute to misplaced and lost specimens.
In addition, laboratory workflow automation helps address the challenges associated with increasing caseloads and volumes by freeing staff from the time-consuming task of sorting blocks and slides into sequential order, allowing them to spend more time on critical activities that support patient care.

PS-25-015
Collagen I type expression changes in anterior abdominal wall hernias repair (experimental study)
S. Ryabtseva[1], M. Korneeva[1]
[1]Institute of Physiology of National Academy of Sciences of Belarus, Centre of Morphological Research, Minsk, Belarus

Background & Objectives: A stimulation of collagen type I synthesis in the connective tissue increases its strength. The aim of the study was to evaluate the expression level of collagen type I in the skin and aponeurosis of rats after various modifications of anterior abdominal wall hernia repair.
Methods: 36 male Wistar rats (220-250 g) were included in three study groups: in the first group (n=12) a polypropylene mesh was placed under the aponeurosis of anterior abdominal wall of rodents; in the second group (n=12) polypropylene mesh with platelet-rich plasma (30 µl) and with a platelet activator (5 µl) was applied also under the aponeurosis of rodents; in the third group (n=12) platelet-rich plasma (30 µl) with a platelet activator (5 µl) was administered under the aponeurosis. Collagen type IA2 - antibody (Elabscience, dilution of 1:400) was used. The expression was analysed by the image analysis software Aperio Image Scope [v12.4.6.5003].
Results: On the 28th day of the experiment the positivity of collagen type I expression in skin of rats of first group was 17.5 (15.0; 19.0) %, of second group – 85.5 (84.0; 88.0) % and after implantation of platelet-rich plasma – 65.5 (64.0; 71.0) %. The median positivity of collagen type I expression in aponeurosis of rats of first group was 13.5 (52.0; 61.0) %, in second group – 90.5 (89.0; 91.0) %, in thirds group – 74.5 (73.0; 77.0) %. The maximal activation of collagen type I synthesis in skin ($p = 0.0005$) and in aponeurosis tissue ($p = 0.0005$) of the anterior abdominal wall of rodents was found after implantation of a polypropylene mesh with platelet-rich plasma.
Conclusion: This study showed that the implantation of polypropylene mesh with platelet-rich plasma during hernia repair increase the

strength of both connective and scar tissue by activation of collagen type I synthesis.

Funding: This research was supported by the Belarusian Foundation for Basic Research

PS-26 Poster Session Pulmonary Pathology

PS-26-001

Immune phenotypes in patients with non-small cell lung cancer and their association with smoking

A. Denysenko[1], Y. Moskalenko[2], R. Moskalenko[1]
[1]Sumy State University, Department of Pathology, Sumy, Ukraine, [2]Sumy State University, Department of Oncology and Radiology, Sumy, Ukraine

Background & Objectives: One of the important mechanisms leading to non-small cell lung cancer (NSCLC) recurrence is changes in the tumour microenvironment and the formation of certain immune phenotypes.
Aim: To investigate the prevalence of immune phenotypes in NSCLC and their association with smoking.
Methods: An immunohistochemical study of 40 NSCLC tumour samples was conducted using anti-CD8+ antibodies. Immune phenotypes were classified based on CD8+ spatial distribution: the immune desert phenotype (low CD8+ in tumour nests and stroma), the immune-excluded phenotype (high CD8+ in the stroma but low in nests), and the inflamed phenotype (high CD8+ in both). Pearson's rank correlation coefficient was used to assess the association with smoking.
Results: Among 20 adenocarcinoma samples, 5 (25.0%) had the immune desert phenotype, 3 (15.0%) immune-excluded, and 12 (60.0%) inflamed. Among 20 squamous cell carcinoma samples, 1 (5.0%) was immune desert, 13 (65.0%) immune-excluded, and 6 (30.0%) inflamed. Smoking history was present in 13 (65.0%) adenocarcinoma and 19 (95.0%) squamous cell carcinoma patients. The inflamed phenotype was most common in never-smokers ($\chi^2 = 9.8322$; p= 0.007).
Conclusion: The inflamed phenotype predominates in adenocarcinoma, while the immune-excluded phenotype is more frequent in squamous cell carcinoma. Smoking is associated with the immune-excluded phenotype.

PS-26-002

The impact of spread through air spaces extent and morphology on prognosis in non-small cell lung carcinoma

G. Aydogan[1], G. Serin[1], A. Ozdil[2], D. Nart[1]
[1]Ege University Faculty of Medicine, Department of Pathology, Izmir, Turkey, [2]Ege University Faculty of Medicine, Department of Thoracic Surgery, Izmir, Turkey

Background & Objectives: STAS (spread through air spaces)is defined as tumour cells spreading within air spaces beyond the edge of the main tumour. Some studies suggest that its distance and morphological patterns may have prognostic value, but this remains unclear and is not routinely reported. This study aims to evaluate the prognostic role of STAS extent and patterns.
Methods: This study retrospectively analysed the correlations between the extent of Stas and clinicopathologic characteristiscs and prognostic significance in 104 completely resected stage I-III non-small cell lung carcinomas between 2017 and 2023 at our centre.STAS was grouped as limited (<1000 μm) or extended (>1000 μm) based on distance from the tumour. Patterns were classified as single cells, micropapillary clusters, or solid nests.
Results: STAS was present in 65 cases (62.5%): 18 limited(17,3%) and 47 extended (45,2%). Single-cell pattern was seen in 7 cases (6,7%), micropapillary in 23 (22,1%), and solid in 35 (33,7%). Median overall survival (OS) and progression-free survival (PFS) were 33.5 and 27 months, respectively. Extended STAS was more frequently found in patients with adenocarcinoma and/or pleural invasion.It was associated with significantly lower OS compared to STAS negative group (p=0.028). Although 45% of patients experienced recurrence; PFS was not significantly different in this group(p=0.075).There was no significant difference between limited versus extended STAS, or between limited versus negative STAS. No recurrence or death was seen in single-cell pattern cases. Solid and micropapillary patterns were associated with poorer OS and PFS (p=0.007 and p=0.011, respectively). In multivariate analysis, extended STAS was found as an independent poor prognostic factor for survival (p=0.023).
Conclusion: In conclusion, limited or single-cell STAS did not affect prognosis,and some may represent artifacts, while extended STAS was linked to worse survival,therefore it appears to be more reliable and clinically significant.Reporting the extent and pattern of STAS may help lead pathological evaluation and treatment decisions.

PS-26-003

Interobserver variability in subtyping and spread through air spaces assessment of lung adenocarcinomas: are we seeing the same patterns?

A. Saruhan[1], M. Oz[1], O. Ertunc[1]
[1]Gazi University, Pathology, Ankara, Turkey

Background & Objectives: Invasive non-mucinous lung adenocarcinomas are classified by predominant histologic subtype, though multiple patterns often coexist. Subtyping and the evaluation of spread through air spaces (STAS) are clinically relevant for grading and prognosis, but both can be challenging. This study evaluates interobserver agreement in subtyping and STAS assessment among pathologists with varying experience and specialization.
Methods: An online survey was conducted using selected static digital images from resected non-mucinous lung adenocarcinoma cases diagnosed at our institution. Fifty-seven pathologists participated, each evaluating two different cases. For each case, they estimated the proportion of five histologic subtypes using predefined percentage ranges. STAS assessment was based on two representative images per case, with responses recorded as present, absent, or not sure. Interobserver agreement was assessed using the intraclass correlation coefficient (ICC) for subtype scoring and Fleiss' kappa for STAS. Participants were categorized into three groups based on experience: thoracic pathology specialists, pathologists with more than five years of experience, and those with less than five years.
Results: The overall ICC for subtype scoring was 0.77, indicating good agreement. Some subtypes could not be statistically evaluated due to minimal score variation, suggesting strong concordance. Frequency analysis showed consistent scoring for acinar and lepidic patterns. In contrast, papillary and micropapillary patterns—especially in Case 2—exhibited broader distributions. Fleiss' kappa for STAS was 0.48. Scoring patterns varied by experience, with specialists showing more consistency.
Conclusion: Despite overall agreement, interpretive variability in certain subtypes and STAS highlights the need for improved standardization and training, especially for diagnostically ambiguous features. The influence of experience and specialization on scoring consistency supports the value of targeted education and consensus development. Standardized criteria may improve reproducibility and diagnostic confidence, contributing to more consistent clinical decision-making in pulmonary pathology.

PS-26-004

Immune biomarkers in advanced NSCLC: the role of PDL-1 and CD8+ T Lymphocytes in survival

R. Rendón[1], A.M. Montaña Ramírez[1], A. Álvarez Muñoz[2], A. López Prieto[1], G. Lara Medina[1], M.A. Idoate Gastearena[3]
[1]Hospital Universitario Virgen Macarena, Seville, Spain, [2]Hospital Virgen Macarena, Seville, Spain, [3]Hospital Universitario Gregorio Marañón, Madrid, Spain

Background & Objectives: Immunotherapy has transformed advanced non-small cell lung cancer (NSCLC) treatment, with PDL-1 expression as a key biomarker. Tumour microenvironment complexity suggests additional immune factors, such as CD8+ T-cell infiltration (TILs), may impact treatment efficacy. This study examines their relationship and prognostic significance.
Methods: A retrospective study analysed 50 NSCLC patients treated with immunotherapy (2016–2021, median follow-up: 43.5 months). CD8+ TILs were assessed using Donnen's classification. PDL-1 expression was determined by immunohistochemistry, and molecular profiling by next-generation sequencing (NGS). Associations with progression-free survival (PFS) and overall survival (OS) were evaluated.
Results: Higher stromal TIL density correlated with improved OS (median, $p = 0.04$), whereas intraepithelial TILs showed no survival impact. In a Cox regression model, both high stromal TILs and PDL-1 $\geq 50\%$ were significantly linked to lower mortality (HR stromal TILs: 0.46, $p = 0.037$; HR PDL-1 $\geq 50\%$: 0.49, $p = 0.046$). Molecular analysis identified EGFR, TP53, ROS1, BRAF, and KRAS mutations, though none correlated significantly with clinical response. These findings suggest that stromal TIL infiltration and PDL-1 expression serve as independent prognostic biomarkers in NSCLC patients receiving immunotherapy, highlighting their potential role in treatment stratification and outcome prediction. Further investigation of additional immune and molecular factors is warranted.
Conclusion: PDL-1 expression and stromal TIL infiltration are key prognostic markers in NSCLC patients treated with immunotherapy. Their combination identified distinct clinical outcome subgroups, supporting their relevance in personalized treatment. Despite frequent genetic mutations, no significant association with therapy response was found, underscoring the need for further research on tumour microenvironment interactions. These findings reinforce the importance of integrating immune biomarkers into clinical decision-making to optimize therapeutic strategies and improve patient outcomes in advanced NSCLC.

PS-26-005

Morphofunctional features of alveolar type II cells of offspring that developed in utero under maternal genitourinary system chronic inflammatory process conditions

L. Sukharieva[1], M. Myroshnychenko[1]
[1]Kharkiv National Medical University, Department of General and Clinical Pathological Physiology named after D.O. Alpern, Kharkiv, Ukraine

Background & Objectives: Maternal chronic inflammatory processes of the genitourinary system (GUS) often complicate the course of pregnancy and childbirth, negatively affecting the offspring health. The objective was to identify the morphofunctional features of alveolar type II cells of offspring that developed in utero under conditions of maternal chronic inflammatory process of the GUS caused by *Streptococcus pyogenes*.
Methods: An experiment was conducted on rats of the WAG population. Group 1 included 318 one-week-old, 204 one-month-old, and 214 two-month-old rats from mothers with physiological pregnancy. Group 2 included 257 one-week-old, 134 one-month-old, 121 two-month-old rats from mothers whose pregnancy occurred against on the background of a chronic inflammatory process of the GUS caused by *Streptococcus pyogenes*. Fragments of the offspring lungs were the study material. Microscope slides were stained with haematoxylin and eosin, sudan 3.
Results: During survey microscopy in group 2, compared to group 1, alveolar type II cells were characterized by focal dystrophic, necrotic and desquamative changes. In some visual fields, in areas of dystelectasis and atelectasis, alveolar type II cells were not detected or were found in the alveoli lumen. The relative number of such cells increased ($p<0.05$) with age of the rats ((11.9 ± 0.8) % in one-week-old rats, (20.5 ± 0.3) % in one-month-old rats, (32.2 ± 0.8) % in two-month-old rats). In group 2 compared to group 1, the sudanophilic layer on the alveolar cells surface, which was a surfactant, characterized by uneven thickness and were not detectable in some places.
Conclusion: Maternal chronic inflammatory process of the genitourinary system caused by *Streptococcus pyogenes* changes the morphofunctional state of the offspring alveolar type II cells. These changes increase with the animals' age and are manifested by focal dystrophic, necrotic and desquamative changes, which lead to a deficiency of surfactant as a result of its rapid destruction or insufficient production.

PS-26-006

Clinical and pathological characteristics of multiple primary malignancies in patients diagnosed with lung carcinoma: a single-centre retrospective analysis

M.M. Ustaoglu[1], H. Yavuz[2], D. Demir[3], T.I. Akcam[4], D. Nart[3]
[1]Ege University Faculty of Medicine, Institute of Health Sciences, Molecular Pathology, Izmir, Turkey, [2]Mardin Training and Research Hospital, Thoracic Surgery, Mardin, Turkey, [3]Ege University Faculty of Medicine, Pathology, Izmir, Turkey, [4]Ege University Faculty of Medicine, Thoracic Surgery, Izmir, Turkey

Background & Objectives: Multiple primary malignancies (MPMs) represent a significant clinical challenge due to their complexity in diagnosis, treatment, and follow-up. While MPMs involving breast, gynaecologic, and gastrointestinal cancers are well-documented, data regarding those associated with lung carcinoma remain limited. This study aimed to retrospectively evaluate the clinical, pathological, demographic, and prognostic features of patients diagnosed with primary lung carcinoma with additional primary malignancies.
Methods: This retrospective study included 76 patients diagnosed with MPMs between 2005-2023 at a single centre, all with a primary lung carcinoma diagnosis. Data collected included demographic characteristics, tumour locations, histopathological types, treatment modalities, comorbid conditions, prognostic indicators, and survival outcomes.
Results: Of the patients, 76.3% were male (male-to-female ratio: 3.22), with a mean age of 66.39 years (range: 33–86). Smoking history was present in 57.9% of patients. Common comorbidities included chronic obstructive pulmonary disease, diabetes mellitus, hypertension, and cardiovascular disease. The most frequent histological types were adenocarcinoma (55.3%) and squamous cell carcinoma (26.5%). Secondary primary malignancies commonly affected the bladder, larynx, breast, prostate, colon, and other sites. Twelve patients developed a third primary cancer. Synchronous tumours were observed in 26.3% of cases, with significantly shorter intervals between malignancy diagnoses ($p<0.001$). The mean interval between the first and second malignancy was 45.46 months, and between the second and third was 42.9 months. Kaplan-Meier analysis revealed a mean overall survival of 164 months. Though patients with synchronous tumours had shorter survival, the difference was not statistically significant ($p=0.191$).
Conclusion: MPMs in patients with lung carcinoma are clinically complex and limited in the literature. Recognition of associated malignancies is crucial for effective clinical management, emphasizing the importance of risk factors such as smoking and chronic diseases. Early detection, a comprehensive multidisciplinary approach, and vigilant long-term surveillance are essential for optimizing outcomes in patients with multiple malignancies including primary lung carcinoma.

PS-26-008

IgG4-related lung disease

Z. Bayramoglu[1,2], A. Boduroglu[1,2]
[1]Dokuz Eylul University Faculty of Medicine, Pathology, Izmir, Turkey, [2]The Institutte of Health Sciences, Department of Molecular Pathology, Izmir, Turkey

Background & Objectives: Immunoglobulin G4-related lung disease (IgG4-RLD) is a rare entity. We retrospectively analysed the clinical and histopathological features of patients with pathologically confirmed IgG4-RLD to increase the diagnosis rate and reduce the risk of misdiagnosis.
Methods: We examined our patients with suspected IgG4-RLD in lung surgery specimens between 2020-2024 at Dokuz Eylul University Faculty of Medicine Hospital with histopathological and immunohistochemical findings.
Results: Among 37 patients with suspected IgG4-RLD, only 3 had storiform fibrosis and lymphoplasmacytic infiltrate and a high IgG4/IgG ratio (above 40%). Inflammatory myofibrablastic tumour was diagnosed in 1 of these patients and connective tissue disease in the other. As a result, we diagnosed only 1 patient with IgG4-RLD. This patient was a 42-year-old female patient with a complaint of cough. Histopathological examination revealed abundant lymphoplasmacytic cell infiltration and stroriform fibrosis accompanied by eosinophils. Giant cells and granuloma were not observed. Immunohistochemical examination revealed an IgG4/IgG ratio of 55%. IgG4-RLD was diagnosed based on histopathological and immunohistochemical findings.
Conclusion: In our study, we found that it was quite difficult to diagnose IgG4-RLD. In conclusion, it is not sufficient to look only at the IgG4/IgG ratio when making a diagnosis for IgG4-RLD; other diseases with high IgG4/IgG ratio should also be considered in the differential diagnosis.

PS-26-009

Development of a novel integrin beta-6 IHC assay for clinical evaluation of sigvotatug vedotin in nonsquamous non-small cell lung cancer specimens

S. Kapucija[1], J. Christian[1], J. Gutierrez[1], N. Lapointe[1], V. Tanna[1], T. Okouneva[1], S. Alvarez[1], J. Berndt[2], K. Borgert[1], V. Parimi[2], P. Cronin[2], E. Oroudjev[1]
[1]Agilent Technologies, Research and Development, Carpinteria, USA, [2]Pfizer, Clinical Diagnostics, Washington, USA

Background & Objectives: Integrin beta-6 (IB6) is a heterodimeric integrin protein that has elevated expression in a broad range of solid tumours compared to benign epithelial tissues. This expression pattern and the localization of IB6 to the surface of tumour cells makes it a highly relevant target for potential IB6-directed therapeutics such as the antibody-drug conjugate sigvotatug vedotin (SV). We developed an optimized immunohistochemistry (IHC) assay for the detection of IB6 expression in formalin-fixed, paraffin-embedded nonsquamous non-small cell lung cancer (nsqNSCLC) specimens for investigational use in support of clinical studies conducted with SV.
Methods: The optimized Integrin Beta-6 IHC 6.2A1 pharmDx assay uses EnVision FLEX detection system on the Dako Omnis staining platform. Sensitivity was performed by conducting a survey of IB6 expression in a cohort of >600 nsqNSCLC specimens. Specificity testing investigated IB6 expression by IHC in a variety of normal and abnormal tissues, as well as western blot testing of cancer cell lines. Precision testing in nsqNSCLC specimens included IHC staining reproducibility under various laboratory conditions and scoring reproducibility.
Results: Performance testing in nsqNSCLC demonstrated high sensitivity, specificity, and precision. A dynamic range from 0-100% IB6 expression was detected in 614 nsqNSCLC specimens. Specificity testing in normal and abnormal tissues resulted in expected expression patterns and localization primarily to the cell membrane. Western blot testing using predicted IB6 positive and negative cancer cell lines confirmed specific detection of IB6. Staining precision resulted in ≥95% of scores within expected variability limits for all parameters. Scoring precision resulted in ≥90% agreement for both intra-observer and inter-observer comparisons when evaluating different IB6 expression cutoffs.
Conclusion: The novel Integrin Beta-6 IHC 6.2A1 pharmDx assay demonstrated high sensitivity, specificity, and precision for the detection of IB6 expression. The assay is suitable for testing of nsqNSCLC subjects for investigational use in an ongoing SV phase 3 trial.

PS-26-010

Multi-site external platform comparison of PD-L1 IHC 22C3 pharmDx performance on Dako Omnis and Autostainer Link 48 for non-small cell lung cancer using Tumour Proportion Score

G. Cherryholmes[1], D. Moquin[2], G. Toland[2], S. Tabuena-Frolli[2], K. Kersch[2], S. Hund[2], M. Polewski[1]
[1]Agilent Technologies, Organization of the Chief Medical Officer, Carpinteria, USA, [2]Agilent Technologies, Research and Development, Carpinteria, USA

Background & Objectives: PD-L1 IHC 22C3 pharmDx is a qualitative immunohistochemical (IHC) assay to detect PD-L1 expression in formalin-fixed, paraffin-embedded (FFPE) tissues. This study sought to demonstrate concordance of PD-L1 IHC 22C3 pharmDx on both Autostainer Link 48 (ASL48) (Code SK006) and Dako Omnis (Code GE006) staining platforms for non-small cell lung cancer (NSCLC).
Methods: This was a three-site, blinded, and randomized study of PD-L1 IHC 22C3 pharmDx on FFPE NSCLC specimens. To investigate inter-platform performance, one pathologist at each of the three testing sites evaluated two replicate sets of 120 NSCLC specimens: one set prestained using PD-L1 IHC 22C3 pharmDx on ASL48 and one set prestained on the Dako Omnis platform. Pathologists determined the PD-L1 expression level for the NSCLC specimens using a Tumour Proportion Score (TPS) at established diagnostic cutoffs: TPS ≥ 1% and TPS ≥ 50%.
The analytical agreements of the diagnostic outcome (positive/negative) were estimated by evaluating negative, positive and overall percent agreement (NPA/PPA/OA) using SK006 as reference with corresponding percentile bootstrap confidence intervals (CIs). Ninety-six specimens were predesignated for analysis at each cutoff. The predetermined acceptance criteria for all endpoints are that the lower-bound (LB) of a two-sided 95% CI for NPA, PPA, and OA must meet or exceed 85.0%.
Results: The study met all acceptance criteria for the TPS ≥ 1% and TPS ≥ 50% cutoffs. For TPS ≥ 1%, the 95% CI LB of the endpoints were 94.2% for NPA, 96.9% for PPA, and 96.5% for OA. For TPS ≥ 50%, the 95% CI LB of the endpoints were 85.3% for NPA, 94.2% for PPA, and 91.0% for OA.
Conclusion: This study demonstrates concordance between ASL48 and Dako Omnis platforms with respect to identifying PD-L1 expression in NSCLC specimens at the TPS ≥ 1% and TPS ≥ 50% cutoffs using PD-L1 IHC 22C3 pharmDx.

PS-26-011

Immunohistochemical subtyping of small cell lung carcinoma

M. Kovacevic[1], G. Vlacic[1], I. Kern[1]
[1]University Clinic for Pulmonology and Allergology Golnik, Pathology, Golnik, Slovenia

Background & Objectives: Emerging concept of small cell lung carcinoma (SCLC) subtyping relies on immunohistochemical (IHC)

studies. The aim of this study was to determine expression of ASCL1, NEUROD1, POU2F3 and YAP1 in surgical samples of SCLC.
Methods: 24 surgically resected tumours from 24 different patients were included. After confirming the diagnosis of SCLC, we formed tissue microarrays (TMAs), taking 1 to 4 (median 3) samples from different parts of each tumour. TMAs were stained with haematoxylin/eosin. IHC stainings wiith neuroendocrine (NE) markers (CD56, INSM1, synaptophysin, chromogranin) and transcription factor (TF) markers (RB1, ASCL1, NEUROD1, POU2F3 and YAP1) were performed. The expression of IHC markers was evaluated semiquantitatively and expressed in percentages. Since the samples showed spacially heterogenous expression of IHC markers, we chose the ones with the highest expression as representative. Cutoff point for positive staining was 10% of tumour tissue.
Results: 91,7% of samples stained positive for CD56 and INSM1 (not the same samples). We observed lower intensity and distribution of INSM1 compared to CD56. Synaptophysin was expressed in 71% of samples. Chromogranin was positive in only one sample, possibly due to the antibody clone. RB1 was positive in only one sample. ASCL1 and NEUROD1 were positive in two thirds of samples, with 21% showing expression of both markers, 16,7% and 29,2% were positive only for ASCL1 and NEUROD1, respectively. POU2F3 was expressed in five samples (20,8%), but only three (12,5%) did not express other TF markers. YAP1 was positive in 21% of samples. IHC suptyping found 6 (25%) SCLC-A, 10 (41,7%) SCLC-N, and 3 (12,5%) SCLC-P tumours. YAP1 was negative in all the remaining five samples (20,8%) - possible SCLC-QN subtype.
Conclusion: Our study showed concordant results with previous studies, However, it also points to some challenges, such as co-expression of different TF markers and heterogenous expression in different parts of tumour.

PS-26-012
DLL3 expression in small round cell tumours: a potential therapeutic target for SMARCA4-deficient tumours
H. Song[1], U. Jo[1], J.-M. Park[1], Y.M. Cho[1], J.S. Song[1]
[1]Asan Medical Centre, Pathology, Seoul, Republic of Korea

Background & Objectives: Small round cell tumours (SRTs) comprise diverse neoplasms characterized by small, round, hyperchromatic cells with high nuclear-to-cytoplasmic ratios. Delta-like ligand 3 (DLL3), an inhibitory Notch pathway ligand highly upregulated in small cell lung cancer, may serve as a therapeutic target. We aimed to characterize DLL3 expression across SRTs to identify potential therapeutic strategies.
Methods: We analysed DLL3 expression in 128 SRTs including alveolar rhabdomyosarcoma, desmoplastic small round cell tumour, Ewing sarcoma, malignant rhabdoid tumour, olfactory neuroblastoma, synovial sarcoma, NUT carcinoma, SMARCB1/A4-deficient undifferentiated tumours, and undifferentiated small round cell tumours, using immunohisto-chemistry with 1% and 5% cut-offs. We assessed cytotoxicity of Rovalpituzumab tesirine (Rova-T) in SMARCA4-deficent lung cancer (H661), small cell lung cancer (H82), and normal bronchial (BEAS-2B) cell lines.
Results: At the 1% cut-off, 14.1% of SRTs were DLL3-positive, while 7.0% were positive at the 5% cut-off. DLL3 expression significantly correlated with tumour diagnosis (p=0.001). SMARCA4-deficent undifferentiated tumours (SMARCA4-dUT) showed the highest DLL3 positivity (50% at 1% cut-off; 41.7% at 5% cut-off, p=0.001 vs. non-SMARCA4-dUTs). Synaptophysin expression significantly associated with DLL3 positivity (p=0.011). Western blot confirmed DLL3 protein in H661 cells, and immunostainings of H661 cell block demonstrated DLL3 expression and loss of BRG-1 expression. Rova-T demonstrated dose-dependent efficacy against both H661 (IC50=0.07686 μM) and H82 (IC50=0.1061 μM), with BEAS-2B showing similar sensitivity (IC50=0.09885 μM). No significant survival differences were observed between DLL3-positive and DLL3-negative SRTs.
Conclusion: DLL3 is expressed in a subset of SRTs, with significantly higher rates in SMARCA4-dUT. The association between DLL3 and synaptophysin suggests neuroendocrine differentiation. These findings identify DLL3 as a potential therapeutic target for SMARCA4-dUTs, warranting further investigation the absence of survival differences in our clinical cohort.

PS-26-013
Peribronchiolar metaplasia: an immunohistochemical study
S. Ivanova[1], A. Fakirova[1], B. Ilcheva[1], R. Hristoskova[1], D. Dikov[1]
[1]Military Medical Academy - Sofia, General and Clinical Pathology, Sofia, Bulgaria

Background & Objectives: Chronic irritation of the bronchial mucosa and the lung parenchyma lead to adaptation, the most common of it – the metaplasia. And if the bronchial squamous cell and stromal smooth muscle cell metaplasia are very well known to the pathologist, it's not the same with the peribronchiolar lung metaplasia (PBM). The latest is a pathological lesion, whose study has been gaining momentum in recent years, mainly due to its combination with chronic nicotine intoxication and interstitial fibrosis of the lung parenchyma, including recovering from COVID-19. The aim of this study is the immunohistochemical profile of PBM.
Methods: We investigated immunohistochemically PBM in 20 cases of lung specimens.
Results: Two immunohistochemichal profiles of PBM have been described. In the initial stages, the prevailing phenotype of PBM is Cytokeratin7-positive, TTF1-positive, p63-positive, CC16-positive and has higher proliferative activity, demonstrated by higher Ki67-index. In the more advanced stages, the cells are still Cytokeratin7-positive, p63-positive, but alter their expression to TTF1-negative, CC16-negative and have lower proliferative Ki67-index.
Conclusion: PBM is dynamic process in immunochistochemicall regard, and progresses stepwise from alveolar to bronchial phenotype. The main role in the process of the indirect epithelial metaplasia have the CC16-positive club cells.

PS-26-014
Histopathological features of pleuroparenchymal fibroelastosis based on deep learning analysis: quantification of collagen fibre and two types of elastic fibre
A. Yoshizawa[1,2], H. Katsuragawa[2], H. Ito[2], H. Haga[2]
[1]Nara Medical University, Department of Diagnostic Pathology, Kashihara, Japan, [2]Kyoto University Hospital, Department of Diagnostic Pathology, Kyoto, Japan

Background & Objectives: Pleuroparenchymal fibroelastosis (PPFE) is classified as a rare idiopathic interstitial pneumonia, though these features are also observed in secondary interstitial lung disease. To diagnose PPFE correctly is often problematic because various patterns of fibrosis can coexist. We analysed digital images of lungs resected for transplantation using deep learning to detect the differences between PPFE and non-PPFE and between idiopathic and secondary cases, to identify histological findings useful in improving PPFE diagnosis.
Methods: Among patients who underwent lung transplantation, 174 patients with interstitial lung diseases were enrolled and classified into 14 idiopathic PPFE (IPPFE), 34 secondary PPFE (SPPFE), and 126 non-PPFE based on multidisciplinary discussion diagnosis. Altogether, 1728 slides were digitized, and elastic and collagen fibre areas were identified and quantified using deep learning. We defined strong elastic fibre as elastic fibre consisting alveolar framework,

and weak elastic fibre as faint elastic fibre found inside the strong framework.
Results: In the upper lobe, the median collagen fibre area/fibrosis area ratio in the non-PPFE was higher than that in IPPFE ($P < 0.0001$) and SPPFE ($P < 0.0001$) and that in SPPFE was higher than that in the IPPFE ($p = 0.0197$). The median elastic fibre area/fibrosis area ratio in the non-PPFE group was lower than that in IPPFE ($P < 0.0001$) and SPPFE ($P < 0.0001$). Similar trends were observed in the lower lobe except collagen fibre.
Conclusion: Fibroelastosis comprised a uniform strong elastic fibre framework with weak elastic fibres; fibroelastosis of SPPFE showed heterogeneous manifestations with a mixture of collagen fibres.

PS-26-015
Molecular findings in CPAM with synchronous adenocarcinoma
V. Almeida[1,2], M. Viseu[2], A. Alarcão[2], A.F. Ladeirinha[2], M. Silva[2], T. Ferreira[2], R. Silva[2], J. Pimentel[1,2], G. Fontinha[1,2], V. Sousa[1,2], L. Carvalho[1,2]
[1]Coimbra University Hospital, Pathology, Coimbra, Portugal, [2]Univ Coimbra, Faculty of Medicine, Coimbra, Portugal

Background & Objectives: Congenital pulmonary airway malformations (CPAM) are rare developmental lesions of the lung, occasionally reported in association with mucinous adenocarcinomas. The clonal relationship between these entities remains unclear. This study aimed to investigate the molecular profiles of CPAM and contiguous mucinous adenocarcinomas to assess potential neoplastic progression.
Methods: We identified six cases of adult CPAM with contiguous mucinous adenocarcinoma, validated as distinct components for histopathological and molecular analysis. The cohort included 3 women (aged 44–76) and 3 men (all aged 74), with tumour staging ranging from pT1a to pT3, and N0 (n=4) to N1 (n=1). DNA extracted from formalin-fixed paraffin-embedded tissues underwent targeted next-generation sequencing (NGS) using a 50-gene panel, applied independently to CPAM and tumour areas.
Results: Across the six cases, several oncogenic mutations were identified in both CPAM and tumour components, involving genes such as *TP53*, *KRAS*, *EGFR*, *FGFR3*, *MTOR*, *CTNNB1*, and *GNAS*. In three cases (50%), identical *TP53* mutations were detected in both lesions, suggesting a clonal relationship:

- Case 1: *TP53* c.743G>A; p.(Arg248Gln)
- Case 2: *TP53* c.524G>A; p.(Arg175His)
- Case 3: *TP53* c.524G>A; p.(Arg175His) and c.517G>T; p.(Val173Leu)

In the remaining cases, CPAM and tumour components harboured distinct mutational profiles. These findings support a potential clonal link in a subset of cases, while also highlighting genetic heterogeneity among mucinous adenocarcinomas arising in the context of CPAM.
Conclusion: Our findings provide molecular evidence supporting a potential precursor–tumour progression from CPAM to mucinous adenocarcinoma, particularly via early *TP53* alterations and loss of function. The observed mutational heterogeneity in adenocarcinomas suggests variable carcinogenic pathways. These results underscore the importance of thorough histological and molecular assessment of congenital lesions in adults. Despite the limited sample size, this study contributes to a better understanding of CPAM-associated carcinogenesis and supports the hypothesis of a neoplastic continuum.

PS-26-016
Targeting pulmonary carcinoid tumours: analysis of gene fusions using RNA-based NGS panel
J. Niinimäki[1], S. Kytölä[2], A. Ristimäki[1], J. Arola[1], T. Vesterinen[1]
[1]University of Helsinki and Helsinki University Hospital, Department of Pathology, Helsinki, Finland, [2]University of Helsinki and Helsinki University Hospital, Department of Genetics, Helsinki, Finland

Background & Objectives: Pulmonary carcinoid (PC) tumours are well-differentiated neuroendocrine tumours, comprising 1–2% of all malignant lung tumours. PCs are classified as typical carcinoids (TCs) or atypical carcinoids (ACs) based on morphology and mitotic index. Treatment options for unresectable PCs remain limited, emphasizing the need for novel, targeted therapies. However, PC-associated gene fusions are understudied. This study aimed to analyse gene fusions in 17 lung cancer–related genes using RNA-based next-generation sequencing (NGS) in a relatively large PC cohort.
Methods: A retrospective cohort of formalin-fixed, paraffin-embedded primary tumours from Helsinki University Hospital (1990–2018) was analysed. RNA was extracted from tissue cores/scrolls, and targeted RNA-based NGS (FusionPlex Lung v2 panel) was performed to detect oncogenic fusions in *ALK, BRAF, EGFR, ERBB2, FGFR1, FGFR2, FGFR3, KRAS, MET, NRG1, NTRK1, NTRK2, NTRK3, NUTM1, PIK3CA, RET, and ROS1*.
Results: NGS was successfully performed on 65 PC tumours (49 TCs, 16 ACs), identifying 10 different gene fusions. Seven were found in local TCs (*PWWP2A::NRG1, TFG::ROS1, MUC2::ROS1, USP17L24::ALK, SFRP5::ALK, RHOBTB1::NTRK3,* and *PRPF4B::ROS1*) and two in metastatic TCs (*MMP16::FGFR2* and *CCDC89::ALK*). One TC patient harboured two distinct fusions (*MUC2::ROS1* and *USP17L24::ALK*). In a local AC, one gene fusion (*ZNF618::NTRK3*) was identified. Additionally, a BRAF exon-skipping event was detected in a metastatic AC tumour.
Conclusion: Compared to other neuroendocrine lung cancers, PCs exhibit a low mutational burden. However, in this series, 14% of the tumours harboured a gene fusion. Since targeted therapies are available for most of the identified fusions, genomic screening should be prioritized to guide personalized therapy. Additionally, some detected gene fusions are associated with aggressive disease and poor prognosis, necessitating more vigilant patient follow-up.

PS-26-017
Investigating novel therapeutic targets in NSCLC: deciphering the relationship between NTRK, PD-L1, and PD-1 expression
J.M. Gutierrez Herrera[1], M.Á. Montero Fernández[2], G. Kokaraki[3], L. De Petris[4], R. Maia Falcão[5], R. Guijarro Jorge[6], S. Ekman[3], C. Ortiz-Villalón[7]
[1]Karolinska University Hospital, Klinisk Patologi/Cancerdiagnostik, Stockholm, Sweden, [2]Liverpool University NHS Foundation Trust, Department of Cellular Pathology, Liverpool, United Kingdom, [3]Karolinska Institute, Department of Oncology-Pathology (Onkpat), Stockholm, Sweden, [4]Karolinska University Hospital, Theme Cancer, Thoracic Oncology Centre, Stockholm, Sweden, [5]Federal University of Rio Grande do Norte, Metrópole Digital Institute, Natal, Brazil, [6]Valencia University, Department of Surgery, Valencia, Spain, [7]Malmö University Hospital, Department of Clinical Genetics, Pathology and Molecular Diagnostics, Malmö, Sweden

Background & Objectives: Lung cancer remains the leading cause of cancer-related mortality worldwide, with non-small cell lung cancer

(NSCLC). Precision medicine has introduced immune checkpoint inhibitors (ICIs) and tyrosine kinase inhibitors (TKIs) as promising therapeutic strategies. However, the interplay between PD-L1 expression and *NTRK* rearrangements in NSCLC remains largely unexplored.
Methods: This study analysed a cohort of 482 NSCLC patients. Immunohistochemical (IHC) staining was performed to assess PD-L1 and pan-TRK expression, while whole exome sequencing (WES) was used to identify *NTRK* somatic mutations, copy number variations (CNVs), and gene fusions. Statistical analyses were conducted to evaluate associations with clinicopathological features and prognosis. Additionally, possible connections through cellular pathways were studied through multiple databases and using the cytoscape v 3.10.3 program.
Results: PD-L1 expression (TPS ≥1%) varied across antibody clones, with positivity rates of 41.5% for 28-8, 34.2% for 22C3, 42.7% for SP263, and 10.4% for SP142. High PD-L1 expression (TPS ≥50%) was significantly associated with poorer overall survival (OS) in NSCLC patients assessed with SP142 ($p = 0.045$). TRK expression was detected in 4.56% (22/482) of cases, predominantly in squamous cell carcinoma (72.7%). Combined expression of pan-TRK and PD-L1 across all clones was statistically significant ($p < 0.001$), with co-expression present in 4.6% of cases. WES identified 3/482 *NTRK* fusions, but no significant survival association was observed.
Conclusion: PD-L1 and pan-TRK expression demonstrate a significant correlation in NSCLC, particularly in squamous cell carcinoma and high-grade tumours. Although PD-L1 expression is a prognostic factor, TRK expression alone does not significantly impact survival. This study suggests an interplay between NTRK1 and PD-L1 that could influence therapeutic resistance. Further studies are needed to elucidate the therapeutic implications of PD-L1 and NTRK co-expression, which may aid in optimizing personalized treatment strategies in particular needed to overcome resistance mechanisms in NSCLC.

PS-26-018
Characterization of non-small cell lung carcinoma with TTF-1 and p40 co-expression
M. Braun[1], J. Sołek[1], G. Stępień[1], A. Masłowska[1], M. Kamecki[2], P. Antosik[3], B. Tomasik[4], D. Grzanka[3], R. Kordek[1]
[1]Medical University of Łódź, Department of Pathology, Chair of Oncology, Łódź, Poland, [2]Medical University of Łódź, Department of Chemotherapy, Łódź, Poland, [3]Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University, Department of Clinical Pathomorphology, Faculty of Medicine, Bydgoszcz, Poland, [4]Medical University of Gdańsk, Department of Oncology and Radiotherapy, Gdańsk, Poland

Background & Objectives: Non-small cell lung carcinoma (NSCLC) accounts for the majority of lung cancer cases and requires precise histological subtyping for optimal therapeutic decision-making. TTF-1 and p40 are standard lineage markers used to distinguish adenocarcinoma (ADC) from squamous cell carcinoma (SCC), respectively. However, a subset of tumours co-expresses both markers, posing diagnostic uncertainty. This study aimed to characterize the clinicopathological and molecular features of NSCLCs with TTF-1 and p40 co-expression.
Methods: We retrospectively analysed 94 NSCLC cases with available TTF-1 and p40 immunohistochemistry. Co-expression of both markers was identified in 18 tumours. Clinicopathological data, survival outcomes, and molecular alterations were evaluated. Next-generation sequencing (NGS) was performed on tumour samples to assess mutational profiles.
Results: TTF-1/p40 co-expressing tumours exhibited a significantly higher frequency of solid growth patterns compared to other NSCLCs ($p = 0.028$). No significant differences in overall survival were observed ($p = 0.458$). Pathogenic mutations were present in 15 of 17 cases (88.2%), most commonly involving *TP53* (64.7%) and *KRAS* (23.5%). Alterations in *FGFR1–3* were identified in 29.4% of cases. Immunohistochemical analysis showed frequent expression of p63 and p53 across the co-expressing group.
Conclusion: NSCLCs with TTF-1 and p40 co-expression represent a biologically distinct, poorly differentiated subset frequently harbouring *TP53* and *FGFR* pathway alterations. These tumours may be more appropriately classified as non-small cell carcinoma, not otherwise specified (NSCC, NOS), rather than as classical ADC or SCC. Given their molecular complexity, broad genomic profiling should be considered even in cases with squamous-like morphology, where such testing is not routinely performed.

PS-26-019
Transbronchial biopsy in the diagnostic algorithm of fibrotic hypersensitivity pneumonitis: 2-year experience from a pulmonary pathology reference unit
J. Coelho Lima[1,2], G. Maggioni[2], F. Lunardi[2], F. Pezzuto[2], N. Bernardinello[3], E. Balestro[3], R. Polverosi[4], F. Calabrese[2]
[1]Cambridge University Hospitals NHS Foundation Trust, Department of Histopathology, Cambridge, United Kingdom, [2]Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Padua, Italy, [3]Azienda Ospedale Universita di Padova, Unita Operativa Complessa di Pneumologia, Padua, Italy, [4]Instituto Diagnostico Antoniano - Affidea, Padua, Italy

Background & Objectives: Hypersensitivity pneumonitis (HP) is a challenging diagnosis, particularly fibrotic HP. In the 2022 ATS/JRS/ALAT HP diagnosis guideline, whilst bronchoalveolar lavage (BAL) is considered a crucial diagnostic step, the complementary role of transbronchial biopsy (TBB) remains unclear, especially in suspected fibrotic HP. Here, we present our experience with TBB in the diagnostic approach to HP cases.
Methods: Retrospective, observational study including all consecutive cases of suspected interstitial lung disease (ILD) assessed at a reference pulmonary pathology unit (Jan/2023-Dec/2024). Clinical, radiologic, pulmonary function test, BAL, TBB and multidisciplinary meeting (MDM) outcome data were reviewed.
Results: Out of 149 TBB performed for ILD assessment, 12 (8%) cases were clinically and/or radiologically suspicious for HP. Most patients were female (58%), elderly [mean(±SD) age, years=66(±11)] and non-smokers (75%). Eleven (92%) patients had exposure to identifiable inciting agents. Most patients showed restrictive functional pattern (50%). Radiologically, traction bronchiectasis (42%), ground glass opacities (42%), and subpleural/peribronchial reticulation (42%) were the most frequent findings. Bronchoscopy with BAL and TBB was performed in all patients. Following radiologic-pathologic integration at MDM, 4 (33%) cases were diagnosed as fibrotic HP, 4 (33%) as nonfibrosing HP, 2 (17%) as non-specific interstitial pneumonia (NSIP), and 2 (17%) as indeterminate for fibrosing ILD. HP cases showed a tendency towards higher BAL lymphocyte percentages [HP vs. non-HP, mean(±SD): 25%(±19%) vs. 8%(±4%)]. On TBB, HP cases displayed higher frequency of loose granulomas (38% vs. 25%) and multinucleated cells (13% vs. 0%) compared with non-HP, with similar interstitial inflammation and organising pneumonia frequency. Fibrotic HP cases showed higher fibrosis frequency (75%) than nonfibrosing HP (25%).
Conclusion: In our experience, TBB is a useful minimally-invasive tool in the diagnostic work-up of suspected HP cases with a diagnostic yield of 66%, which was similar for fibrotic and nonfibrosing HP. We reinforce BAL diagnostic value in this setting.

PS-26-020

Histopathological and molecular features of non-small cell carcinomas in breast cancer survivors: a retrospective case series

F. Pezzuto[1], M. Tinè[1], C. Bruno[1], S. Zanella[1], F. Fortarezza[2], F. Lunardi[1], C. De Chellis[1], E. Faccioli[1], F. Rea[1], G. Pasello[1], F. Calabrese[1]

[1]University of Padova, Padova, Italy, [2]Azienda Ospedale Università di Padova, Padova, Italy

Background & Objectives: Non-small cell cancer (NSCC) arising in women with a previous diagnosis of breast cancer (BC) is an uncommon clinical scenario. With increasing BC survival rates and broader use of systemic therapies, characterizing subsequent malignancies is of growing interest to pathologists.

Methods: We retrospectively analysed 36 cases of NSCC in BC survivors from 2021 to 2024. Histological review included histotype, tumour differentiation, necrosis, fibrosis, vascular invasion, and spread through air spaces (STAS). Molecular profiling and PD-L1 expression were assessed in all cases. Clinical data included BC stage, symptoms, treatment, latency interval, radiological features, and follow-up.

Results: Thirty-five cases were diagnosed as lung adenocarcinoma (LUAD). Only one case was a squamous cell carcinoma. The median age at BC diagnosis was 55 years. BC was of no special type in 18 cases. Among 17 staged BCs, 15 were stage 0–II. The median interval between BC and LUAD was 11 years. Tumours were asymptomatic in 20 cases, peripheral in 22, and solid on imaging in 25. Histologically, 13 LUAD were moderately differentiated and 3 poorly differentiated; STAS was seen in 4 cases and vascular invasion in 2. The detected mutations included EGFR (9 cases, 26%), BRAF (2 cases, 6%), KRAS mutations (8 cases, 18%), ALK rearrangement (1 case, 3%), and MET alterations (2 cases, 6%). Co-mutations were observed in 3 cases (9%), including two cases with KRAS mutations combined with STK11, MTOR, and PIK3CA, and one case with MET exon 14 skipping along with TP53 and MTOR mutations. PD-L1 expression had a median of 2%, with 8 cases (23%) ≥50%. At diagnosis, 15 LUADs were stage I. At the last follow-up, 29 patients were alive.

Conclusion: In LUAD following BC, a high frequency of oncogene addiction was detected. These findings warrant further validation and investigation to better understand the underlying mechanisms.

PS-26-021

Analysis of 9 years of real-world biomarker testing and positivity rates in non-small cell lung cancer (NSCLC) from the Spanish Prospective Central Lung Cancer Biomarker Testing Registry (LungPath)

J. Martin Lopez[1], S. Gatius[2], L. Auz Alexandre[3], A.B. Enguita[4], C. Camacho García[5], C.A. Vasquez Dongo[6], D. Carcedo Rodríguez[7], JF. Garcia[8], S. Arranz[7], I. Tonic[8], C. Salas Antón[1]

[1]Hospital Universitario Puerta de Hierro, Pathology, Madrid, Spain, [2]Hospital Universitario Arnau de Vilanova, Universitat de Lleida, Oncological Pathology Group, IRB, Lleida, Spain, [3]Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain, [4]Hospital Universitario 12 de Octubre, Pathology, Madrid, Spain, [5]Complejo Hospitalario Universitario Insular Materno-Infantil, Pathology, Gran Canaria, Spain, [6]Hospital Universitario Dr. Josep Trueta, Pathology, Girona, Spain, [7]Hygeia Consulting S.L., Health Economics, Madrid, Spain, [8]Roche Farma, Médico, Madrid, Spain

Background & Objectives: LungPath is a Spanish on-line registry that provides the largest amount of real-world data on biomarker testing in lung cancer. We aimed to describe the testing and positivity rates of current essential biomarkers in non-small cell lung cancer (NSCLC) and analyse potential associated factors in Spain.

Methods: A retrospective observational study was conducted, including biomarker determinations of all types of NSCLC samples from 61 Spanish hospitals between March 2018 and October 2023 recorded in LungPath registry. Only adenocarcinoma and NSCLC not-otherwise-specified (NSCLC-NOS) histologies were included. Testing and positivity rates for the current essential biomarkers in NSCLC (*EGFR, ALK, ROS1, PDL1, BRAF, KRAS, MET, RET* or *NTRK1*) were calculated and multivariable logistic models developed to assess the effect of covariates on testing and positivity rates.

Results: 12,709 NSCLC samples tested for essential biomarkers were analysed. *EGFR* (86.0%), *ALK* (84.2%) and *ROS1* (72.0%) were the most commonly tested biomarkers. Testing rates were lower for other biomarkers with newer targeted therapies, such as *MET* (15.6%), *RET* (15.4%) or *KRAS* (16.4%), and these were tested more frequently in surgical specimens compared to biopsies (*MET* (OR [95%-CI]): 1.30 [1.15-1.48]; *RET*: 1.33 [1.17-1.51]; *KRAS*: 1.82 [1.61-2.05]). The positivity rates for the current essential biomarkers in Spain were in line with figures reported in the literature. PD-L1 expression was statistically more frequent in samples with alterations in *BRAF* (2.00 [1.31-3.05]), *KRAS* (1.59 [1.27- 2.01]), and *ALK* (1.39 [1.08- 1.79]). In contrast, a positive *EGFR* result was inversely related to PD-L1expression (0.64 [0.55- 0.74]).

Conclusion: Our results show that testing rates for biomarkers with newer targeted therapies are still low and their growth is low. Widespread use of comprehensive genomic profiling (GCP) is expected to increase testing rates in the coming years.

PS-26-022

Incidence of *FGFR* mutations in lung carcinomas

V. Sousa[1,2,3], A.F. Ladeirinha[1,3], A. Alarcão[1,3], M. Reis Silva[1,3], T. Ferreira[1], M. Viseu[1], R. Silva[1], V. Almeida[2,1], J. Pimentel[2,1], G. Fontinha[2,1], L. Carvalho[2,1,3]

[1]Institute of Anatomical and Molecular Pathology, Faculty of Medicine of the University of Coimbra, Coimbra, Portugal, [2]Pathology Service, ULS Coimbra, Coimbra, Portugal, [3]CIMAGO – Research Centre for Environment, Genetics and Oncobiology, Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background & Objectives: Genetic alterations of FGFs in lung carcinomas, namely amplifications, mutations and translocations in the *FGFR* genes, are closely linked to the carcinogenesis, progression and resistance to therapy, suggesting targeting FGF/*FGFR* as an attractive therapeutic strategy for lung cancer prognosis. Since *FGFR* mutations (oncogenic or likely oncogenic) were described in Non-Small Cell Lung Cancer NCCN Guidelines version 1.2025, as emerging biomarkers to identify novel therapies for patients with metastatic NSCLC, we reviewed our cases with *FGFR* alterations, diagnosed in 2024.

Methods: We report 13 cases in 2024 with *FGFR* positive alterations in NSCLC. Next Generation Sequencing (Genexus, Oncomine Precision Assay Panel, Thermo Fisher Platform) after manual macrodissection was performed and nucleic acid extraction was carried out with the MagMAX FFPE DNA/RNA Ultra Kit. All cases were evaluated for oncogenic or likely oncogenic *FGFR* mutations.

Results: *FGFR*1/2/3 gene alterations were detected in 13/240 cases (5,4%). 6 cases presented SNV and 7 cases with amplification. 4/6 cases with mutations (SNVs) are classified by NCCN guidelines as emerging biomarker linked to sensitivity to Erdafitinib (*FGFR3*: D641G, R248C, G380R, and D641N) and for 2/6 (V550M and V550L) there are no therapeutic approval. In the emerging biomarker mutations identified, one case showed no concomitant targetable mutation and three cases harboured concomitant mutations namely *EGFR* L858R (2 cases) and *EGFR* E746_A750 (1 case). None of the case had isolated mutations in *FGFR* alone. Amplification is not considered as an emerging biomarker actually.

Conclusion: *FGFR*1/2/3 gene alterations are not so infrequent (5,4%). Careful interpretation is needed as concomitant mutations are frequent, some of them in targetable genes. These cases should be discussed with clinicians especially when two targetable mutations are present knowing that some *FGFR* mutations are considered as emerging biomarkers.

PS-26-023

Pulmonary carcinomas: *KRAS – EGFR – ALK* mutations and PD-L1 immunoexpression

V. Sousa[1,2,3], A. Alarcão[1,3], A.F. Ladeirinha[1,3], M. Reis Silva[1,3], T. Ferreira[1], M. Viseu[1], R. Silva[1], V. Almeida[2,1], J. Pimentel[2,1], G. Fontinha[2,1], L. Carvalho[2,1,3]
[1]Institute of Anatomical and Molecular Pathology, Faculty of Medicine of the University of Coimbra, Coimbra, Portugal, [2]ULS Coimbra, Pathology Service, Coimbra, Portugal, [3]CIMAGO – Research Centre for Environment, Genetics and Oncobiology, Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background & Objectives: PD-L1 expression and *KRAS/EGFR/ALK* alterations may influence tumoral microenvironment. The association between PD-L1 expression and *KRAS/EGFR/ALK* targetable alterations are not well understood namely concerning therapeutic responses. The authors intends to evaluate the concomitance of *EGFR*, *KRAS*, *ALK* mutations with PD-L1 > 1% immunoexpression in pulmonary carcinomas.
Methods: Mutations research performed by Genexus, OPAPanel, ThermoFisher. PD-L1 scoring (22C3-DAKO) according with guidelines.
Results: 240 cases evaluated in 2024, 31 only with *KRAS* mutation, 20 with only *EGFR* mutations and 5 with only ALK fusions. For *KRAS* mutations cases we found 11/31 (35%) negative PD-L1 cases, and 20/31 (65%) positive cases where 10/20 (50%) showed PD-L1 ≥50%. For *EGFR* mutations cases we found 6/20 (30%) negative PD-L1 cases, and 14/20 (70%) positive cases where only 4/14 (28%) showed PD-L1 ≥50%. All (100%) ALK fusions cases showed PD-L1 positivity ranging from 10% to 70% (TPS score), with TPS ≥50% identified in 2 cases (40%).
Conclusion: PD-L1 expression on survival is unclear and may depend on other biomarkers including *EGFR/KRAS/ALK* alterations. Studies indicate that tumours with *EGFR*/*ALK* alterations generally have low/intermediate PD-L1 expression and do not respond well to immunotherapy, even with high PD-L1 as *EGFR* mutated tumour cells may have an immunosuppressive microenvironment, or ALK pathway activates immunosuppressive mechanisms. Studding concomitance of *EGFR*/*KRAS*/*ALK* mutations and PD-L1 expression may impact the choice of treatment in NSCLC. *KRAS* mutations especially G12C frequently presents with high PD-L1 scores. *KRAS* mutations could induce tumoral inflammation activating the axe PD-1/PD-L1. NCCN guidelines also alert that (PD-1)/PD-L1 inhibitor could be less effective as monotherapy irrespective of PD-L1 expression, in *EGFR* exon 19 deletion or exon 21 L858R, *ALK*+ NSCLC. Large studies/clinical trials are needed to understand the implications of PD-L1 expression concomitant with gene alterations, to validate combined therapies and identify groups of better responders avoiding the administration of potentially less effective therapies.

PS-26-024

Comparison of typical and atypical carcinoids using vibrational spectroscopy

L. Anzic[1], K. Serec[2], S. Seiwerth[3]
[1]University Hospital Centre Zagreb, Department of Pathology and Cytology, Zagreb, Croatia, [2]School of Medicine, University of Zagreb, Department of Physics and Biophysics, Zagreb, Croatia, [3]School of Medicine, University of Zagreb, Department of Pathology and Cytology, Zagreb, Croatia

Background & Objectives: Carcinoids are tumours originating from neuroendocrine cells and belong to the family of neuroendocrine tumours (NETs) due to the presence of neurosecretory granules in their cytoplasm. Lung carcinoids make up 2% of lung tumours and can be classified as typical or atypical. In comparison to atypical carcinoids, typical ones show a much lower metastatic potential and a significantly higher survival rate. Our goal was to compare the vibrational spectra of typical and atypical carcinoids using vibrational spectroscopy and explore the potential difference as a new diagnostic tool.
Methods: Diagnosis was verified by an experienced pulmonary pathologist, and paraffin blocks with the most suitable material were selected. The tissue was stained with haematoxylin-eosin stain to identify the carcinoid areas and deparaffinized. Paraffin blocks were then cut, yielding 140 slides from 28 biopsies of 25 patients (60 typical, 80 atypical). After vacuum desiccation, FTIR spectra of 140 samples were recorded in transmission mode using a PerkinElmer Spectrum GX spectrometer (MCT detector, KBr beam splitter). Data were processed in MatlabR2010b with the Kinetics add-on and PLS Toolbox. PCA, SVMDA, and KNN were used for multivariate analysis.
Results: Not only did PCA successfully visually separate typical from atypical carcinoids, but it also showed clear grouping of atypical ones by size, recurrence, and invasiveness. SVMDA proved to be a better predictive method with 82.5% accuracy.
Conclusion: FTIR spectroscopy and PCA effectively distinguish typical carcinoids from atypical ones, with differences in size, invasiveness, and recurrence in atypical cases. Developed SVMDA model showed high accuracy in atypia classification. FTIR spectroscopy has significant potential as a diagnostic tool for automated lung carcinoid diagnosis in the future. Downside of this method is the variability in recording conditions, requiring better process standardization, along with significant investment in equipment and time for data analysis.

PS-26-025

Correlation between *TP53* mutations and p53 protein expression patterns in neuroendocrine lung carcinomas

D.A. Salas Díaz[1], K. Sáez de Gordoa[1], E. Ortiz[1], P. Alonso[1], I. Victoria[1], D. Martínez[1], C. Teixido[1]
[1]Hospital Clinic, Pathology Department, Barcelona, Spain

Background & Objectives: *TP53* mutations play a key role in various cancer types and, together with *RB1* mutations, are characteristic of small cell lung carcinoma (SCLC) and certain cases of large cell neuroendocrine carcinoma (LCNEC). This retrospective study aims to evaluate the correlation between *TP53* mutations and p53 expression patterns in SCLC and LCNEC cases diagnosed at a single centre.
Methods: We reviewed medical records to identify all lung tumours harbouring pathogenic *TP53* mutations since 2018, selecting cases diagnosed as SCLC or LCNEC. Biopsy, cytology, and surgical specimen samples were reviewed. Mutational analysis was performed using next-generation sequencing (NGS) with the Oncomine Solid Tumour DNA panel (Thermo Fisher Scientific; S5 Gene Studio). We recorded the mutation type, its location within the protein domain, and its functional impact. p53 expression was assessed by immunohistochemistry (DO7, Roche; Ventana), with a wild-type pattern defined as normal, and altered patterns classified as null, cytoplasmic, or overexpressed.
Results: A total of 18 samples (6 cytology, 4 biopsies, and 8 surgical specimens) from 16 LCNEC and 2 SCLC cases were analysed. *TP53* mutations were identified in all cases. Among the detected mutations, 15 were missense, 2 were splicing mutations, and 1 was a nonsense mutation. Mutations were distributed across exons 5 (n=6), 8 (n=6), 7 (n=5), and 10 (n=1); 17 affected the DNA-binding domain, while one involved the tetramerization domain. Immunohistochemical analysis revealed normal p53 expression in one case, null expression in two

cases, and overexpression in 15 cases. Expression patterns correlated with the identified TP53 mutations, as the two null expressions harboured splicing mutations.
Conclusion: In SCLC and LCNEC, TP53 mutations predominantly affect the DNA-binding domain, resulting to loss of protein function. Immunohistochemical analysis of p53 is a useful tool for identifying TP53 gene mutations, with expression patterns correlating with mutation type.

PS-MD-01 Poster Session Molecular Pathology Diagnostics Symposium

PS-MD-01-001
High-sensitivity methylation profiling in cfDNA with methylation-sensitive restriction enzyme digestion (MSRE) on droplet digital PCR (ddPCR)

E. van Collenburg[1], S. van den Berg[2], N. Kumar[1], J. van Kuik[2], W. de Leng[2], F. Bizouarn[1]
[1]Bio-Rad Laboratories, Digital Biology Group, Pleasanton, USA, [2]UMC Utrecht, Pathology, Utrecht, The Netherlands

Background & Objectives: Mounting evidence demonstrates the utility of analysing methylation status as an indicator of early-stage cancer development and as a method for monitoring tumour response to therapy. Detecting methylation changes in cfDNA is attractive given the noninvasive nature of blood draws. Unfortunately, sensitive, robust, and cost-effective methods to perform methylation analysis on cfDNA samples remain an unmet need. Here we demonstrate how Methylation-Sensitive Restriction Enzymes (MSRE) digestion combined with Droplet Digital PCR enhances analysis of precious samples.
Methods: This method mitigates the drawbacks of bisulfite conversion, such as extensive DNA degradation and high starting material input requirements. Since analysis is based on restriction enzyme cleavage, the amplicon sequence must include MSRE cleavage sites. To mitigate this potential limitation and provide high specificity, a range of different MSRE enzymes and cut sites are available that can be used in combination.
To reliably measure DNA methylation, we designed a range of assays for cancer relevant targets with at least two but not more than four restriction sites within the amplicon. To detect the methylation status at a specific locus, control samples were digested by a range of methylation-sensitive restriction enzymes and analysed with Droplet Digital PCR. When using probe-based detection methods, multiplexing several methylation sites or targets is possible.
Results: Our experiments were designed in a duplex reaction with a reference target (no restriction sites) such as RPP30. The reference assay is used to normalize and correct for small input differences between duplicate digested and undigested control reactions caused by pipetting. Percentage methylation status was calculated with high precision via Droplet Digital PCR by measuring DNA concentration in samples with (MSRE+) and without (MSRE-) enzyme.
Conclusion: With our method we have successfully demonstrated that methylation status can be determined with inputs as low as 1ng. Using this methodology we tested >50 most published oncology methylation targets.

PS-MD-01-002
Development and validation of the OncoCompass® Mate Assay for the detection of DNA and RNA variants in tumours

Q. You[1], X. Yang[1], J. Su[1], S. Zhang[1], C. Yang[1], M. Wu[1], S. Zhang[1], B. Li[1]
[1]Burning Rock Biotech, Shanghai, China

Background & Objectives: NGS-based cancer diagnostics have proven effective for diverse genomic alterations. As new actionable targets emerge, the need for integrated DNA and RNA analysis is growing. To address this, we developed OncoCompass® Mate, a dual-calling assay for comprehensive genomic profiling in a single workflow.
Methods: OncoCompass® Mate is designed for comprehensive pan-cancer genomic profiling. It provides in-depth analysis of 520 genes for DNA variants, 115 genes for RNA fusions and splice variants, as well as key genomic signatures. It allows simultaneous DNA and RNA analysis from a single sample, with single-calling available.
Results: The analytical performance of OncoCompass® Mate has been validated using reference standards and clinical samples across multiple cancer types. Specifically, it was able to identify SNVs and Indels in DNA at an allele frequency as low as 2% and gene fusions and splice variants from RNA at a LOD of 3 transcript copies per nanogram. The assay was further evaluated on 123 FFPE samples from various cancer types, including lung, colon, liver, bile duct, endometrium, sarcoma, and pilocytic astrocytoma. Among these samples, 58 were also analysed using the TruSight Oncology 500 (Illumina) assay. The results showed a positive percent agreement (PPA) and negative percent agreement (NPA) of 100% (95% CI, 87.7-100%) and 100% (95% CI, 88.4-100%), respectively, indicating excellent concordance between the two assays. Notably, two samples containing the KIAA1549-BRAF fusion (K16:B9), which had been missed by the single-calling module, were successfully identified by the dual-calling algorithm and confirmed by fluorescence in situ hybridization. These results highlight the diagnostic benefits of integrating DNA and RNA profiling in clinical practice.
Conclusion: OncoCompass® Mate offers a comprehensive solution to enhance diagnostic accuracy and support therapeutic decisions across various cancer types. Leveraging an advanced automation and bioinformatics platform, the assay enables seamless integration into existing laboratory workflows.

PS-MD-01-003
Potential association of MYCN gain, segmental chromosomal aberrations and MDM2/CDK4 amplification with reclassification into high-risk neuroblastoma

R. Bruinsma[1], W. de Leng[2], M. Fiocco[1,3,4], M. Dierselhuis[1], L. Kester[1], M. van Noesel[1,2], C. van de Ven[1], M. Wijnen[1], R. de Krijger[1,2], A. van der Steeg[1]
[1]Princess Máxima Centre for Paediatric Oncology, Utrecht, The Netherlands, [2]University Medical Centre Utrecht, Utrecht, The Netherlands, [3]Leiden University Medical Centre, Department of Biomedical Data Science, Section Medical Statistics, Leiden, The Netherlands, [4]Leiden University, Mathematical Institute, Leiden, The Netherlands

Background & Objectives: Patients initially diagnosed with non-high-risk neuroblastoma who later reclassify into high-risk have poor survival outcomes. Little research has focused on this subgroup. We aimed to identify molecular aberrations explaining why some non-high-risk neuroblastomas progress to high-risk.
Methods: Data were collected from non-high-risk neuroblastoma patients diagnosed at our centre over 7 years, yielding 89 patients, of whom 13 reclassified into high-risk. Fluorescent in situ hybridization (n=72), single nucleotide polymorphism array (n=48) and next generation sequencing (n=69) were used to detect MYCN gain (gene/centromere ratio 1.5-4.0), copy number variations, amplifications and mutations. Fisher's exact test was employed to assess the relationship between MYCN gain and reclassification. Log-rank tests were employed to compare overall survival (OS) and event-free survival (EFS) since diagnosis for MYCN gain and segmental chromosomal aberration (SCA) profile. A univariate logistic regression model was estimated to assess the effect of SCA count on reclassification. Multiple imputation was used to impute missing SCA counts. Pooled odds ratio (OR) and 95% confidence interval (CI) were computed with Rubin's rule.

Results: MYCN gain was not significantly associated with reclassification (11/13 vs. 56/57, p=0.086). Patients with MYCN gain showed poor 5-year OS (67% S.E. 0.272 vs. 91% S.E. 0.035, p=0.193) and EFS (37% S.E. 0.272 vs. 75% S.E. 0.055, p=0.185). All reclassified neuroblastomas showed SCA profile (9/9) whereas 9/39 non-reclassified cases had no SCA profile. Five-year OS for patients with SCAs was 90% (S.E. 0.0049), no other patients died. Patients with SCA profile had poor EFS (74% S.E. 0.074 vs. 89% S.E. 0.105, p=0.370). After imputation, SCA count was associated with reclassification (pooled OR 1.256 with 95% CI 1.006-1.568, p=0.044). Two patients, both reclassified, exhibited MDM2/CDK4 amplification.
Conclusion: MYCN gain, SCA profile, SCA count, and MDM2/CDK4 amplification may be associated with reclassification into high-risk neuroblastoma. Larger studies are needed to draw firm conclusions.

E-PS-01-001
Urorectal septum malformation sequence - a post-mortem diagnosis

J.L. Amaral[1], J.M. Pimentel[1,2], S. Girgin[1], C. Cerdeira[1], A. Lai[1], R. Pina[1]
[1]Unidade Local de Saúde de Coimbra, Anatomical Pathology, Coimbra, Portugal, [2]University of Coimbra, Faculty of Medicine, Coimbra, Portugal

Background & Objectives: The urorectal septum malformation (URSM) sequence is an extremely rare anomaly that consists of an association of absent perineal and anal openings with ambiguous genitalia and urogenital, colonic and lumbosacral anomalies. In the presence of a single perineal and anal opening draining a common cloaca the findings are better described as a partial URSM, which is compatible with life but with notable comorbidity.
Methods: We present a case of a 20 year old pregnant woman at 30 gestational weeks, with no previous follow-up on our hospital, whose ecographic findings revealed: dilation of colon, bilateral hydronephrosis with loss of corticomedular differentiation, disproportionate thoracic and abdominal perimeters, associated with a pelvic cystic cavity interpreted as a urethral obstacle with bladder distension. Sacrum was also described as disproportionately short, raising the differential diagnosis of caudal regression syndrome. Due to multiple malformations a medical termination of pregnancy was performed.
Results: Autopsy findings include association of imperforated anus, ambiguous external genitalia and markedly distended pelvic organs: megabladder with 5,5x4,5x2,5 cm; hydrocolpus with 5,5x3x3,5 cm and colon with 2,5 cm of maximum perimeter. The urethra and rectum had stenosis and both communicated with the vagina through fistulas. The kidneys had increased weight and pyelocalicial dilation, without evidence of dysplasia. Additional findings include double uterus, lumbar hemi-vertebra and fusion of the last two sacral vertebrae. The placental evaluation revealed a single umbilical artery. The diagnosis was consistent with URSM sequence.
Conclusion: URSM sequence is a severe congenital anomaly of unknown aetiology, involving multiple organ systems, associated with cloacal malformations. The findings of ambiguous genitalia and dilated colon can raise the suspicion of this diagnosis during the pre-natal ecographic screening and prompt medical termination of pregnancy. Careful pathological examination is important to identify this complex malformation sequence and allow correct follow-up and further investigation.

E-PS-01-002
Fatal outcome of a perilaryngeal cavernous haemangioma with laryngeal extension: a case report

L. Muresan[1], A. Bucur[1,2], E.H. Stefanescu[3,4], F. Zara[1,2]
[1]Emergency City Hospital, Pathology, Timisoara, Romania, [2]University of Medicine and Pharmacy "Victor Babes", Microscopic Morphology, Timisoara, Romania, [3]Emergency City Hospital, Otorhinolaryngology, Timisoara, Romania, [4]University of Medicine and Pharmacy "Victor Babes", Otorhinolaryngology, Timisoara, Romania

Background & Objectives: Cavernous haemangiomas are benign vascular malformations that can present in various organs, most frequently in the skin and liver. Involvement of the larynx and perilaryngeal tissues is rare but may lead to life-threatening complications. This report presents an interesting case of multifocal cavernous hemangiomatosis with fatal outcome due to airway obstruction, aiming to highlight the potential severity of these lesions and the importance of long-term follow-up.
Methods: A postmortem examination was performed on a 77-year-old female with a known history of cavernous haemangiomas of the skin and a previously resected laryngeal haemangioma. Clinical history, gross and histopathological findings were correlated to determine the cause of death.
Results: The autopsy revealed a large cavernous haemangioma located in the perilaryngeal soft tissue with direct extension into the laryngeal structures. The lesion caused marked glottic oedema and extensive haemorrhagic suffusions within the laryngeal mucosa. These findings resulted in critical upper airway obstruction and subsequent acute respiratory failure. Multiple cutaneous cavernous haemangiomas were observed on the laterocervical region, along with hepatic hemangiomatosis. Histopathological examination of the pancreas revealed incidental findings of low-grade pancreatic intraepithelial neoplasia (PanIN-1), without evidence of invasive carcinoma.
Conclusion: This case illustrates a rare but severe presentation of cavernous haemangioma involving the perilaryngeal and laryngeal structures, leading to fatal airway compromise. It underscores the importance of considering recurrent or progressive vascular malformations in patients with a history of multiple haemangiomas, even after long periods of clinical stability. Early recognition and long-term monitoring of such lesions are essential to prevent potentially life-threatening outcomes.

E-PS-01-003
Idiopathic giant cell myocarditis: an autopsy case report

D. Rus-Gonciar[1,2], M. Mureșan[1]
[1]County Emergency Hospital Cluj-Napoca, Department of Pathology, Cluj-Napoca, Romania, [2]"Iuliu Haţieganu" University of Medicine and Pharmacy, Department of Morpho-Functional Sciences, Cluj-Napoca, Romania

Background & Objectives: Idiopathic giant cell myocarditis is a rare condition, with immune-mediated pathogenesis, that mainly affects young to middle-aged patients, and may rapidly progress to arrhythmias and heart failure. We present an autopsy case of fatal idiopathic giant cell myocarditis in a 40-year-old female patient, with previous history of thymoma and doxorubicin treatment.
Methods: An autopsy was performed and relevant tissue samples were collected for microscopic evaluation on haematoxylin-eosin stain. Special stains and immunohistochemistry assessments were also conducted.
Results: The heart exhibited pressure-overload hypertrophy. In the superior mediastinum, an encapsulated tumour was identified, measuring 7.5/4.3 cm, adherent to the visceral and parietal pleura

of the left lung. In the left paravertebral, supradiaphragmatic region, another nodular tumour was observed, with a similar aspect, measuring 8.5/5.5 cm. The microscopic examination of the myocardium revealed a marked inflammatory infiltrate, with neutrophils, eosinophils, lymphocytes, macrophages, and multinucleated giant cells, with foci of cardiomyocyte necrosis. No well-formed granulomas were observed. The special stains performed were negative for the presence of infectious agents. The sections examined from the two tumours were compatible with thymic carcinoma.
Conclusion: This case illustrates a rare case of idiopathic giant cell myocarditis that occurred in a patient with at least two risk factors (thymoma/thymic carcinoma and previous chemotherapy), with fulminant and fatal evolution. The marked left ventricular hypertrophy without gross evident signs of myocarditis is another particular aspect of this case, emphasizing the importance of correlation with clinical and microscopic findings.

E-PS-01-004
Case report of a foetal GLI3-related Pallister-Hall syndrome and literature review
E. Tornay Mora[1], M.A. Abad Vintimilla[1], R.M. Regojo Zapata[1], V. Hincapié Baena[1], V. Diaz Castro[1], G.H. López Arze[1]
[1]Hospital Universitario La Paz, Madrid, Spain

Background & Objectives: GLI3-related Pallister-Hall syndrome (PHS) is an autosomal dominant disorder causing a wide range of abnormalities, including mesoaxial or postaxial polydactyly, hypothalamic hamartoma, bifid epiglottis, and other malformations affecting the limbs, genitourinary system and midline. Around 25% of cases result from de novo mutations.
Methods: Our findings have been obtained from a necropsy of a 22+3 weeks of gestation foetus. Interruption of the pregnancy was performed due to foetal malformations, with right renal agenesis and an presumptive ecographic diagnosis of arthrogryposis due to lower limb hyperextension and upper limb hyperflexion diagnosed at 21 weeks of gestation. We also performed a radiological study and a study of the placenta.
Results: The necropsy revealed bilateral renal hypoplasia, with a remnant of the right kidney measuring 5 mm showing dysplasia and left kidney pelvicalyceal dilation, imperforate anus, bilobed right lung, septate uterus, and empty sella. Radiological findings included postaxial polydactyly in the right hand, oligodactyly in the left hand, postaxial polydactyly with syndactyly in the left foot and delayed ossification. Placental histology showed dysmorphic villi with trophoblastic pseudoinclusions. Exome sequencing in amniotic fluid identified a de novo GLI3 mutation, confirming Pallister-Hall syndrome.
Conclusion: The present report highlights a rare case of PHS syndrome. Although some of the characteristic features were not confirmed in this case (bifid epiglottis, hypothalamic hamartoma), many findings were concordant with it, including oligodactyly, polydactyly and renal and uterus malformations. Absent or small pituitary gland has been described in some case reports, although is not a classical sign.

E-PS-01-005
A rare case of atelosteogenesis type II in the diastrophic dysplasia sulfate transporter spectrum: foetal autopsy findings and pathological features
M. Mexia Leitão[1], M. Zbronska[1], G. Carrola[1], F. Lima Coelho[2], M. Abreu[3], D. Macedo Cardoso[3], A. M. G. Pereira[1]
[1]Unidade Local de Saúde de Santo António (ULSSA), Pathology Department, Porto, Portugal, [2]Unidade Local de Saúde de Santo António (ULSSA), Radiology Department, Porto, Portugal, [3]Jacinto Magalhães Centre for Medical Genetics, Unidade Local de Santo António (ULSSA), Medical Genetics Service, Porto, Portugal

Background & Objectives: Mutations in the Diastrophic Dysplasia Sulfate Transporter (DTSDT, gene *SLC26A2*) cause a spectrum of skeletal dysplasias, ranging from lethal to non-lethal forms. These include Achondrogenesis Type 1B (ACG-IB), Atelosteogenesis Type II (AO2), Diastrophic Dysplasia (DTD), and recessive Multiple Epiphyseal Dysplasia (rMED). The sulfate transporter is essential for sulfate ion uptake, which is crucial for cartilage matrix integrity. Impaired cartilage sulfation in AO2 leads to abnormal endochondral ossification and severe skeletal deformities.
Methods: We report a case of an a 19-week foetus presenting with large cystic hygroma, short limbs, and persistent fixed limb hypokinesia on ultrasound, raising suspicion of severe skeletal dysplasia. Due to the poor prognosis, the pregnancy was medically terminated, and a postmortem examination was performed. Amniocentesis showed a normal karyotype and no abnormalities on array CGH.
Results: Radiographic findings revealed billateral trident acetabula and shortening of the long bones in both upper and lower limbs, consistent with a rhizomelic pattern. Autopsy showed facial dysmorphism and skeletal abnormalities, with most pronounced changes in the appendicular skeleton. These included macrocephaly, microretrognathia, shortened limbs with angulation, hitchhiker thumbs and halluces, brachydactyly, syndactyly, bilateral clubfoot, and a bell-shaped thorax. Histologically, there were signs of foetal hypoxia, with irregular and intramembranous ossification in long bones. Additionally, cystic/myxoid degeneration of resting cartilage pointed to abnormal skeletal development. Molecular analysis identified the pathogenic variants *c.532C>T p.(Arg178*) and c.835C>T p.(Arg279Trp),* in compound heterozygosity, seen in both AO2 and DTD.
Conclusion: The overlap in radiological, pathological, and genotypic findings between AO2 and DTD complicates diagnosis, requiring a multidisciplinary approach. AO2 was favoured due to its severe presentation and poor prognosis, with most affected infants not surviving beyond the neonatal period. In contrast, DTD is typically diagnosed later, presents with a milder phenotype, often manageable with appropriate treatment, and can allow for a significantly longer life expectancy, even a normal lifespan.

E-PS-01-006
Filamin A mutation associated malformations: a necropsy report
V. Díaz Castro[1], M.A. Abad Vintimilla[1], E. Tornay Mora[1], V. Hincapié Baena[1], C.R. Mena Soria[1], M. Parron Pajares[2], R.M. Regojo Zapata[1]
[1]Hospital Universitario La Paz, Anatomic Pathology, Madrid, Spain, [2]Hospital Universitario La Paz, Radiology, Madrid, Spain

Background & Objectives: Filamin A (FLNA) stabilizes actin networks, aiding cell motility. FLNA mutations cause developmental cardiovascular, skeletal malformations, periventricular nodular heterotopia and otopalatodigital spectrum disorders, exhibiting genotype-phenotype correlation and likely gain of function effects.
Methods: Our findings have been obtained from a complete necropsy of a 31 weeks old male foetus with postmortem radiology, placenta analysis, and genetic studies of the amniotic fluid. The studies were initiated following an ultrasound detecting cardiac and brain abnormalities later confirmed by foetal brain magnetic resonance imaging (MRI). Pregnancy was terminated due to severe malformations.
Results: The 31+6 weeks stillborn (1560 g, p50-75) presented microretrognathia, low-set ears, and hypertelorism. Radiology showed short, symmetric first fingers with clinodactyly, delta-shaped proximal phalanges, broad distal phalanges, and a small distal notch in the left hand. The feet had short proximal first-toe phalanges. Long bones were slightly thin, ribs were short and bell-shaped, with six lumbar vertebrae and asymmetric sacroiliac ossification. Brain histological anomalies included dentate nucleus and bulbar olive dysplasia. During foetal life, genetic analysis detected a hemizygous variant in the

FLNA gene. Prenatal imaging revealed vascular ring, right aortic arch with aberrant left subclavian, and left isomerism. Foetal brain MRI showed cerebellar vermis hypoplasia and corpus callosum dysgenesis. The placenta showed a dysmorphic and hypoplasic villous.
Conclusion: This case reinforces the crucial role of FLNA in organogenesis, demonstrating its involvement in multiple developmental pathways. The genotype-phenotype correlation observed in this case highlights the complexity of FLNA mutations and their variable expressivity. The combination of phenotype, radiological, histological, and genetic analyses provides a comprehensive understanding of the syndrome's manifestations. Further research on filamin A function will improve diagnostic approaches and potential therapeutic strategies for related disorders.

E-PS-01-007
Myocarditis at autopsy: review of 3 cases with different aetiological factors
S. Jogai[1]
[1]University Hospital Southampton NHS Foundation Trust, Cellular Pathology, Southampton, United Kingdom

Background & Objectives: The diagnosis of myocarditis may remain challenging during life. At autopsy the macroscopic findings may be subtle and inconclusive. However on microscopy the striking findings within the myocardium can help render the diagnosis. In this series I would like to present three cases with different aetiological factors.
Methods: Case 1: A 36-year-old man presented with history of fever and feeling unwell. Investigations showed left ventricular impairment and raised troponin and he died before a conclusive diagnosis. The clinical differential diagnoses included an unusual infection, myocarditis, systemic inflammatory condition or a pulmonary embolism.
Case 2: A 62-year-old male was admitted with one day history of fever. He had a background history of allogeneic peripheral blood stem cell transplant for myelodysplastic syndrome. Investigations showed evidence of neutropenic sepsis and it was suspected that he had an infective source in the central nervous system. He had a VT arrest and it was suspected that this could be drug induced Brugada syndrome.
Case 3: A 51-year-old male became unresponsive in a car park and an echocardiogram performed at emergency department showed a standstill heart. He had a background history alcohol misuse, drug overdose and mental illness for which he was receiving olanzapine.
Results: All 3 cases showed evidence of myocarditis
Case 1: Florid lymphocytic myocarditis, further investigations revealed very high SARS-Cov-2 antibodies. This was concluded as a case of multisystem inflammatory syndrome-adults (MIS-A, post COVID-19).
Case 2: Florid lymphocytic myocarditis and occasional toxoplasma cysts identified, consistent with toxoplasma myocarditis.
Case 3: Eosinophilic myocarditis and taking into account the background history olanzapine induced eosinophils myocarditis was proposed as the most likely cause of death
Conclusion: These three cases exemplify the important role that histology plays in arriving at the correct diagnosis of myocarditis and offering an accurate cause of death.

E-PS-01-008
Short Rib Polydactyly syndrome in a Filipino infant: a case report
K.A.J. Curso[1], P.M. Dy[1], B.J.A. Veloso[1], E.M. Yturralde[1], J.H. Mendoza[1]
[1]Philippine General Hospital, Laboratories, Manila, Philippines

Background & Objectives: Skeletal dysplasias (SD) are rare genetic disorders affecting bone and cartilage development, leading to abnormal growth. Prenatal ultrasound findings, such as short or dysmorphic long bones, often suggest SD, confirmed by postnatal X-rays and physical examination.
Methods: This autopsy involves a preterm infant born at 35 weeks AOG to a 35-year-old primigravid. Prenatal ultrasounds and postmortem X-rays suggest SD. Craniofacial abnormalities include a midline cleft lip and low-set, dysplastic ears. The thorax is narrow, and all extremities are short, with postaxial polydactyly and syndactyly of the right 4th and 5th fingers. The right lung is hypolobated, and the foetal lung weight to body weight ratio is <10th percentile. Microscopic lung examination shows a radial alveolar count of <4, indicating pulmonary hypoplasia. The kidneys are light, with multiple cysts, indistinct corticomedullary junctions, and poorly defined medullary pyramids. The cysts are lined by cuboidal epithelium, with immature stromal elements, primitive tubules, glomeruli, and cartilage islands, indicating multicystic dysplastic kidneys. The genitalia are ambiguous, but karyotyping confirms a 46, XY male.
Results: SDs occur in 1 in 4000 births, with 25% of affected infants stillborn. Short Rib Polydactyly Syndrome, characterized by a narrow thorax, short extremities, postaxial polydactyly, pulmonary hypoplasia, and craniofacial/genitourinary abnormalities, aligns with this case. Diagnosis is mainly clinical, radiologic, and pathologic, but genetic testing for the DYNC2H1 gene, which encodes motor proteins essential for ciliogenesis, offers a definitive diagnosis.
Conclusion: Limited access to genetic testing restricts the ability to definitively diagnose overlapping SDs. This case highlights the importance of a comprehensive autopsy, combined with prenatal and postmortem radiologic findings, in providing diagnostic clarity, aiding in parental counselling and prenatal care.

E-PS-01-009
The death of a 25-year-old male with sickle cell trait and lymphocytic myocarditis. Histopathological, molecular, and ultrastructural findings: an autopsy case report
G. Rojas Echarry[1], P. Molina Aguilar[2], C. Fernández-Sellers[2], R. Blanco-Máñez[1], D. Ramos Soler[1]
[1]Hospital Universitari i Politecnic La Fe, Pathology, Valencia, Spain, [2]Institute of Legal Medicine and Forensic Sciences, Forensic Pathology Service, Valencia, Spain

Background & Objectives: Sickle cell trait (SCT) is typically considered a benign and asymptomatic carrier state (Hb AS); however, recent studies have indicated it may increase the risk of sudden death under certain circumstances. Lymphocytic myocarditis (LM), characterized by lymphocyte-mediated myocardial inflammation is also recognized as a major cause of sudden unexpected death in young adults. This report aims to present and discuss the clinical, pathological, and molecular findings in a case of sudden death in a young patient with SCT and LM, highlighting potential clinical implications.
Methods: A comprehensive pathological examination was performed in a 25-year-old male patient who presented sudden cardiac arrest at home, preceded by bradycardia and unconsciousness. Methods included macroscopic and histological assessment of the heart and other organs, immunohistochemical staining for CD3-positive T lymphocytes, ultrastructural examination of erythrocytes within myocardial capillaries, molecular identification of the Hb S mutation through next-generation sequencing (Devyser Thalassemia panel), and PCR-based testing for viruses commonly associated with myocarditis (HHV8, Parvovirus B19, and adenovirus).
Results: Macroscopically, cardiomegaly (550 g) was observed with signs of systemic congestion, but no evidence of pulmonary or

coronary thrombi or emboli. Histological analysis revealed a lymphocytic inflammatory infiltrate (up to 21 cells/mm²), myocardial focal necrosis, and subendocardial hypereosinophilic areas. Ultrastructurally, abundant sickle-shaped erythrocytes were identified within myocardial capillaries, arranged as fiber bundles. Molecular testing confirmed the heterozygous c.20A>T (Hb S) mutation, consistent with sickle cell trait. Viral PCR results were all negative.
Conclusion: The sudden death of this young male patient with sickle cell trait and lymphocytic myocarditis remains unclear, as neither condition alone can be definitively established as the sole cause. The coexistence of myocardial inflammation, focal necrosis, and ultrastructural evidence of sickled erythrocytes within myocardial capillaries suggests a potential multifactorial scenario. Further research is needed to determine whether these conditions contributed independently or synergistically to the patient's death.

E-PS-01-010
Hypoxic-Ischemic injury and its relationship with placental lesions: a 20-year analysis of foetal, perinatal and infant autopsies
S. Quinones[1], C. Simón de Blas[2], M. De Uribe-Viloria[3], V. Macarrón[1], E.P. Sánchez-López[1], G. Barrios[4], J. Andrade-Restrepo[1], A. Andreu-Cervera[5], V. Company[5], M. Martínez-Sempere[5], E. Puelles[5], E. Maranillo[6], R.M. Regojo[1], I. Esteban-Rodríguez[1]
[1]La Paz University Hospital, Pathology, Madrid, Spain, [2]Universidad Rey Juan Carlos, Computer Science and Statistics Department, Madrid, Spain, [3]Clínico de Valladolid University Hospital, Valladolid, Spain, [4]Health Diagnostic. QuirónSalud Group, Madrid, Spain, [5]Institute of Neurosciences (CSIC-UMH), Campus de San Juan, Alicante, Spain, [6]Faculty of Medicine, Universidad Complutense, Department of Anatomy and Embryology, Madrid, Spain

Background & Objectives: Central nervous system (CNS) development depends on maternal health, placental function, and neonate´s cardiopulmonary system, influencing susceptibility to hypoxic-ischemic encephalopathy (HIE). Several studies suggest that placental abnormalities play a critical role in brain injury pathophysiology. This study aims to analyse the relationship between selective acute neuronal necrosis (SANN) and placental lesions, identifying the most vulnerable brain regions.
Methods: We reviewed foetal (from week 22), perinatal, and infant autopsy records from 2000 to 2019. Cases with selective acute neuronal necrosis (SANN) in more than one vascular territory were selected, and associated placental lesions were classified using the Amsterdam Consensus Criteria.
Results: Among 205 SANN, placental studies were available in 122 cases (122/205, 59.5%), with some type of lesion observed in 97 cases (97/122, 79.5%). The most frequent placental pattern was maternal vascular malperfusion (MVM), presented in 68 cases, either alone or combined with other lesions (55.7%). It was followed by foetal vascular malperfusion (FVM) in 47 cases (38.5%), chronic villitis in 38 cases (31.1%) and ascending intrauterine infection (AII) in 30 cases (24.6%). More than half (51.6%) presented extreme placental percentiles (<p10 and >p90).
Both MVM and FVM were significantly associated with greater damage to the pons (p=0.003). In cases of AII, there was a slight correlation with the pons, although it did not reach statistical significance (p=0.078). Additionally, MVM was linked to increased involvement of the dentate nucleus (p = 0.047). In contrast, chronic villitis was not significantly associated with any specific area.
Conclusion: Our findings demonstrate a clear association between placental lesions and hypoxic-ischemic injury. Moreover, they highlight the predictive value of these abnormalities, as specific placental lesions correlate with involvement in different brain areas. These results underscore the importance of placental examination in understanding neuropathological injury.

E-PS-01-011
Approaches to the pathoanatomical study of lymphatic vessels of the lower limb in conditions of military trauma
Y. Kuzyk[1], Y. Maksymchuk[2]
[1]Danylo Halytsky Lviv National Medical University, Pathological Anatomy and Forensic Medicine, Lviv, Ukraine, [2]Danylo Halytsky Lviv National Medical University, Normal Anatomy, Lviv, Ukraine

Background & Objectives: The issue of limb amputation has become one of the most pressing problems of military surgery in the conditions of the Russian- Ukrainian war. The visualization of lymphatic vessels remains out of the attention of pathologists due to the complexity of their study.
This study aims to develop an accessible pathoanatomical method for examining the lymphatic vessels of the skin in amputated limbs.
Methods: The study was conducted on eight re-amputated stumps of male patients aged 25 to 40. The surgical material included stumps below the knee.
Results: A separated skin preparation with subcutaneous fat and superficial fascia, heated in warm water, was laid on a wooden surface with the epidermis facing up. The injection mass, which included 1 g of artistic oil paint "Perlin blue" and 20 mL of chloroform, was injected into the distal edge with a 1.0 mL insulin syringe at the exact site of the incision, under the epidermis. After each subsequent injection, the skin preparation was massaged with a glass cylinder toward the injection site. The successful injection procedure was indicated by the leakage of the injection mass from the proximal end of the preparation section. After that, the preparation was fixed in a 10% formalin solution. Then, fragments measuring 1.0 cm × 1.0 cm each, with an injected lymphatic vessel in the centre, were cut out for histological examination. During histological examination, lymphatic vessels were contrasted with blue, unlike arteries and veins. When using this technique, chloroform, which is diluted with oil paint, evaporates, leaving the paint in the lumen of the lymphatic vessel.
Conclusion: Studying the condition of the lymphatic vessels of limb stumps allows you to determine the pathomorphological changes occurring in them. This can improve patient treatment, preserving a larger portion of the lower limb for subsequent prosthetics.

E-PS-01-012
Prevalence of cardiac amyloidosis in forensic autopsies: a clinicopathological analysis (2023-2024)
L. Hato Salmon[1], È. Iglesias-Martínez[1], J. Arrieta[1], B. Morentin[1]
[1]Basque Institute of Legal Medicine, Forensic Pathology, Bilbao, Spain

Background & Objectives: Amyloidosis is a heterogeneous disease characterized by extracellular deposition of misfolded proteins in organs and tissues. Cardiac involvement is associated with high morbidity and mortality. This study aims to analyse the epidemiological and clinicopathological characteristics of cardiac amyloidosis (CA) identified in forensic autopsies.
Methods: Retrospective study based on forensic autopsies conducted in a Southern European province between 2023 and 2024. Autopsies were performed according to the Association for European Cardiovascular Pathology guidelines, including histopathological analysis. All cases with histologically confirmed CA were included. The following variables were analysed: sex, age, cardiovascular risk factors, cardiac imaging findings, clinical manifestations associated with CA, and both macroscopic and microscopic autopsy findings. Results were statistically analysed using SPSS.
Results: A total of 36 cases (3%) of CA were identified among 1,251 autopsies performed during this period, with one previously diagnosed and one suspected during life. The mean age was 87.4 years (SD 8; range: 65–100). Prevalence was higher in individuals ≥75 years (33/364; 9%) and in males (81% vs. 19%) (p=0.01). 24

cases were violent deaths, and among the remaining natural deaths, 8 were of cardiac origin, including one due to CA. Cardiovascular risk factors were present in 31 cases and clinical features of CA in 29, mainly atrial fibrillation and bundle branch blocks. All cases showed increased heart weight at autopsy. Amyloid deposits in other organs (mainly lungs) were found in 15 subjects.
Conclusion: CA is a relatively common autopsy finding in elderly individuals, especially men over 75. In most cases, the disease had not been diagnosed during life. Although violent death was the most common cause, some cases suggested that CA may have contributed to mortality. Clinical findings such as atrial fibrillation, conduction abnormalities, and unexplained cardiac hypertrophy in elderly males should raise clinical suspicion to improve early diagnosis and potentially prevent fatal outcomes.

E-PS-01-013
Can structural changes in the parotid salivary glands serve as a compensatory mechanism in type 2 diabetes?
V. Mironov[1], A. Ivanov[2], E. Lyalina[2], N. Zhuravleva[3], E. Guryanova[1,3], N. Ukhterova[3]
[1]Postgraduate Doctors Training Institute, Cheboksary, Russia, [2]Respublican Buro, Cheboksary, Russia, [3]Chuvash State University by I.N. Ulianov, Cheboksary, Russia

Background & Objectives: In diabetes, hypertrophy of the salivary glands occurs as a compensatory mechanism: increased production of parotene and synthesis of insulin-like substances partially compensate for the deficiency of insulin in the pancreas. The aetiology of sialadenosis remains poorly understood, and the role of LV in compensating for insulin deficiency has been proven. The aim of the work was to identify the morphological features of changes in the parotid gland in diabetic sialodenosis.
Methods: 62 salivary glands taken from the deceased aged 45 to 56 years were examined. The first group included people with type 2 diabetes mellitus (N=36), and the second group included people without diabetes mellitus (N=26). Anatomical and histological structures of the salivary glands were studied, the severity of dyscirculatory disorders, dystrophic changes and compensatory adaptive reactions were determined.
Results: Patients with diabetic sialodenosis showed a significant increase in the mass (38.9±1.2 g) and volume (by 34%) of the parotid salivary glands compared with the control group. The area of terminal acinuses in group 1 exceeded the control values by 8.11±0.73 mm2 ($p<0.001$) due to hypertrophy of secretory cells with granular inclusions. The ratio of parenchyma to stroma is 69:31 in group 2, 47:53 in group 1, which is associated with fat replacement and stroma fibrosis. An increase in the area of the insertion ducts (38.19±4.74 mm2 versus 21.98±2.19 mm2) and the presence of eosinophilic secretions in 23% of cases indicate compensatory hyperfunction of the salivary glands. In group 1, the nuclei in the acinus cells were shifted to the apical part (72%), which correlated with an increase in the optical density of serocytes.
Conclusion: The revealed patterns indicate an active secretory function and reflect the compensatory role of these characteristics in case of insulin deficiency.

E-PS-01-014
Toothpaste tumour or caseous calcification of the mitral valve: a rare autopsy finding
A. Pryalukhin[1], M. Kozak[2], M. Tscharre[3], W. Hulla[1]
[1]University Hospital Wiener Neustadt / Danube Private University, Department of Pathology and Molecular Pathology Thermenregion, Wiener Neustadt, Austria, [2]University Hospital Wiener Neustadt, Department of Pathology and Molecular Pathology Thermenregion, Wiener Neustadt, Austria, [3]University Hospital Wiener Neustadt, Clinical Department of Internal Medicine II, Cardiology, Nephrology and Internal Intensive Care Medicine, Wiener Neustadt, Austria

Background & Objectives: So-called "toothpaste tumours" of the heart, medically referred to as caseous calcification of the mitral valve (CCMV), are rare pathological findings. These lesions are predominantly reported in radiological and cardiological literature and are scarcely mentioned in standard pathology textbooks. Their rarity and imaging appearance can pose a diagnostic challenge, particularly in autopsy settings where the lesion may be misinterpreted. This case highlights the importance of pathologists being familiar with such entities.
Methods: During a standard clinical autopsy of a 77-year-old female patient with known secondary mitral valve insufficiency, type I diabetes mellitus, advanced arteriosclerosis, and a cardiac pacemaker implanted three years prior, the heart was examined macroscopically and photographed. Following formalin fixation, representative tissue samples were embedded in paraffin and analysed histologically using haematoxylin and eosin (H&E), alcian blue / PAS, Masson's trichrome, and Gram stains. Immunohistochemistry included CD45, CD3, CD20, CD163, CD68. All slides were digitized.
Results: The lesion was not identified in the emergency setting via transesophageal echocardiography. The cause of death was determined to be acute heart failure due to ischemic cardiomyopathy and chronic valvular disease. On gross examination, a homogeneous, beige, toothpaste-like mass was observed in the mitral annular region. The mitral valve exhibited nonbacterial thrombotic endocarditis with pronounced calcifications, alongside chronic occlusive coronary disease. Histology revealed amorphous, amphophilic, acellular material surrounded by macrophages, neutrophilic granulocytes, plasma cells, and predominantly CD3-positive T-lymphocytes. Adjacent myocardial tissue showed multifocal calcifications and areas of fibrosis. Histochemical stains for fungi and bacteria were negative.
Concl.usion: This rare autopsy finding of a toothpaste-like mass in the mitral annulus underscores the need for pathologists to be aware of caseous calcification of the mitral valve. Proper histological interpretation and clinical correlation are essential, as these lesions may be underrecognized. Collaborative discussion with cardiology is recommended to ensure accurate diagnosis and documentation of such unusual cases.

E-PS-01-015
Eosinophilic pulmonary vasculitis in Sjögren's syndrome: un unusual association
D. Mulone[1], E. Nardi[2,3], V. Arena[3]
[1]Anatomia Patologica, Dipartimento di Diagnostica e Sanità Pubblica, Università di Verona, Verona, Italy, [2]Anatomia Patologica, Dipartimento di Scienze della Salute, Università di Firenze, Firenze, Italy, [3]Area Anatomia Patologica, Fondazione Policlinico Universitario A. Gemelli, Dipartimento di Scienze della Salute della Donna, del Bambino e di Sanità Pubblica, Roma, Italy

Background & Objectives: Sjögren's syndrome (SS) is an autoimmune disorder primarily affecting the salivary and lacrimal glands, causing dry mouth and eyes. In 10-20% of cases, the lungs are involved, manifesting as interstitial lung disease (ILD). This report presents an unusual case of pulmonary eosinophilic vasculitis (PEV) in a patient with SS.
Methods: A 71-year-old woman with a medical history of SS, systemic hypertension, diverticular disease, asthmatic COPD, and allergy to NSADs was admitted for persistent nausea and vomiting for 10 days, along with a recent rectal bleeding. Blood tests showed hypereosinophilia and elevated inflammatory markers. Stool analysis for parasites and fungi yielded negative results. During hospitalization, she developed progressive dyspnea, prompting a CT scan that

revealed diffuse thickening of the bronchial walls and peribronchial tissue in the lungs, consistent with chronic bronchitis. On the day following admission, she was found deceased in her bed. Clinicians suspected cardiac arrest; however, autopsy was performed to rule out hypereosinophilic enteritis. Upon necropsy, the large intestine featured oedematous walls and numerous rectal ulcers, with no evidence of hypereosinophilic enteritis. Other organs exhibited pallor, attributed to chronic anaemia. Notably, the lungs appeared oedematous with reinforcement of perivascular and peribronchial tissues. Histological examination confirmed mucus plugs in the bronchial lumen, associated with smooth muscle hypertrophy and inflammatory infiltrate, supporting the asthma diagnosis. Unexpectedly, a dense eosinophilic infiltrate was observed in the perivascular space and within the walls of small- and medium-caliber lung vessels, sparing the interalveolar septa. No inflammatory vascular involvement was detected in other organs. Consequently, isolated PEV was diagnosed.
Results: In SS patients, ILD is often observed as a pulmonary condition. Although PEV alongside SS is infrequent, it is recognized as a potential scenario, with few documented cases.
Conclusion: This case highlights the importance of including PEV in the differential diagnosis for SS patients with blood hypereosinophilia.

E-PS-01-016
Advanced adrenocortical carcinoma with brain metastasis. A case report
A. Dobriakov[1], K. Opalenov[1], M. Alexandrova[1], A. Tokmakov[1], A. Chelyukanov[1], E. Kuznetcova[1]
[1]Moscow City Hospital F.I. Inozemtsev, Pathological Anatomy Department, Moscow, Russia

Background & Objectives: We report an autopsy case of advanced ACC with multiple liver, lung and brain metastasis.
An 82-year-old white male patient with a history of sudden and progressive deterioration of consciousness, vomiting, and left-sided hemiparesis was admitted to emergency department in the severe state. Non-contrast computed tomography (NCCT) and contrast-enhanced computed tomography (CECT) of the brain revealed hematoma in occipital lobe of the left hemisphere. He died in ten hours of multiple organ failure.
Methods: Autopsy. Histological examination of autopsy material using routine histological stains.
Results: The findings at autopsy were both right and left adrenal tumours with multiple metastasis involving liver, left lung, multiple lymph nodes and the occipital lobe of the left hemisphere of the brain with massive brain hematoma. Histological examination of primary adrenal tumours and metastatic tumour tissue from the brain revealed advanced adrenocortical carcinoma (oncocytic variant). The immediate cause of death was massive brain hematoma.
Conclusion: Adrenocortical carcinoma (ACC) is a rare aggressive malignancy with an annual incidence of 0.5–2 cases per 1 million population. Most cases of ACC are considered to be sporadic, but it can also present as part of hereditary syndromes such as Li–Fraumeni syndrome (LFS), Beckwith–Wiedemann syndrome, Carney complex and Multiple Endocrine Neoplasia (MEN)I. Up to 40% of patients already present with metastatic disease frequently involving liver, lung and bone at the time of diagnosis.

E-PS-01-017
Retrospective analysis of maternal mortality: obstetric direct and indirect causes in Kazakhstan in 2024
A. Sapargaliyeva[1,2], I. Yefimenko[3], N. Cherepkova[2]
[1]Almaty Pathology Bureau, Almaty, Kazakhstan, [2]Kazakh National University named after Al-Farabi, Faculty of Fundamental Medicine, Almaty, Kazakhstan, [3]Research Centre for Obstetrics, Gynaecology and Perinatology, Department of Pathology, Almaty, Kazakhstan

Background & Objectives: An analysis of 24 cases of maternal mortality out of 37 cases of maternal mortality registered in the Republic of Kazakhstan in 2024 was conducted.
Methods: The Research Centre for Obstetrics, Gynaecology, and Perinatology, Department of Pathology conducted a thorough analysis of autopsy reports spanning from January 1st, 2024, to December 31st, 2024 from different regions of Kazakhstan. We divided all cases into direct (11) and indirect maternal deaths (10).
Results: The analysis of obstetric maternal mortality cases showed that there were 4 cases of severe preeclampsia and HELLP syndrome; 2 cases of obstetric (maternal) sepsis; 2 cases of amniotic fluid embolism; 2 cases of postpartum haemorrhage; 1 case of acute fatty liver of pregnancy. In the group of obstetric maternal mortality, iatrogenic pathology in the intensive care unit was detected: tracheal necrosis complicating endotracheal intubation and mechanical ventilation-associated purulent bronchopneumonia, osmotic nephrosis. We attributed a case of uterine suture failure after caesarean section, which caused post-caesarean severe sepsis and uterine wound disruption, as iatrogenic pathology. Analysis of 10 cases of indirect causes showed that infectious diseases were detected in 4 cases: 3 cases -community-acquired pneumonia; 1 case - acute intestinal infection with necrotizing colitis. In all cases of infectious diseases, there was late consultation. Non-infectious pathology included 2 cases of subarachnoid haemorrhage; 2 cases of hyperthyroidism and thyrotoxicosis and in one case death occurred as a result of thyroid storm; in 1 case - unilateral renal agenesis and chronic tubulointerstitial nephritis of the right kidney; in 1 case - acute generalized lymphedema complicated by pulmonary embolism.
Conclusion: The analysis showed that obstetric maternal mortality dominates over indirect maternal mortality. Most cases of obstetric maternal mortality can be classified as manageable, while all cases of indirect maternal mortality are manageable.

E-PS-01-018
Arteriovenous brain malformation findings in forensic pathology
C. Amalinei[1,2], L.A. Riscanu[1,2], A. Grigoras[1,2]
[1]Grigore T. Popa University of Medicine and Pharmacy, Morphofunctional Sciences I, Iaşi, Romania, [2]Institute of Legal Medicine, Histopathology, Iaşi, Romania

Background & Objectives: Arteriovenous brain malformations (AVMs) represent vascular system developmental anomalies, composed of tangles of abnormal blood vessels, with arteries directly connected to veins, without interposing capillaries. Our study aims to analyse the characteristics of brain AVMs (BAVMs) associated with brain bleeding, diagnosed during autopsy, in the last 10 years, in our institution.
Methods: Autopsy examination has been associated with collection of tissue specimens for microscopy. Routine haematoxylin-eosin, elastin staining, along with SMA immunohistochemistry have been performed.
Results: The review of our files identified nine cases, which were diagnosed in five women (55.55%) and four men (44.45%), with age range between 20 and 85 years old, 66,66% being registered in people $\geq$ 50 years. Brain gross examination showed variable areas of intraparenchymal and subarachnoid space haemorrhages. The microscopic examination of the BAVMs revealed, beside haemorrhagic areas, high vascular density, variable degrees of venous enlargement, intimal hyperplasia, abnormal muscular layers, intra-luminal fibrin, infiltration with inflammatory cells in the vascular walls and in the perivascular spaces, and variable areas of gliosis. BAVM was associated, in a case, with a cyst lined by meningothelial cells, with areas of fibrosis and calcifications, diagnosed as an arachnoid cyst. The differential diagnosis included

other vascular pathologies, such as aneurysm, thrombosis, dissection, and stroke.
Conclusion: BAVMs show a large age distribution, with a relatively higher incidence in people of 50 years or older and women. Their main complication is cerebral haemorrhage, which is involved in the mechanism of death. The microscopic examination may add valuable information for diagnosis in these cases, showing haemorrhages, vessels anomalies, along with variable inflammation and glial cells reaction. Although relatively rare, BAVMs diagnosis is important in forensic practice, considering their involvement in thanatogenesis.

E-PS-01-020
Multiple (plasma cell) myeloma and systemic amyloidosis: clinical and histological characteristics
Z. Gioeva[1], L. Mikhaleva[1], V. Pechnikova[1], N. Shakhpazyan[1], K. Midiber[1], A. Tsytsaev[1], N. Gutyrchik[1,2], A. Tebenkova[1], L. Kakturskij[1]
[1]Avtsyn Research Institute of Human Morphology of Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Pathology, Moscow, Russia, [2]Peoples' Friendship University of Russia named after Patrice Lumumba, Moscow, Russia

Background & Objectives: Multiple myeloma (MM) is one of the common underlying causes of systemic AL amyloidosis. The study objective is to describe histopathological features of amyloid deposits in different organs of the patients with MM and systemic AL amyloidosis.
Methods: The study included 23 autopsy cases (15 males and 8 females). Histological sections were stained with haematoxylin and eosin and Congo red. Immunohistochemistry with a broad panel of antibodies against various amyloid types was used. Myeloma cells were verified with Syndecan-1/CD138 antibody.
Results: Based on clinical data, 12 patients had MM with monoclonal IgG of lambda type associated with extensive bone destruction, Durie-Salmon stage II (n=5) and III (n=7). In 7 patients the diagnosis of MM with monoclonal IgG of kappa type, Durie-Salmon stage III, was established. And in 4 cases a non-secretory MM, Durie-Salmon stage II and III, was found. Amyloidosis was diagnosed in 14 of 23 patients before death.
Microscopic postmortem examination revealed multiple amyloid deposits in the myocardial stroma, blood vessel walls. Findings in the liver included multiple sites of infiltration with atypical plasma cells with amyloid deposits in the spaces between hepatic plates and vascular walls. Diffuse amyloid deposits were detected in kidneys.The microscopy of vertebral bodies revealed accumulations of atypical polymorphic multinucleated plasma cells of various stages of maturity, plasmablasts and proplasma cells. Presence of immunoreactivity was proven in myeloma cells by using CD138 immunohistochemical staining. Based on IHC typing, AL lambda amyloidosis was determined in 16 cases (70%) and AL kappa – in 7 (30%).
Conclusion: The study demonstrated that patients with MM and co-occurring systemic AL amyloidosis had extensive amyloid deposits in organs leading to a rapid development of multiple organ failure.
Patients with MM should be investigated for coexisting systemic amyloidosis, which is an independent poor prognostic factor for MM.

Funding: This work was supported by the Russian Science Foundation, grant No 23-15-00138

E-PS-01-021
Histomorphological profile of postmortem inflammatory lung lesions
E.-R. Avadanei[1], R.-A. Balan[1], L. Lozneanu[1], S.-E. Giusca[2], C. Amalinei[1], I.-D. Caruntu[1]
[1]"Grigore T. Popa" University of Medicine and Pharmacy, Histology, Iassy, Romania, [2]"Grigore T. Popa" University of Medicine and Pharmacy, Pathology, Iassy, Romania

Background & Objectives: **Background:** The lung is a major organ involved in almost all fatal events. The lungs develop inflammatory lesions in the context of infectious and occupational diseases and, quite frequently, neoplasms. Postmortem examination provides unbiased, objective and useful information to understand the peculiarities of each individual's response to a given pathogen in relation to sex, age and comorbidities present.
Aims: To study the postmortem histopathological pattern of lung lesions in 26 cases.
Methods: We performed an observational study on 26 postmortem lung specimens collected at the Pathology Department of the Infectious Diseases Hospital "St. Parascheva", Iasi, over a period of 1 year from August 2023. The lung specimens were examined macroscopically and sections were taken from the most representative areas. These sections were processed for paraffin blocks; slides were prepared and stained with routine haematoxylin and eosin. The slides were examined microscopically and the results were recorded.
Results: Of the 26 cases, 15 cases showed changes of bronchopneumonia, 7 cases of pneumonia; 1 case of granulomatous pathology, 2 cases of chronic venous congestion and 1 case of non-specific terminal lesions.
Conclusion: The most common inflammatory lung disease leading to death is bronchopneumonia, which is usually complicated by sepsis. Lesions of the pneumonic type are less common, usually diagnosed in young patients, followed by tuberculosis. Efforts should therefore be made to prevent these infectious diseases.

E-PS-01-022
Autopsies and their significance: a survey of knowledge, attitudes, and practices among non-pathology residents at Korle Bu Teaching Hospital, Ghana
B. Adjei- Mensah[1], P. Pepra- Ameyaw[1]
[1]Korle Bu Teaching Hospital, Pathology, Accra, Ghana

Background & Objectives: Autopsy rates have experienced a decline in Ghana and globally. In anatomic pathology residency, residents to gain experience through hospital autopsies, both for educational purposes and to provide diagnostic services to clinicians. Autopsies offer insights into various medical conditions and even treatment modalities which may not be evident outside post-mortem examination. However, there have been alarming barriers to conducting hospital autopsies including a lack of clinician interest, family reluctance to consent to autopsies, and the increasing workload on pathologists, who are responsible for both coroners' and hospital autopsies in Ghana.
Methods: A survey was developed and distributed to non-pathology residents at Korle Bu Teaching Hospital. Responses were collected anonymously using Google Forms. Of the 42 residents invited, 30 participated, yielding a 71% response rate. The survey employed a 3-point Likert scale to assess residents' perceptions of the importance of autopsies, their knowledge of autopsy request procedures, interactions with pathologists, and perceived barriers to requesting autopsies.
Results: Respondents were from various specialties and exposure to autopsies varied, with 77% having observed an autopsy during their training, while 23% had no exposure to autopsy procedures. None of the respondents had assisted in or independently performed an autopsy. There was strong consensus regarding the value of autopsies. Regarding interactions with pathologists, only 10% of respondents felt that pathologists were easily accessible for discussing autopsy cases.The data suggested that clinicians highly value collaboration with pathologists with 96.67% of respondents reporting that they value educational discussions with pathologists after an autopsy. Perceived barriers to autopsy requests were significant: 76.7% believed autopsies were unnecessary when the cause of death

seemed obvious, 66% hesitated to request autopsies due to families being too distressed.
Conclusion: The survey shows that non-pathology residents value autopsies, but improving pathologists' accessibility and resident education on autopsy procedures will be important in improving hospital autopsy requests.

E-PS-01-023
Undiagnosed congenital heart defect in children under 5 years of age. Autopsy study from two pathology centres in South Africa
M. Khaba[1], N. Moganedi[1], C. Charmaine Van Wyk[2]
[1]Sefako Makgatho Health Sciences University, Anatomical Pathology, Pretoria, South Africa, [2]Sefako Makgatho Health Sciences University, Forensic Pathology, Pretoria, South Africa

Background & Objectives: Congenital heart defect is a hereditary abnormality of the heart structure arising from improper embryogenesis; it is the commonest birth defect that affects 1% to 2% of all live births across the world. The prevalence of congenital heart disease may be under-reported in Africa due to limited resources.
The objectives of this study was to report on the prevalence and subtypes of undiagnosed congenital heart defects at the two pathology centres in South Africa.
Methods: This was a retrospective, descriptive study of autopsies performed on children under 5 years at two pathology centres in Ga-Rankuwa, South Africa, between 01 January 2012 and 31 December 2020. The clinicopathological data concerning both the mother and baby were retrieved from the National Health Laboratory Service's laboratory information system and Forensic Pathology Services death registers. Data was analysed using a statistical software package.
Results: Within the study period, a total of 472 autopsies were performed on children aged 0 – 5 years at the two pathology centres. Of these, only 25 met the inclusion criteria and formed the study cohort, thus having a prevalence of 5.3%. The most frequent congenital heart disease diagnoses were atrial septal defect (8), ventricular septal defect (6), Tetralogy of Fallot (4), transposition of great vessels (4), atrioventricular septal defects (2) and patent ductus arteriosus (1). Associated lesions of the congenital heart disease comprised patent ductus arteriosus (6), atrial septal defect (2), hypertrophic right ventricle (2), and single atrium (1). Down syndrome was noted in 2 cases, while Treacher-Collins Syndrome was noted in 1 case.
Conclusion: The study highlights the complexity of undiagnosed CHD in infants, suggesting that academic entities in various fields should continue seeking state assistance to reduce healthcare delivery backlogs and invest in human resources through collaborative and financial efforts.

E-PS-01-024
Keratinizing squamous cell carcinoma of the cervix presenting with sister Mary Joseph nodule – a rare autopsy case report and a review of literature
P. Pepra-Ameyaw[1], B. Adjei-Mensah[1]
[1]Korle Bu Teaching Hospital, Pathology, Accra, Ghana

Background & Objectives: A 50-year-old female presented with a year-long history of postmenopausal bleeding, severe anaemia, and weight loss. Clinical signs included a cervical mass and a Sister Mary Joseph nodule at the umbilicus, a rare indicator of metastatic malignancy. Differential diagnoses included ovarian, endometrial, and cervical cancer. However, the patient declined to biopsy.
Methods: This case is a retrospective review of an autopsy following the patient's death. Clinical investigations indicated advanced malignancy, with signs of uremia from obstructive uropathy and distant metastases. The autopsy aimed to confirm the diagnosis and explore the malignancy's spread, including the possibility of spread to the umbilicus.
Results: Autopsy revealed a large, fungating cervical tumour extending to the uterus and bladder, causing bilateral hydronephrosis. The Sister Mary Joseph nodule was ulcerated with a necrotic core. Distant metastases were observed in the liver, spleen, and diaphragm. Histopathology confirmed keratinizing squamous cell carcinoma with keratin pearl formation and lymphovascular invasion. Tumour deposits were found in the umbilical nodule, bladder, liver, and spleen. These findings align with the aggressive metastatic behaviour of cervical cancer, emphasizing its capacity for early and widespread dissemination, often overlooked in traditional diagnostic frameworks. Advanced imaging and molecular profiling have revealed a growing understanding of the rapid spread of such cancers, especially through epithelial-mesenchymal transition (EMT), underscoring the importance of a comprehensive diagnostic approach.
Conclusion: This rare case highlights the unusual presentation of cervical squamous cell carcinoma with a Sister Mary Joseph nodule. It emphasizes the need for heightened awareness in postmenopausal bleeding cases, especially when metastatic signs are present. Early detection and intervention are critical, as this case illustrates the aggressive nature of cervical cancer, which, once metastasized, leads to a poor prognosis.

E-PS-01-025
Case report of Mitochondrial encephalomyopathy with lactic acidosis and stroke-like episodes (MELAS) syndrome and literature review
E. Tornay Mora[1], V. Diaz Castro[1], V. Hincapié Baena[1], M.I. Esteban Rodriguez[1], C. Gonzalez Garcia[1], M.A. Abad Vintimilla[1]
[1]Hospital Universitario La Paz, Madrid, Spain

Background & Objectives: MELAS is a mitochondrial syndrome characterized by stroke-like episodes, lactic acidosis, ragged-red fibres, and encephalopathy. Neuropathological findings include necrotic foci in the cortex, especially the occipital and temporal lobes, perivascular calcifications in the basal ganglia and sparing of the white matter.
Methods: A complete autopsy was performed on a 65-year-old female diagnosed with MELAS syndrome with genetic confirmation of m.3243A>G mutation. Additionally, a literature review was conducted.
Results: After reviewing the clinical history, the patient exhibited symptoms consistent with MELAS syndrome, including recurrent migraines, sensorineural hearing loss, hypertrophic cardiomyopathy, and type 2 diabetes. She presented to the ER with a refractory status epilepticus affecting the bilateral temporo-parietal region, compatible with a stroke-like episode. She died a month later due to ventilator associated pneumonia. CNS findings revealed diffuse brain atrophy, cortical laminar necrosis in the right temporal gyrus, arteriosclerosis, and signs of subarachnoid haemorrhage. Cardiopulmonary findings included slightly asymmetric hypertrophic cardiomyopathy, pulmonary hypertension and bronchopneumonia. Postmortem muscle biopsy showed a mild increase in lipid content with Oil Red O stain.

Conclusion: The findings in this case align with previous MELAS reports, including cardiomyopathy, white matter involvement with gyral predilection sparing sulci and gray matter, and diffuse brain atrophy. However, the typical perivascular calcifications in the basal ganglia were absent. While pulmonary hypertension is not a classic feature of MELAS, it has been reported in other autopsy cases. These findings highlight the variability in MELAS presentations and the importance of thorough neuropathological evaluation.

E-PS-01-026

Can AI replace the pathologist? Insights from 10 cases of indirect maternal mortality

A. Sapargaliyeva[1,2], R. Jumasheva[2], L. Sarsenova[2]
[1]Almaty Pathology Bureau, Almaty, Kazakhstan, [2]Kazakh National University named after Al-Farabi, Faculty of Fundamental Medicine, Almaty, Kazakhstan

Background & Objectives: An analysis of 10 cases of indirect maternal mortality was conducted using AI (ChatGPT Plus). The main goal of the study was to evaluate the accuracy and reliability of artificial intelligence in analysing autopsy data related to indirect maternal deaths, with and without expert input.
Methods: The Research Centre for Obstetrics, Gynaecology, and Perinatology, Department of Pathology, conducted a thorough analysis of autopsy reports spanning from January 1st, 2024, to December 31st, 2024, from various regions of Kazakhstan. We analysed all cases of indirect maternal deaths (10 cases).
The analysis of maternal mortality cases using artificial intelligence involved two approaches.
In four cases, the AI system was provided with complete expert-reviewed medical documents, including autopsy report with the final version of the diagnosis formulated by pathologist.
In six cases, all expert comments and remarks, as well as the expert's diagnosis, were removed. The AI was asked to create the final diagnosis in all cases.
Results: In both groups, there was a tendency for simplified interpretation of the final diagnosis. For example, in a case of rupture of a saccular basilar artery aneurysm, signs of obstetric sepsis such as purulent thromboendometritis were not considered, even as a underlying condition. There were also excessive diagnoses within the structure of conclusions, such as sepsis, which lacked morphological confirmation. In almost all cases, the cause of death was simplified to acute heart failure. In one case, the diagnosis of "alcoholic cardiomyopathy" was proposed, despite the absence of any history of alcohol use.
Conclusion: The use of AI in analysing cases of indirect maternal mortality revealed notable limitations in diagnostic accuracy. It is difficult to imagine AI even as a supportive tool, because it lacks the understanding of the context of the pathological process development. Attention to detail and nuanced interpretation remain a key advantage of an expert.

E-PS-01-027

Autopsy as a definitive diagnostic tool: a case of an occult primary collecting duct carcinoma

A. Alves[1], A. Lai[1], J. Maldonado[1], R. Almeida[1]
[1]ULS Coimbra, Coimbra, Portugal

Background & Objectives: Despite significant advances in imaging and molecular studies over the past decade, post-mortem examination remains an important tool for confirming diagnoses, identifying rare diseases and resolving clinical uncertainties. Besides providing clarity in individual cases, it continues to play a crucial role in medical education and quality improvement.
Methods: We present the case of a male patient in his 70s who developed sudden, intense lower back pain. Imaging studies revealed lytic lesions on the L3-vertebra and the left iliac bone, the latter involving the surrounding soft tissues. A biopsy of the iliac lesion showed an epithelial malignant neoplasia with an immunohistochemical profile suggesting a primary renal origin, though other sites could not be definitively excluded. Subsequent imaging studies and renal biopsy failed to identify the primary tumour, while revealing an increase in the iliac lesion size and multiple other skeletal metastasis. The patient died 4 months after symptom onset.
Results: Besides confirming the presence of multiple osteolytic masses, autopsy revealed an ill-defined perihilar mass in the right kidney, measuring 2.9cm. Histologically, the tumour displayed a tubular, vaguely papillary architecture, with cuboidal, focally fusiform, and even hobnail neoplastic cells. Mitotic activity was remarkable. The iliac mass, measuring 12cm, was histologically similar to the renal tumour. The immunohistochemical profile of both iliac and renal lesions was diagnostic of Collecting Duct Carcinoma (CDC). Molecular studies performed on the initial iliac biopsy showed *NF2* and *SETD2* mutations, both described in CDC, reinforcing our diagnostic certainty.
Conclusion: CDC is a rare and aggressive renal cell carcinoma, often arising in the renal medulla and frequently metastatic at diagnosis. Its diagnosis requires the exclusion of other renal malignancies. Due to its aggressiveness and usual location, an accurate, in vivo diagnosis can be challenging—as in our case—reminding us that autopsy can provide the final answer to clinical uncertainty.

E-PS-01-028

Autopsy-revealed miliary tuberculosis: a diagnostic challenge in sudden death cases

M. Hamdani[1], Y. Nouma[2], H. Ennouri[2], K. Belhaj Ali[3], A. Khabir[3]
[1]Regional Hospital Sadok Mkadem of Djerba, Department of Pathology, Djerba, Tunisia, [2]University Hospital of Medenine, Department of Forensic Medicine, Medenine, Tunisia, [3]University Hospital of Medenine, Department of Pathology, Medenine, Tunisia

Background & Objectives: Miliary tuberculosis (MT) is a severe, disseminated form of *Mycobacterium tuberculosis* infection, often presenting with non-specific clinical signs, leading to diagnostic challenges. Despite global efforts in tuberculosis control, MT remains a significant cause of mortality, especially in vulnerable populations. Autopsy plays a crucial role in identifying undiagnosed cases and understanding disease patterns.
Methods: We report three cases of autopsy-confirmed miliary tuberculosis, all discovered postmortem due to sudden and unexplained death. Complete gross and histopathological examinations were performed to confirm tuberculous aetiology.
Results: •**Case 1**: A young incarcerated male with no prior medical history was found dead in his cell. Pulmonary and hepatic granulomas with caseous necrosis confirmed MT.

- **Case 2**: A young female presenting with prolonged fever and neurological deterioration prior to death. Autopsy revealed meningeal, pulmonary, and hepatosplenic tuberculosis.
- **Case 3**: A Somali refugee found dead in a hotel after reporting abdominal pain. Autopsy demonstrated a multi-visceral tuberculous involvement with a pseudo-tumoral bronchial aspect, affecting the liver, spleen, lymph nodes, and peritoneum.

Conclusion: Miliary tuberculosis remains an elusive diagnosis, often missed ante-mortem due to its protean manifestations. These cases underscore the crucial role of autopsy in detecting undiagnosed tuberculosis. Postmortem identification is essential not only for determining the cause of death but also for preventing contagion by enabling contact tracing and timely treatment of exposed individuals.

E-PS-01-029

The diagnostic value of autopsy in Potter syndrome: implications for genetic counselling

M. Boros[1,2], D. Stefaroi[2], C. Beiusanu[1], I.R. Boros[1], A.A. Vesa Barbis[1]
[1]University of Oradea, Faculty of Medicine and Pharmacy, Morphological Disciplines, Oradea, Romania, [2]County Emergency Clinical Hospital Oradea, Pathology Department, Oradea, Romania

Background & Objectives: Potter sequence is a fatal condition affecting 1 in 4,000–6,000 newborns. The associated oligohydramnios is caused either by renal agenesis, renal cystic disease (including autosomal dominant and recessive polycystic kidney disease), or premature rupture of membranes. All of these conditions lead to pulmonary hypoplasia, along with facial and lower limb deformities. In this study, we present a case of Potter syndrome due to polycystic kidney disease.
Methods: Data for this case study were obtained from the autopsy report and the clinical information of both the infant and the mother.
Results: A 16-year-old primigravida and primipara woman with an unsupervised pregnancy presented to the hospital with hypogastric pain. Ultrasonographic examination revealed a term pregnancy with oligohydramnios and a plurimalformed foetus, characterized by enlarged kidneys and pulmonary hypoplasia. A mature female infant weighing 2700 grams was delivered vaginally. She required resuscitation in the delivery room and was admitted to the Neonatal Intensive Care Unit, where she died four hours later.
Autopsy revealed classical Potter facies, including low-set ears, widely spaced eyes with epicanthal folds, a flattened nose, retrognathia, and bilateral clubfoot.
A thorough internal examination showed bilateral pulmonary hypoplasia (2 × 1.5 cm), hypoplasia of the urinary bladder, and bilaterally enlarged, spongy kidneys (10 × 4 cm) with uniformly distributed small cysts, absence of cortico-medullary differentiation, and fusiform dilatation of the collecting ducts. These findings were associated with bilateral ureteral atresia and hepatic fibrosis.
Histopathological findings were suggestive of autosomal recessive polycystic kidney disease. The histology of the placenta did not provide any additional insights.
Conclusion: The necropsy results in this case highlight the crucial role of postmortem examination in identifying conditions that warrant genetic counselling, thereby aiding in the management of future pregnancies.

E-PS-01-030
Clinical and morphological features of fatal hypothermia
P. Aksenova[1], O. Reshetnikova[1], A. Ermakov[1]
[1]Immanuel Kant Baltic Federal University, Kaliningrad, Russia

Background & Objectives: Post-mortem diagnosis of a fatal hypothermia remains relevant in modern forensic medicine due to the uncertainty and inconsistency of pathomorphological diagnostic criteria. The aim of this study was a clinical and morphological analysis of deaths from cold injury.
Methods: Seventy-six cases of standardized autopsies in cases of deaths related to fatal hypothermia were performed. The study group included 60 males' and 16 female's bodies. The investigation reviewed clinical data, autopsy protocols, postmortem toxicological analyses. Histological slides stained with haematoxylin and eosin were studied at magnifications x 5; x20; x40. The findings were analysed together with clinical data from the medical records.
Results: Present study has revealed that 79% were male and 21% of female patients included into the group. Most often, victims were within the following age groups: 45-59 years old - 37 people (28 men and 9 women); 60-74 years old - 29 people (24 men and 5 women); 25-44 years old – 7 people (all men); 75-89 years old – 3 people (1 man and 2 women). Cases of fatal cold injury in the specified years occurred mainly in the winter months. Post-mortem examination has shown foci of pulmonary emphysematous lesions (90% of cases), mucostasis in goblet cells of bronchial epithelium (37%), oedema of cardiomyocytes (85%), decreased content of glycogen granules in the cytoplasm of chest muscle fibres or liver parenchyma (100%), increased proliferation of spermatogenic epithelium of convoluted seminiferous tubules of testicles (85%), tightening of testicles to entrances to inguinal canals (88%), "goose bumps" in the thigh area (66%), haemorrhages under the mucous membrane of the renal pelvis (40%), presence of vitreous mucus in the lumen of the stomach (96%), Wischnewski spots under the mucous membrane of the stomach (98%).
Conclusion: Correlation of clinical, pathomorphological data with the results of toxicological, biochemical analysis will improve the accuracy of diagnosing fatal hypothermia.

E-PS-01-031
Correlation of autopsy findings with premortem diagnostics for invasive pulmonary aspergillosis in critically ill cirrhosis patients
L. Maessen[1], J. Heylen[1], S. Feys[1], G. Hermans[2], C. Jacobs[1], K. Lagrou[3], H.M. Lauwers[1], P. Meersseman[1], M. Peetermans[1], S. Van Der Merwe[4], A. Wilmer[1], G. De Hertogh[5], J. Wauters[1]
[1]KU Leuven, Laboratory for Clinical Infectious and Inflammatory Disorders, Leuven, Belgium, [2]KU Leuven, Laboratory of Intensive Care Medicine, Leuven, Belgium, [3]KU Leuven, Laboratory of Clinical Microbiology, Leuven, Belgium, [4]KU Leuven, Hepatology Research Unit, Leuven, Belgium, [5]KU Leuven, Department of Imaging & Pathology Functions, Leuven, Belgium

Background & Objectives: Critically ill patients with cirrhosis are at increased risk of invasive pulmonary aspergillosis (IPA). This study investigates the correlation between pre-mortem diagnostics and post-mortem pathological findings.
Methods: This monocentric retrospective study included cirrhosis patients with a fatal intensive care unit (ICU) stay between 2007 and 2020. Autopsy with systematic sampling of each lung lobe was performed as part of routine care after death at our ICU. Premortem IPA diagnosis was made according to an adapted version of the ECMM/ISHAM criteria including cirrhosis as a host factor. Premortem clinical findings were compared to autopsy results.
Results: This study included 79 patients with sufficient pre-mortem diagnostic data to classify patients as probable IPA or not. Median duration of antifungal therapy was 3 days (IQR 1-11). Probable IPA was diagnosed pre-mortem in 22 patients (27%). On autopsy, invasive hyphal growth was identified in 10 out of 22 patients with a pre-mortem probable IPA diagnosis. Autopsy identified 4 additional cases of proven IPA that were missed pre-mortem. Galactomannan (GM) on bronchoalveolar lavage had a sensitivity and specificity of 73% and 76% respectively for proven IPA. GM on serum had a sensitivity and specificity of 62% and 91% respectively for proven IPA. The positive predictive value of tracheobronchitis on bronchoscopy was 67% for proven IPA on autopsy. The adapted diagnostic criteria showed a sensitivity and specificity of 71% and 81% respectively for proven IPA. When only considering patients with less than 3 days of antifungal therapy, specificity of probable IPA increased to 94% for proven IPA.
Conclusion: Proven IPA is found regularly in deceased ICU patients with cirrhosis, highlighting the importance of IPA awareness in this population. Current diagnostic methods correlate only modestly with postmortem findings. However, true rates of proven IPA might be underestimated due to sampling bias at autopsy and prior antifungal therapy.

E-PS-01-032
An autopsy case report: cystic tumour of the atrioventricular (AV) node – a rare neoplasm with fatal outcome
M. Životić[1], M. Jovanović[1], R. Bajović[1], S. Glumac[1]
[1]Institute of Pathology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background & Objectives: The cystic tumour of the atrioventricular (AV) node is an extremely rare benign epithelial neoplasm. Despite its non-aggressive histological appearance, its location within the cardiac conduction system can lead to fatal arrhythmias and sudden death.

Methods: An 80-year-old male patient died suddenly while having dinner. An autopsy was performed at the Institute of Pathology, Faculty of Medicine, University of Belgrade.
Results: In addition to chronic findings including liver cirrhosis and nephrosclerosis, microscopic analysis of the heart revealed myocyte hypertrophy and attenuation in several regions. Notably, a well-demarcated but non-encapsulated lesion was identified in the proximal interventricular septum near the right ventricle. The lesion consisted of compressed cystic and duct-like structures, occasionally filled with luminal debris, with sparse solid epithelial nests. The cystic areas were lined by non-ciliated, flat to cuboidal epithelial-like cells lacking cytological or nuclear atypia. Immunohistochemistry demonstrated epithelial differentiation (diffusely positive for EMA, focally for pCEA and CA19-9), while mesothelial and vascular markers (Calretinin, WT1, CD31, D2-40, GLUT-1, ERG, CD34) were negative. The stroma consisted of dense fibrous collagenous tissue infiltrated with inflammatory cells.
Conclusion: The morphological and immunophenotypic features are consistent with a cystic tumour of the atrioventricular node. Although histologically benign, such tumours can compromise the cardiac conduction system and may be a cause of sudden unexpected death. This case highlights the crucial role of autopsy in identifying rare cardiac lesions with potentially fatal outcomes.

E-PS-01-033
The development of septic shock associated with DIC (Disseminated Intravascular Coagulation) resulting from salpingitis: a case report
J. Carneiro Melo[1], E. Tomé de Sousa[1], A. Regina Werneck Frota[1], L. Damasceno de Queiroz Maia[1], B. Pires Moreira[1], B. Sena Macedo[1], M. Aguiar Nore[1], D. Nunes Oliveira[1]
[1]University of Fortaleza, Fortaleza, Brazil

Background & Objectives: Pelvic Inflammatory Disease (PID) can progress to tubo-ovarian abscess (TOA), which leads to septic shock. This condition induces coagulation dysregulation and organ dysfunction. Early salpingitis diagnosis is indispensable to prevent fatal outcomes. This study highlights the impacts of untreated salpingitis.
Methods: This case study examines a 17-year-old patient analysed post-mortem through medical records, examinations, and death certificate review. Initially treated for UTI due to hypogastric pain. However, two days later, symptoms progressed to purpura, nausea, anorexia, and febrile sensation. After one week, on the day of her death, the patient experienced hematemesis and subsequently passed away.
Results: The histopathological analysis showed haemorrhage in the lungs, heart, liver, spleen and fallopian tubes; congestion in the liver and spleen; pulmonary oedema; and serosanguinous substrate with narrowing of the lumen.On macroscopic examination, the fallopian tubes were expanded, which were both 1,5cm in diameter, and with inflammatory characteristics and petechiae were observed on various serous membranes, such as the heart and lungs. Thrombi were also identified in medium-caliber pulmonary vessels and in the left lobe of the cerebellum. Necrosis was also identified in segments of the small intestine loops and the cecal region.
Conclusion: It is evident that the consequences of an improperly treated inflammation – as PID – can lead to a severe septic shock, culminating in DIC (Disseminated Intravascular Coagulation) and death. This case highlights the importance of a meticulous inflammatory investigation, such as imaging methods, urinary exams and hemograms, which can help the detection of a salpingitis, as described before. Under those circumstances, this analysis enables early diagnosis and treatment, preventing fatal outcomes even in young individuals.

E-PS-01-034
Undiagnosed rheumatic fever: autopsy report
J. Carneiro Melo[1], E. Tomé de Sousa[1], N. Diógenes Pinheiro Neto[1], B. Fernandes Garcia[1], A. Nascimento da Rocha[1], B. de Moura Fé Rios[1], J. de Melo Bezerra Sodré[1], D. Nunes Oliveira[1], D. Isabelle Magno Cavalcante[2], L. Vasconcelos Cavalcante[3], M. de Fatima Figueiredo[3], A. Valêsca Ponto de Lima[1], D. Nunes de Melo[4]
[1]University of Fortaleza, Fortaleza, Brazil, [2]Federal University of Fortaleza, Pathology, Fortaleza, Brazil, [3]University of Fortaleza, Morphofunctional laboratory, Fortaleza, Brazil, [4]Ceará Health Department, Fortaleza, Brazil

Background & Objectives: Rheumatic fever (RF), prevalent in developing countries, is a systemic autoimmune disease commonly resulting from streptococcal pharyngotonsillitis caused by group A beta-haemolytic Streptococcus pyogenes, with several complications such as arthritis, carditis, subcutaneous nodules, erythema marginatum and chorea.
Methods: A 27-year-old woman who, two hours before death, had a dyspnea and vomiting crisis and was taken to the hospital. The medical report describes severe respiratory syndrome refractory to the measures used, with hemodynamic instability.
Results: At autopsy, the brain showed no macroscopic changes, the lungs were enlarged due to oedema and marked congestion/haemorrhage. The heart showed dilation of the right atrium and severe stenosis of the mitral valve. Hepatic steatosis, intense renal congestion. The intestines showed no macroscopic changes, myomatous uterus, with 4 nodules. Histopathological analysis of the heart revealed congestion, intercellular oedema and cardiomyocyte hypertrophy, presence of Aschoff nodules and mitral valve fibrosis; congestion, inflammation and pneumonia in the lung; congestion and acute tubular necrosis in the kidney; congested sinusoids in the liver and congested spleen.
Conclusion: The anatomical and histological findings correlated with the patient's clinical history indicate rheumatic fever as the cause of the undiagnosed cardiac comorbidity that led to severe heart failure (severe mitral valve stenosis and enlargement of the right atrium), leading to the patient's death due to oedema and pulmonary congestion.

E-PS-02 E-Posters Breast Pathology

E-PS-02-001
A retrospective clinicopathological analysis of HER2-low breast cancer: experience from a tertiary care centre
A.-M. Gurău[1], D. Mihalache[2,3], L.F. Rebegea[4,5]
[1]Clinical County Emergency Hospital 'Sf. Ap. Andrei', Pathology, Galați, Romania, [2]Dunărea de Jos, University of Galați, Faculty of Medicine and Pharmacy, Doctoral School of Biomedical Science, Pathology, Galați, Romania, [3]Brăila County Emergency Clinical Hospital, Pathology, Brăila, Romania, [4]Dunărea de Jos, University of Galați, Faculty of Medicine and Pharmacy, Doctoral School of Biomedical Science, Oncology/Radiotherapy, Galați, Romania, [5]Clinical County Emergency Hospital 'Sf. Ap. Andrei', Oncology/Radiotherapy, Galați, Romania

Background & Objectives: HER2-low breast cancer, defined by immunohistochemical expression of HER2 1+ or 2+/negative ISH, has emerged as a distinct category with potential therapeutic relevance. Accurate HER2 assessment is crucial for tumour classification and treatment decisions. This study aimed to describe the histopathological features of HER2-low breast carcinomas in a single-centre cohort, focusing on molecular subtypes and proliferative index.
Methods: A retrospective analysis was conducted on 171 patients diagnosed with invasive breast carcinomas at the Clinical County

Emergency Hospital "Sf. Ap. Andrei" Galați, Romania, over an 9-month period (April 2024 to December 2024), all of whom provided written informed consent. Variables collected included tumour type, TNM classification, Nottingham grade, lymphovascular invasion, perineural invasion, axillary nodal metastases, hormone receptor status, Ki-67 index, and molecular classification.
Results: Out of 171 invasive breast cancer cases, 27% were classified as HER2-low. The median age was 62 years, with 83% of patients being postmenopausal. Most tumours were diagnosed at stage T2, and the predominant histopathological type was invasive ductal carcinoma of no special type (78%), with Nottingham Grade 2. Lymphovascular invasion was present in 8% of cases, perineural invasion in 2% of cases, and axillary nodal metastases were identified in 10% of cases. Molecular subtypes were distributed as follows: Luminal B-57%, Luminal A-30% and triple negative breast cancer-13%. Ki-67 values were <14% in 26% of cases, between 14-20% in 28% of cases and >20% in 46% of cases. This distribution indicates increased proliferative activity, even in hormone receptor-positive tumours, in line with curent literature on HER2-low cancers.
Conclusion: In this cohort, HER2-low breast carcinomas showed hormone receptor positivity, but also high proliferative indices in nearly half of the cases, suggesting significant biological heterogenity. These findings highlight the importance of accurate and standardized pathological evaluation of HER2 status, with potential implication for therapeutic decision and further understanding of this tumour subgroup.

E-PS-02-002
Polymorphous adenocarcinoma: a rare entity of the breast
S.B. Yolburun[1], I. Buldum[2], H.E. Pestereli[1]
[1]Akdeniz University Hospital, Pathology, Antalya, Turkey, [2]Manchester University NHS Foundation Trust, Pathology, Manchester, United Kingdom

Background & Objectives: Polymorphous adenocarcinoma of the breast, a rare malignancy, consists of monotonous neoplastic cells and shares histomorphological similarities with its salivary gland counterpart. Classified as a rare and salivary gland-like tumour by the WHO in 2022, this tumour remains poorly understood in terms of prognosis and treatment. The aim of this study is to present a case diagnosed with polymorphous adenocarcinoma of the breast and to contribute to the literature.
Methods: A 50-year-old female patient presented to our hospital for diagnostic confirmation. Imaging showed a 29x27 mm mass in the left breast. The patient was diagnosed with triple- negative invasive breast carcinoma. Following neoadjuvant chemotherapy, the patient underwent lumpectomy. The resected tumour measured 1.8 cm and consisted of monotonous cells with tubular structures. Immunohistochemical tests revealed negative staining for oestrogen receptor, progesterone receptor, human epidermal growth factor receptor 2, P63, and GATA3, but Bcl-2 was positive. The Ki67 proliferation index was 2%. Based on these findings, the diagnosis of polymorphous adenocarcinoma of the breast was confirmed. The patient received adjuvant chemoradiotherapy, and no recurrence was observed during 8 months of follow-up.
Results: Polymorphous adenocarcinoma of the breast is extremely rare, with only four reported cases in the literature. Three of these were presented by Asioli et al. in 2006, and a molecular analysis was conducted by Trihia et al. in 2019. The average age at diagnosis is 55.7 years, and the typical tumour size is about 2.5 cm. In our case, the tumour size after treatment was 1.8 cm. One case presented by Asioli showed widespread metastasis after 3 years, but no recurrence has been observed in our patient after 8 months.
Conclusion: Polymorphous adenocarcinoma of the breast is significant not only due to its rarity but also because of the lack of reliable prognostic markers and established treatment protocols.

E-PS-02-003
Comparison of histopathological characteristics of breast cancer between young and older women
M. Zghal[1], M. Triki[1], O. Boudawara[1], M. Mellouli[1], L. Ayedi[1], I. Bahri[1], T. Boudawara[1], S. Graja[1]
[1]Habib Bourguiba University Hospital, Pathology, Sfax, Tunisia

Background & Objectives: Breast cancer (BC) in young women is uncommon and tend to present with aggressive clinico-pathological characteristics. We aimed to compare the histopathological characteristics of BC between young women and older women.
Methods: We retrospectively reviewed all consecutive female BC cases diagnosed between January 2018 and December 2023 at our department over a period of 6 years. Histopathological characteristics were compared between young (≤ 40 years old) and older women (>40 years old).
Results: Of a total of 449 patients included in the analysis, 82 were younger than 40 years (18.26%) and 367 were older than 40 years (81.74%). Younger women had a greater tumour size (4cm vs 3cm, p<0.001), higher frequency in terms of high histological grade (54.9% vs 36.2 %, p=0.006), positive surgical margins (24.7 % vs 13.6 %, p=0.01), high pathological stage (pT3/pT4) (36.6% vs 20.4%, p=0.002), triple negative tumour (36.6 % vs 11.7 %, p<0.001) and diagnosed at an advanced stage disease (stage III/IV) (52.4 % vs 39.8 %, p= 0.036) compared to older women. No statistical difference was identified between the two-age group regarding bilateral tumour, histological subtype, lympho-vascular invasion, lymph node involvement, pathological nodal stage and Her2 status.
Conclusion: The incidence of BC among young women is widely heterogeneous worldwide. In our study, 18.26% of patients were aged less than 40 years; this fraction is relatively higher than that reported in western countries. Young women are felt to be diagnosed at an advanced stage and bear more aggressive BC, which could be explained by the fact that mammography screening is targeted to older women or related to the aggressive biological behaviour of BC in young women. Our study was consistent with most of the earlier research and proved that BC in young women needs more attention as the presentation has more aggressive behaviour at advanced stages.

E-PS-02-004
Tall cell carcinoma with reverse polarity: a case report
A. Gerdzhikova[1], D. Tashkova[1]
[1]Complex Oncology Centre- Plovdiv, General and Clinical Pathology, Plovdiv, Bulgaria

Background & Objectives: Tall cell carcinoma with reverse polarity is a rare subtype of invasive breast carcinoma, which can grow in solid or papillary patterns, thus creating diagnostic difficulties, especially on small core biopsies. Therefore, its' distinguishing can be difficult for the general surgical pathologist therefore reporting and discussing such cases is of great importance.
Methods: The methods used are light microscopy, H-E staining, IHC testing. Genetic tests were not performed due to high monetary cost.
Results: A 68 -year old female patient with history of Multiple myeloma was sent for a CAT-CT scan by her haematologist, where a lump is discovered in the left breast- lower inner quadrant: 2.5x2 cm in size with one reactive axillary lymph node. The ultrasonograph score was BI-RADS 5. The patient underwent excision biopsy and the permanent section showed solid nests consisting of tall columnar cells with nuclei oriented away from the basal membrane. Some of the nests showed thin fibrovascular cores demonstrating solid papillary pattern. The neoplastic nests were surrounded by a thin rim of capillary vessels. Mitotic figures were scarce. IHC showed low expression of ER-10%, PR-5%, HER2- negative- HER2-0, Ki67-10% and E-cadherin- positive (+). Ck5/6 showed mosaic cytoplasmic

expression and Calretinin- positive, while p63 was negative in the invasive component of the tumour. Androgen receptor tested negative.
Conclusion: TCCRP as a rare entity can mimic both benign and malignant lesions and shows an interesting IHC profile, which poses a dilemma during the diagnostic process. This subtype of carcinoma with an indolent clinical course has much more favourable prognosis than other triple negative carcinomas, meaning that the treatment can vary drastically. Other malignant lesions like solid papillary carcinoma and metastatic thyroid carcinoma should be excluded before proceeding to it.

E-PS-02-005
Nipple adenoma in a young female: a case report
A. Milićević[1], O. Živković[1], A. Lazarević[1], L. Ilić[1], K. Obradović[2], Z. Inić[3]
[1]Institute for Oncology and Radiology of Serbia, Department of Pathology, Belgrade, Serbia, [2]Institute for Oncology and Radiology of Serbia, Department of Radiology, Belgrade, Serbia, [3]Institute for Oncology and Radiology of Serbia, Clinic for Oncological Surgery, Belgrade, Serbia

Background & Objectives: Nipple adenoma is a rare, benign breast lesion arising from the glandular tissue of the nipple-areolar complex, primarily affecting women in their fifth decade. It presents the proliferation of lactiferous duct epithelial cells. Due to its rarity and resemblance to other breast lesions, misdiagnosis is common.
Methods: A 26-year-old female with a family history of breast cancer presented with a firm, palpable mass in her right nipple. Physical examination revealed a non-tender, mobile mass without skin changes or nipple discharge. Nipple adenoma typically appears as a solitary, well-defined, oval-shaped nodule, though imaging findings are often nonspecific. A punch biopsy indicated a benign lesion with proliferating ductal structures and usual ductal hyperplasia, consistent with nipple adenoma. Surgical excision was performed for definitive diagnosis, confirming nipple adenoma histopathologically.
Results: The Gross specimen examination revealed a grayish, solid tumour measuring 18 x 13 x 10 mm. Microscopically, the lesion displayed a well-circumscribed tumour with ductal hyperplasia and papillary proliferation of glandular stroma, characteristic of nipple adenoma. Histological findings showed glandular and tubular structures lined by an inner layer of epithelial cells and an outer layer of myoepithelial cells. Immunohistochemical staining revealed ductal epithelial cells positive for AE1/AE3 and CK5/6, while the myoepithelial layer showed p63 and Calponin expression, confirming the diagnosis.
Conclusion: Due to their rarity, nipple adenomas can be challenging to distinguish from other nipple and areolar masses, such as intraductal papillomas and breast carcinoma, without histopathological confirmation. Surgical excision is the treatment of choice, offering an excellent prognosis and low risk of recurrence. Early recognition, imaging, and histopathological evaluation are crucial for differentiation. A comprehensive understanding of the pathological and immunohistochemical features of nipple adenoma is essential for accurate diagnosis.

E-PS-02-006
Breast amyloid tumour and Sjogren syndrome: a rare association
R. Lyrio[1], A. Lopes[1], R. Veiga[1]
[1]Hospital da Luz, Surgical Pathology, Lisbon, Portugal

Background & Objectives: Systemic amyloidosis is a well-known condition characterized by abnormal amyloid deposits in multiple organs. Breast amyloidosis (BA) is a rare form of localized amyloidosis, involving amyloid protein accumulation exclusively in the breast tissue. Given the rarity of this condition, our aim is to shed light on this unique case, review the literature, emphasize the growing association between Sjögren syndrome (SS) and BA, and elucidate the importance of proper diagnosis to prevent unnecessary interventions.
Methods: A 74-year-old woman with a history of SS, hypertension and diabetes, came to our hospital for a breast outpatient clinic appointment, after noticing a few palpable nodules in her left breast. Mammographic examination showed nodular lesions with calcifications and suspicious signs of malignancy. A core needle biopsy was then performed.
Results: Histologic examination of the breast biopsy revealed a diffuse deposition of eosinophilic amorphous material throughout the breast parenchyma, and also surrounding blood vessels and lobulo-acinar structures. This material was Congo red-positive, with a characteristic apple-green birefringence under polarized light, thus confirming the diagnosis of amyloidosis. The nodular area was then rebiopsied and eventually surgically excised, confirming the diagnosis of BA. No neoplasia was found on any of the additional specimens. After clinical and laboratory investigation, no signs of systemic involvement were found, rendering the final diagnosis of localized BA. Our literature review suggests a possible increased association between BA and SS.
Conclusion: Though exceptionally rare, localized BA should be considered when evaluating breast nodules, especially in patients with autoimmune conditions like SS. Because these lesions can mimic malignancies, a thorough histopathological evaluation is crucial to ensure accurate diagnosis and avoid unnecessary surgical treatments. This case underscores the importance of clinical awareness and rigorous use of diagnostic techniques, to provide the best possible care for patients with this rare but significant condition.

E-PS-02-007
Clinicopathological features of breast carcinomas with group 4 HER2 FISH results
L. Cardisciani[1,2], F. De Paola[3], F. Di Donato[1], A. Farnedi[4], P. Possanzini[3], M. Costantini[3], L. Saragoni[1,5], F. Vasuri[1,5], A. Ambrosini Spaltro[3]
[1]Santa Maria delle Croci Hospital, Pathology Unit, Ravenna, Italy, [2]School of Anatomic Pathology - University of Bologna, Department of Biomedical and Neuromotor Sciences, Bologna, Italy, [3]Morgagni Pierantoni Hospital - AUSL Romagna, Pathology Unit, Forlì, Italy, [4]Hub Laboratory - AUSL Romagna, Clinical Pathology Unit, Cesena, Italy, [5]Bologna University, Department of Medical and Surgical Sciences, Bologna, Italy

Background & Objectives: The American Society of Clinical Oncology/College of American Pathologists (ASCO/CAP) defined the guidelines in 2018 to address issues arising from uncommon HER2 fluorescence *in situ* hybridization (FISH) results. We aimed to collect a series of invasive breast carcinomas with equivocal FISH results, focusing on group 4.
Methods: From 2019 to 2025, all breast carcinomas classified as group 4 (HER2/CEP17 Ratio<2.0; Average HER2 Signals/cell ≥4.0, and <6.0) by FISH were retrieved. By FISH, all cases were examined with PathVysion HER2 DNA Probe Kit (PathVysion Kit). By immunohistochemistry (IHC), slides were stained using an automatic immunostainer (Benchmark Ultra, Roche) with the following antibodies: oestrogen receptor (ER-SP1), progesterone receptor (PR-1E2), Ki67 (Mib-1), HER2 (4B5). Cases were defined as ER-positive and PR-positive when ≥10% and with high Ki67 when ≥20%. HER2 IHC was scored using ASCO/CAP guidelines. Cases classified as group 4 by FISH only in the biopsy and not confirmed in the subsequent surgical specimens were excluded.
Results: A total of 99 specimens from 88 patients were collected. Cases were predominantly composed of surgical specimens (82%), diagnosed as invasive carcinoma not otherwise specified (NST) (84%), followed by lobular carcinoma (11%). Tumours were

predominantly high-grade (57%) and frequently multifocal (34%). By FISH, ratio HER2/CEP17 varied from 1.4 to 1.5, mean 1.5±0.1; HER2 signal varied from 4.0 to 5.2; mean: 4.6±0.8. By IHC, all cases were scored as HER2 2+. Ki67 varied from 5% to 80%, mean: 27.3±13.8%; most cases (67%) showed high Ki67 values. Most cases were ER-positive (91%) and PR-positive (76%).
Conclusion: Breast invasive carcinomas with group 4 HER2 FISH results usually show high grade, high Ki67 expression, positivity for both ER and PR, and are frequently multifocal. The clinical correlations are ongoing.

E-PS-02-008
Breast adenoid cystic carcinoma: a retrospective study upon 2 decades
W. Mokni[1], S. Yakoub[1], H. Abbessi[2], S. Frini[1], Z. Nfikha[1], M. Mokni[1]
[1]Farhat Hached University Hospital, Pathology, Sousse, Tunisia, [2]Farhat Hached University Hospital, Obstetrics and Gynaecology, Sousse, Tunisia

Background & Objectives: Adenoid cystic carcinoma of the breast (BACC) is a rare tumour, accounting for < 0,1% of all breast cancers (BC). Although often classified as a triple-negative tumour, ACC typically has a favourable prognosis, with a low risk of metastasis and high survival rates. This study aimed to review the clinical and pathological characteristics of breast ACC.
Methods: This is a clinical and pathological retrospective analysis conducted at the pathology department of Farhat Hached university hospital, including all BACC that were diagnosed over a period of 23 years (2000-2023)
Results: Only 4 BACC were diagnosed representing 0.07% of all BC, The mean age for ACC patients was 66 years ± 5.47 years. Clinically, three patients presented with nodules, one had nipple discharge, and one experienced mastodynia. Histologically, preoperative and final diagnoses were consistent across all cases, showing epithelial and myoepithelial proliferation. Architecturally, all cases exhibited trabecular, cord-like and cribriform structures centreed by pale material. One case showed high grade features including high mitotic rate (without atypia), necrosis and solid structures covering 50% of the tumour area. No vascular emboli nor lymph node metastases were detected in any of the cases. All tumours were of triple negative phenotype with one case showing <1% of RE and RP expression limited to luminal cells. The Ki67 proliferation index ranged from 1% to 5% in three cases and was 20% in one case. After 10 years of follow-up, only one patient had died. This patient did not exhibit high-grade histological features.
Conclusion: This study highlights the distinctive clinicopathological features of BACC. They occur mainly in elderly women, and exhibit the same histological patterns as ACC of salivary glands. It is a triple negative BC with a favourable prognosis , though distant metastases are possible. Diagnosis must be held on core needle biopsies to avoid overtreatment.

E-PS-02-009
Epithelioid schwannoma of the breast
I. Čović[1], T. Čeprnja[1], S. Tomić[1]
[1]University Hospital Centre Split, Department of Pathology, Forenscic Medicine and Cytology, Split, Croatia

Background & Objectives: Epithelioid schwannomas are an uncommon histologic variant of benign peripheral nerve sheath tumours. Due to their morphological overlap with other tumour forms, epithelioid schwannomas have a low prevalence and are frequently difficult to diagnose. Epithelioid schwannoma of the breast represents an unusual localization of this tumour.
Methods: A 45-year-old woman was admitted to our hospital with a history of hypoechogenic, well-circumscribed lesion between the upper lateral quadrant and upper medial quadrant of the right breast, which was diagnosed by ultrasound examination. The first ultrasound examination was performed in 2022, and the follow-up examination in 2024. The lesion remained the same size. Fine needle biopsy was done. Cytologic analysis showed epithelial atypia. A tumorectomy was performed, and a firm lesion measuring 2,5 x 2 x 1,3 cm was sent for histological examination.
Results: On gross examination, the lesion was yellowish. Nodularity was observed on the cut surface. Microscopic examination revealed a multilobular tumour composed of epithelioid cells with round nuclei and eosinophilic cytoplasm in a hyalinised, myxoid background. Some of the cells had prominent nucleoli. Immunohistochemically, epithelioid cells were positive for S100 and vimentin and negative for cytokeratin 8/18, cytokeratin AE3/AE5, actin, desmin, h-caldesmon, p63 and p40. CD34 (cluster of differentiation 34) immunostain was patchy. Estrogen, progesterone and androgen receptors were negative, and HER2 (human epidermal growth factor receptor 2) score was graded 0. Ki-67 proliferation index was 2-3%. A follow-up examination showed no recurrence.
Conclusion: Due to their enhanced cellularity and epithelioid morphology, epithelioid schwannomas can cause diagnostic challenges and result in diagnostic errors. Immunohistochemistry may be helpful, as schwannomas stain diffusely positive for S-100 and are negative for breast markers (oestrogen, progesterone and HER2).

E-PS-02-010
Adenoid cystic carcinoma of the breast: a case report and literature review
O. Ait Ouhssain[1], C. Dabaj[1], H. Rachidi[1], H. Rais[1]
[1]University Hospital of Mohammed VI, Pathology, Marrakesh, Morocco

Background & Objectives: Adenoid cystic carcinoma (ACC) of the breast is a rare subtype of breast carcinoma, accounting for 0.1% to 3.5% of all breast cancers. Although it has a triple-negative phenotype, ACC generally has a favourable prognosis. This work presents a case report followed by a literature review to better understand this pathological entity.
Methods: A 52-year-old nulligravid woman presented with a palpable right breast mass. Imaging revealed a lesion classified as ACR5. A fine-needle biopsy showed a poorly differentiated carcinoma, and the patient underwent a lumpectomy.
Results: Macroscopic examination identified a well-defined 5×5×3 cm tumour. Histological analysis revealed a dual epithelial and myoepithelial proliferation with a characteristic cribriform architecture. The tumour cells exhibited minimal to moderate nuclear atypia and a low mitotic index, with no vascular or lymphatic invasion. Immunohistochemistry confirmed a triple-negative phenotype, with positive expression of CD117 and p63. Axillary lymph node dissection retrieved 30 non-metastatic lymph nodes.
Breast ACC shares histological features with its salivary gland counterpart but generally has a less aggressive clinical course. It is characterized by an epithelial and myoepithelial cellular component arranged in tubular, cribriform, or solid structures. Immunohistochemical analysis typically reveals positivity for cytokeratins and myoepithelial markers. On a molecular level, MYB-NFIB fusion is frequently observed. The main treatment is breast-conserving surgery, with postoperative radiotherapy recommended in certain cases. Axillary lymph node dissection or sentinel lymph node biopsy may not always be necessary.
Conclusion: Breast ACC is a rare tumour with a favourable prognosis. A multidisciplinary approach, including precise histopathological evaluation and conservative surgical treatment, is essential for optimal

clinical outcomes. Further studies are needed to better understand its biology and identify potential prognostic biomarkers.

E-PS-02-011

Tall cell carcinoma with reversed polarity: report of two cases with clinical, histopathological and molecular insights

B. Lopes[1,2], M. Brito Pereira[3,2], S. André[1,2]
[1]IPO Lisboa, Pathology, Lisbon, Portugal, [2]Nova Medical School, Lisbon, Portugal, [3]CUF Descobertas Hospital, Lisbon, Portugal

Background & Objectives: Tall Cell Carcinoma with Reversed Polarity (TCCRP) is a rare type of breast carcinoma with fewer than 100 cases reported to date and first described by Eusebi *et al*. in 2003. It is histologically characterized by tall columnar cells with reverse polarity and most commonly associated with IDH2 mutations. Due to its rarity TCCRP can pose significant challenges in its diagnosis.
Methods: We present two cases involving 68 and 79-year-old females without significant medical history. They presented with 20mm and 19mm breast nodules, respectively, and underwent vacuum-assisted biopsy.
Results: In the first case, the biopsy revealed a papillary solid tumour composed of tall columnar cells with apical nuclei and eosinophilic cytoplasm, positive for CK5 and negative for p63, oestrogen, progesterone and androgen receptors and ERBB2. The proliferation index was low.
Regarding the second case, the biopsy revealed a mixed invasive lesion. The first component was similar to the reported in the first case. The second component was a well differentiated invasive carcinoma, with a basal phenotype, positive for CK5.
Both tumours were removed with clear margins and no lymph node metastasis. Histopathological and immunohistochemical analysis confirmed the diagnosis of TCCRP. Molecular testing for the IDH2 R172 (R120) mutation is currently ongoing. Follow-up has shown no recurrence in either case.
Conclusion: TCCRP must be distinguished from other triple-negative carcinomas associated with aggressive behaviour. Due to its similarity to other tumours, such as metastatic thyroid carcinoma an accurate diagnosis is essential.

E-PS-02-012

Atypical presentation of histiocytoid lobular carcinoma of the male breast

L.-F. Dragostin[1], A. Coman[1], A. Cioroianu[1]
[1]Colentina University Hospital, Department of Pathology, Bucharest, Romania

Background & Objectives: The histiocytoid variant of invasive lobular breast carcinoma is a very rare presentation of breast cancer, usually affecting postmenopausal women, with only a few cases described in males. We report a case of an unusual and underrecognized manifestation of the disease, with a first presentation as skin involvement of the axilla in a male patient.
Methods: We present the case of a 39-year old male with an axillary nodule clinically diagnosed as a cyst with erythematous and thickened overlying skin, developed over the course of a few months. The surgically removed tissue was submitted for microscopic and immunohistochemical examination.
Results: Microscopic examination revealed a dermic and hypodermic invasive neoplastic proliferation, arranged in cords and isolated, discohesive cells, without tubular/gland formation, composed of bland epithelioid cells with abundant pale-eosinophilic cytoplasm and irregular, hyperchromatic or vesicular nuclei, some with prominent eosinophilic nucleoli, moderate nuclear pleomorphism and inconspicuous mitotic activity. Perineural invasion was observed. In immunohistochemical studies, neoplastic cells were positive for cytokeratins (AE1/AE3, CK7), breast tissue markers (GATA3, GCDFP-15, mammaglobin-focally), ER (Allred 4 score) and negative for PR and HER2 (1+), with a low ki-67 index (10%). Negative E-cadherin further supports the diagnosis of a lobular breast carcinoma. Imaging studies confirmed the presence of a breast mass.
Conclusion: Skin involvement of histiocytoid lobular carcinoma is a rare manifestation of invasive breast carcinoma, especially in the male population, with limited representation in literature which poses significant diagnostic challenges. Considering the similar morphologic features shared with other entities, such as xanthogranulomatous lesions or primary cutaneous histiocytoid carcinoma, the latter also sharing its immunohistochemical profile, clinical and imaging correlations are critical. Even though there is a predilection for women, it is still an important diagnosis to be taken into consideration in male patients.

E-PS-02-013

Fibromatosis-like metaplastic carcinoma: a case of a rare breast tumour

B.N. Baysal[1], A. Bayram[1], S. Bağbudar[1], B. Özçinar[2], S. Önder[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Pathology, Istanbul, Turkey, [2]Istanbul University, Istanbul Faculty of Medicine, General Surgery, Istanbul, Turkey

Background & Objectives: Fibromatosis-like metaplastic carcinoma (FLMCa) is classified as a rare histologic subtype of metaplastic carcinoma in the last WHO Classification of Breast Tumours (2019). FLMCas are spindle cell lesions of the breast showing mild nuclear atypia. Morphologically, it can be difficult to diagnose FLMCas as carcinomas and differentiate from other bland spindle cell lesions. Here, we present a case of this rare entity.
Methods: A 63-year-old female patient admitted to hospital with an irregular mass in the upper outer quadrant of the right breast . A core needle biopsy was performed and revealed a spindle lesion and then lumpectomy was performed.
Results: On macroscopic examination, there was a white, firm lesion 2.5×1.8×1.5 cm in diameter with irregular borders. Microscopically, the tumour was predominantly composed of bland spindle cells with pale eosinophilic cytoplasm and mild nuclear atypia. These cells infiltrated the surrounding fat tissue and normal breast parenchyma. The trapped ducts were present within the spindle cell areas, along with keloid-like collagenized stroma. Additionally, a focal area of squamous metaplasia was identified in a few section.
Immunohistochemically, the spindle tumoral cells were diffusely positive for CK5/6 and negative for oestrogen receptor (ER), progesterone receptor (PR), and CerbB-2. Smooth muscle actin (SMA), smooth muscle myosin (SMM), p63, and p40 showed focal positive expression. The Ki-67 proliferation index was low, at approximately 8%. With this findings, a diagnosis of fibromatosis-like metaplastic carcinoma was reached.
Conclusion: Fibromatosis-like metaplastic carcinoma should be considered in the differential diagnosis of low-grade breast bland spindle cell lesions with collagenous stroma and infiltrative margins. This diagnosis should be confirmed by immunohistochemical analysis especially with keratins.

E-PS-02-016

The clinical and pathological evaluation of 34 cases of Phyllodes Tumours

H. Kandemir[1], E.E. Pala[1], S. Ekmekci[1], C. Karaali[2]
[1]Health Sciences University, Izmir Faculty of Medicine, Tepecik Training and Research Hospital, Department of Medical Pathology, Izmir, Turkey, [2]Health Sciences University, Izmir Faculty of Medicine, Tepecik Training and Research Hospital, Department of General Surgery, Izmir, Turkey

Background & Objectives: Phyllodes tumours (PT) are rare biphasic fibroepithelial neoplasms, accounting for 0.3% to 1% of breast

tumours, primarily in women aged 45-49. Classified by the WHO into benign, borderline, and malignant categories, these tumours exhibit varying degrees of stromal atypia, cellularity, and mitotic activity. Although most are benign (35%-64%), both stromal and epithelial components can become malignant, with recurrence rates of 10%-17%. Differentiating benign phyllodes tumours from cellular fibroadenomas remains a challenge. This study aims to evaluate the clinicopathological characteristics of phyllodes tumours.
Methods: PT cases diagnosed between 2010 and 2022 at SBÜ Izmir Medical Faculty Tepecik Training and Research Hospital were retrospectively reviewed, and all cases were re-evaluated. Tumours were classified as benign, borderline, or malignant based on tumour margins, stromal cellularity, stromal atypia, stromal overgrowth, mitotic activity, and the presence of malignant heterologous elements.
Results: A retrospective review of 34 PT cases in women (mean age 38.7 years) found 18 benign (53%), 11 borderline (32.4%), and 5 malignant (14.8%). Leaf-like patterns were observed in 13 cases, and heterologous elements in 1. Tumour sizes averaged 3.95 cm (benign), 5.7 cm (borderline), and 6.1 cm (malignant). Mitoses were 1.8 (benign), 8.7 (borderline), and 19 (malignant) per 10 HPF. Malignant tumours showed well-circumscribed (3) and infiltrative (1) patterns. Borderline tumours had a mix of circumscribed and infiltrative types. Stromal overgrowth was common in malignant and borderline cases.
Conclusion: PT often mistaken for benign lesions are challenging to differentiate from cellular juvenile fibroadenomas, especially in core biopsies. Key factors for diagnosis include stromal cellularity, mitotic count, nuclear pleomorphism, and atypia Stromal cellularity may upgrade after excision. Study showed four benign cases upgraded to borderline post-excision. Accurate preoperative diagnosis and management are vital due to their recurrence and malignant potential. Tumours with increased stromal cellularity or atypia in biopsies should be excised with a 1 cm surgical margin.

E-PS-02-018
Angiosarcoma following breast-conserving surgery without radiation therapy or axillary lymph node dissection: a case report
H.-c. Lee[1,2], O.-J. Lee[1,2], S.-M. Son[1,2], C.G. Woo[1,2]
[1]Chungbuk National University College of Medicine, Pathology, Cheongju, Republic of Korea, [2]Chungbuk National University Hospital, Pathology, Cheongju, Republic of Korea

Background & Objectives: Angiosarcoma is the most common mesenchymal tumour of the breast. Radiation therapy (RT) and lymphedema due to axillary lymph node dissection (ALD) are the most well-known risk factors of secondary angiosarcoma. We report a case of angiosarcoma following breast-conserving surgery without RT or ALD for encapsulated papillary carcinoma in an 88-year-old female.
Methods: The patient initially visited Chugbuk National University Hospital with a left breast mass at the age of 82. She underwent breast-conserving surgery and sentinel lymph node biopsy. RT was not performed due to her old age. She presented with a fast-growing mass at the previous surgery site 66 months after the initial surgery. Total mastectomy and sentinel lymph node biopsy for the second mass was performed. Pathological examinations including immunohistochemical (IHC) assays were performed for both breast lesions.
Results: The initial mass was a grossly well-demarcated whitish-gray mass, measuring 4 x 3 x 2.3 cm. Microscopically, the mass showed a proliferation of monotonous round cells with papillary architecture and was surrounded by thick fibrous capsule. IHC results were hormone receptor-positive and HER2-negative. The second mass was grossly ill-defined red mass with multifocal necrosis, measuring 9 x 6.5 x 3.3 cm. Microscopic examination showed that the tumour cells were a mixture of round and spindle cells without conspicuous epithelial features. Both tumour cells were positive for CD31 and negative for pan-cytokeratin, epithelial membrane antigen, and desmin. IHC results for CD34 and c-myc varied according to the cell types: round cells were positive for c-myc and negative for CD34, whereas spindle cells were CD34-positive and c-myc-negative.
Conclusion: The diagnosis of angiosarcoma should not be ignored in patients with breast cancer who have previously undergone breast-conserving surgery without RT or ALD.

E-PS-02-019
Clinicopathological features of encapsulated papillary carcinoma in a cohort of predominantly African-American/Black women
L. Pelkey[1], G. Jagannathan[1], M. Mosunjac[1]
[1]Emory University, Pathology, Atlanta, USA

Background & Objectives: Encapsulated papillary carcinoma (EPC) is an uncommon low-grade carcinoma that has morphologic and immunohistochemical overlap with other papillary lesions of the breast. The classification of EPC as an in situ or invasive lesion, its long-term behaviour, and its management remain a matter of debate. Here we examined the clinical course of EPC in an almost exclusively African-American/Black population.
Methods: We identified thirty-one resection specimens with EPC between 2013 and 2024 to determine the long-term behaviour of this carcinoma, primarily in African-American/Black women. Clinicopathologic and follow-up data from the electronic medical record was reviewed for all cases.
Results: Our study population was predominately African-American/Black women (94%; 29/31), with a median age of 71 (range: 41 – 88). Pure EPC comprised 26% (8/31) of cases, EPC with invasive carcinoma [with and without ductal carcinoma in situ (DCIS)] represented 55% (17/31) of cases, and EPC with DCIS formed the remainder (19%, 6/31). The majority of invasive carcinomas arising in association with EPC were ER+ and PR+ (88%, 15/17, for both), and HER2-ve (94%, 15/16). Pure EPC and EPC with DCIS were collectively ER+ (100%, 13/13), PR+ (92%, 11/12), and HER2-ve (100%, 5/5). Median time of follow-up after diagnosis was 3.6 years (range: 1 week – 11.6 years). No recurrences were seen in pure EPC while four cases of EPC with invasive carcinoma or DCIS recurred, which was found after a median of 2.2 months (range: 2.0 – 15.9 months) after diagnosis.
Conclusion: No study has yet investigated the clinical course of EPC in African-American/Black women. Our findings indicate that EPC often coexists with invasive carcinoma and/or DCIS. In pure EPC, the prognosis was excellent with no recurrences, and even in cases with associated invasive carcinoma, the clinical course was indolent.

E-PS-02-020
CD8+ and CD20+ TILs in residual triple-negative breast cancer: a novel prognostic indicator
A. Sahli[1], A. Gouasmia[2], L. Beddar[1]
[1]University Hospital Dr Benbadis, Pathology Department, Constantine, Algeria, [2]Regional Military University Hospital Constantine, Pathology Department, Constantine, Algeria

Background & Objectives: Tumour-infiltrating lymphocytes (TILs) have been positively correlated with longer disease-free survival (DFS) and improved overall survival (OS) in patients with triple-negative breast cancer (TNBC), particularly when assessed in pre-neoadjuvant chemotherapy (NAC) biopsies. However, studies evaluating TILs after NAC setting remain scarce. This study evaluates the prognostic significance of CD8+ and CD20+ lymphocyte infiltration in residual TNBC post-NAC.
Methods: We reviewed 398 cases of TNBC across two centres in a period of 5 years (January 2019-December 2023). Of these, only 48 cases met the eligibility criteria for our study. Immunohistochemical staining for CD8 and CD20 was evaluated following the hotspot

method. Statistical analysis was conducted using SPSS Statistics, with outcome correlation assessed via Kaplan-Meier survival analysis.
Results: Our study found that 47.9% of patients were staged as ypT2, highlighting TNBC's chemoresistance and the need for additional prognostic markers beyond tumour shrinkage.
In terms of survival outcomes, the 3-years DFS rate was 68.8%, while OS was 72.1% in 5 years.
Immunohistochemical analysis showed a predominance of CD8+ T-lymphocytes over CD20+ B-lymphocytes, with a CD8/CD20 ratio>1 in 91.7% of cases. This suggests that cytotoxic T-cell infiltration plays a dominant role in shaping the post-chemotherapy immune microenvironment in TNBC.
A higher CD8/CD20 ratio>1 was correlated with better survival outcomes than those with a ratio<1, with a significantly improved 3-year DFS (75.2% vs. 25%, p = 0.002) and 5-year OS (79% vs. 66.7%, p = 0.01), emphasizing the pivotal role of T-cell-mediated anti-tumour immunity while also highlighting the supportive function of B-lymphocytes in antigen presentation and immune modulation.
Conclusion: Despite its limitations, our study suggests that a high CD8/CD20 ratio in residual TNBC following NAC is a strong prognostic indicator, correlating with improved DFS and OS. These results underscore the potential of immune profiling in refining post-chemotherapy prognostic stratification and guiding future therapeutic strategies.

E-PS-02-023
Association of pretreatment neutrophil-to-lymphocyte ratio with clinicopathological parameters in breast cancer
R. Sinha[1], P. Kumari[2]
[1]All India Institute of Medical Sciences Patna, Department of Pathology, Patna, India, [2]AIIMS New Delhi, Department of Pathology, New Delhi, India

Background & Objectives: Inflammation and tumour microenvironment have an important role in the different stages of cancer development - initiation, promotion and metastasis. Infiltrating leukocytes secrete a wide variety of factors which promote tumour growth and suppress host's immune response. Neutrophil-to-lymphocyte ratio (NLR) is an easily measurable marker of subclinical inflammation. Recent literature has demonstrated use of these inflammation markers for prognostication in various solid cancer, including breast cancer (BC). Breast cancer is the leading cause of cancer and cancer mortality in India. This study, evaluated the association of preoperative NLR with clinicopathological parameters and molecular subtypes of BC in India.
Methods: A hospital-based cross-sectional prospective study was conducted over 18 months on 228 histologically proven cases of BC. Molecular classification into four subtypes was based on IHC expression of ER, PR, Her2, and Ki67. Pre-treatment complete blood count was performed on Sysmex XN1000. Cutoff value of NLR was calculated using receiver operator characteristic curve (ROC) by STATA software. Statistical analysis was performed using Jamovi 2.3.18.0.
Results: Most common histological type was invasive ductal carcinoma, NST (97.4%) and the commonest molecular subtype was Luminal B (37.7%). There was no statistical association of molecular subtype with clinicopathological parameters except clinical TNM stage (P=0.019). Cutoff value of NLR was 2.64. High NLR (≥2.64) was most common in triple-negative BC (70.6%) and least in Luminal A (20.8%) which was statistically significant (P<0.001). Advanced cTNM was also statistically associated with elevated NLR (P=0.022). Significant association of high NLR was observed with ER/PR negative status (P=0.005) and high Ki67 (P=0.006). No association of NLR was found with age, gender, histological type, tumour grade, nodal status, metastasis.
Conclusion: High NLR is associated with unfavourable factors in BC. Pretreatment NLR has potential application as a simple, reproducible and inexpensive biomarker for prognostication in BC. It may help in pretreatment risk stratification.

E-PS-02-024
A systematic approach to the diagnosis of rare and salivary gland tumours of the breast and literature review
V. Pant[1]
[1]Center for Oncopathology, Histopathology, Mumbai, India

Background & Objectives: Rare and salivary gland tumours of the breast often present with a triple negative phenotype . However their biological behaviour is not the same as the more comman triple negative breast carcinomas of no special type. The 5th edition of WHO classification of breast tumours has placed these tumours as a separate class under the category of epithelial tumours . Experience with the diagnosis of these tumours in the breast is limited due to their rarity at this site . At the same time their recognition is crucial as they are treated differently from triple negative breast carcinomas of no special type which they mimic owing to their triple negative phenotype.
Methods: Cases of Tall cell carcinoma with reversed polarity, adenoid cystic carcinoma in breast , secretory carcinoma breast and breast microglandular adenosis along with literature review will be used to illustrate a systematic approach to recognise important clues on histology which will prompt the appropriate IHC panel to recognise these rare tumours. The differential diagnosis of breast mucoepidermoid carcinoma and breast polymorphous adenocarcinoma will also be covered in the discussion.
Results: The presentation will use some representative cases of this class of tumours ,which rarely present in the breast, and highlight important clues to differentiate them from their more comman breast tumour mimics.
Conclusion: Review of literature and a systematic approach to diagnose rare and salivary gland tumours in the breast as it has significant management implications.

E-PS-02-025
Breast cancer in young women: the experience of a portuguese tertiary centre
C. Leal[1,2], A. Marques[1,2], I. Rodrigues[1], J.C. Almeida[1,2]
[1]Unidade Local de Saúde de São João, Pathology Department, Porto, Portugal, [2]Faculdade de Medicina da Universidade do Porto, Pathology Department, Porto, Portugal

Background & Objectives: Breast cancer is the most common malignancy in women worldwide and the leading cause of cancer-related death in women under 45 years old. Its incidence has been increasing in this age group. In December 2024, the Portuguese Direção-Geral da Saúde (DGS) extended the age range for population screening to women aged 45-74, aiming for earlier detection.
Methods: Between 2022 and 2023, our institution diagnosed and managed 84 cases of breast cancer in women ≤45 years of age. Clinical and histopathological variables were analysed, including morphological and immunohistochemical characteristics, as well as treatment regimens, presence of metastasis, and clinical outcomes.
Results: The majority of patients presented with grade III (49%) "no special type" (NST) invasive carcinoma (87%). Most tumours were hormone receptor-positive (68%) with a high percentage of triple-positive tumours (14%). The median tumour size at presentation was 27.8mm. 30% of patients had homolateral lymph node metastasis at presentation. 46% of patients received neoadjuvant chemotherapy, followed by breast-conserving surgery in 63%. A complete pathologic response was achieved in 25%. Only 10% had distant metastasis.

Most patients did not have a family history of breast cancer (55%), and genetic studies revealed no alterations (63%). Two patients died of the disease, six are alive with disease, undergoing palliative care, and 90% are alive without evidence of disease. We also analysed the correlation between the presence of necrosis and tumour infiltrating lymphocites (TILs) in the invasive carcinoma on biopsy and the response to chemotherapy.
Conclusion: Our results are consistent with published literature, indicating that breast cancer in young women tends to be more aggressive, with larger tumour sizes and higher grades at diagnosis, as well as higher incidences of HER2 and triple-negative disease. The rising incidence of breast cancer in young women requires further investigation into environmental and genetic factors contributing to its aggressive biology.

E-PS-02-026
Clinicopathological characteristics of male patients with breast cancer in our centre
H. Kandemir[1], S. Ekmekci[1], S. Salimoglu[2], E.E. Pala[1], C. Kelten Talu[3]
[1]Health Sciences University, Izmir Faculty of Medicine, Tepecik Training and Research Hospital, Medical Pathology, Izmir, Turkey, [2]Health Sciences University, Izmir Faculty of Medicine, Tepecik Training and Research Hospital, General Surgery, Izmir, Turkey, [3]Health Sciences University, Izmir Faculty of Medicine, Tepecik Training and Research Hospital, Department of General Surgery, Medical Pathology, Izmir, Turkey

Background & Objectives: Male breast cancer, while considerably rarer than female breast cancer, has seen a rising incidence in recent years. The typical complaint is a palpable mass in the breast, with many symptoms being overlooked, leading to delays in diagnosis and treatment. Several etiological factors, including age, race, family history, obesity, genetic predispositions, gynecomastia, Klinefelter syndrome, liver diseases, and radiation exposure, play a role in the development of this disease. The most common histopathological type found in male breast cancer is invasive carcinoma of no special type (NST), which constitutes 80-90% of cases. Generally, oestrogen receptor (ER) positivity is reported in 65-97% of cases, progesterone receptor (PR) positivity in 60-85%, and HER2 positivity varies from 3-28%. Secondary malignancies are observed in 5-33% of male breast cancer patients. This study evaluates the clinicopathological characteristics of male patients diagnosed with primary breast cancer in our centre.
Methods: A retrospective review was performed on the pathology archives from 2009 to 2023, focusing on 26 male patients diagnosed with primary breast cancer. Clinical data were obtained from our hospital's automation system, assessing age, tumour size, histological type, grade, biomarker status, and survival.
Results: Patients' ages ranged from 38 to 87 (mean age: 70.6 years). Involvement was predominantly unilateral, with 34.6% on the left and 61.5% on the right. Tumour sizes varied between 3 mm and 36 mm (mean size: 22.6 mm). All patients were alive. Of the cohort, 62% presented with breast swelling. All were diagnosed with invasive carcinoma-NST. Notable findings included axillary involvement in 15.4% and ER positivity in 92.3% of patients, while two cases of prostate cancer were recorded as secondary malignancies.
Conclusion: Male breast cancer, though rare, is on the rise. Delayed diagnoses often lead to advanced stages, underscoring the importance of early detection for successful treatment outcomes.

E-PS-02-027
A rare case of metastatic metaplastic breast carcinoma in the anal canal
N. Ntalakos[1], M. Arnaouti[1], E. Arkoumani[1]
[1]Saint Savvas Anticancer Hospital of Athens, Department of Surgical Pathology, Athens, Greece

Background & Objectives: A 58-year-old woman with a known history of breast adenocarcinoma 18 years ago and metastatic breast adenocarcinoma involving the ovaries and uterine corpus 3 years prior, presented with a newly detected anal canal mass.
Methods: Following surgical excision, the specimen was sent to the pathology department for further examination. Macroscopically, the tumour appeared as a well-circumcised, multilobulated neoplastic mass, measuring 6 cm in diameter, with white-to-greyish cut surface. Microscopic examination and extensive immunohistochemical analysis were required to determine the diagnosis.
Results: Histopathological examination revealed a biphasic malignancy with an epithelial neoplastic component that abruptly transitioned to a mesenchymal component of chondroid differentiation. Immunohistochemical analysis revealed expression of CK7, EMA and GATA-3 in the epithelial component, while the mesenchymal component showed expression for S100 and SATB-2.
Conclusion: The morphological and immunohistochemical findings, in correlation with the patient's medical history, confirmed the diagnosis of metastatic metaplastic breast carcinoma with heterologous mesenchymal differentiation, also referred to as "matrix-producing carcinoma". This case not only highlights a rare metastatic site for metaplastic breast carcinoma, but also emphasizes the role of intratumoral heterogeneity in the tumour's metastatic propensity and immune evasion. Notably, while the vast majority of metaplastic carcinomas are categorized as triple-negative, in this case the tumour exhibited expression of HER2 [SCORE (2+)].

E-PS-02-029
Myoid hamartoma of the breast: an extremely rare diagnostic challenge
M.l. Marrakchi[1]
[1]EPH Bordj Bou Arreridj, BBA, Algeria

Background & Objectives: Myoid hamartoma of the breast is an extremely rare entity, first described by Davies and Riddell in 1973, with only a few cases reported in the literature. It represents a unique variant of mammary hamartomas, characterized by a variable composition of glandular, fibrous, and adipose tissue, with a prominent smooth muscle component. The rarity of this lesion, combined with its histological complexity, makes its diagnosis particularly challenging.
Methods: A 48-year-old female patient, with no medical or surgical history, presented with a right breast nodule. Ultrasound examination revealed a solid, hypoechoic nodule in the upper outer quadrant of the right breast, initially suggestive of a fibroadenoma and classified as BI-RADS3.
A wide excision of the lesion with histological verification was performed.
Results: Macroscopically, the specimen was a well-circumscribed 3 × 2 cm nodule with a smooth surface and firm consistency. On sectioning, the cut surface appeared fleshy and whitish-gray.
Histologically, the breast parenchyma consisted of atrophic lobules within an abundant fibrous stroma, interspersed with numerous adipocytes and congested blood vessels. Rare peripheral ducts displayed a regular dual-layered epithelium without atypia. A predominant component of fascicles of spindle cells with regular nuclei was observed.
Immunohistochemical analysis confirmed the smooth muscle nature of the spindle cells, showing strong and diffuse positivity for smooth muscle actin and H-caldesmon. p63 was negative in the spindle cells and marked only the myoepithelial cells of the ducts. CD34 and S100 were negative.
Conclusion: Breast hamartoma is an uncommon and often underrecognized benign lesion. When it exhibits a predominant smooth muscle component, it is classified as myoid hamartoma, an even rarer entity. Its diagnosis can be challenging due to multiple differential diagnoses,

necessitating careful histopathological assessment. Immunohistochemical studies play a crucial role in confirmation.
Given its rarity and complexity, awareness of this lesion is essential to prevent diagnostic errors and potential mismanagement.

E-PS-02-032
Pleomorphic adenoma of the breast: report of two cases, one with malignant transformation
A. Córdoba[1], I. Amat[1], R. Beloqui[1], M.I. Cevallos[1], L. Ruiz[1]

[1]Hospital Universitario de Navarra, Pathology, Pamplona, Spain
Background & Objectives: Pleomorphic adenoma of the breast (PAB) is a rare benign mixed epithelial-myoepithelial neoplasm that morphologically resembles its salivary gland and skin counterparts.
Since its first description in 1906, only isolated cases of these lesions have been described in the breast (less than 100 cases).
Correct diagnosis is often difficult by core needle biopsy. Malignant transformation of BAPs is an extremely rare complication that has only been reported on three occasions. We present two new cases, one of which masked an invasive epithelial component (pleomorphic exadenoma carcinoma).
Methods: The two women were aged 67 and 57 years respectively. They presented with a new retroareolar mass of 10 and 13 mm in the left and right breast, from which an excisional biopsy was taken in both patients.
Results: The neoplasm consisted of two components. The epithelial component had a glandular or nest cell pattern. The mesenchymal myoepithelial component contained myxoid and chondroid areas. By immunohistochemistry, the glandular epithelial cells expressed CKAE1/AE3, CK 18, CK7. Myoepithelial cells expressed smooth muscle actin, p63 and CK5/6. Cartilaginous stromal cells expressed S-100. In the second case, an infiltrative epithelial growth, corresponding to an invasive carcinoma, is observed at the periphery of the BAP.
Conclusion: Pleomorphic adenoma is a mixed benign (epithelial-myoepithelial) and is one of the so-called salivary gland type mammary tumours. This tumour commonly occurs in the salivary gland, and rarely originates in the breast.
The tumour consists of epithelial, myoepithelial and stromal components, characteristically consisting of bone and/or cartilage. Differential diagnoses in the breast include fibroadenoma, phyllodes tumour, metaplastic carcinoma and mucinous carcinoma.
Pleomorphic adenomas on core needle biopsy may be misdiagnosed as a primary sarcoma or metaplastic breast carcinoma. Malignant transformation is extremely rare, having been described only three times before we presented our case.

E-PS-02-033
Expression of LEF- 1, β- catenin and Ki -67 labelling index in fibroepithelial neoplasms of breast
M. Rao[1], H. Vel[1], P. Elhence[1], A. Nalwa[1], S. Khera[1], J. Vishnoi[2], R. Chaudhary[3]
[1]All India Institute of Medical Sciences (AIIMS), Jodhpur, Pathology & Lab Medicine, Jodhpur, India, [2]All India Institute of Medical Sciences (AIIMS), Jodhpur, Surgical Oncology, Jodhpur, India, [3]All India Institute of Medical Sciences (AIIMS), Jodhpur, General Surgery, Jodhpur, India

Background & Objectives: Diagnostic challenges exist in distinguishing Phyllodes Tumour (PT) from Fibroadenomas (FA) and accurately grading them, especially in core needle biopsy (CNB) specimens. Lymphoid Enhancer Binding Factor 1 (LEF-1) is an important component of the Wnt/β-catenin signalling pathway. This study was undertaken to assess expression of LEF-1, β-catenin and Ki-67 labelling index in fibroepithelial neoplasms of the breast and assessing their utility as potential markers for differentiating between FAs, benign PTs, borderline PTs, and malignant PTs.
Methods: Expression of LEF-1, β-catenin, and Ki-67 labelling index was assessed by immunohistochemistry (IHC) on 100 cases of fibroepithelial neoplasms (study period January 2019 to 2023), of which 67 were resection specimens (30 FA and 37 PT). IHC was also put up on 21 CNBs for which subsequent resection specimen was available for comparison of IHC expression between CNBs and the corresponding resection specimens.
Results: Among PTs, 61.4% were benign tumours, 25% were borderline tumours, and 13.6% were malignant PTs. PTs were more commonly observed in older individuals, with a mean age of 42.10 years compared to FA patients with a mean age of 25.43 years. The size of PTs was significantly larger than FAs, with a mean size of 8.42 cm compared to 3.89 cm, respectively. Except for mitotic count, there were no statistically significant differences observed in terms of cellularity, atypia, stromal overgrowth, and heterologous elements between core needle biopsies and their corresponding resection specimens. Immunohistochemical analysis revealed increased expression of LEF-1, beta-catenin, and Ki-67 labelling index in the stroma of PTs compared to FAs. Also, the immunohistochemical expression of LEF-1 and beta catenin in CNBs corresponded to that in the subsequent resection specimens. Ki-67 labelling index in CNBs did not correspond with that in the subsequent resection specimens.
Conclusion: LEF1 and beta catenin can be useful in CNBs for refining diagnosis of fibroepithelial neoplasms

E-PS-02-034
A pitfall to avoid: Langerhans dendritic cells in lymph nodes may mimic metastases from breast cancer
S. Aviel-Ronen[1], N. Balint-Lahat[2], M. Schvimer[2], D. Frank[2], D. Rosin[3], G. Schiby[4]
[1]Sheba Medical Centre / Ariel University, Pathology / Adelson School of Medicine, Ramat Gan / Ariel, Israel, [2]Sheba Medical Centre, Pathology, Ramat Gan, Israel, [3]Sheba Medical Centre / Tel Aviv University, Ambulatory Surgery Department / Faculty of Medicine and Health Sciences, Ramat Gan / Tel Aviv, Israel, [4]Sheba Medical Centre / Tel Aviv University, Pathology / Faculty of Medicine and Health Sciences, Ramat Gan / Tel Aviv, Israel

Background & Objectives: Langerhans dendritic cells (DCs) present tumour-derived antigens to T cells, facilitating anti-tumour response, and their presence in axillary lymph nodes has been linked with breast cancer prognosis. Here, we address a possible pitfall in diagnosis stemming from this connection by presenting a rare case of occult metastatic invasive lobular carcinoma (ILC) in a lymph node (LN).
Methods: The medical records and pathological findings of a 68-year-old patient who went through right breast mastectomy due to metastatic infiltrating duct carcinoma (IDC) are presented. Her medical background included lung lepidic adenocarcinoma treated by left upper lobectomy (7 years prior) and metastatic ILC of the left breast (10 years before) treated by lumpectomy and combination hormonal-targeted drug therapy. The patient showed a complete response.
Results: The right breast showed IDC, grade 2, with micropapillary features and extensive lymphovascular invasion. Three right axillary sentinel LNs showed metastases of IDC and extensive fibrosis. Surprisingly, AE1/AE3 immunostaining of the LN metastases demonstrated two staining patterns: strong membranous staining of the IDC with micropapillary features and an additional moderate cytoplasmic

staining of single spreading cells that were also positive for GATA3 and oestrogen (ER) and negative for TTF1 and progesterone (PR). Similarly, the stain for E-cadherin showed two patterns of staining: strong membranous staining of the IDC and an additional moderate cytoplasmic staining in a non-aggregated pattern of cells that were also positive for CD1a, S100, and langerin (CD207) and constituted Langerhans DCs. Indeed, the cytokeratin-positive single spreading cells located between the DCs were negative for E-cadherin and represented occult metastatic ILC.
Conclusion: This unusual case of dual metastatic ILC-IDC breast carcinoma brings to attention the intriguing contribution of Langerhans dendritic cells to immunity and their intimate association with tumour cells. It also highlights the pivotal role of careful and diligent pathological evaluation in reaching an accurate interpretation and diagnosis.

E-PS-02-035
Breast biomarker dynamics in primary and metastatic settings: insights from a tertiary cancer centre in India highlighting changes of expression pattern and its clinical impact
Z. Chowdhury[1], P. Majumdar[1], S. Haiyat[1], I. Dhal[1], S. Patne[1], P. Paul[1], A. Kapoor[2], M. Tripathi[3], P. Giridhar[4]
[1]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Oncopathology, Varanasi, India, [2]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Medical Oncology, Varanasi, India, [3]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Surgical Oncology, Varanasi, India, [4]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Radiation Oncology, Varanasi, India

Background & Objectives: Breast cancer (BC) is the second most common cancer globally and the leading cause of cancer mortality in women. Immunophenotypic discordance between primary and metastatic sites can impact treatment outcomes. While international guidelines suggest rebiopsy of metastatic lesions to reassess tissue biomarkers, studies focusing on Indian BC cohorts are limited.
Objective: To analyse the dynamics of BC biomarkers in primary versus metastatic sites and its impact on prognosis and survival.
Methods: This retrospective study, conducted at a tertiary cancer centre over a 5-year period, included BC cases with metastasis at presentation or during the disease course, with available biopsy samples from both primary and metastatic sites. Clinical metrics and immunohistochemical expression of oestrogen receptor (ER), progesterone receptor (PR), and HER2/neu were analysed.
Results: Out of a total of 113 cases, the commonest histological subtype was invasive breast carcinoma (no special type). 6 cases presented with metastasis at diagnosis, while 107 developed metastasis during follow-up. Common metastatic sites were lung, liver, bone, and brain. The majority of the cases were Type 1 [ER+PR+/-HER2-] (42 cases; 37.2%) followed by Type 4 [ER-PR-HER2-] (28 cases; 24.8%), Type 2 [ER+PR+/-HER2+] (24, 21.2%) and Type 3 [ER-PR-HER2+] (19, 16.8%). ER conversion was recorded in 24.8%, PR conversion in 39.8%, and HER2 conversion in 14.2% of cases. Conversion was predominantly from positive to negative in all three biomarkers. ER, PR conversion mainly occurred in Type 2, with HER2 conversion predominantly in Type 1 cases. Lung was the commonest site of conversion for all biomarkers. In 25% of ER conversion cases, disease progression occurred, while 22.2% of PR conversion cases and 18.75% of HER2 conversion cases experienced progression.
Conclusion: Biomarker status does change during metastatic progression in BC. Rebiopsy of metastatic sites with re-appraisal of breast biomarkers is essential for treatment re-stratification, allowing for tailored and specific therapy.

E-PS-02-036
Two rare cases of tuberculous mastitis mimicking breast carcinoma
F. Muresan[1], E. Magheran[2], A.V. Tudor[2]
[1]Carol Davila University of Medicine and Pharmacy, Pathology, Bucharest, Romania, [2]Institute of Pneumophysiology Marius Nasta, Pathology, Bucharest, Romania

Background & Objectives: The breast is particulary resistant to tuberculosis invasion. Tuberculous mastitis (TBM) is a rare, often misdiagnosed condition, affecting <0.1% of breast specimens in the USA, altough, the only estimates date back to 1985, when only 500 cases were reported world-wide.
Methods: We report the only two cases of TBM extracted from the 2000-2025 digital archive of *Marius Nasta Institute of Pneumophitsiology*, Romania. The patients initially exhibited clinical and radiological features suggestive of malignancy or breast abscesses, prompting further histopathological and microbiological investigations. Based on the clinical and pathological presentation, the most likely routs of breast invasion are discussed.
Results: ***Case1*:** A 73-year-old woman presented with extreme weight loss (BMI=15, W=37kg), a firm breast mass, and bilateral axillary lymphadenopathy. CT scan showed diffuse pulmonary consolidations and mediastinal lymphadenopathy. Core breast biopsy revealed multiple clasical caseating granulomas with acid-fast bacilli on Ziehl-Neelsen staining.
***Case2*:** A 21-year-old woman presented with a breast lump consisting of multiple, non-caseating granulomas, initially diagnosed as granulomatous mastitis. Tuberculous aetiology was confirmed by Ziehl-Neelsen stain.
Both patients were diagnosed with nodular secondary TBM and had poor initial response to antibiotics. Clasically, TBM is considered to affect young, lactating women from the indian subcontinent. These cases highlight the diverse epidemiology of the disease, beyond clasical risk groups.
Conclusion: Given its rarity, TBM poses a significant diagnostic challenge and should be considered in the differential diagnosis of any granulomatous breast lesion. There are no specific standardized treatment protocols and initial treatment often fails, requiering a second, more aggressive antibiotic regiment or surgical intervention. Although tuberculosis is regarded as a disease of the past, the rise of extreme- or multidrug-resistant strains highlights the critical need for accurate diagnosis and tailored treatment strategies.

E-PS-02-037
Two cases of low-grade triple-negative breast carcinomas: is it enough to assign them as such?
O. Boudaouara[1], S. Graja[1], M. Bouhamed[1], M. Mellouli[1], S. Charfi[1], T. Sellami-Boudawara[1]
[1]Habib Bourguiba Hospital, Pathology Department, Sfax, Tunisia

Background & Objectives: Triple-negative-breast-carcinomas (TNBC) are defined by the lack of expression of hormone and HER2 receptors and comprise a heterogenous group of invasive carcinomas with significant molecular, morphological and clinical heterogeneity. Although the majority are high-grade tumours, low-grade TNBC (LGTNBC) do occur and demonstrate characteristic

morphological and immunohistochemical profiles as well as indolent behaviours.
In this study, we illustrate histological and immunohistochemical features of two cases of LGTNBC (secretory carcinoma (SC) and adenoid cystic carcinoma (ACC)), highlighting the need for suggesting or diagnosing a specific histological-subtype, ideally as-soon-as the biopsy is analysed.
Methods: We report 2 cases of LGTNBC in two women aged 57 and 64 years-old respectively. Both patients were diagnosed as such on a preoperative-core-needle-biopsy and subsequently on the corresponding breast-surgical-specimen.
Results: On histologic sections, the first tumour was predominantly composed of tubules and cribriform structures with low-grade cytological features. Immunohistochemical analysis demonstrated a characteristic dual-cell population of luminal (CK7+, CD117+) and myoepithelial-basal cells (CK5/6+, p40+), as well as a basal-like phenotype (ER-, PR- and HER2-) and a low-proliferative-index. These findings were consistent with a LGTNBC further categorized as a classic-ACC. The second tumour was composed of tumour cells with low-grade cytological atypia arranged in microcystic/honeycomb, and tubulo-papillary growth pattern. Additionally, eosinophilic intracellular and extracellular secretions were evidenced and stained positively with PAS and Alcian blue. Tumour cells were of basal-like phenotype and S100-positive. Proliferative-index was low. Given these findings, we concluded to a LGTNBC, suggesting a SC. Nevertheless, ETV6-NTRK3 fusion could not be demonstrated given the non-availability of appropriate molecular tests in our pathology department.
Conclusion: LGTNBC is a descriptive term that could be used as a provisional diagnosis if a specific subtype could not be established, mainly in core-needle-biopsies. Indeed, accurate histological subtyping is crucial as prognoses and therapeutic strategies may differ among entities.

MUC2 is a useful diagnostic marker for distinguishing primary mucinous cystadenocarcinoma and mucinous carcinomas of the breast: report of a case and comparative study

C. Taverna[1,2], S. Sutti[3], P.C. Rassu[4], F. Millo[5], E.L. Ratto[5], R.J. Dasilva[6], R. Buosi[7], E. Bo[8], R. Gaeta[9]
[1]Local Hospital San Giacomo, Pathology Unit, Novi Ligure, Italy, [2]University of Eastern Piedmont "Amedeo Avogadro" UNIUPO, Department of Health Sciences, Novaraital, Italy, [3]University of Eastern Piedmont "Amedeo Avogadro" UNIUPO, Department of Health Sciences and Interdisciplinary Research Centre for Autoimmune Diseases, Novara, Italy, [4]Local Hospital San Giacomo, General Surgery, Novi Ligure, Italy, [5]Local Hospital SS Antonio e Margherita, Breast Unit, Tortona, Italy, [6]Local Hospital San Giacomo, Radiology Unit, Novi Ligure, Italy, [7]Local Hospital Santo Spirito, Oncology Unit, Casale Monferrato, Italy, [8]Local Hospital SS Antonio e Margherita, Oncology Unit, Tortona, Italy, [9]University Hospital of Pisa, Second Division of Surgical Pathology, Pisa, Italy

Background & Objectives: Primary mucinous cystadenocarcinoma of the breast (MCA) represents an exceedingly rare neoplasm, with 45 cases described so far, distinct from mucinous carcinoma (MC).
Especially in small biopsies, the differential diagnosis with mucinous carcinomas (MC) can be challenging.
Mucin expression is occasionally and often only partially studied in MCA, with only 7 other cases reported in literature, all negative for MUC2.
We investigated mucin expression in one case of MCA and in a pool of 35 MC cases to evaluate differences and compare our results with literature.
Methods: Immunoistochemical data of MUC1, MUC2, MUC4, MUC5AC and MUC6 were evaluated using a semi-quantitative score. In all cases, a complete immunoprofile of molecular subtype for breast carcinoma was also performed.
Results: MCA showed a triple negative molecular subtype, expressed CK7 and was negative for CDX2 and CK20.
Out of 35 MC, 33 were luminal and 2 had a HER2 enriched immunoprofile.
The MCA case expressed MUC1 and focally MUC5ac, while MUC2, MUC4 and MUC6 showed negative stains.
All MC cases (35, 100%) expressed MUC1, 29/35 (82,8%) showed positive stain for MUC2, 2 cases (5,71%) were positive for MUC4, 18 (51,4%) demonstrated MUC5 expression and 22 (62,14%) were positive for MUC6.
In relation to clinicopathological features, MUC1 expression was significantly related to Nottingham score (p=0.0310), MUC1 and MUC5 score with vascular invasion (p=0.0268 and p=0.0204, respectively) and MUC5 with nodal status (p=0.0485).
Conclusion: The results of our study show that MUC2 could be a useful marker in the differential diagnosis between MCA and MC, particularly on limited biopsy material and especially in hypocellular or micropapillary MC cases.
The case herein reported increased the number of MCA cases with mucin immunoprofile.
Moreover, MUC1 and MUC5 expression in MC cases can have prognostic value.

E-PS-02-039

Upgrade rate and predictive factors for phyllodes tumour in fibroepithelial lesions of the breast in patients aged over 50 years

L. Barzinjy[1], T. Salisbury[2], K. Oscilowicz[3], G. Sokhanran[4], P. Sokhanran[4], A. Zamani[5], R. Alaghehbandan[6]
[1]Anderson C.V.I., Whitby, Canada, [2]Royal Columbian Hospital, Pathology, Vancouver, Canada, [3]Regional Specialist Hospital, Pathology, Wrocław, Poland, [4]University of British Columbia, Vancouver, Canada, [5]Simon Fraser University, Vancouver, Canada, [6]Cleveland Clinic, Pathology, Cleveland, USA

Background & Objectives: Fibroepithelial lesions (FELs) of the breast are heterogeneous neoplasms that can present diagnostic challenges, especially in core needle biopsy (CNB). The aim of this study was to determine the upgrade rate of FEL core biopsies to phyllodes tumour (PT) and identify associated predictive factors in women over the age of 50.
Methods: This is a retrospective, population-based study of fibroadenomas (FELs) of the breast, including fibroadenoma (FA), FEL-indeterminate, and phyllodes tumour (PT) diagnoses, based on core biopsies conducted over a three-year period (2017-2019) in Vancouver, BC, Canada. Core biopsy diagnoses were compared with surgical pathology resection findings, and clinical and radiologic factors were analysed to identify features associated with PT.
Results: Of 104 core biopsies of fibroadenomas (FELs), including 90 diagnosed as fibroadenoma (FA), 3 as phyllodes tumour (PT), and 11 as FEL-indeterminate, 23 proceeded to excisional biopsy, with a 39.1% upgrade rate to PT. Of the 10 core biopsies initially diagnosed as FA, 1 was upgraded to PT on excisional biopsy, yielding a negative predictive value (NPV) of 90%. Among the 3 core biopsies diagnosed as PT, all were confirmed as PT on excisional biopsy, resulting in a positive predictive value (PPV) of 100%. The mean mass size was significantly larger in the PT group (3.3 cm) compared to the FA group (1.1 cm) (p<0.0001). A logistic regression model identified tumour size as a strong predictor of PT. Factors such as BIRAD score, needle gauge, clinical presentation, and a history of breast cancer were not associated with an upgrade to PT.
Conclusion: Core biopsy demonstrates high sensitivity and specificity in the stratification of FELs of the breast. In cases of indeterminate core biopsies, relevant clinical factors, such as tumour size, may assist

in making informed decisions. Core biopsy is essential in preventing unnecessary surgical procedures for FELs.

E-PS-02-040

Assessment of tumour microenvironment in malignant phyllodes tumour by immunohistochemistry and the clinical pathological parameters association

S.S. Ahmed[1], J. Iqbal[1], G.F. Tan[1]
[1]Singapore General Hospital, SingHealth, Anatomical Pathology, Simgapore, Singapore

Background & Objectives: Phyllodes tumour (PT), a biphasic tumour with epithelial and stromal components, account for <1% of all breast neoplasms. A combination of histological features of the stromal component such as cellularity, overgrowth, mitoses, atypia & tumour borders determine the benign, borderline and malignant classification. These histological features do not always accurately predict tumour behaviour, affecting clinical management.
We studied the tumour microenvironment (TME) in malignant phyllodes tumour (MPTs) in relation to various clinicopathological parameters.
Methods: Immunohistochemistry was performed on tissue microarrays from 30 MPTs with CD3, CD20, CD4, CD8, CD138, CD163 and PD-L1(SP263), and numerical immune cell scores assigned accordingly for each category. Immune cell scores were compared to clinicopathological parameters, disease free survival (DFS), overall survival (OS) outcomes.
Results: Macrophage scores were significantly higher in MPT than in benign breast tissue ($p<0.001$). Higher macrophage scores correlated with increased stromal cellularity ($p=0.025$).
Patient age ranged from 15 to 79 years (median 43 years). CD3 and CD8 scores were significantly correlated with increased age ($p=0.035$ & $p=0.023$), while CD8 scores also correlated with presence of stromal heterologous elements ($p=0.046$). No significant correlation was found between immune cell scores and survival outcomes. There was no expression of PD-L1 in MPTs.
Conclusion: Tumour-associated macrophages (TAMs) are a heterogeneous group of macrophages with varied functions, and can facilitate tumour growth by immunosuppression, invasion & metastasis. The diversity of phenotypes is a critical factor in development of therapeutic resistance. The significant presence of TAMs in MPTs in our study may provide new avenues in the diagnosis and development of therapeutics in this challenging field.

E-PS-02-041

To assess the concordance of breast lesion size of patients in radiology ultrasound and breast mammograms with breast pathology specimens

R. Sadavarte[1], E. Cobby[1]
[1]Shrewsbury and Telford Hospital, Pathology, Shrewsbury, United Kingdom

Background & Objectives: To ensure high level of concordance between the pathology breast specimen and imaging.
Methods: Data was collected from Shrewsbury and Telford NHS trust hospitals clinical portal system in the United Kingdom. The data that was reviewed included patient mammogram and radiology ultrasound breast lesion sizes. An individual patient's radiology index data was collected; this included a score from R1 to R5 as well as ultrasound score from U1 to U5. The size of the breast lesion was documented from both the ultrasound and mammogram data from clinical portal data system on an excel spreadsheet. Breast tumour lesion sizes were also obtained from the pathology reports (both microscopic and macroscopic) and were documented also on an excel spreadsheet.
Results: 76% of the datasets between radiology ultrasound and mammogram to the pathology analysis were concordant. Concordancy was assessed in relation to TNM staging. Of the 59 datasets collected, 14 patients had discordancy between radiology and pathology tumour sizes. Of these 14 patients that had discordant results, eight patients had lobular and multifocal carcinomas in the pathology samples. Three of the 14 patients had started neoadjuvant therapy and the remaining three patients had high grade ductal carcinoma. In the discordant data, 50% of patients that had multifocal, lobular cancers also had additional tumours that were detected in the pathology review. The time taken from imaging to surgery with the 14 patients that have discordant results was on average 1.5 months. All discordant data patients did not require further surgery- they were all followed up with chemotherapy or radiotherapy and hormonal based treatments.

Conclusion: This project will help to improve collaboration between pathology and radiology teams by ongoing multidisciplinary discussions for best patient care. The next steps are for pathologists to re-familiarise with the breast cancer dataset on measuring tumour sizes.

E-PS-02-043

Sarcomatoid metaplastic carcinoma or sarcoma: immunohistochemical analysis of CK-negative or -minimal positive sarcomatoid breast tumours

H. Sun[1], L. Huo[1], K. Sweeney[1], W. Yu[1], L. Middleton[1], L. Khazai[1], Y. Wu[1], H. Chen[1], C. Albarracin[1], A. Sahin[1], Q. Ding[1]
[1]University of Texas MD Anderson Cancer Centre, Pathology, Houston, USA

Background & Objectives: Distinguishing sarcomatoid metaplastic breast carcinoma (MBC) from breast sarcoma is challenging, particularly when the tumour lacks evidence of epithelial differentiation. In this study, we investigated if the commonly used breast epithelial markers — GATA3, SOX10, and TRPS1 — could help resolve this diagnostic dilemma.
Methods: This study included 48 malignant sarcomatoid breast tumours with high-grade spindle or pleomorphic cells and no or minimal (<5%) expression of multiple cytokeratins (CKs). These tumours were divided into two groups. Group 1 included 19 cases with biphasic morphology, featuring both sarcomatoid and epithelial (IDC and/or DCIS) components. Group 2 included 29 cases without epithelial components, of which 14 had a history of invasive breast carcinoma (IBC) and radiation therapy, 15 had no IBC history. Immunohistochemical stains for GATA3 (Cell Marque, L50-823), SOX10 (Leica, clone 991), and TRPS1 (Zeta, ZR380) were performed, and staining intensity and percentage in sarcomatoid elements were assessed.
Results: In Group 1, all cases showed intermediate to high TRPS1 positivity. TRPS1 with GATA3 and/or SOX10 was observed in 10 cases. In Group 2, among the 14 cases with IBC and radiation history, 1 case was negative for the 3 markers. TRPS1 with GATA3 or SOX10 was observed in 9 cases, and TRPS1 alone was positive in 4 cases. Among the 15 cases without IBC history, 5 cases were negative for the 3 markers. TRPS1 along with GATA3 or SOX10 was observed in 5 cases, and TRPS1 alone was positive in 5 cases.
Conclusion: Our study found that while sarcomatoid MBC may lose common epithelial markers, TRPS1 expression is consistently retained in these tumours (Group 1). The absence of CK, TRPS1, GATA3, and SOX10 may suggest primary sarcoma or terminal sarcomatoid differentiation of MBC, while the presence of TRPS1 with GATA3 and/or SOX10 supports an epithelial origin, such as MBC, potentially even in radiation-induced cases.

E-PS-02-045

Fibromatosis of the breast: a 20-year institutional experience

A. Córdoba[1], M.I. Cevallos[1], A. De Oliveira[1], I. Amat[1], R. Beloqui[1]
[1]Hospital Universitario de Navarra, Pathology, Pamplona, Spain

Background & Objectives: Fibromatosis of the breast represents a rare type of desmoid tumour and is characterised by a clonal fibroblast proliferation with an unpredictable clinical course. It represents only 0.2% of all breast tumours. It is a nonmalignant tumour that often resembles cancer in both its clinical presentation and radiologic imaging characteristics, posing unique diagnostic and management challenges. The aim was to review our institutional experience of breast fibromatosis, in the last 20 years.
Methods: A search of pathological databases within a tertiary institution for all patients diagnosed with fibromatosis of the breast over a 20-year period (2005–2025) was performed.
Results: Twelve patients were identified. Median age at diagnosis was 55 (range 24–74). There are 11 females and 1 male. The mean lesion size was 17.2 mm (between 50 and 5 mm). Radiologically they were considered BIRAD 4 lesions. In 10 cases the diagnosis was made by core needle biopsy. In two cases surgery was performed directly. The diagnosis was confirmed by immunohistochemical study of B-catenin with nuclear expression. Margins were positive in 8 cases. No recurrences have been observed with a follow-up in 10 patients between 20 and 1 year. Two patient had a history of infiltrating carcinoma.
Conclusion: Breast fibromatosis is a rare entity, clinically and radiologically mimicking breast cancer.
The differential diagnosis is broad and should be made with Scar, Nodular fasciitis, Dermatofibrosarcoma protuberans, Low grade fibromatosis-like metaplastic carcinoma, Myofibroblastoma and Benign phyllodes tumour.
Breast augmentation has been described as a risk factor for the development of breast fibromatosis, but has not been explicitly linked to cancer breast surgery.
A literature search showed that there have been only 9 reported cases of male breast fibromatosis
We have not confirmed the high recurrence rate in our series, as no recurrence was detected in the 8 cases with follow-up and affected edges.

E-PS-02-047
Impact of different CE-IVD IHC assays on HER2 status in breast cancer with focus on HER2-low and HER2-ultralow
K.B. Anderson[1], S. Nielsen[1], B. Truumees[1], R. Røge[1]
[1]Aalborg University Hospital / NordiQC, Pathology, Aalborg, Denmark

Background & Objectives: The European Medicines Agency (EMA) recently approved trastuzumab deruxtecan for treating patients with unresectable or metastatic HR-positive breast cancer (BC) that is HER2-low or HER2-ultralow. HER2 status should be determined using a CE-IVD-approved immunohistochemistry (IHC) assay. While staining differences among IHC-assays are well known, a direct comparison of the three main CE-IVD-approved assays is lacking. Additionally, previously published comparisons provide limited information on analytical performance due to post-analytical variability in the studies.
This study evaluates the analytical performance of three most frequently used CE-IVD-approved HER2 IHC-assays and their clinical implications for categorizing HER2-low and HER2-ultralow BC.
Methods: Two tissue microarrays (TMAs) were constructed for other quality control studies, including triple-negative and ductal BC. Serial sections, minimizing tumour heterogeneity, were stained with three CE-IVD approved IHC-assays: PATHWAY rmAb 4B5, 790-2991 (Ventana/Roche), HercepTest pAb, SK001 (Dako/Agilent) and HercepTest rmAb DG44, GE001 (Dako/Agilent). All BCs were scored as HER2 0, ultralow, 1+, 2+ or 3+. The amplification status was available for HER2 2+ cases based on fluorescence in situ hybridization of the original tissue.
Results: In total 109 BCs were analysed. A 97% concordance was observed across all three assays, classifying samples into the classical two groups: HER2 negative (0, ultralow, 1+, 2+ unamplified) and HER2 positive (3+, 2+ amplified). For HER2-low and HER2-ultralow a low inter-assay agreement was seen as the HER2 0 classification differed between assays: PATHWAY classified 34% (37 samples) as HER2 0, compared to 25% (27 samples) with HercepTest rmAb and 31% (34 samples) with HercepTest pAb.
Conclusion: This study shows strong concordance among the three IHC assays using the classical interpretation, which classifies BC as HER2 positive or negative. However, under the indication, where only HER2 0 patients are untreated, assay choice affects treatment decisions, with PATHWAY rmAb classifying more patients as HER2 0 compared to the two HercepTest assays.

E-PS-02-048
Undifferentiated pleomorphic sarcoma of the breast: a case report and review
Y. Aksoy[1], H.E. Peştereli[1], İ. Zihni[2]
[1]Akdeniz University, Department of Pathology, Antalya, Turkey, [2]Akdeniz University, Department of General Surgery, Antalya, Turkey

Background & Objectives: Undifferentiated pleomorphic sarcoma (UPS) of the breast is a rare tumour. Histologically, it is composed of pleomorphic cells with epithelioid and spindle cell morphology, histiocytoid features with vacuolated cytoplasm, and karyorrhectic giant cells. The tumour exhibits areas of necrosis and frequent mitotic activity. Due to its rarity, we present this case to contribute to the literature.
Methods: Examination included formalin fixation and paraffin embedding (FFPE) of the tumour tissue. Haematoxylin and eosin (H&E) staining was performed to evaluate cellular morphology, necrosis, and mitotic activity. Immunohistochemical staining was conducted using a panel of markers, including desmin, SMA, caldesmon, S100, myogenin, MYOD1, CD34, PanCK, CDK4, MDM2, HMB45, H3K27ME3, ALK, and CD30, to exclude other differential diagnoses and confirm the diagnosis of UPS.
Results: A 52-year-old female presented with a palpable mass in the left breast. Histological examination revealed pleomorphic cells with epithelioid and spindle morphology, frequent mitoses, and areas of necrosis. Immunohistochemical analysis was negative for desmin, SMA, caldesmon, S100, myogenin, MYOD1, CD34, PanCK, CDK4, MDM2, HMB45, H3K27ME3, ALK, and CD30. Based on these findings, a diagnosis of **undifferentiated pleomorphic sarcoma of the breast** was established.
Breast UPS is an extremely rare malignancy, with only a few cases reported in the literature. Cases have been observed in patients aged 22-76 years, with tumour sizes ranging from 1 to 17 cm. Most diagnoses occur within months of symptom onset. Our case involved a 52-year-old patient with a 7 cm tumour.
Conclusion: Undifferentiated pleomorphic sarcoma of the breast is a rare neoplasm that shares morphological similarities with UPS in other anatomical locations. Due to its rarity, further case reports are needed to better understand its behaviour and optimal management.

E-PS-02-049
Glycogen-rich carcinoma of the breast: a report of two new cases
N. Ibisevic[1], J. Redžepagić[1], F. Skenderi[2], S. Vranic[3]
[1]Clinical Centre University of Sarajevo, Pathology, Sarajevo, Bosnia and Herzegovina, [2]UniMed Clinic, Sarajevo School of Science and Technology, Pathology, Sarajevo, Bosnia and Herzegovina, [3]College of Medicine, QU Health, Qatar University, Pathology, Doha, Qatar

Background & Objectives: Glycogen-rich carcinoma (GRCC) of the breast is a rare histological variant (pattern) of invasive breast carcinoma of no special type. It is characterized by tumour cells with abundant, clear, glycogen-filled cytoplasm. Reported expression

levels of steroid receptors (Estrogen receptor/ER/ and progesterone receptor/PR/) and HER2 vary in the literature.
Methods: We present two new cases of GRCC in a 66-year-old and a 51-year-old patient.
Results: Both tumours displayed predominantly solid growth patterns with clear, PAS-positive/PAS-D-sensitive cells. In Case 1, the tumour had moderate cellular atypia with low mitotic activity (grade 2). Immunohistochemically, it was ER-positive, PR-negative, and HER2-positive (score 3+). In contrast, Case 2 showed high mitotic activity (grade 3) and was triple-negative (ER-negative, PR-negative) with a low HER2 phenotype (score 1+). Staging revealed pT1cN0 disease in Case 1 and pT2N0 in Case 2. Both patients underwent primary surgery with axillary dissection, followed by adjuvant systemic therapy. Case 1 also received anti-HER2 and endocrine treatments.
Conclusion: GRCC is heterogeneous in its clinical presentation and molecular features. However, its management predominantly depends on the tumour's pathological and molecular profiles. Further follow-up will be necessary to determine if this rare variant of invasive breast carcinoma demonstrates a distinct clinical course compared to other breast cancers.

E-PS-02-050
Mismatch repair protein expression in breast cancer
N. Kumari[1], S. Gupta[1], T. Agarwal[1], N. Srivastava[2]
[1]All India Institute of Medical Sciences, Raebareli, Pathology & Lab Medicine, Raebareli, India, [2]All India Institute of Medical Sciences, Raebareli, General Surgery, Raebareli, India

Background & Objectives: Breast cancer (BCa) is the leading cause of cancer diagnosed in women. Multifactorial risk factors including increased body mass index (BMI), obesity, alcoholism, smoking and hyperoestrogenic states have been postulated. Mismatch repair (MMR) has been a causative germline alteration in several cancers. BCa exhibiting deficient-MMR (dMMR) often display unique molecular features and tend to have higher mutational burden, potentially influencing response to therapy. Few reports indicate that dMMR occurs in a small subset of BCa, with a prevalence of approximately 1-3%.
Objectives:

- To assess the prevalence of mismatch repair deficiency in patients with breast carcinoma
- To correlate mismatch repair deficiency with clinicopathological and molecular profile of breast carcinoma in Indian patients.

Methods: A total of 42 cases of histologically proven BCa were reviewed for histopathology, hormonal immunohistochemistry and socio-demographic variables were noted. MMR expression for all 4 MMR antibodies were studied.
Results: A total of 42 cases of invasive ductal carcinoma were analysed. All the patients were females and with a mean age of 47. Of the 42 cases, core biopsies were done in 36 cases, in 14 cases core biopsies were followed by modified radical mastectomy and in the other 6 cases, only modified radical mastectomy was done. Immunohistochemistry for hormonal profiling revealed that of those 42 cases, 2 cases were Luminal A, 18 cases were Luminal B, 13 cases were HER2 enriched and 9 cases were triple negative BCa. Simultaneously, immunohistochemistry for mismatch repair showed that PMS2 and MSH6 was deficient in 2 out of 42 cases.
Conclusion: MMR deficiency testing done in the Western population, are noted in about 1-3 % of cases in previous studies. In the present study, MMR deficiency was noted in 4.7 % cases, however, owing to limitation of small size, further studies are needed to assess the frequency of alteration of MMR system.

E-PS-02-052
Expression of SOX17 in triple negative breast carcinomas
B. Virine[1,2], E. Slodkowska[1,2], F.-I Lu[1,2], R. Han[1,2], S. Nofech-Mozes[1,2]
[1]Sunnybrook Health Sciences Centre, Toronto, Canada, [2]University of Toronto, Department of Laboratory Medicine and Pathobiology, Toronto, Canada

Background & Objectives: Triple-negative breast carcinoma (TNBC) is a heterogeneous group of tumours defined by the absence of oestrogen receptor and progesterone receptor expression, and HER2 overexpression. Diagnostic challenges often arise, particularly in metastatic settings, where differentiation from other malignancies is critical. PAX8, commonly used as a marker of müllerian origin, may be expressed in up to 40% of TNBCs depending on the clone, limiting its specificity. SOX17, a transcription factor recently proposed as a diagnostic marker, is expressed in a majority of endometrial and ovarian carcinomas, including mesonephric-like carcinoma. This study aimed to evaluate SOX17 expression in TNBC.
Methods: Tissue microarrays (TMAs) containing 308 TNBCs (triplicate 1 mm cores) were immunostained for SOX17, PAX8 (SP348) WT1 (6F-H2), GATA3 (L50-823), and TTF1 (SPT24) using standardized protocols and scored using a modified Allred scoring system. Tumours were classified histologically per WHO guidelines.
Results: SOX17 expression was identified in only 1 of 308 TNBCs (0.3%), limited to focal positivity (<5% of tumour cells, weak to moderate intensity). This tumour, classified as invasive carcinoma of no special type, also expressed GATA3 and WT1 but was negative for TTF1 and PAX8. Endothelial cells exhibited consistent SOX17 positivity, serving as an internal control. Interpretation of SOX17 was occasionally challenging, in distinguishing endothelial cells from neoplastic cells of spindle cell metaplastic carcinomas.
Conclusion: SOX17 is absent in 99.7% of TNBCs, supporting its utility as a discriminatory marker when differentiating TNBC from endometrial or tubo-ovarian carcinomas. In the appropriate clinical context, SOX17 expression may aid in identifying a non-mammary origin. However, interpretation requires caution, particularly in metaplastic carcinomas, and recognition of non-specific staining in endothelial cells is essential to validate immunostain adequacy.

E-PS-02-053
Beyond HER2 'Negative': Do We Need to Do More?
A. Oruç[1], A.E. Akın[1], H. Avcı[2], A. Üner[1]
[1]Hacettepe University, Pathology, Ankara, Turkey, [2]Hacettepe University, Biostatistics, Ankara, Turkey

Background & Objectives: Breast cancers are currently classified as HER2-positive or HER2-negative based on the evaluation of HER2 status using immunohistochemistry (IHC) and/or in situ hybridization (ISH). Recent clinical trials suggest that patients within the HER2-negative group (those with low or ultralow levels of expression) may benefit from HER2-targeted therapies. This study investigates whether HER2 subgroup classification changes when IHC is performed on multiple tumour blocks and/or metastatic lymph nodes.
Methods: Clinicopathological data from 74 breast cancer patients, initially scored as HER2 '0' per ASCO-CAP guidelines in their pathology reports, were retrieved. Patients with fewer than three formalin-fixed paraffin-embedded tumour blocks and those who received neoadjuvant therapy were excluded. HER2 IHC was performed on two additional tumour blocks and the largest metastatic lymph node (n=24) if present. The original HER2-stained slide and the newly stained additional slides were independently scored by three pathologists and categorized into subgroups based on HER2 expression levels.
Results: HER2 assessment on multiple blocks led to the reclassification of 9.5% (n=7) of cases as '1+' and 9.5% (n=7) as '2+,' requiring ISH. Additionally, within the '0' group, 31.1% (n=23) of cases could be

categorized as 'HER2-ultralow.' Testing the largest metastatic lymph node did not provide additional information beyond what was already obtained from analysing two additional primary tumour blocks.
Conclusion: Despite a limited sample size, reassessing HER2 on multiple tumour blocks led to a 19% reclassification rate from '0' to '1+' or '2+.' This suggests that evaluating more than one tumour block could improve the identification of patients eligible for HER2-directed therapies in the lower end of the HER2 expression spectrum.

E-PS-02-054

Expression of miR-21 and miR-127 in metastatic breast carcinoma, primary breast tumour, and normal breast tissue among patients from Tondo Medical Centre, Philippines

G.A. Espiritu[1,2,3], Q.M. Abena[1], I.A. Collantes[1], C. Olalia[1], D.A. Lat[2]
[1]De La Salle University, Department of Biology, Manila, Philippines, [2]Antipolo City Molecular Laboratory, Antipolo Rizal, Philippines, [3]Centro Escolar University, School of Medicine, Manila, Philippines

Background & Objectives: Breast carcinoma is the most prevalent cancer in women globally and locally. Great strides have been made with regards to its treatment, however, there are still patients who succumbed to aggressive types of breast cancer (i.e. metastasizing breast carcinoma). This study aims to investigate the role of microRNAs (miRs) in metastatic and primary breast carcinoma, which may identify potential targets for therapy.
Methods: RNA was extracted from formalin-fixed, paraffin-embedded (FFPE) tissues of the primary breast tumour, normal breast tissue, and lymph node metastatic lesion among four (4) Tondo Medical Centre patients with breast carcinoma with lymph node metastasis. Expression of miR-21 and miR-127 was determined using reverse transcriptase and quantitative polymerase chain reaction (qRT-PCR). Cycle threshold (C_T) values were correlated with histopathologic data between the three groups.
Results: All four (4) patients, aged 43 to 63 years old, had primary breast carcinoma with Nottingham Histologic Score II. Tumour sizes ranged from 3.0 cm to 8.0 cm. Three of four primary tumours expressed miR-21. The primary tumour without miR-21 expression had the smallest tumour size (3.0 cm). All primary tumours did not express miR-127. One of four normal breast tissues expressed miR-21. Interestingly, this normal breast tissue had co-expression of miR-127 consistent with its tumour suppressor role. One of four metastatic (lymph node) lesions expressed miR-21. Of note, this patient had the most number of lymph node metastases (11 out of 13 or 84.62% positive). The remaining three only had 21.05% to 40% positive lymph node metastases. All four metastatic lesions were negative for miR-127.
Conclusion: The results suggest the role of miR-21 in promoting tumour growth and metastasis, which can be a potential target in the development of an alternative therapy. The possible tumour suppressor activity of miR-127 against miR-21 needs further investigation.

E-PS-02-055

A rare case of malignant melanoma masquerading as a breast tumour

V. Winter[1], O. Kiss[1], K. Dezső[2]
[1]Ekvimed Zrt., Pathology, Budapest, Hungary, [2]Semmelweis University, Department of Pathology and Experimental Cancer Research, Budapest, Hungary

Background & Objectives: The histopathological diagnosis of malignant melanoma requires not only the fulfillment of morphological criteria: immunohistochemical and genetic analyses are also necessary in poorly differentiated cases. We report a case of melanoma with no Melan-A and HMB-45 immunoreactivity, extensively involving the breast parenchyma.
Methods: The radiologist reported a breast mass of 14 cm in diameter infiltrating most of the left breast and a lesion above the left clavicle of a 42-year-old woman. The lesion had radiologically sharp contours. A core needle biopsy was performed: histopathological examination showed a tumour consisting of enlarged tumour cells with irregular nuclei and prominent eosinophilic nucleoli in several foci, surrounded by myxoid stroma. The mitotic activity was moderate. Morphological findings raised the possibility of malignant melanoma, clear cell sarcoma and epitheloid malignant peripheral nerve sheath tumour (MPNST). Extended immunohistochemical analysis and additional molecular analysis have also been performed on formaline-fixed paraffin-embedded (FFPE) tissue blocks.
Results: Immunohistochemical analysis showed that tumour cells were strongly and diffusely positivity for vimentin, S100, PRAME and SOX-10 and focal expression of pan CK was also observed. The tumour was negative for ER-receptors, PR-receptors, HER2, Melan-A and HMB-45. Subsequent immunoreactions indicated negative, desmin and Myf-4 reactions. Neither BRAF (V600E) positivity nor INI1 deficiency were detected. Fluorescent in situ hybridization (FISH) was preformed to analyse the translocation of the EWSR1 gene: the lack of the translocation suggested the exclusion of clear cell sarcoma.
Conclusion: As no epidermal involvement was found after a comprehensive dermatological examination, further investigations are needed to determine the exact origin of this tumour. However, primary cutaneous dermal malignant melanoma is an acceptable diagnosis, and the preserved INI1 expression does not completely exclude or strengthens the diagnosis of MPNST.

E-PS-02-057

HER2-low status in invasive lobular carcinoma: a retrospective study at the Medical University of Vienna

K. Tendl-Schulz[1,2], S. Danzinger[3], U. Heber[1,2], Z. Srndic[1,2], E. Gurnhofer[1], M. Hirdler[1], G. Hofstetter[1], E.-M. Langthaler[1], M. Rudas[1], R. Exner[4], M. Marhold[5], R. Bartsch[5], C. Singer[3], Z. Bago-Horvath[1,2]
[1]Medical University of Vienna, Department of Pathology, Vienna, Austria, [2]Medical University of Vienna, Comprehensive Cancer Centre, Vienna, Austria, [3]Medical University of Vienna, Department of Obstetrics and Gynaecology, Vienna, Austria, [4]Department of General and Visceral Surgery, Division of Oncology, Vienna, Austria, [5]Medical University of Vienna, Department of Medicine I, Vienna, Austria

Background & Objectives: Invasive lobular breast cancer (ILC) diagnosis relies on morphological features like dyscohesive growth pattern, typically linked to bi-allelic CDH1 loss, which encodes for the cell-adhesion molecule E-Cadherin. Yet, similar morphology can arise from other genetic changes as well. This study examined the link between loss of E-Cadherin expression and HER2 expression in invasive lobular breast cancers, assessing their impact on DFS and OS.
Methods: We studied 162 patients, aged 32-87, diagnosed with primary invasive carcinoma with lobular morphology at the Medical University of Vienna between 2005-2012 over a 13- to 20-year follow-up. Diagnostics followed current WHO guidelines, with HER2 expression assessed per ASCO/CAP standards. E-Cadherin expression was evaluated via immunohistochemistry, according to current ESMO guidelines. Association between HER2, E-Cadherin expression and clinicopathological parameters was studied by chi^2 test. Disease-free survival (DFS) and overall survival (OS) were analysed using the log rank test, based on E-Cadherin and HER2 expression.

Results: E-Cadherin expression was absent in 106 (65.4%) tumours with lobular morphology. These tumours displayed a significantly higher expression of ER/PR and lower grade and pT stage ($p<0.05$). Ki67 proliferation rate was generally lower in E-Cadherin negative tumours, although not statistically significant ($p=0.1$). Low HER2 expression was more common in tumours with loss of E-Cadherin expression (60.9% vs. 39.1%), though not statistically significant ($p=0.293$). Low HER2 expression did not significantly affect DFS or OS, regardless of E-Cadherin expression.
Conclusion: We observed a trend toward increased incidence of low HER2 expression in breast carcinomas lacking E-Cadherin, without impacting DFS or OS in long term follow-up. Larger cohort studies are warranted to validate our results.

E-PS-02-058
Breast Desmoid Tumour: a retrospective study of 18 cases with review of the literature
Y. Loukil[1], S. Kamoun[1], F. Loued[1], S. Ayadi[1], A. Goucha[1], I. Bettaieb[1], Y. Houcine[1], M. Driss[1]
[1]Salah Azeiz Institute, Pathology Department B, Tunis, Tunisia

Background & Objectives: Breast desmoid tumour (BDT), also known as aggressive fibromatosis, is a rare benign myofibroblastic proliferation characterized by aggressive behaviour and a high recurrence rate. Its clinical presentation often mimics malignancy, and pathology represents the gold standard for diagnosis. A history of trauma or prior surgery is considered the main risk factor. The recommended treatment is wide local excision with clear margin. This study aims to analyse the histopathologic features, treatment approaches and essential differential diagnosis of this rare neoplasm.
Methods: We conducted a retrospective study of 18 cases of BDT diagnosed at Pathology department B over the past 20 years (2005-2025).
Results: The cohort consisted of 13 female patients, with a mean age of 50 years (range: 26–82 years). Most patients had no risk factors, although two had undergone prior procedures on the ipsilateral breast. The type of procedure performed included local excision for three patients, lumpectomy for seven patients and biopsy only was available for three patients.
Among patients who underwent surgery, five cases were purely intraparenchymal while four cases involved the chest wall. The margin status was positive in two cases, negative in six and close in two cases. Pre-operative biopsy was performed in seven cases, with three confirming the diagnoses of BDT. Three patients proceeded directly to surgery with no preoperative percutaneous biopsy.
BDT diagnosis was made by histology alone in two cases and with both histology and immunohistochemistry in 11 cases. Additionally, Cutaneous invasion was observed in two patient and one patient had bifocal BDT.
Conclusion: BDT is a rare neoplasm that predominantly affects females. The principal differential diagnosis includes fibromatosis-like metaplastic breast carcinoma, scar tissue, myofibroblastoma and nodular fasciitis. Immunohistochemical staining for beta-catenin in association with histological features is the key for diagnosis.

E-PS-02-059
Prognostic significance of ROR1, BMI-1 expression and PIK3CA mutation in luminal breast cancer
S. Vtorushin[1,2], V. Tarakanova[1], N. Babyshkina[3], P. Gervas[3], N. Krakhmal[1,2]
[1]Cancer Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Department of General and Molecular Pathology, Tomsk, Russia, [2]Siberian State Medical University of the Ministry of Health of Russia, Pathology Department, Tomsk, Russia, [3]Cancer Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Laboratory of Molecular Oncology and Immunology, Tomsk, Russia

Background & Objectives: Luminal breast cancer (BC), defined by hormone receptor expression, accounts for approximately 70% of all breast cancers. While endocrine therapy improves prognosis, a subset of patients experiences disease progression due to underlying molecular alterations. This study aimed to evaluate the prognostic relevance of ROR1 and BMI-1 protein expression (assessed by immunohistochemistry) and PIK3CA gene mutations (detected by PCR) in patients with luminal HER2-negative BC receiving aromatase inhibitors, with an emphasis on relapse-free survival (RFS).
Methods: The study included 80 postmenopausal women with primary operable luminal HER2-negative BC (T1-2N0-1M0) treated with surgery, radiotherapy, and adjuvant hormone therapy using aromatase inhibitors. Immunohistochemistry was performed to detect ROR1, BMI-1, and cyclin D1 expression in tumour tissues. PIK3CA mutation status was determined using real-time PCR. Statistical associations were analysed using Kaplan-Meier survival curves, χ^2 test, and Cox's F-test ($p<0.05$ considered significant).
Results: ROR1 and BMI-1 expression was observed in 57.5% and 82.5% of tumours, respectively. High expression of both markers was associated with the luminal B subtype. PIK3CA mutations were detected in 30% of cases and were significantly linked to reduced 5-year RFS ($p=0.03$). Cyclin D1 overexpression (in 37.5% of tumours) was strongly associated with ROR1 expression ($p=0.0003$). Co-expression of ROR1 and BMI-1 showed a trend toward more aggressive disease. BMI-1 expression was confirmed in all tumours from patients who experienced relapse.
Conclusion: ROR1 and BMI-1 protein expression, along with PIK3CA mutations, represent clinically relevant biomarkers in luminal BC. Their expression correlates with adverse features such as the luminal B subtype and disease progression. These findings support the integration of immunohistochemical and genetic profiling into clinical practice to enhance risk stratification and guide targeted treatment strategies. Future research should focus on combining PI3K inhibitors with endocrine therapy to overcome resistance and improve survival outcomes in hormone receptor-positive BC.

E-PS-02-060
Breast cancer with choriocarcinomatous differentiation: a case description and review of management and prognosis
A. Diez[1], M. Martinez Lopez[1]
[1]Hospital Universitario 12 Octubre, Madrid, Spain

Background & Objectives: Breast cancer with choriocarcinomatous differentiation is an extremely rare variant, with only 16 cases reported by 2022, half of which are triple-negative. This subtype is characterized by elevated human chorionic gonadotropin (hCG) levels and presents clinically as a conventional breast carcinoma. Treatment usually involves complete surgical excision followed by chemotherapy, but there is no standardized protocol. The prognosis is poor, with survival often limited to a few months due to lymphatic and distant metastases. A key distinction in diagnosis is between primary invasive breast carcinoma with choriocarcinomatous differentiation and metastatic choriocarcinoma in the breast. The former has a poor response to chemotherapy, while the latter responds more favorably.
Methods: A case study of a 62-year-old woman diagnosed in 2021 with bilateral invasive ductal carcinoma (triple-negative, stage IV) is described. She underwent treatment, but in 2023, surgery revealed affected margins. Disease progression continued, and by 2024, her hCG levels rose to 46,714 mU/ml, with metastases in the lungs, liver, and axillary lymph nodes. She passed away the same year.
Results: We analysed 4 cylinders of breast mass with a whitish coloration and elastic consistency, measuring 0.1 cm in diameter,

and ranging in length from 1.4 cm (smallest) to 2 cm (largest). The diagnosis was grade 3 invasive ductal carcinoma with choriocarcinomatous differentiation (score 8: 3+3+2), with an intratumoral lymphocytic infiltrate of < 1%. Giant cells positive for immunohistochemical staining of hCG were identified in the tumour. Molecular study by NGS revealed the p.E542K variant of PIK3CA and the p.E286V variant of TP53.
Conclusion: This variant is characterized by highly atypical cancer cells resembling choriocarcinoma, mixed with epithelial or mesenchymal components. It presents as an aggressive, highly malignant ductal carcinoma with a very poor prognosis, leading to rapid metastases and early mortality. Surgery remains the primary treatment, though no effective chemotherapy regimen has been established.

E-PS-02-061
Primary angiosarcoma of the breast in a breastfeeding woman: a case report
S. Mitrović[1,2], B. Babić[1,2], L. Tadić-Latinović[1]
[1]University Clinical Centre of the Republika Srpska, Department of Pathology, Banja Luka, Bosnia and Herzegovina, [2]University of Banja Luka, Faculty of Medicine, Banja Luka, Bosnia and Herzegovina

Background & Objectives: Primary angiosarcoma (PAS) is defined as a malignant primary endothelial neoplasm of the mammary parenchyma, not associated with radiation exposure. It is extremely rare, accounting for less than 0.05% of all primary malignancies of the breast. A pathologist plays a key role in diagnosis and in establishing prognosis by determining the histologic grade.
Methods: A 32-year-old breastfeeding woman presented with a palpable, soft, elastic, mobile left breast mass that had been enlarging for 4 months without axillary lymphadenopathy. She had given birth 8 months ago to a female, full-term newborn. She had no personal history of breast surgery, breast irradiation, long-term hormonal use and no family history of malignancy. Ultrasonography revealed a 6.5 cm lobulated hypoechoic formation in the upper lateral quadrant. Due to lactation and the overall heterogeneous echostructure of both breasts, the described formation was initially interpreted as a probably benign finding (BI-RADS 3). Cessation of lactation was proposed. A control examination after 2 months showed a 10 cm mass. Because of the significant enlargement, a core needle biopsy (CNB) of the mass and fine needle aspiration biopsy (FNAB) of the lymph node were performed.
Results: The case was diagnosed as grade 3 PAS without axillary metastasis. Microscopic examination revealed interanastomosing vascular channels filled with erythrocytes, lined with pleomorphic endothelial cells, with infiltrative growth through normal structures. There were punctate necrotic foci, blood lakes, and irregular mitoses. The tumour was positive for vimentin, CD31, CD34, and Factor VIII, negative for AE1/AE3, with Ki67 above 90%, and no detected C-MYC amplification or NTRK fusion. Radical mastectomy was performed, confirming our diagnosis (PAS, pT3N0). The patient underwent three cycles of Adriamycin chemotherapy and radiotherapy.
Conclusion: We report a case of PAS in a breastfeeding woman, with a full description of clinical manifestation, radiology, histology, next-generation sequencing results, and treatment.

E-PS-02-062
Metastatic lobular carcinoma identified within a uterine polyp and fallopian tubes, representing the initial presentation of a previously undiagnosed breast malignancy
T. Guchashvili[1], N. Chelidze[1], M. Sarishvili[1], M. Gudadze[1]
[1]MEGALAB, Pathology, Tbilisi, Georgia

Background & Objectives: Metastatic breast carcinoma involving the female gynaecological system represents an uncommon pathology. A review of accessible PubMed data spanning 1983 and 2024 identified only 23 reported cases of breast cancer metastasizing to uterine polyps. Notably, most of these cases were associated with tamoxifen therapy and morphologically were compatible to lobular carcinoma.
Methods: This case describes a 52-year-old woman with no significant medical history who presented with menorrhagia and an ultrasound diagnosis of a uterine polyp. She underwent a total hysterectomy and bilateral salpingo-oophorectomy. Macroscopic examination identified a 5 mm intrauterine polyp, with no additional structural abnormalities observed in the uterine body, cervix, or adnexal structures. Tissue samples were subsequently reproduced and processed for histological evaluation in accordance to established laboratory protocols.
Results: Within the uterine polyp, against a background of mild fibrosis and interspersed partially atrophic endometrial glands, nests and cords of round atypical cells displaying hypochromatic nuclei and scarce mitotic activity were identified. Similar linear cords and scattered individual cellular elements were also observed bilaterally in the otherwise unaffected walls of the fallopian tubes. Immunohistochemical staining of the target cellular population revealed phenotypic characteristics, including diffuse positivity for CK7, GCDFP-15, GATA3, and ER, findings consistent with metastatic breast carcinoma. Clinical imaging conducted after the histopathological report confirmed the presence of a mass in the breast.
Conclusion: Given the potential for metastatic cells to infiltrate endometrial polyps as well as seemingly unaffected regions of the uterus, pathologists should perform a comprehensive examination to prevent diagnostic pitfalls.

E-PS-02-063
Radial danger: radial scars of the breast- a diagnostic and management dilemma and a university pathology department's 15-year experience
E. Lappa[1]
[1]University Hospital of Heraklion PAGNI, Pathology Department, Heraklion, Greece

Background & Objectives: Radial scars/complex sclerosing lesions (RSL) of the breast are benign lesions with glandular structures in fibroelastotic stroma, with or without proliferative epithelial changes. They often pose a radiology dilemma as they mimic breast carcinoma on imaging and induce controversial management strategies. We present a recent case of a radial scar diagnosed on a core needle biopsy, and the statistical analysis' results of diagnosed radial scars over a 15-year period in a University Pathology Department, to raise awareness.
Methods: A tru-cut needle biopsy of a suspicious lump in the left breast of a 44-year old female was performed, and the sample was sent to the Pathology laboratory for histopathological examination. Immunohistochemical stains were performed. We reviewed the histopathological reports of radial scars over a 15-year period and performed statistical analysis.
Results: The histopathological examination revealed lobulocentric architecture with dense hyalinized stroma and after the immunohistochemical evaluation the presence of myoepithelial cells was confirmed. The findings were consistent with radial scar of the breast.
The statistical analysis revealed that in 5 cases (38,5%)the radial scar was the only finding, 2 (15,3%) had concomitant ductal papillomatosis and intraductal papilloma, 3 (23%) had additional atypical ductal hyperplasia, 5 (38,5%) had DCIS and/or invasive ductal carcinoma (4 with negative lymph nodes and 1 with positive lymph nodes). There were two peaks in the incidence of radial scars, one on the 4th and the other on the 6th decade of life.
Conclusion: These lesions comprise both a possible histological and imaging pitfall. The histopathological evaluation may underestimate

atypical and malignant lesions, due to tissue size limitations and pathologists should be aware of the potential danger. As the management of radial scar and complex sclerosing lesion detected on mammography remains controversial, the need for more systematic and retrospective reviews, as well as patient long-term follow-up, becomes imperative.

E-PS-02-064

Spontaneous regression of invasive lobular carcinoma: a case report

G.G.M. Attanasio[1,2], M. Failla[1,2], M.P. Foschini[1], G.G. Magro[2], G. Broggi[2]

[1]Alma Mater Studiorum Universita' di Bologna, Ospedale Bellaria C.A. Pizzardi - AUSL Bologna, Anatomia Patologica, Bologna, Italy, [2]Università degli Studi di Catania, Presidio Ospedaliero "G. Rodolico", Anatomia Patologica, Catania, Italy

Background & Objectives: Spontaneous regression (SR) of oestrogen receptor (ER)-positive invasive lobular carcinoma (ILC) of the breast is an exceptionally rare phenomenon, with very few cases documented in the literature. The present study aims to report a case of SR in ER-positive ILC, potentially associated with hormonal therapy for endometriosis.

Methods: A 47-year-old woman, receiving progestin-based therapy for endometriosis, developed a parareolar breast mass associated with ipsilateral axillary lymphadenopathy. A core needle biopsy (CNB) confirmed ER-positive, progesterone receptor (PR)-positive, HER2-negative ILC, grade 2. Fine-needle aspiration cytology (FNAC) of an ipsilateral axillary lymph node was positive for carcinoma. The patient subsequently underwent quadrantectomy and axillary lymph node dissection.

Results: Histological examination of the surgical specimens revealed only minimal residual foci of ILC within the breast tissue, accompanied by marked lymphocytic infiltration. Axillary lymph node dissection identified necrotizing epithelioid granulomas and isolated tumour cells (ITCs) limited to the nodal capsule, without evidence of viable metastatic carcinoma.

Conclusion: The observed spontaneous regression may be associated with the hormonal therapy administered for endometriosis, which likely induced a hypoestrogenic state, potentially facilitating an immune-mediated response. Progestins' anti-estrogenic effects could have reduced oestrogen-mediated immunosuppression, enhancing immune recognition and clearance of tumour cells. The presence of necrotizing granulomas supports the hypothesis of immune activation. This case suggests a potential link between hormonal modulation and SR of ER-positive ILC, encouraging further studies on the interplay between endocrine therapy and immune mechanisms in breast cancer.

E-PS-02-065

Atypical myofibroblastoma in a young patient – case report

A. Lazarevic[1], L. Ilić[1], A. Milićević[1], M. Backović[1], O. Živković[1], E. Filipović[2], Z. Milovanović[1]

[1]Institute of Oncology and Radiology of Serbia, Department of Pathology and Other Diagnostics, Belgrade, Serbia, [2]Institute of Oncology and Radiology of Serbia, Clinic for Oncology Surgery, Belgrade, Serbia

Background & Objectives: Myofibroblastoma (MFB) of the breast is a rare, benign mesenchymal tumour composed of spindle cells with myofibroblastic differentiation. It belongs to the spectrum of benign spindle cell tumours and originates from hormonally responsive mammary stromal cells. Myofibroblastoma typically presents as a slow-growing, painless, non-tender mass. It is most commonly observed in older men (median age 60–70 years) and postmenopausal women.

Methods: A 19-year-old female patient presented for evaluation due to a tumour-like mass she had palpated in her left breast. Clinical and ultrasound examinations revealed a well-defined tumour with benign characteristics, most consistent with a fibroadenoma. However, histopathological findings from a core needle biopsy suggested a mesenchymal tumour classified as B4. A wide local excision of the left breast tumour was subsequently performed, and the specimen was sent for pathological examination.

Results: Macroscopic examination revealed a relatively well-defined, whitish tumour with a whorled structure, elastic consistency, and a glassy sheen, measuring 20 mm in diameter. Microscopic examination showed that the tumour consisted primarily of spindle-shaped cells, with large, pleomorphic atypical cells diffusely distributed among them, along with occasional multinucleated floret-like cells. Mitoses and necrosis were not observed. Immunohistochemical analysis demonstrated expression of CD34 in tumour cells, along with positivity for ER, PR, and AR, with an absence of Desmin expression. Based on histopathological and immunohistochemical findings, the tumour was classified as atypical myofibroblastoma.

Conclusion: Atypical myofibroblastomas are generally considered benign, with a low risk of recurrence or metastasis. However, due to their histological overlap with other mesenchymal neoplasms, accurate diagnosis is crucial to avoid overtreatment or misclassification as a more aggressive tumour. Surgical excision remains the standard treatment. This case highlights that even young women can develop this rare tumour, emphasizing the importance of considering myofibroblastoma in the differential diagnosis of breast masses in younger patients.

E-PS-02-066

Primary breast sarcomas: a 20-year experience

P. Kousidis[1], I. Sidiropoulos[1], G. Panselinas[1], R. Iosifidou[2], F. Pavlidou[2], C.C. Kontos[2], N. Salveridis[2], S. Parpoudi[2], A. Nikolaidou[1]

[1]"Theageneio" Anticancer Hospital, Pathology, Thessaloniki, Greece, [2]"Theageneio" Anticancer Hospital, Breast Surgical Oncology, Thessaloniki, Greece

Background & Objectives: Primary breast sarcomas are exceptionally rare, with an estimated incidence of 17 cases per million female patients per year. A limited number of published clinicopathologic series on these pathologies currently exist. We present an analysis of the pathologic characteristics of the cases of primary breast sarcomas examined in our Pathology Department over the prior 20-year period.

Methods: Pathology reports with a diagnosis of primary breast sarcoma were retrieved from our Department's files, from 2004 to 2024. Only complete reports and only excision specimens were included. All reports and tissue slides underwent a separate review from a different than the diagnosing pathologist. Subsequently, patient records were accessed to determine patient characteristics.

Results: In total, 13 patients were identified. All 13 (100%) were female. Median age at diagnosis was 70 years (IQR 21 years). The type of specimen was local excision for 6 patients (46.2%) and mastectomy for 7 patients (53.8%). The right breast was affected in 8 patients (61.5%), while the left breast in 5 patients (38.5%). Median maximal dimension of the tumour was 5.5 cm (IQR 6.25 cm). The histopathologic diagnosis was angiosarcoma in 5 cases, malignant fibrous histiocytoma in 2 cases, low-grade myofibroblastic sarcoma in 2 cases, well-differentiated liposarcoma in 1 case, leiomyosarcoma in 1 case, stromal sarcoma NOS in 1 case and sarcoma NOS in 1 case. Additional variables were also measured and analysed.

Conclusion: Primary breast sarcomas are rare, with the understanding of their characteristics, epidemiology and management stemming mainly from case series of major cancer centres. Their management is challenging. Our study extends the available literature and enhances the knowledge surrounding these rare pathologies.

E-PS-02-067

A case report of a rare type of biphasic breast lesion

P.B. Kemenesi-Gedei[1], O. Kiss[2], A.M. Tőkés[3], K. Dezső[4]
[1]Esprint Kft., Pathology, Szolnok, Hungary, [2]Ekvimed Zrt., Pathology, Budapest, Hungary, [3]Semmelweis University, Department of Pathology, Forensic and Insurance Medicine, Budapest, Hungary, [4]Semmelweis University, Department of Pathology and Experimental Cancer Research, Budapest, Hungary

Background & Objectives: Periductal stromal tumour (PDST) is a biphasic fibroepithelial lesion: the periductal spindle-cell stroma and the lacking leaf-like architecture of the epithelial component distinguish it from phyllodes tumours. In cases of incomplete resection recurrence can occur, and beyond, sarcomatoid transformation has also been detected in low number of cases. We present a 30-year-old woman with a 16 mm lobulated lesion in the left breast with uncertain radiologic dignity. The histological diagnosis based on ultrasound-guided core needle biopsy.
Methods: Formalin-fixed paraffin-embedded (FFPE) tissue blocks were prepared from biopsies followed by haematoxylin-eosin staining and immunohistochemistry (IHC).
Results: Microscopic examination showed a fibroepithelial proliferation with stromal spindle-cell hypercellularity around the breast ducts. The abscence of the epithelial leaf-like growth-pattern was characteristic. The immunohistochemical reactions showed positivity for both smooth muscle actin (SMA) and CD34. The nuclear negativity of β-catenin excluded the possibility of fibromatosis. The immunoreactivity against desmin was also negative. The proliferation activity of the stromal cells presented less than 1% (Ki-67). The CK14- and p63-positivity supported the integrity of the myoepithelial cell layer.
Conclusion: The PDST of the breast is a rare biphasic entity accounting for less than 1% of breast carcinomas. The negativity for β-catenin excluded the possibility of fibromatosis. We suggested complete removal with wide surgical margins to avoid the local recurrence and potential malignant transformation. Additional IHC examinations are in progress to investigate further breast tumour-related markers. Presentation of this case indicates that PDST should be kept in mind as a differential diagnosis of biphasic stromal-predominant lesions.

E-PS-02-068

Siglec-15 expression in breast cancer and its association with clinical and pathological features

H. Sun[1,2], Q. Gan[1], X. Wang[2], S. Zhang[3]
[1]University of Texas MD Anderson Cancer Centre, Pathology, Houston, USA, [2]University of Texas McGovern Medical School at Houston, Pathology and Laboratory Medicine, Houston, USA, [3]Baylor College of Medicine, Pathology and Immunology, Houston, USA

Background & Objectives: Immune checkpoint blockade with PD-1/PD-L1 has limited success in breast cancer (BC) patients, partly due to alternative immune checkpoint molecules. Sialic acid–binding immunoglobulin-type lectins (Siglecs), expressed on immune cells, are potential new targets for immunotherapy. Siglec-15, a member of the Siglecs family, has been reported to be expressed in in lung and gastric cancer, but its expression in BC remains unclear.
Methods: Siglec-15 expression was evaluated in 88 invasive BC samples on tumour tissue microarray (TMA) using immunohistochemistry with anti-Siglec-15 antibody (PA5-72765, Thermo Fisher Scientific, USA, 1:200). Staining intensity was categorized as negative, weak, or moderate to strong. Siglec-15 expression was correlated with patient clinical (age, neoadjuvant chemotherapy) and pathological (tumour biomarker status, histology grade, stage, and lymph node status) features.
Results: Siglec-15 was expressed in 82.9% (77/82) of BC samples. Its intensity was not influenced by patient age or neoadjuvant chemotherapy. Moderate to strong staining was more common in ER+/HER2- tumours (64.6%) compared to ER-/HER2- tumours (11.7%) (p=0.0004) and in grade 1 and grade 2 tumours (66.7% and 65.2%) compared to grade 3 tumours (27.2%) (p=0.013). For pT1 and pT2 tumours, there was no significant difference in moderate to strong staining (52.8% vs. 60%), but pT1 tumours had fewer negative stains (5.5%) and more weak stains (41.7%) than pT2 tumours (23.3% negative and 16.7% weak staining) (p=0.026). Siglec-15 intensity was not associated with lymph node stage.
Conclusion: Siglec-15 is widely expressed in invasive BC, particularly in ER+/HER2- and lower-grade tumours. Further studies with larger cohorts are needed to confirm these findings and assess the potential of Siglec-15 as an immunotherapy target.

E-PS-02-069

Clinicopathological characteristics of HER2-low breast cancer in Latvia: a single centre experience

J. Āboliņš[1], T. Karpovska[1], A. Grjunbergs[1], T. Zablocka[1], S. Isajevs[1], Tatjana Karpovska 3, Aleksandrs Grjunbergs 3, Tatjana Zablocka 1,3, Sergejs Isajevs 1,3
[1]Faculty of Medicine and Life Sciences, University of Latvia, Riga East University Hospital, Centre of Pathology, Riga, Latvia

Background & Objectives: HER2-low breast cancer (BC) was defined as those with a HER2 immunohistochemical (IHC) score of 1 + or 2 + without ERBB2 amplification in most of clinical trials. Previous studies showed that immunohistochemical HER-2 (2+score) expression combined with a negative HER-2 status on in situ hybridization was found to be an adverse prognostic factor. The aim of our study was to evaluate the clinical and histopathological characteristics in patients with HER-2 low breast cancer (IHC 2+score).
Methods: 98 patients undergoing core needle biopsy of BC in 2023-2024 in Riga East University Hospital with subsequent histopathological examination were enrolled in the study. Histopathological, immunohistochemical and chromogenic in situ hybridisation (CISH) examination was performed.
Results: 98 patients with breast cancer with IHC 2+ score HER-2 expression were enrolled in the study. The median patient age was 66 ± 12.54 years. The positive ER expression (>10.0%) was observed in 86.59% of cases, whereas the positive PR expression was observed in 72.16% of cases. The median Ki-67 index was 25 ± 24. 10%. In 62.88% of cases these tumours were Grade 2 tumours, whereas Grade 3 tumours were found in 16.49 % of cases.
The association between the tumour Grade, Ki-67 and immunohistochemical HER-2- (2+) expression have not been found.
Conclusion: In this study, HER2-low BC accounted for 94.9% of all tumours, with the vast majority (86.59%) being hormone (HR) positive.
Our data showed the complex characteristics of HER2-low BC, to which HR status is closely related, however associations between IHC 2+ score HER-2 expression and patient age, tumour grade and Ki-67 index has not been observed.

E-PS-02-070

Integrated analysis of triple-positive breast cancer: BC360-based PAM50 transcriptomic profiling, *FGFR1–4* expression and genomic characterization with clinico-pathological correlation

M. Braun[1], B. Tomasik[2], B. Galikowska[3], D. Piasecka[3], I. Dróżdż[4], A. Zielińska[1], J. Sołek[1], J. Kopczyński[5], D. Nejc[6], J. Jassem[2], R. Kordek[1], R. Sądej[3], H. Romańska[1]
[1]Medical University of Łódź, Department of Pathology, Chair of Oncology, Łódź, Poland, [2]Medical University of Gdańsk, Department of Oncology and Radiotherapy, Gdańsk, Poland, [3]Medical University

of Gdańsk, Laboratory of Molecular Enzymology and Oncology, Intercollegiate Faculty of Biotechnology, Gdańsk, Poland, [4]Medical University of Łódź, Department of Clinical Genetics, Łódź, Poland, [5]Holycross Cancer Centre, Department of Surgical Pathology, Kielce, Poland, [6]Medical University of Łódź, Department of Surgical Oncology, Łódź, Poland

Background & Objectives: Triple-positive breast carcinoma (TPBC; ER+/PR+/HER2+) represents a biologically diverse subset of breast cancer that often eludes precise therapeutic stratification. This study aimed to characterize TPBC through an integrated clinico-pathological assessment, BC360-based PAM50 transcriptomic profiling, and comprehensive FGFR1–4 analysis at the proteomic, transcriptomic, and genomic levels.
Methods: A total of 134 patients with treatment-naïve invasive breast carcinoma of no special type, diagnosed between 2012 and 2021, were retrospectively recruited. Pathological samples were reviewed per current WHO criteria, and clinical data were collected. IHC was used to assess ER, PR, HER2, and FGFR1–4 expression in FFPE tissue. Transcriptomic profiling of 121 tumours was performed using the NanoString® BC360™ panel for PAM50 subtyping, *FGFR1–4* mRNA quantification, and pathway signature analysis. Additionally, *FGFR1–4* were NGS-sequenced using a QIAseq targeted DNA/RNA custom panel (Qiagen) on the Illumina platform.
Results: Among 134 tumours, 38 (28.4%) were classified as TPBC. PAM50 subtyping revealed marked heterogeneity, with TPBCs distributed across luminal A (50%), luminal B (23.7%), and HER2-enriched (26.3%) subtypes. HER2-enriched and luminal B tumours were associated with higher histological grade, increased proliferation (Ki-67), and inferior disease-free and overall survival comparing to luminal A tumours. *FGFR1–4* mRNA and protein expression varied significantly across subtypes: FGFR4 was most prominent in HER2-enriched tumours, whereas FGFR1 expression was more abundant in luminal A/B subtypes. Transcriptomic analysis via BC360 revealed several distinct molecular signature profiles in TPBC compared to other immunophenotypes. Targeted NGS of *FGFR1–4* was successfully completed in all TPBC cases with data being analysed.
Conclusion: Triple-positive breast cancer is molecularly heterogeneous and cannot be fully defined by immunophenotype alone. Integrating PAM50 subtyping with FGFR1–4 protein and genomic profiling identifies prognostically and therapeutically relevant subgroups. These results support routine molecular testing, especially PAM50, to guide proper stratification and personalized treatment in TPBC.

Validation of a triple negative breast cancer patient stratification strategy for neoadjuvant chemotherapy utilizing FOXC1 immunohistochemistry

I. Arun[1], G. Mukherjee[1], R. Ahmed[2], S. Agarwal[2], T. Ray[3], P.S. Ray[3]
[1]Tata Medical Centre, Histopathology, Kolkata, India, [2]Tata Medical Centre, Surgery, Kolkata, India, [3]Onconostic Technologies, Inc., Evanston, USA

Background & Objectives: Neoadjuvant chemotherapy (NACT) in the setting of early-stage triple negative breast cancer (TNBC) to obtain pathologic complete response (pCR) is accepted standard of care. However, there is currently no effective patient stratification strategy (PSS) to determine predicted responders (PR)/non-responders (PNR) to NACT in TNBC.
Methods: TNBC patient samples from a NACT trial NKI dataset (n=178) was analysed for FOXC1 (plasticity marker) and MKI67 (proliferation marker) RNA expression values, correlated with observed pCR and used to develop an AI-enabled prediction algorithm using an iterative knowledge-driven engine. For the validation study, real-world TNBC patients (n=40) who had undergone NACT treatment at Tata Medical Centre (TMC) Kolkata were identified from the breast cancer database and FOXC1 immunohistochemistry (IHC) was performed using the VERESCA FOXC1 CE-Marked kit (Onconostic Technologies, Inc.) using validated protocols already reported (ECP 2024) along with standard MIB1 Ki67 IHC on the patients' pre-treatment core needle biopsy FFPE tissues on a Leica Bond III auto-stainer. The proprietary AI-enabled algorithm developed using the training dataset was then tested using the validation dataset.
Results: PNR as well as 2 categories of PR (moderate + high) were correctly predicted on the basis of FOXC1 and MKI67 expression values in both the training (Sensitivity 97% overall, $p<0.0001$ high PR group) and validation (Sensitivity 85% overall, $p<0.024$ high PR group) datasets with a high level of accuracy, regardless of whether RNA or protein expression were utilized as data inputs.
Conclusion: Routine IHC detection of FOXC1 utilizing the VERESCA FOXC1 kit affords a highly cost-effective PSS when considering NACT in early-stage TNBC. In conjunction with the VERESCA FOXC1 test's predictive utility for neoadjuvant chemoimmunotherapy (ESMO IO 2022), the test presents a pragmatic approach to achieve Precision Oncology goals in early-stage TNBC for both PR and PNR patients to either chemotherapy or chemoimmunotherapy regimens.

E-PS-02-072

Unmasking the unusual: metastatic malignant peripheral nerve sheath tumour, Ewing sarcoma, and melanoma to the breast

S.A. Androniadou[1], O.I. Rantis[1], R. Iosifidou[2], G. Efthimiopoulos[3], P. Kousidis[1], S. Mavropoulou[1], A. Nikolaidou[1]
[1]"Theageneio" Anticancer Hospital, Pathology, Thessaloniki, Greece, [2]"Theageneio" Anticancer Hospital, Breast Surgical Oncology, Thessaloniki, Greece, [3]"Theageneio" Anticancer Hospital, General Surgical Oncology, Thessaloniki, Greece

Background & Objectives: Metastasis to the breast from extramammary malignancies is a rare occurrence, making up only a small fraction, just 0.5-5% of all malignant breast lesions. Melanoma is recognized as one of the most common neoplasms metastasizing to the breast, in contrast with Ewing sarcoma and malignant peripheral nerve sheath tumour (MPNST), which are exceedingly uncommon in this setting. We report three cases, one of metastatic MPNST, one of Ewing sarcoma and one of melanoma as metastases to the breast, the diagnoses of which were confirmed through histopathology and immunohistochemistry.
Methods: All three patients had undergone initial surgical treatment for their primary respective malignancies. Approximately 12-24 months following their surgical treatment, during screening mammography, the three patients' imaging findings indicated a breast mass. The differential diagnosis led to the dilemma of a primary breast malignancy versus a metastasis, based on their patient history, and warranted breast biopsy samples for further evaluation.
Results: All patients were female, with ages of 20 - 68 years. The tumour size ranged from 2.2 - 15.5 cm. One patient underwent simple mastectomy and two patients were treated with local excision. The excision specimens were analysed by the Pathology team, which confirmed the final diagnoses of metastatic Ewing sarcoma, melanoma and malignant peripheral nerve sheath tumour (MPNST) to the breast.

Conclusion: Metastases to the breast are rare. These entities have the ability to radiographically mimic primary breast carcinoma but also cause differential diagnostic challenges in pathologic examination. Performing clinicopathologic correlation and providing a complete patient history are of utmost importance, so that misdiagnosis and inappropriate management can be avoided.

E-PS-02-073

Prognostic significance of fibrosis in the tumour stroma in triple negative breast carcinoma

I. Erken[1], N.S. şeker[1], F. Albayrak[1], B. Durak Aras[2]
[1]Osmangazi University Medical School, Pathology, Eskişehir, Turkey, [2]Osmangazi University Medical School, Genetics, Eskişehir, Turkey

Background & Objectives: Breast carcinoma continues to be the most common cancer and cause of death in women worldwide. Tumour microenvironment is an important pathological finding in all known solid cancers, both in terms of prognostic and treatment options. Stromal fibrosis is responsible for the treatment resistance of tumour cells by preventing oxygen circulation and drug transport around the tumour. Our aim in this study is to evaluate the relationship between fibrosis and histopathological findings in triple negative breast carcinomas.
Methods: Our study included 27 cases who were operated on for breast carcinoma between 2018-2025. Masson-Trichrome histochemistry was applied tumour-containing blocs. For each case, fibrosis was recorded as diffuse or focal. The largest fibrotic focus size was measured. The relationship between the extent of fibrosis and histopathological data was investigated. SPSS IBM 21.0 was used for statistical analysis.
Results: When the fibrosis size threshold value was taken as 15 mm, a significant difference was found between tumour size, age, and Ki-67 proliferation index values. Patients were younger in the fibrosis >15 mm group ($p<0.05$), tumour size was larger in the fibrosis>15 mm group ($p<0.05$), Ki-67 proliferation index was lower in the fibrosis>15 mm group ($p<0.05$). Since most of the cases had high nuclear and tumour grades, no statistical difference was found between these findings.
Conclusion: The tumour microenvironment is a wide area of research that also affects the treatment of the disease. Triple negative breast carcinoma is also in a poor prognostic group. We believe that the presence of fibrosis, which can affect the treatment process and prognosis of the disease and is quite easy to evaluate histopathologically, can be more clearly demonstrated with studies conducted with a larger number of cases.

E-PS-02-075

Idiopathic granulomatous mastitis: from aetiology toward therapeutic approaches

N. Karmous[1,2], A. Masmoudi[1], B. Bouguerra[1,2]
[1]Charles Nicolle Hospital, Gynaecology and obstetrics department B, Tunis, Tunisia, [2]Faculty of medicine of Tunis- University Tunis el Manar, Tunis, Tunisia

Background & Objectives: Idiopathic granulomatous mastitis (IGM) is an evolving problem with no definitive treatment guidelines. Its pathogenesis is thought to involve ductal pathology. Excision of the sinus or fistulous tract, combined with lesion's wide local excision (WLE), may provide a curative approach.
The objective was to explore the underlying aetiology of IGM and assess the effectiveness of WLE with total or partial duct excision as a treatment modality.
Methods: Retrospective study conducted over four years (2021–2023) at a single institution, involving 13 patients diagnosed with IGM. The patients were divided into three groups : Group A received steroid therapy, Group B underwent WLE alone and Group C received WLE with total or partial duct excision.
Preoperative investigations were conducted, and postoperative follow-up ranged from 6 months to 2 years. Histopathological examination (HPE) of excised tissue was performed to confirm the diagnosis and assess the nature of the disease.
Results: HPE was identified as the most reliable diagnostic tool for confirming IGM. The results demonstrated varying recurrence rates across the groups: Group B (WLE alone) had the highest recurrence rate (76.3%). Group A (steroid therapy) had a recurrence rate of 39%. Group C (WLE with duct excision) had the lowest recurrence rate (4.6%).
Statistical analysis showed that patients in Group C had a significantly lower chance of recurrence compared to both Group A and Group B ($p < 0.05$). HPE of excised ducts from patients in Group C revealed ductal disruption, leakage, and periductal granulomas in 70% of cases.
Conclusion: IGM is primarily a disease of the mammary ducts. WLE combined with total or partial duct excision is an effective and curative approach for patients who do not respond to steroid therapy or WLE alone. This approach should be considered a viable treatment option for non-responding IGM cases.

Primary mucinous cystadenocarcinoma of the breast with coexisting invasive ductal carcinoma: a case report and literature review

E. Selki[1], E.B. Balaban Yilmaz[1], F. Cambaztepe[2], F. Vardar Aker[1]
[1]University of Health Sciences, Haydarpasa Numune Training and Research Hospital, Pathology, Istanbul, Turkey, [2]University of Health Sciences, Haydarpasa Numune Training and Research Hospital, General Surgery, Istanbul, Turkey

Background & Objectives: Mucinous cystadenocarcinoma (MCA) of the breast is an exceptionally rare subtype of primary breast carcinoma, newly recognized in the WHO 5th edition classification. Due to its extreme rarity and histological resemblance to mucinous tumours of the ovary and pancreas, distinguishing MCA from metastatic disease is crucial for accurate diagnosis. We reported a rare case of primary breast MCA with an adjacent microscopic focus of invasive ductal carcinoma (IDC), highlighting its diagnostic, histopathological, and immunophenotypic features. Additionally, we compare our case with previously reported cases to contribute to the limited literature on this entity.
Methods: 76-year-old woman presented with mass in the left breast. MRI revealed a 30×25 mm multilocular, predominantly cystic BI-RADS 4A lesion. Core needle biopsy suggested "at least high-grade ductal carcinoma in situ (DCIS)." Patient underwent breast-conserving surgery and sentinel lymph node biopsy; no metastasis was detected intraoperatively. Gross examination revealed a 3.5 cm, mucin-rich, heterogeneous mass. Histopathological analysis demonstrated cystic structures with papillary projections lined by columnar mucinous epithelium, consistent with MCA, adjacent to a microscopic IDC focus. Immunohistochemical analysis was performed to further characterize the tumour.
Results: The MCA component was quadruple-negative with a Ki-67 index of 5–10%. IDC area exhibited weak ER positivity, PR negativity, AR positivity, HER2 0, and a Ki-67 index of 10–15%. No lymph node metastasis was detected. At the 6-month follow-up, the patient remained disease-free.
Conclusion: Despite its quadruple-negative phenotype, MCA appears to follow an indolent clinical course. The coexistence of IDC with distinct receptor status suggests potential divergent differentiation, raising questions about the tumour's histogenesis and biological behaviour. Given its rarity, this case underscores the importance of thorough histopathological and immunohistochemical evaluation to differentiate primary breast MCA from metastatic mucinous tumours. Our findings add to the limited knowledge surrounding this rare entity and highlight the need for further research.

E-PS-02-077

Comparative study of the Nottingham Prognostic Index (NPI) in breast cancer patients at a public hospital in southern Brazil

D. S C Vieira[1,2], A.P. Beltrame Farina Pasinato[1], L. Marins[2], L. Melfior[3], L. Golfetto[2], G. Felipe Staudt[4], M.C. Santos da Silva[5]
[1]Federal Universidade of Santa Catarina, Pathology, Florianopolis, Brazil, [2]Federal Universidade of Santa Catarina, Unidade de Laboratorio de Anatomia Patologica, Florianopolis, Brazil, [3]Federal Universidade of Santa Catarina, Pathology, Florianopolisbra, Brazil, [4]Federal Universidade of Santa Catarina, Clinica Medica, Florianopolis, Brazil, [5]Federal Universidade of Santa Catarina, Analises Clinicas, Florianopolis, Brazil

Background & Objectives: Breast cancer treatment relies on prognostic tools. In Brazil, women treated in the public system have limited access to expensive tests. Low-cost methods, such as the Nottingham Prognostic Index (NPI), may be promising. This study evaluates the application of the NPI, aiming to classify prognostic subgroups with variables.
Methods: Cross-sectional study to analyse the prognostic profile of women with breast cancer in a public hospital between 2020 and 2021. The variables were: age, size, lymph node metastasis, histological grade and immunophenotypic subtypes. Ages were grouped into three categories, and the NPI was calculated.
Results: G1: 14 patients aged between 18 and 49 years, G2: 28 aged between 50 and 69 years and G3: 5 aged 70 years or older. G2 had lower NPI and mean tumour size. 17.02% were histological grade I, 42.55% II and 40.43% III. The mean NPI of patients without lymph node metastasis was 3.66, and that of patients with metastasis was 5.07 (NPImín) and 6.07 (NPImax). Based on Todd et al, 1987, the NPI was subdivided into three prognostic groups, with overall survival rates at five years: good, intermediate and poor. In the sample, 9 patients were classified as having a good prognosis (NPI $\leq$ 3.4), 28 as intermediate (NPI $>$ 3.4 and $\leq$ 5.4) and 10 as poor (NPI $>$ 5.4). Of the sample, 5 were of the Luminal A subtype (10.64%) and 22 were of the Luminal B/HER2- subtype (46.81%), with the Luminal A and Luminal B/HER2- subtypes presenting lower mean NPI values, demonstrating a more favourable prognosis in relation to the other subtypes.
Conclusion: The main findings indicated that the NPI has good prognostic capacity in HR-positive/HER2-negative immunophenotypes. Patients undergoing mammographic screening had better prognoses. The robustness of the NPI in different populations was identified, as well as its importance as a low-cost tool applicable in clinical practice.

E-PS-02-078

Prevalence and reproducibility of HER2 immunohistochemistry scoring in breast cancer: insights from a Portuguese tertiary healthcare institution

J. Almeida Tavares[1], T.A. Oliveira[1,2], J.F. Boavida[1,3], D. Lopez-Presa[1]
[1]Unidade Local de Saúde Santa Maria, Pathology, Lisbon, Portugal, [2]NOVA Medical School, Lisbon, Portugal, [3]Faculdade de Medicina da Universidade de Lisboa, Instituto de Anatomia Patológica, Lisbon, Portugal

Background & Objectives: With the rise of new therapeutic schemes for metastatic breast cancer (BC) patients, accurate evaluation and correct categorization of HER2 status gains further clinical relevance, specifically for HER2-low and HER2-ultralow groups. Our main goal is to characterize the distribution of different HER2 groups, in all BC biopsies registered over a year, in a tertiary centre in Portugal, with additional re-evaluation of HER2 immunohistochemistry (IHC) scores 0 and 1+ to determine the reproducibility of results.
Methods: Pathology reports of 155 BC biopsies, registered from January 2nd to December 31st 2024, were analysed, HER2 IHC scores were extracted and its distribution was established. Re-evaluation of HER2 IHC scores 0 and 1+ was undertaken, using the ASCO/CAP 2018 guidelines, while keeping in mind the extended therapeutic eligibility criteria, allowing comparison between previously recorded scores and re-evaluated scores.
Results: Previously recorded cases with HER2 IHC scores 0, 1+, 2+ and 3+ prevalence was 47% (n=72), 21% (n=33), 18% (n=28) and 14% (n=22), respectively. Re-evaluated HER2 IHC scores 0, 1+, 2+ and 3+ prevalence was 45% (n=70), 20% (n=30), 21% (n=33) and 14% (n=22), respectively. Concordance rates were significantly higher for the HER2 0 group (87.5%) than for the HER2 1+ group (57.6%); particularly, the re-evaluation of HER2 IHC 0 cases allowed the identification of 9 additional HER2 IHC 1+ cases (HER2-low) and 14 HER2 IHC>0 <1 (HER2-ultralow); re-evaluated HER2 IHC 1+ cases revealed additional discrepancies with previous scores, leading to 5 "newly" identified HER2 IHC +2 cases and another 7 cases as HER2 IHC>0 <1 (HER2-ultralow).
Conclusion: Despite the relatively limited number of cases included in our study and considering clinical management implications, initial results indicate that reproducibility of results need to be improved through different strategies, such as HER2 scoring training or consensus meetings. Further analysis is being performed to determine inter-observer reproducibility.

E-PS-02-079

Accuracy of cytological assessment in detecting HER2-low status in primary and metastatic breast carcinoma

G. D'Abbronzo[1], S. Lucà[1], I. Cozzolino[1], M. Accardo[1], C.M. Della Corte[2], F. Iovino[3], S. Parisi[3], I. Tedesco[1], F. Ingallinella[1], F. Grasso[4], R. Franco[1], M. Montella[1]
[1]Università degli Studi della Campania "Luigi Vanvitelli", Department of Mental and Physical Health and Preventive Medicine, Naples, Italy, [2]Università degli Studi della Campania "Luigi Vanvitelli", Department of Precision Medicine, Naples, Italy, [3]Università degli Studi della Campania "Luigi Vanvitelli", Department of Advanced Since and Surgery, General, Mini-Invasive, Oncological and Obesity Surgery, Naples, Italy, [4]ASL Caserta, Pathology Unit, Caserta, Italy

Background & Objectives: HER2-low breast cancer nowadays is a significant clinical subtype that expanded therapeutical options, especially with the introduction of anti-HER2 antibody–drug conjugates. Fine-needle aspiration cytology (FNAC) is a minimally invasive technique useful when core needle biopsy (CNB) is not a possible choice. The aim of this study is to assess accuracy of HER2-low status detection from cell blocks (CBs) obtained through FNAC, in comparison to the respective histological specimens.
Methods: We selected 46 cases of invasive breast carcinoma diagnosed via FNAC at Vanvitelli Hospital and we collected data related to evaluation of immunocytochemistry (ICC) analysis for oestrogen receptor (ER), progesterone receptor (PR), and HER2 on FNAC-derived CBs. Then, we compared evaluation with the assessment of corresponding histological specimens. For case with HER2-2+ evaluation we performed a fluorescence in situ hybridization (FISH). Finally, we calculated sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV), and we evaluated diagnostic accuracy through ROC curve analysis.
Results: The 46 examined cases show the following data: average age: 62 years, 73.9% was primary breast carcinoma, while 26.1% was metastatic cases.
The ICC and IHC results showed a strong agreement for ER (Cohen's K: 0.81) and a moderate agreement for PR (K: 0.51). Regarding to HER2-low cases (1+ or 2+ without amplification), ICC demonstrated high specificity (92.9%) and PPV (95%), with moderate sensitivity (59.4%) and NPV (50%). The ROC analysis produced an AUC of 0.76, indicating good diagnostic accuracy.
Conclusion: FNAC-derived CBs represent a valid alternative to histological samples in the assessment of HER2-low breast cancer, particularly when CNB is not available. While a positive ICC result (1+ or 2+) is highly predictive of HER2-low status, a negative result (0) may warrant

further investigation due to moderate sensitivity. Cytological evaluation can support therapeutic decision-making in selected clinical contexts.

E-PS-02-080

Solid-basaloid adenoid cystic carcinoma of the breast: TRPS1 expression and clinicopathological findings in two cases

M. de Brito Pereira[1,2], P. Borralho Nunes[1,3], R. Fonseca[1]
[1]CUF Descobertas Hospital, Pathology Department, Lisbon, Portugal, [2]NOVA Medical School - Faculdade de Ciências Médicas, Lisbon, Portugal, [3]Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal

Background & Objectives: Adenoid cystic carcinoma (ACC) of the breast is a rare malignancy, accounting for <0.1% of invasive breast neoplasms. The rare solid-basaloid (SB) pattern, first described in 2002, has been recently evaluated for TRPS1 expression, a new histochemical marker of breast origin. This study reviews clinicopathological features of ACC-SB cases diagnosed in our institution.
Methods: We review all pathological reports of ACCs of the breast, recorded in our institution since 2005. The inclusion criteria were the presence of a reported triple-negative invasive carcinoma with a solid-basaloid pattern in biopsy, with more than 90% SB pattern in the gross specimen and in which other differential diagnosis had been excluded (namely small cell carcinoma). The clinical data was reviewed, histological slides reassessed, and TRPS1 expression evaluated.
Results: Among 12 ACC codified cases in system, two met SB criteria (16.7%).
Both females with a median age of 85 years (range: 82 - 89); had a solitary lesion on their left breast.
Biopsies showed an invasive carcinoma composed of basaloid cells with scant cytoplasm, with focal nucleoli in one case, no necrosis and 2 mitosis/mm^2.
The surgical specimens revealed tumours with 30 and 75mm in highest dimension, yellow, firm and spiculated. Histologically, extensive vascular invasions were present in both cases, as well as an increased mitotic activity when compared to the biopsy (2 versus 7 -18 mitoses/mm^2). One patient had lymph node metastasis.
Both tumours were triple negative; TRPS-1 diffusely strong positive; synaptophysin and INSM-1 negative.
Conclusion: ACC-SB is a rare invasive breast carcinoma requiring immunohistochemistry for differential diagnosis. Consistent with literature, our cases showed 100% TRPS1 positivity and no neuroendocrine marker expression.
Due to the low number of reported cases in series, the prognosis for SB remains unclear, with divergent findings in literature. In our cases, there was no disease progression at six-month follow-up.

E-PS-02-081

The impact of the COVID-19 pandemic on the diagnosis of breast cancer in a public reference hospital in southern Brazil

D. S C Vieira[1,2], A.P. Beltrame Farina Pasinato[1], L. Marins[2], K. Charlton[1]
[1]Federal Universidade of Santa Catarina, Pathology, Florianopolis, Brazil, [2]Federal Universidade of Santa Catarina, Unidade de Laboratorio de Anatomia Patologica, Florianopolis, Brazil

Background & Objectives: The COVID-19 pandemic has had a devastating effect on the world population, especially for patients with chronic diseases. One of the most affected groups was cancer patients, because due to the restrictions and cancellations of elective surgeries and exams, considered as non-priority care. In response to the efforts directed to the care of patients at high risk of morbidity and mortality related to COVID-19 infection, there was a decrease in care considered non-emergency. During this devastating scenario of the year 2020, cancer has not changed the prevalence, and despite the pandemic the disease continued to exist. Breast cancer, the high incidence among women in Brazil, represented a strong financial impact on public health systems.
Methods: The aim of the study was to evaluate the relationship between the effect of the Covid-19 pandemic on the diagnosis of breast carcinoma in the population treated at a public hospital, comparing the years 2019 (pre-pandemic) with the year 2020 and the year 2021, after implementation of vaccination of the adult population.
Results: Variables extracted from the SISMAMA program "cancer information system", available on the Ministry of Health platform online, were categorized and coded and included gender, age, benign x malignant diagnosis. The frequencies were calculated. In the triennium (2019-2021), 1,091 patients were treated for the investigation or treatment of breast lesions. Of these, 882 were biopsies in women over 18 years of age, 293 cases of cancer, divided into 130 diagnoses in 2019, 75 in 2020 and 88 cases in 2021.
Conclusion: It can be concluded with the number of biopsies in 2019 (pre-pandemic) compared to the years 2020 (pandemic) and 2021 (vaccine era) had a significant reduction in the number by up to 33% and that the number of malignancy diagnoses had a reduction of up to 42% of cases between 2021 compared to 2020.

E-PS-02-082

Importance of ER, PR, HER2, Ki67, CK19, CD8 and PD-L1 biomarkers for diagnosis, prognosis and assessment of metastasis risk in patients with breast carcinoma

D. S C Vieira[1,2], L. O Walter[3], L. S Oliveira[3], M.C. Santos Silva[3]
[1]Federal Universidade of Santa Catarina, Pathology, Florianopolis, Brazil, [2]Federal Universidade of Santa Catarina, Unidade de Laboratorio de Anatomia Patologica, Florianopolis, Brazil, [3]Federal Universidade of Santa Catarina, Analises Clinicas, Florianopolis, Brazil

Background & Objectives: Breast cancer (BC) has a high incidence among women worldwide. Metastatic disease is the leading cause of death, and one of the main causes of metastasis is dormant cells in the circulation. There is evidence that these cells develop mechanisms to escape the host immune response; therefore, they are associated with more aggressive immunophenotypes of the disease. Subtypes with worse prognosis also express some proteins related to the immune response, such as PD-L1. Therefore, understanding the associations between parameters and protein expression products is essential to establish alternatives that aid in the diagnosis and treatment of BC. Protein expression products have gained prominence in BC research, but the associations of these biomarkers have not yet been investigated.
Methods: To evaluate the importance of the joint analysis of the biomarkers ER, PR, HER2, Ki67, CK19, CD8, PD1, CTLA-4 and PD-L1 for the diagnosis, prognosis and assessment of the risk of metastasis in patients with breast carcinoma. The biomarkers were studied by flow cytometry or immunohistochemistry (IHC) methodologies.
Results: PDL1 by IHC was associated with subtypes with worse prognosis. Of all leukocytes present in peripheral blood, GD T lymphocytes were reduced in samples with CDI. There was a decrease in NKT cells and a decrease in the proportion of CD4/CD8 T lymphocytes in histological samples. The population of DN T lymphocytes is slightly increased in the luminal A subtype and increases in the HER2 and TBNC subtypes. TCD4 and TCD8 lymphocytes in the peripheral blood of patients with BC showed increased expression of the biomarkers CTLA4 and PD1 compared to the control. Regarding the investigation of circulating tumour cells (CTC), they were detected in 6.38% of cases.
Conclusion: This investigation shows the importance of joint assessment of biomarkers and the ability of flow cytometry to detect CTC safely and quickly for monitoring BC.

E-PS-02-083

Tubular adenosis of the breast: a case series with radiological/ pathological correlations

M. Failla[1,2], G. Attanasio[1,1], M. Berezina[1], G. Broggi[2], R. Caltabiano[2], M.P. Foschini[1]

[1]Alma Mater Studiorum - University of Bologna, Anatomic and Histology Pathology - Bellaria Hospital, Bologna, Italy, [2]Università degli Studi di Catania, Department of Medical, Surgical Sciences and Advanced Technologies "G.F. Ingrassia", Anatomic Pathology, Catania, Italy

Background & Objectives: Tubular adenosis (TA), originally described by Oberman in 1984 and subsequently characterized by Lee et al. in 1996, is a rare lesion of the breast that may mimic invasive carcinoma both radiologically and histologically.

TA is characterized by a non-lobulocentric, haphazard proliferation of elongated, narrow, and sometimes branching tubules lined by bland-looking ductal cells, surrounded by an intact myoepithelial layer.

The present study aimed to report the radiological and pathological features of a series of 8 TA cases to better understand its features.

Methods: Eight cases of breast TA were retrieved from the files of the Breast Unit at Bellaria Hospital (Bologna, Italy) diagnosed from 2010 to 2024.

All patients underwent a mammogram and then a vacuum-assisted biopsy and/or surgery.

The specimens were formalin-fixed and paraffin-embedded according to routine procedures.

The radiologic images were reviewed alongside the histology.

Results: Of the eight cases, in 1/8, FA was observed close to an infiltrative lobular carcinoma, and in 1/8, FA was associated with infiltrative carcinoma of non-special type.

In 4/8 cases, FA was close to foci of in situ lobular neoplasia, whereas 3/8 cases were associated with in situ ductal carcinoma. In three out of 8 cases, benign lesions were observed.

The comparison with radiological images revealed that the three cases with benign lesions had been classified as BI-RADS 3, whereas the other five cases had been described as BI-RADS 5.

All patients are alive and free of disease.

Conclusion: TA is a poorly known entity and may be confusing radiologically, leading to biopsies, but also histologically.

It should be taken into consideration in the differential diagnosis when seeing haphazardly arranged tubules that infiltrate fat but maintain myoepithelium.

TA can be associated with in situ or invasive carcinoma and the hypothesis of whether it has premalignant potential requires further research.

E-PS-02-084

Breast cancer: MAF as a predictive biomarker in treatment with adjuvant biophosphonates

V. Sousa[1,2,3], M. Reis Silva[1,3], A. Alarcão[1,3], A.F. Ladeirinha[1,3], T. Ferreira[1], M. Viseu[1], R. Silva[1], J. Pimentel[2,1], G. Fontinha[2,1], V. Almeida[2,1], L. Carvalho[2,1,3]

[1]Institute of Anatomical and Molecular Pathology, Faculty of Medicine of the University of Coimbra, Coimbra, Portugal, [2]Pathology Service, ULS Coimbra, Coimbra, Portugal, [3]CIMAGO – Research Centre for Environment, Genetics and Oncobiology, Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background & Objectives: MAF (v-maf avian musculoaponeurotic fibrosarcoma oncogene homolog- an AP-1 family transcription factor) amplification correlates with poor prognosis and bone metastasis in breast carcinomas (BC), also interfering with biophophonates metabolism, usually prescribed in postmenopausal women with early-stage BC when bone metastases control is important to reduce skeletal–related events and improving life quality. We present preliminary testing of MAF by applying FISH.

Methods: A series of ten FFPE sections of primary BC and a case of lymph node metastases *were evaluated for MAF* amplification using fluorescence in situ hybridization (FISH), MAFTEST (Inbiomotion, Barcelona, Spain). DAPI counterstain was applied, and images were acquired with a Leica DM 5500B microscope. The recommended score for *MAF* amplification, defines a mean number of 2.5 or more *MAF* copies per nucleus.

Results: The MAF status of the 11 tumour samples retrieved between December 2024 and March 2025 was based on tumour haematoxylin-eosin sections for selection of tumoral areas; patients mean age was 55 years (38-68). MAF-FISH was negative in all the 11 breast cancers samples. This result did not correlate with Nottingham Score, as five cases were G1 and the same number G2; as well as high oestrogen receptor and progesterone receptor immunohistochemistry.

Conclusion: The analysis of MAF status, committed the benefit from bisphosphonates therapy in the presented analysed cases. The implementation of MAF FISH as a predictive test into clinical practice, benefits 80% of younger women who have not reached menopause and who are currently excluded from treatment with adjuvant biophosphonates as shown in the literature.

According to the available data (AZURE trial), MAF biomarker selects a benefiting subgroup, including younger premenopausal patients currently excluded as mentioned.

E-PS-02-085

An immunohistochemical analysis of tumour associated interleukins in breast carcinoma

M. Sable[1], P. Mishra[2]

[1]All India India Institute of Medical Sciences, Bhubaneswar, Pathology & Lab Medicine, Bhubaneswar, India, [2]All India Institute of Medical Sciences, Pathology & Lab Medicine, Bhubaneswar, India

Background & Objectives: The pathogenesis of Breast Cancer (BC) is multi-factorial. Several interleukins are particularly relevant in the development and progression of cancer. The aim of this study is to evaluate the immunoexpression of TGF-beta2, IL-1A, IL-17, IL-19, and IL-20 as prognostic factors in BC.

Methods: All cases operated for modified radical mastectomy from 2018 to 2021 were collected. Immunohistochemistry was performed on representative FFPE tissue for TGF-beta2, IL -1A, IL-17, IL- 19, IL- 20. The H score was obtained, giving a range of 0 to 300. Clinicopathological details were obtained. Statistical analysis was done by using SPSS software.

Results: The expression of tTGF-Beta2 was more in post chemotherapy related BCs compared to naïve chemotherapy BCs (Mann-U test- p- 0.0034). Rest all other interleukins expression in naïve and post chemotherapy BCs are statistically insignificant. In naive chemotherapy cases, the low expression of IL1A was associated with negative hormonal receptors status(p value 0.011) and high IL19 expression was associated with higher stage disease (p-0.023). However, in rest other prognostic parameters were insignificant. In post chemotherapy cases, T size of the tumour showed significant association with IL 1A expression (p-0.037), while only HER2 overexpression showed significant association with IL 17 expression (p-0.046). However, in rest other prognostic parameters were insignificant.

Conclusion: IL1A, IL 19, IL17 displayed significant associations with certain prognostic factors of BC. Our study aimed to investigate the immunoexpression of interleukins in post-chemotherapy cases,

comparing them with chemotherapy-naive cases to identify any differences in expression. While the pathogenic role of interleukins in breast cancer progression and development is established, further research is needed to fully understand their implications and potential therapeutic applications in breast cancer treatment.

Microglandular adenosis-associated breast carcinoma: a case series highlighting shared immunophenotype, distinct morphological features, and genetic analysis

B.B. Senay[1], E.B. Balaban Yilmaz[1], M.G. Gurleyik[2], F. Vardar Aker[1]
[1]University of Health Sciences, Haydarpasa Numune Training and Research Hospital, Pathology, Istanbul, Turkey, [2]University of Health Sciences, Haydarpasa Numune Training and Research Hospital, General Surgery, Istanbul, Turkey

Background & Objectives: Microglandular adenosis (MGA)-associated breast carcinoma is a rare and diagnostically challenging entity, often exhibiting a triple-negative phenotype. This case series presents two such patients, highlighting their distinct histopathologic features and shared immunophenotypic profiles.
Methods: We retrospectively analysed the clinicopathologic and immunohistochemical findings of two patients diagnosed with MGA-associated breast carcinoma. Histologic evaluation was performed on biopsy and surgical specimens, and immunohistochemical profiling was conducted to assess diagnostic markers, including ER, PR, HER2, S100 and Ki-67. In addition next-generation sequencing (NGS) was carried out to identify potential pathogenic mutations and molecular alterations in both cases.
Results: The first patient was a 50-year-old female diagnosed with high-grade (grade III) invasive ductal carcinoma arising in a background of MGA. The second patient, a 29-year-old female at 38 weeks of gestation, was diagnosed with bilateral breast tumours, including an invasive carcinoma arising in MGA in the left breast. Both cases exhibited a triple-negative phenotype (ER-, PR-, HER2-) and high proliferative activity (Ki-67: 50–60%).
Conclusion: MGA-associated breast carcinoma may present with diverse morphologic features. Recognizing MGA as a potential precursor lesion is crucial for accurate diagnosis and appropriate clinical management. Despite their rarity, such tumours warrant publication in small case series, as they offer valuable insights into clinicopathologic characteristics, support refinement of diagnostic criteria, and contribute to the development of evidence-based management strategies.

E-PS-02-087

Frequency of HER2-low breast cancer at Fundación Santa Fe de Bogotá

S. Hernandez-Garzón[1,2], A.L. Rozo-Cruz[1,2], M.A. Forero-Rivera[1,2], JS. Rodriguez-Guevara[1,2], FF. Torres[3], B. Wills[3], D.P. Cañon-Solano[1], P.A. Rodriguez-Urrego[1]
[1]University Hospital Fundación Santa Fe de Bogotá, Pathology, Bogotá, Colombia, [2]Universidad de Los Andes, Bogotá, Colombia, [3]University Hospital Fundación Santa Fe de Bogotá, Bogotá, Colombia

Background & Objectives: HER2-low expression represents an emerging subgroup with significant therapeutic implications. This study aims to determine the frequency of HER2-low among primary and metastatic breast carcinomas treated at Fundación Santa Fe de Bogotá (FSFB) between 2019 and 2023, assessing its histologic distribution.
Methods: A retrospective observational cohort study based on the review of medical records and pathology reports of breast cancer patients managed between 2019 and 2023. A total of 786 cases with HER2 immunohistochemistry performed at the FSFB pathology laboratory were analysed, evaluating HER2 classification and its association with histologic subtypes and tumour location.
Results: A total of 411 primary carcinomas were identified, of which 87% were HER2-negative (0, 1+, 2+ with negative ISH), and among these, 46% were classified as HER2-low. Of the HER2-low tumours, 77% were hormone receptor (HR)-positive and 73% corresponded to invasive ductal carcinoma. Additionally, 82% were Nottingham grade 2. Among 78 metastatic cases, 74% were HER2-negative, with 30% of them being HER2-low. The most frequent metastatic sites were non-visceral (67%), visceral (62%), and central nervous system (25%). The frequency of HER2-low in this cohort was lower compared to previous reports in the literature (46% vs. 60%).
Conclusion: This study demonstrates that nearly half of HER2-negative breast carcinomas in this population are HER2-low, which has important therapeutic implications due to the use of antibody-drug conjugates (ADCs). Reassessment of biomarkers using updated criteria is essential to determine eligibility for novel therapies. These findings underscore the need for a multidisciplinary approach to optimize clinical management and outcomes in patients with HER2-low breast cancer.

E-PS-02-088

Histologic and molecular approach to distinguish grade 3 well-differentiated neuroendocrine tumour from poorly differentiated neuroendocrine carcinoma of the breast

Y. Wu[1], J. Estrella[1], Q. Ding[1], L. Middleton[1], K. Sweeney[1], E. Resetkova[1], C. Albarracin[1]
[1]The University of Texas MD Anderson Cancer Centre, Houston, USA

Background & Objectives: Under the most recent WHO classification, all breast neuroendocrine neoplasms are graded based on Nottingham histologic grading scheme. It is difficult to distinguish grade 3 (G3) well-differentiated neuroendocrine tumour (NET) from poorly differentiated neuroendocrine carcinoma (NEC). However, given the treatment difference between these two neoplasms, it is critical to classify these neoplasms accurately.
Methods: Thirteen high-grade neuroendocrine neoplasms of the breast were identified in our surgical pathology file. All cases were graded as G3 based on Nottingham histologic grade. Tumour necrosis, mitosis, Ki-67 proliferation rate, expression of retinoblastoma protein (Rb) and p53 aberrant expression or *Rb* and *TP53* gene mutation were evaluated in each case.
Results: Three of 13 cases revealed Rb protein loss, or p53 abnormal expression or *Rb* and/or *TP53* gene mutation. These 3 cases also demonstrated much higher Ki-67 proliferation rate (>50%), and larger area of tumour necrosis, compared to the remaining 10 cases.
Conclusion: Similar to the pancreas, evaluating Rb, p53 and Ki-67 by immunohistochemistry and/or molecular studies may help to distinguish high-grade (G3) well-differentiated NET from poorly differentiated NEC in the breast. However, due to the rarity of these breast neoplasms, additional studies with larger cohort are warranted.

E-PS-02-089

Estrogen receptor and androgen receptor co-expression in primary and metastatic breast cancer

C. Albarracin[1], H. Chen[1], D. Rosen[2], Y. Wu[1]
[1]Univ of Texas MD Anderson Cancer Centre, Pathology, Houston, USA, [2]Baylor College of Medicine, Pathology, Houston, USA

Background & Objectives: Oestrogen receptors (ER) and androgen receptors (AR) have been used as therapeutic targets in the management of breast cancer. Studies have shown that ER was higher in tumours that metastasized to the bone as compared with tumours that

metastasized to visceral sites. In this study, our goal is to evaluate the status of hormone receptors in primary tumours, lymph node metastases and in recurrent/distant metastatic breast cancer.
Methods: Tissue microarrays of 166 paired cases of primary breast cancers and axillary lymph node metastases. In addition, 77 cases of recurrent/distant metastatic breast carcinomas including metastatic to bone marrow (n=42), liver (n=19), ovary (n=12) and small intestine/colon/omentum/perirectal (gastrointestinal) (n=4). Immunohistochemical studies were performed to evaluate tumour expression of AR and ER.
Results: Primary breast cancer and lymph node metastasis are positive for AR (63%) and ER (79%). AR positive (AR+) tumours are also positive for ER/PR. AR is expressed in 91% (31/34) of carcinomas with lobular or mixed ductal/lobular features and only in 53% (61/115) of ductal carcinomas. Majority of distant metastatic tumours express ER, being positive in 84% (16/19) of liver metastasis, 67% (8/12) of ovarian metastasis and 67% (28/42) of bone metastasis. AR is also positive in distant metastatic sites (50%) being positive in 11/19 of liver metastasis,7/12 of ovarian metastasis and 21/42 of bone metastasis. Although AR positivity is less abundant than ER positivity, an association between these two receptors is suggested by their co-expression in 95% (87/92) of primary breast cancer and in 92% of (37/40) distant metastasis.
Conclusion: AR and ER are frequently expressed in primary and corresponding axillary lymph node metastasis; and in distant metastatic sites of breast cancer. The co-expression of AR in a subset of ER positive cases may provide a potential target in the treatment of tamoxifen-resistant breast cancer patients.

E-PS-02-090
Histo-radiological correlation of BI-RADS 3 lesions in patients under 40 years old. Experience in Albania
I. Plaku[1], E. Kurushi[1], R. Plaku[2]
[1]Universitary Hospital Centre "Mother Theresa" Tirana, Pathology Department, Tirana, Albania, [2]InteRad, Radiology, Tirana, Albania

Background & Objectives: Pathological conditions of the breast at under 40-years old patients have a lower incidence and are mostly benign.
The histopathological recognition of their spectrum in these age groups has a diagnostic and a management importance. During the diagnosis of these lesions, we must keep in mind, in addition to the essential histopathological features, the possibility of the presence of unclear malignant potential lesions or malignant lesions, as happened in some of the cases included in our study.
With the same radiological BIRADS-3 stage diagnoses and different clinical histories, the patients in our study are part of the age group of 20-40 years. Their histopathological diagnoses include benign lesions, primary malignant disease and lesions with low potential malignant transformation (B3 lesions).
Methods: This is a descriptive retrospective study conducted at the Pathology Department of Hospital Universitary Centre "Mother Thersa". In this study have participated 50 patients aged 20-40 that were diagnosed radiologically stage BIRADS-3 and have performed tru cut biopsy and histopatologjical/ imunohistochemistry examination.
Results: After performing histopathological examination and IHC, the study results showed a predominance of fibroadenoma (62%, 31 patients), benign proliferative lesions (B3) in 22%, 11 patients) and in 16%, 8 patients, primary malignant lesion was identified (ductal carcinoma in situ in 3 patients (6%) and invasive ductal carcinoma in 5 patients (10%).
Conclusion: According to our study, lesions staged radiologically BIRADS-3 at patients aged 20-40, are diagnosed histopatologically, at the largest percentage as benign lesions (62%). However, a relatively significant number of patients were diagnosed as B3 lesions (22%) and as malignant lesions (16%) after BIRADS-3 staging, thus concluding on the importance of screening, clinical follow-up and the necessary radiological-histopathological correlation.

E-PS-02-091
Variants of invasive lobular carcinoma: diagnostic and reporting practices, impact on treatment and clinical management
E. Resetkova[1], C. Albarracin[1], Y. Wu[1]
[1]The UT MD Anderson Cancer Centre, Pathology, Houston, USA

Background & Objectives: Invasive lobular carcinoma (ILC) accounts for up to 15% of breast cancers. Except classic ILC, other cytologic and architectural variants exist. This study aims to categorize ILC into variants and assess how pathology reporting on ILC variants may affect patient management and treatment strategies.
Methods: All ILC consecutive cases diagnosed since January 2023 were included in this study. We categorized tumours as variants when any cytologic or architectural variations were present. Clinical and demographic data, including tumour grade, tumour size and margin status, pathologic stage, lymph node status, distant metastasis, prognostic/predictive markers, and molecular studies were documented, and variants characteristics were compared to classic ILC group.
Results: Among 123 ILC cases, 68 were variants, and 55 classic. The most common variants were pleomorphic (27) and signet ring cells (19) and remaining were categorized as alveolar, trabecular, or solid. Pleomorphic ILC presented with a high nuclear and histologic grade ($p<0.0001$) and more frequent axillary lymph node metastases (71% vs. 45%). Distant metastases to liver, bone, brain, and orbits were commonly present in variants (12 of 68 cases) vs. classic type (2 of 55, $p=0.0426$) with pleomorphic and signet ring cells variants the most common. There were no significant differences noted between variants and classic ILC in age (61.5 vs. 64 years), tumour size (3.88 cm vs. 3.76 cm), pathologic tumour stage ($p=0.119$), margin status, and tumour focality. Lymphatic invasion was rare, even in cases with positive lymph nodes. Most tumours were ER/PR-positive, HER2-negative but five cases (2 variants and 3 classic ILC) were triple positive (ER/PR/HER2), and one variant was ER/PR-negative and HER2-positive. Ki-67 proliferation marker was higher in variants vs. classic ILC (21+/-15 vs. 12+/-9, $p=0.0029$).
Conclusion: This study highlights pathologic and molecular diversity of ILC, emphasizing the importance of reporting on type of variants that my impact on treatment and clinical management.

E-PS-02-092
Prognostic significance of p21 protein in breast cancer
S. Mitrovic[1], D. Jovanovic[1], J. Savic[1], M. Spasojevic[1], M. Ilic[1]
[1]University of Kragujevac, Faculty of Medical Sciences, Department of Pathology, Kragujevac, Serbia

Background & Objectives: Breast cancer is the most common malignancy in women. Bearing in mind these circumstances, a review of new molecular mechanisms underlying breast cancer progression, resistance and various aspects of existing therapeutic methods would lead to new insights for biologists and clinicians. In this regard, we conducted a study covering recent advances in breast cancer biology with a focus on the *p21* protein.
Methods: The study included 147 patients diagnosed with invasive breast cancer. The presence of non-invasive lesions was noted in each invasive breast cancer and surrounding tissue. *p21* expression was determined by reading the percentage of nuclear expression in epithelial cells of invasive breast cancer and non-invasive lesions.
Results: Results showed that expression of *p21* increases with the progression of cytological changes in the epithelium; it is significantly

higher in invasive breast cancer compared to non-invasive lesions ($p<0.001$). There is a difference in *p21* expression between different molecular subtypes of breast cancer ($p=0.004$). Statistically significantly higher values of *p21* expression were observed in those breast cancers that showed overexpression of *HER2* compared to *HER2*-negative tumours ($p=0.001$). Depending on *Ki67* expression, the highest *p21* expression is in the group with high *Ki67* expression values ($p=0.019$). The increase in *p21* expression in tumour cells was accompanied by a statistically significantly reduced expression of *ER* ($p=0.015$, $\rho=-0.225$) and *PR* ($p=0.027$, $\rho=-0.205$).

Conclusion: *p21* protein plays an important role in proliferation, malignant transformation, as well as in progression from non-invasive lesions to invasive breast cancer.

Arrhythmogenic right ventricular dysplasia as a cause of sudden death in a 58-year old woman: case analysis

Y. Kuzyk[1], H. Stoliar[2]
[1]Danylo Halytsky Lviv National Medical University, Department of Pathological Anatomy and Forensic Medicne, Lviv, Ukraine, [2]Lviv Regional Clinical Hospital, Department of Pathological Anatomy, Lviv, Ukraine

Background & Objectives: Arrhythmogenic right ventricular dysplasia (ARVD) is a genetic heterogeneous hereditary heart disease characterized by fibro-fatty replacement of the right ventricular (RV) myocardium, accompanied by severe cardiac arrhythmias, including ventricular extrasystole and right ventricular tachycardia with a high risk of sudden cardiac death.
Methods: We present a case of the sudden death of a 58-year-old woman. An autopsy was performed with tissue sampling of internal organs. Standard haematoxylin and eosin staining was used for histological examination.
Results: A 58-year-old woman died suddenly 40 minutes after admission to the hospital. The immediate cause of death was pulmonary thromboembolism. Postmortem examination revealed a probable source of thromboembolism, namely a parietal thrombus in the right ventricular cavity and phlebothrombosis of the right popliteal and tibial veins. The development of deep vein phlebothrombosis of the right leg was directly related to a one-month-old injury to the right leg. During autopsy, a predominant lesion of the right ventricle with specific pathomorphological signs was detected, which allows the diagnosis of isolated cardiomyopathy. The disease was complicated by right ventricular heart failure with thromboembolic syndrome and pulmonary heart failure, which became the immediate cause of death. The underlying disease was not diagnosed in the clinic due to the severity of the condition and the patient's short stay in the hospital.
Conclusion: In our case, the diagnosis of ARDV was a diagnosis of exclusion. The sudden death of a 58-year-old patient, the complete absence of previous medical data or anamnesis, the absence of atherosclerosis, ischemic or inflammatory myocardial damage, pronounced macroscopic changes (gray-yellow thinned wall with a fixed thrombus (and therefore, a clear zone of hypokinesis) in the dilated right ventricle) and the histological picture of transmural fibro-fatty replacement of the right ventricle myocardium allowed us to diagnose ADV.

E-PS-03-002

Application of APE1/Ref-1 in human heart tissue for evaluating Myocardial Infarction: a proof-of-concept study

J.-Y. Na[1,2]
[1]Pusan National University School of Medicine, Department of Forensic Medicine, Yangsan, Republic of Korea, [2]Pusan National University Yangsan Hospital, Department of Pathology, Yangsan, Republic of Korea

Background & Objectives: Myocardial infarction (MI) is a leading cause of mortality worldwide. Apurinic/apyrimidinic endonuclease-1/redox factor-1 (APE1/Ref-1) is a ubiquitously expressed bifunctional protein involved in oxidative stress response, DNA damage repair, and the regulation of redox-sensitive transcription factors.
Methods: Immunohistochemical staining for APE1/Ref-1 was performed on explanted hearts from individuals with different MI histories. Western blot analysis quantified APE1/Ref-1 expression in two opposing myocardial sites (anterior and inferior walls of the left ventricle). Each myocardial site was classified as infarcted or control based on the culprit artery.
Results: APE1/Ref-1 expression was more prominent in the penumbra of the infarcted wall affected by recent ischemic injury (several days prior) compared to the contralateral wall, which had been infarcted approximately four weeks earlier in the same individual. APE1/Ref-1 immunoreactivity was also observed in vascular endothelial cells and granulation tissue in addition to cardiomyocytes. However, in myocardial infarctions occurring one to two months earlier, APE1/Ref-1 was detected only in cardiomyocytes adjacent to granulation tissue. Western blot analysis demonstrated significantly higher APE1/Ref-1 expression in myocardial regions supplied by the culprit artery compared to the contralateral site.
Conclusion: APE1/Ref-1 expression varies according to the time elapsed since MI, with distinct localization in cardiomyocytes, endothelial cells, and granulation tissue. Its differential expression suggests a role of APE1/Ref-1 in myocardial injury influenced by the microenvironment. These findings indicate that APE1/Ref-1 may serve as a useful biomarker for MI assessment, particularly in determining the infarction timeline. Furthermore, they suggest its potential application in postmortem MI diagnosis during autopsy.

Basilical vein aneurysm - a case report of a rare pathological entity

A. Gheju[1], N. Fluieraș[2], A. Pînzariu[3], A. Laluțiu[1], P. Inișca[1], M. Blendea[2]
[1]Emergency County Hospital Deva, Pathology, Deva, Romania, [2]Emergency County Hospital Deva, Surgery, Deva, Romania, [3]Emergency County Hospital Tulcea, Pathology, Tulcea, Romania

Background & Objectives: Venous aneurysms are rare vascular lesions and the term is most commonly applied to dilatations of arteries. However, these lesions may occur in any part of the vascular system. Venous aneurysms were first mentioned in the literature by Osler in 1913. Our study aims to present a rare case of venous aneurysm of the right upper extremity.
Methods: We present the case of a 63-year-old man admitted in the Surgery department of Emergency Hospital Deva for symptoms of discomfort, increasing in size, easily compressible soft tissue mass on the right upper limb. The preoperative CT revealed a "cystic" lesion measuring 3,8 cm in diameter close to the basilical vein/ local venous dilatation. The lesion was excised together with the overlying skin tissue and sent to us for histological examination. The patient was discharged the second postoperative day and his further course was uneventful with great improvement.
Results: Macroscopy and microscopy revealed a lesion located in the subcutaneous tissue, as a saccular/dilated space structure developing from a venous wall, with the lumen lined by flat endothelial cells, filled with blood and thrombi, with characteristic IHC phenotype: CD31

intense and diffuse positive in the endothelial cells, without notable cytonuclear atypia, thinning the inner and middle layers of the basilical vein and replacement of the outer layer by fibrous tissue with decrease of elastic and smooth muscle fibres of the inner and middle layers. A diagnosis of primary venous aneurysm was made. Differential diagnosis includes a wide variety of upper limb soft tissue masses, mainly lipomas or other solid or cystic tumours. Preoperative diagnosis is of immense value.
Conclusion: Venous aneurysms are uncommon vascular malformations that may be identified anywhere in the body, often misdiagnosed as other soft tissue lesions.

E-PS-03-004
Analisis of risk factors affecting the development of thoracic aortic aneurysm
B. Magrupov[1,2], A. Abdurakhmanov[3], M. Obeid[3], O. Sultanov[3]
[1]Center for the Development of Professional Qualifications of Medical Workers, Department of Pathological Anatomy and Forensic Medicine, Tashkent, Uzbekistan, [2]Republican Research Centre of Emergency Medicine, Department of Pathological Anatomy, Tashkent, Uzbekistan, [3]Republican Research Centre of Emergency Medicine, Department of Cardiac Surgery, Vascular Surgery with Microsurgery, Tashkent, Uzbekistan

Background & Objectives: To analyse the risk factors influencing the development of thoracic aortic aneurysm.
Methods: The study included 58 patients who underwent surgery for ascending aortic aneurysms between 2017 and 2024. The average age of the patients was 51.5 ± 2.7 years. The diagnosis was confirmed by transthoracic echocardiography and multispiral computed tomography with contrast. The average diameter of the ascending aorta in the widest part was 7.5 = 0.6 cm. The majority of patients were men - 53 (91%) over the age of 50 (64%).
Results: Of the 58 patients included in the study, 53 (91%) were men and 5 (9%) were women. The average age of the patients was 51.5 ± 2.7 years. More than half of the patients (32 or 55%) had a history of chronic arterial hypertension (24 or 41.3%), which was usually combined with coronary heart disease and various atherosclerotic vascular lesions. In addition, 15 (25.8%) patients were diagnosed with bicuspid aortic valve, which is known to be a congenital anomaly closely associated with an increased risk of aortic aneurysm. The third most common cause was Marfan syndrome, which was observed in 10 (17%) cases. In addition to these main causes, a small number of patients (11%) had other risk factors such as a family history of aortic aneurysm, connective tissue diseases, and trauma. The sizes of the aneurysms were different: the average diameter was 7.5 ± 0.6 cm, and the largest aneurysm was 9.5 cm.
Conclusion: The most common underlying conditions in the development of thoracic aortic aneurysm are atherosclerotic lesions of the aorta with prolonged hypertension, as well as congenital bicuspid aortic valve. Arterial hypertension plays a key role in the development of aortic aneurysm. Early detection and effective treatment of hypertension are crucial factors in the prevention of aortic aneurysm and the prevention of its serious complications.

E-PS-03-005
Study of long-term trends of morphologically-analysed inflammatory myocardial disease in 2002-2023
M. Kuprytė[1,2], I. Paškevičiūtė[2], L. Treinė[1], L. Poškienė[3,2]
[1]Hospital of Lithuanian University of Health Sciences Kauno Klinikos, Pathological Anatomy, Kaunas, Lithuania, [2]Lithuanian University of Health Sciences, Kaunas, Lithuania, [3]Lithuanian University of Health Sciences Kauno Klinikos, Pathological Anatomy, Kaunas, Lithuania

Background & Objectives: Inflammatory myocardial disease, or myocarditis, is considered among one of the most common causes of sudden cardiac death in young adults with estimated prevalence at approximately 1.8 million cases per year worldwide, still leaving true epidemiological disease data in local regions inaccurate. Study objective is to determine long-term trends of myocarditis in 2003-2023 specific for local Lithuanian region.
Methods: 40 cases of suspected / confirmed myocarditis with obtained myocardial tissue processed and examined morphologically applying light microscopy in local Lithuanian pathology laboratory in 2002-2023 were selected for the study. Selected cases were analysed according to myocardial infiltrate type (lymphocytic, neutrophilic granulocyte, giant multinucleated cell), pattern (borderline, focal, diffuse), patient's sex, age, and outcomes in yearly trends. Descriptive statistics, ANOVA, and $\chi 2$ tests were applied ($p<0.05$).
Results: 77.5% (n=31) and 22.5% (n=9) women of similar age were determined in the study (47.61 (16.88) vs (45.56 (13.11) years old; F=1.808, p=0.149). Lymphocytic infiltrate was the most common infiltrate type (67.5%, n=27), and the most predominant infiltration pattern was borderline (32.5%, n=13). Non-lethal outcomes were observed in 62.5% (n=25) of morphologically-analysed myocarditis. Non-lethal outcomes of myocarditis were predominant in 2002-2005 compared to the remaining 2006-2023 yearly trends ($\chi 2=13.156$, p=0.011). Sex and age of patients, myocardial infiltrate type and pattern were similar in 2002-2005, 2006-2010, 2011-2015, 2016-2020, and 2021-2023 yearly periods ($p>0.05$).
Conclusion: Long-term trends of patient's sex, age, and outcomes, as well as, myocardial infiltrate type and pattern in 2002-2023 were characterized in cases of myocardium tissue analysed for inflammatory disease, revealing predominance of non-lethal outcomes of myocarditis in 2002-2005. Considering the study results, it can be hypothesized that long-term data analysis of morphological testing results can serve as an important ancillary tool to monitor local population trends of a clinically significant entity validated by structural tissue analysis.

E-PS-03-006
COVID-19 cardiac injury: involvement of chymase-positive mast cells
A. Filin[1], E. Arkhipova[2], V. Shishkina[3], A. Budnevsky[2], T. Chernik[2], I. Perveeva[4]
[1]Voronezh State Medical University, Department of Pathological Anatomy, Voronezh, Russia, [2]Voronezh State Medical University, Department of Faculty Therapy, Voronezh, Russia, [3]Voronezh State Medical University, Department of Histology, Voronezh, Russia, [4]Voronezh State Medical University, Research Institute of Experimental Biology and Medicine, Voronezh, Russia

Background & Objectives: Acute myocardial injury is observed in 22% of COVID-19 patients. Mast cell proteases play a significant role in lung damage in COVID-19, but their contribution to cardiac damage in this pathology is poorly understood. The aim of the study was to assess the density of chymase-positive cardiac mast cells (CPMCs) in patients who died due to COVID-19 and its association with troponin I level.
Methods: The study sample consisted of 60 patients (28 women and 32 men, mean age 70.0 [62.0; 72.0] years). During hospitalization blood troponin I level were measured. Cardiac tissue samples were obtained from patient autopsies. CPMCs were counted per 1 mm^2, accounting for their degranulation activity.
Results: The median troponin I in the study group was 0.1 [0.0; 0.2] ng/ml, while elevated levels of this marker were observed in 11.7% of patients. The median number of cardiac CPMCs was 0,17 [0,00; 0,85] per 1 mm^2. CPMCs with degranulation were predominant (0,17

[0,00; 0,77] per 1 mm^2), while median of CPMCs without degranulation was 0,00 [0,00; 0,00] per 1 mm^2.
Significant correlations were established between the number of cardiac CPMCs and the level of troponin I: moderate correlation with CPMCs with degranulation (r=0.6711; p=0.0000), with total number of MC of this phenotype (r=0.6558; p=0.0000) and weak correlation with CPMCs without degranulation (r=0.3101; p=0.0172).
Conclusion: The results obtained in the study suggest the involvement of CPMCs in the development of acute myocardial injury in COVID-19 patients. Possible mechanisms underlying this pathological process include the development of the inflammatory process through the activation of proinflammatory cytokines, apoptosis of endothelial cells, and stimulation of fibrosis.

E-PS-03-007

Pathohistological characteristics of semilunar valves in calcific aortic valve disease: Correlation with clinical parameters and comorbidities

M. Jovanović[1], L. Vićentijević[2], I. Petrović[1], M. Matković[3], E. Nestorović[4], B. Đurđević Vukomanović[5], R. Janković[1], S. Glumac[1]
[1]Institute for Pathology, Medical Faculty, University of Belgrade, Beograd, Serbia, [2]Medical Faculty, University of Belgrade, Beograd, Serbia, [3]University Clinical Centre of Serbia, Department for Cardiac Surgery, Belgrade, Serbia, [4]University Clinical Centre of Serbia, Clinic for Cardiac Surgery, Department for Heart Transplantation, Belgrade, Serbia, [5]Military Medical Academy, Pathology and Forensic Medicine Institute, Belgrade, Serbia

Background & Objectives: Calcific aortic valve disease (CAVD) is a progressive, irreversible fibro-calcific remodelling of the aortic valve (AoV) leaflets, leading to aortic stenosis, which is the second-most frequent cardiovascular disease in individuals over 65. Besides aging and congenitally bicuspid AoV, CAVD development is associated with common cardiovascular risk factors such as hypertension, diabetes mellitus, and dyslipidemia. Additionally, one theory suggests that CAVD shares etiopathogenic similarities with atherosclerosis. This study aimed to analyse the pathohistological characteristics of affected AoVs and their correlation with clinical parameters like stenosis severity, ejection fraction, NYHA classification, and comorbidities (obesity, hyperlipidemia, diabetes).
Methods: In this retrospective study 58 surgically removed AoV were analysed from patients diagnosed with aortic stenosis due to CAVD at the University Clinical Centre of Serbia between April and December 2023, which were processed by standard histological techniques. Overall pathological changes of affected AoV were assessed on haematoxylin-eosin slides and classified based on Warren and Yong's grading system. Statistical analysis was performed using descriptive methods and correlation tests, with significance set at $p<0.05$.
Results: The study included 30 male and 28 female patients, with a mean age of 67.9 ± 8.1 years. Most patients (75.9%) were overweight (BMI > 25). A significant correlation was found between serum triglyceride levels and inflammatory cell infiltration around calcific nodules ($p<0.011$). No significant associations were observed between histological changes and cholesterol levels, ejection fraction, or NYHA class. Patients with severe stenosis exhibited increased valvular inflammation and neovascularization ($p<0.001$).
Conclusion: Our findings suggest that triglycerides metabolism may contribute to the progression of CAVD by promoting inflammatory processes within the valve tissue. The lack of correlation between cholesterol levels and histopathological changes supports the hypothesis that CAVD may have a distinct pathogenesis from atherosclerosis, despite some shared mechanisms. Further research is needed to explore the etiopathogenic mechanisms of CAVD.

E-PS-03-008

Primary RNAlater fixation and dissection of endomyocardial biopsies for histology and molecular biology avoids discrepancies resulting from sampling errors

G. Mall[1]
[1]Klinikum Darmstadt, MVZ für Klinische Pathologie, Darmstadt, Germany

Background & Objectives: On occasion of the annual meeting of the DGK 2023 in Mannheim (Germany) primary RNAlater fixation was presented to prevent the well known sampling error of myocarditis diagnoses and virological tests (low sensitivities, between 15 and 80% false negativ virological tests).
Methods: Commonly, three biopsies for histology and two biopsies for molecular diagnostics are taken. Our submitters fixed the biopsies with RNAlater and we dissected the probes for histology and molecular analyses. The diagnostic sensitivity will amount to 97%.
Additionaly we measured myofiber diameters because of their low sampling error and the importance for cadiac structure and function.
Results: **RNAlater fixation:** Between 2020 and 2024 a cohort of 263 endomyocardial biopsies were fixed with RNAlater and have been evaluated in the MVZ für Klinische Pathologie in Darmstadt. The morphologic quality after RNAlater fixation did not differ between RNAlater fixation and formalin fixation. For staining automatic standard procedures of routine histologic laboratories were used.
Myofibre diameters:

1. Increased ventricular volume and nonhypertrophic myofibres in biopsies indicate increase of **fibrous tissue or amyloid**. Absence of interstitial deposits indicate **storage diseases (Glykogenosis, Sphingolipidosis) or hypertrophy and hyperplasia of myofibres, respectively**. Morphometry of myofibre diameters is especially **successful detecting hypertrophic cardiomyopathies.**
2. Normal muscle mass (Echo, MRT, CT) and nonhypertrophied myofibers in association with ventricular dilatation (Echo, MRT, CT) indicate an **acute cardiac event rather than preexisting cardiac remodelling.**

Conclusion: For future clinicopathologic research on RNA molecules pairwise embedding of the dissected biopsies and not pooling seems to be preferred. Measurements on myofibre diameters may be usefully included.

E-PS-03-009

Takayasu aortitis complicated with aortic pseudoaneurysms and foetal death: a case report and literature review

C. Pontinha[1,2], C. Sá Fontes[2], N. Gião[1,2], A. Cruz Tomás[3], T. Garcia[4], A. Félix[2,5]
[1]Local Health Unit of São José, Anatomical Pathology, Lisboa, Portugal, [2]NOVA Medical School, Faculdade de Ciências Médicas, NMS, FCM, Universidade NOVA de Lisboa, Lisboa, Portugal, [3]Local Health Unit of São José, Cardiothoracic Surgery, Lisboa, Portugal, [4]Local Health Unit of São José, Internal Medicine, Lisboa, Portugal, [5]IPO Lisboa – Portuguese Institute of Oncology of Lisbon, Anatomical Pathology, Lisboa, Portugal

Background & Objectives: Pregnancy in Takayasu arteritis (TA) patients is associated with vascular remodelling and severe cardiovascular complications (aortic aneurysms, pseudoaneurysms and coronary artery disease). We report the morphology of a clinical case with multiple aortic pseudoaneurysms and foetal death.
Methods: A 32-year-old female diagnosed with TA, was hospitalized for acute cardiorespiratory dysfunction. Imaging revealed large aortic pseudoaneurysms with hemodynamical dysfunction and foetal death (unknown pregnancy of 20 weeks and 6 days). Total thoracic aortic reconstruction was performed, and foetal spontaneous expulsion

occurred. Frozen elephant trunk (FET) surgery, which uses antegrade deployment of thoracic endovascular aortic repair (TEVAR) endografts along with total arch replacement, was selected as the best surgical approach. Examination of the aorta, placenta specimens, and clinical foetal autopsy were performed.
Results: Surgical specimen composed of a thick fragment of aorta (55x35 mm) was examined and necrotizing aortitis with intimal and adventitial scarring without dissection was seen. Active inflammatory and healed lesions were seen with predominance of lymphocytes, plasmocytes, giant cells and some ill-defined granulomas. Verhoeff staining highlighted severe fragmentation of elastic fibres and no acid-fast bacili were identified. Isolated aortitis, lymphoplasmocytic aortitis and autoimmune-associated aortitis in differential diagnosis were excluded. No major alterations were found at the placenta and the post-mortem examination of the foetus revealed no malformations or foetal growth restriction.
Conclusion: This case illustrates why pregnancies in patients with TA should be considered high risk, requiring close monitoring and collaboration of different medical specialties. In this case, we highlight the importance of clinical-pathological integration, to make a correct differential diagnosis and future therapeutic management of the patient and also of the offspring.

E-PS-03-010
Quantitative assessment of myocardial vascular network density depending on cause of death
I.E. Pleșea[1,2], M.-S. Șerbănescu[3], V.T. Grigorean[4,5], L.E. Nica[6], I.D. Avramescu[7], L. Eftimie[8], R.M. Pleșea[9]
[1]"Carol Davila" University of Medicine and Pharmacy, Doctoral School, Bucharest, Romania, [2]"Bagdasar-Arseni" Emergency Clinical Hospital, Pathology, Bucharest, Romania, [3]University of Medicine and Pharmacy, Medical Informatics and Biostatistics, Craiova, Romania, [4]"Carol Davila" University of Medicine and Pharmacy, 10th Clinical Department - General Surgery, Bucharest, Romania, [5]"Bagdasar-Arseni" Emergency Clinical Hospital, General Surgery, Bucharest, Romania, [6]University of Medicine and Pharmacy, Doctoral School, Craiova, Romania, [7]Emergency University Hospital, Pathology, Bucharest, Romania, [8]"Carol Davila" Central Military Emergency University Hospital, Pathology, Bucharest, Romania, [9]University of Medicine and Pharmacy, Cellular and Molecular Biology, Craiova, Romania

Background & Objectives: Diseases causing death became more and more diverse and each of them can influence structural and functional changes of myocardial tissue. The authors compared the variations of myocardial interstitial capillary network density-VD between the different cardiac wall regions depending on patients' cause of death (COD).
Methods: Five epicardium-to-endocardium cross sections (left ventricle wall-LVW: anterior-LV_AW, lateral-LV_LW and posterior-LV_PW, interventricular septum-IVS and right ventricle wall-RVW) were taken during autopsy from 95 patients died with different causes of death (vascular diseases-V_P, non-vascular diseases-NV_P, and suspect/violent cause of death-S/V_Dth, named also control group-CG) in the hospital. Tissue samples were processed and immunomarked with CD34 antibody. Slides were digitized. The VD was measured with a dedicated software "in-house" designed. Average values-AV were compared using chi square test.
Results: The VD had lowest values in V_P group and highest values in CG in general and in both sexes. Its values increased from LVW to RVW in V_P group and CG and decreased in NV_P group in general and in both sexes. They also increased from LV_AW toward LV_PW in all groups of COD and in both sexes.
The VD values were higher in women than in men in CG and NV_P group and higher in men than in women in V_P group. Its values were lowest in both sexes in V_P group but highest in men in NV_P group and in women in CG.
Conclusion: The diseases causing death determine different pathways of interstitial capillary network remodelling both along the different regions of the cardiac wall and in the two sexes, the most important being the capillary density decrease in vascular diseases as compared with all other causes of death.

E-PS-03-011
Non-Infectious Aortitis: 14 years' institutional experience
H. Ashe[1], L. Burke[1], C. O'Brien[1]
[1]Cork University Hospital, Cork, Ireland

Background & Objectives: Non-Infectious aortitis (NIA) is a rare, commonly incidental finding in Thoracic Aortic specimens. Once diagnosed, patients are at higher risk of future vascular complications, including aneurysmal development. Some cases may be part of a wider systemic condition or 'clinically isolated' in nature. Appropriate pathological evaluation is therefore key to guiding appropriate patient management and follow-up.
To appraise the pathological handling and reporting of surgically resected thoracic aortic specimens in our institution to the recommendations published by the Society for Cardiovascular Pathology / Association for European Cardiovascular Pathology in 2015. To evaluate the clinical details received, surgical indications, histopathological features, and incidence of NIA.
Methods: A 'CORVU' search of the Laboratory Information Management System at the Dept. of Pathology, Cork University Hospital from January 1st 2010 to December 31st 2024 was performed, utilizing SNOMED codes for Aorta and Aortitis. Study data was collected and analysed using Microsoft Excel.
Results: 6% (n=23) of the total 416 thoracic aorta specimens received were diagnosed with NIA, all located in the ascending aorta. Thoracic aortic aneurysm repair was the most common surgical indication (61%). 43% of aneurysm patients needed concurrent valvular repair. All cases were sampled according to consensus recommendations (average of 8.3 pieces of tissue per 3.4 cassettes). Atheromatous change was identified in 74% of cases and medial degeneration in 87% of cases. Granulomatous/giant cell (GCC) pattern was the most common histopathological pattern (96%). One case had no definitive pattern diagnosed due to mixed features. Only one GCC case had a diagnosis of Polymyalgia Rheumatica included in the clinical details.
Conclusion: NIA is a rare but important entity to recognize through optimal specimen handling and reporting, to ensure appropriate follow-up for this patient cohort. Although systemic disease was identified in only one our cases to date, an extended chart review is to follow.

E-PS-03-012
Histological structure of the atrial appendages in patients with persistent atrial fibrillation after cardiac surgery
Z. Gioeva[1], N. Gutyrchik[1,2], L. Kakturskij[1], A. Stonogin[1], S. Solovieva[1], V. Savina[1], N. Tikhonova[1], L. Mikhaleva[1]
[1]Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Moscow, Russia, [2]Peoples' Friendship University of Russia named after Patrice Lumumba, Moscow, Russia

Background & Objectives: Atrial fibrillation (AF) is one of the most common arrythmias associated with a higher risk of thromboembolism and stroke. The incidence of AF is increasing globally, especially in the elderly population. The study aimed to perform histomorphometry of the atrial appendages removed during cardiac surgery in patients with persistent AF.
Methods: Eighty atrial appendages removed during cardiac surgery were examined: 50 – from patients with AF and 30 – from patients without AF (control group). Haematoxylin and eosin, Van Gieson's, Mallory's, and Lie-staining were used for histological examination of

the paraffin sections. The severity of myocytolysis and cardiomyocyte contraction impairment, intramural oedema, fibrosis and lipomatosis of the myocardial stroma were evaluated by histostereometric method. Monoclonal antibodies to desmin, S100 and CD117 were employed as immunohistochemical markers to characterize cytoskeleton and detect telocytes.

Results: The damages of cardiac myocytes, such as myocytolysis and cardiomyocyte contraction impairment, increase in relative interstitial volume, sclerosis and lipomatosis of the myocardial stroma were more pronounced in patients with AF. The difference was statistically significant ($p<0.001$). The structure of cytoskeletal components was damaged in cardiac myocytes affected by myocytolysis. AF was also associated with an increased vascular permeability and focal lymphohistiocytic infiltrates. In AF patients, endocardial sclerosis was accompanied by mucoid oedema and mural thrombosis. Using S100 and CD117, a moderate quantity of telocytes was detected in the myocardial stroma. The number of telocytes in patients with AF was significantly lower than in the control group.

Conclusion: Mainly non-specific histopathological changes were detected in the left auricle appendages of patients with persistent AF. The most informative findings included such acute damages of cardiac myocytes as myocytolysis, contractures and wave-like deformation, amid interstitial oedema and increased vascular permeability. Chronic changes (cardiosclerosis and stromal lipomatosis) were also more common in the AF patients.

Funding: This work was supported by the Ministry of Education and Science of the Russian Federation within the framework of the state order No 123030700101-2

E-PS-03-013

Early and late complications of stenting and coronary artery bypass grafting

B. Magrupov[1,2], V. Ubaydullaeva[2,1], T. Vervekina[2,1]
[1]Center for the Development of Professional Qualification of Medical Workers, Patanatomy and Forensic Medicine, Tashkent, Uzbekistan, [2]Republican Research Centre of Emergency Medicine, Department of Cardiac Surgery, Vascular Surgery with Microsurgery, Tashkent, Uzbekistan

Background & Objectives: Stenting and coronary artery bypass grafting (CABG) are among the most widely used methods of treating coronary heart disease.

Methods: The autopsy results of 119 patients who underwent stenting (59 cases) or ABG (60 cases) after diagnosis of myocardial ischemia were studied.

Results: Men were 2.5 (71.2%) times more likely to undergo stenting and 2.7 times (72.7%) more likely to undergo ABG compared with women (28.8% and 27.3%). The most frequently performed stenting of the anterior interventricular artery (AIA) and the formation of an Aortic graft -AIA. Stenting of 2 or more arteries was performed in 22%, and the use of 2 or more grafts for ABG was performed in 89%. The peak of stenting deaths was observed from the day of stent placement to 10 days, the second peak was from 6 months to 2 years. With ABG, the first peak was from the day of surgery to 1 month, and the second peak occurred for a period of 10 years or more after ABG.

Deaths on the first day were associated with early complications: damage during puncture of the main artery, stent deformation, acute arterial thrombosis, occlusive dissections. With ABG, all patients underwent bypass surgery due to a violation of the adequate functioning of grafts- thrombosis.

In the first 10 days after stenting, patients died from acute coronary artery thrombosis, occlusive dissection, and myocardial infarction. During ABG, bypass thrombosis, bleeding from the internal thoracic artery, acute cerebrovascular accident, iatrogenic complications, reperfusion complications, and technical complications were recorded. Late complications of stenting included thrombosis, restenosis, and neointimal hypertrophy. With ABG performed for 5 years or more, shunt dysfunction with the development of atherosclerosis and stenosis, venous bypass thrombosis were determined.

Conclusion: Conducting autopsy examinations helps to detail the causes of death and is aimed at preventing complications.

E-PS-03-014

A comprehensive clinical and histological approach to the diagnosis and treatment of cardiomyopathy after radiation therapy

Z. Gioeva[1], Y. Frolova[1], K. Vilizhinskaya[1], M. Fomin[1], L. Kakturskij[1], D. Areshidze[1], M. Kozlova[1], E. Evseev[1]
[1]Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Moscow, Russia

Background & Objectives: Overall, malignant neoplasms (MN) are considered as one of the biggest health challenges worldwide. A key modality of MN treatment is radiation therapy (RT).

Histopathological evaluation, characterizing the severity of fibrosis, plays an important role in clinical settings for the timely therapy revision in patients with heart diseases and for the cardiac surgery risk assessment. The study objective is to assess the contribution of a comprehensive clinical and morphological approach to the diagnosis and treatment of radiation-induced heart disease.

Methods: From January 2012 to December 2024, surgery was performed on 39 patients with radiation-induced heart disease, 26 (66%) of whom were women. RT was conducted for Hodgkin lymphoma in 25 (64%) cases, breast cancer in 10 (24%), and mediastinal teratoblastoma in 1 case. The time interval from the completion of RT course to cardiac surgery was 26.2 ± 11.4 years. Haematoxylin and eosin, picrofuchsin acc. to van Gison, Lee's and Mallory's stains were used for staining all sections.

Results: The heart valve surgery was performed in 36 (92%) patients, one-stage coronary artery bypass surgery – 8 (20%), and subtotal pericardiectomy – in 3 patients.

Histopathological assessment of the surgical specimens revealed that the epicardium contained large areas of coarse fibrosis with the sites of angiomatosis. In most cases the fibrotic areas were associated with haemorrhages, sometimes in combination with lymphohistiocytic infiltration. Extensive vacuolization of sarcoplasm was present in cardiomyocytes in the subepicardial regions.

Conclusion: It is crucial to continue the investigation of histopathological patterns associated with the development of radiation-induced restrictive cardiomyopathy which not only complicates the clinical course of CHF and the choice of optimal medical therapy but also influences the timeline of cardiac surgery. Our histological data prove that the healthy heart tissues and structures are replaced by collagen and fibrin with the further formation of coarse fibrosis and calcification.

E-PS-03-015

Unexpected, sudden and deadly aortic aneurysm complication

R. Henriques de Gouveia[1], F. Corte Real[2]
[1]Universidade da Madeira (& UMa - RISE-Health, LANA, INMLCF), Pathology, Funchal - Madeira, Portugal, [2]INMLCF (& FMUC), Legal Medicine, Coimbra, Portugal

Background & Objectives: Aortic Aneurysm is responsible for relevant morbidity and mortality. Globally, aorta aneurysm-related deaths rose by 74.2% from 1990 to 2021, getting up to 153,927 deaths (2021). The authors aim to present a deadly aneurysm complication, discovered during medico-legal postmortem investigation.

Methods: A 73-years old male died suddenly, without history of personal or familial pathological antecedents. A postmortem study was

performed at a Branch of our National Medico-Legal and Forensic Sciences Institute, which included autopsy with toxicological and anatomo-pathological examinations.
Results: Relevant autopsy findings were 1100 cc of blood inside the intestine lumen, adherence of the duodenum wall to an abdominal aorta aneurysm (11cm diameter), a hole at the duodenum mucosa extending to the inner cavity of the aneurysm through a linear continuity solution. Inside the aneurysm were atherosclerotic plaques and parieto-luminal thrombus. Microscopic evaluation confirmed the lesions observed macroscopically and characterized the type of atherosclerotic plaques ("IV" and "VI" - *American Heart Association)*. Toxicology results were negative for alcohol, licit/illicit drugs, pesticides. Death was declared natural, sudden, unexpected, due to rupture and fistulisation to the duodenum of a thrombosed atherosclerotic aneurysm of the abdominal aorta, with massive intra-intestinal bleeding.
Conclusion: *Primary Aorto-duodenal Fistula (PADF)* is a rare condition (incidence: 0.04%-0.07%), with abdominal aorta aneurysm as risk factor. Yet, PADF is severe, life-threatening, mostly due to acute, massive and hard-to-control haemorrhage. Without treatment, 80%-100% are fatal, eventually suddenly and unexpectedly. The outcome is so dismal, that even with intervention, perioperative mortality ranges 18%-63%. Complete Medico-Legal postmortem examination (including anatomo-pathological and toxicological studies) are of major relevance, to disclose the cause of unpredicted deaths, as well as to clarify post-surgical in-hospital deaths.

E-PS-03-016
Morphological changes of coronary capillaries in different stages of cardiopulmonary bypass
K. Gurska[1], V. Zakharova[1], R. Vitovskyi[2], P. Semeniv[2]
[1]Amosov National Institute of Cardiovascular Surgery, Pathomorphological, Kyiv, Ukraine, [2]Amosov National Institute of Cardiovascular Surgery, Surgical, Kyiv, Ukraine

Background & Objectives: Complex cardiac surgery may require long-term cardiopulmonary bypass (CB), which can be complicated with heart failure. The study is aimed at studying the features of coronary hemocapillaries damage at different stages of the CB.
Methods: At different stages of CB, myocardial fragments from 4 patients with ischemic heart disease and left ventricle valves failure were taken from papillary muscles to be removed during mitral valve replacement. Morphological changes of capillaries were assessed by light and electron microscopy.
Results: In the first 30 minutes after the introduction of the cardioplegic solution, the most characteristic change of the capillaries were microclasmocytosis and electronically transparent lumens.
After 60 minutes of CB, the surface of the endothelial cells became smoother, an increased number of micropinocytotic vesicles was noted. The gaps were losing their electron transparency. The fragments of cellular detritus were found in swelled interstitium.
After 120 minutes of CB, endothelial cells retained their transport function mostly in small areas near the adjacent cardiomyocytes. The thickness of the endothelial layer was minimal. In the intercellular space, the severity of oedema and amount of cellular detritus were growing. The walls of the capillaries were becoming electron dense with extremely thinned layer of endothelium.
At the point of 185 minutes of CB, the tendency to dilate capillaries, as well as thinning of their walls, was progressing. Capillaries, postcapillaries, and venules had a balloon-like appearance, the thinned layer of the endothelium was very electron dense. The capillaries with signs of irreversible changes were noted.
Conclusion: 1. The duration of CB directly correlates with the severity of microvascular damage.
2. When CB lasts for more than 120 minutes, a critical impairment of endothelial function occurs, which can contribute to the postoperative complications.
3. There is need to develop measures to minimize endothelial damage, in particular by optimizing the CB duration.

E-PS-03-017
Medial degeneration in dissected thoracic aortas: meta-analysis
I. Kholová[1], E. Jämsen[2], T. Halmesmäki[2], D. Kalfert[3], A. Mennander[4], T. Paavonen[2]
[1]University of Eastern Finland and Tampere University, Pathology, Kuopio and Tampere, Finland, [2]Tampere University, Pathology, Tampere, Finland, [3]Charles University, Faculty Hospital Motol, Prague, Czech Republic, [4]Tampere University, Heart Hospital, Tampere, Finland

Background & Objectives: Systematic review on dissected aortic cases analysed according to the criteria from the Society for Cardiovascular Pathology and the Association for European Cardiovascular Pathology consensus statement was performed to analyse histopathological features in media aortic layer and feasibility of consensus in everyday practice.
Methods: The Pubmed serach resulted in 174 articles out of which ten articles met inclusion criteria for extraction of the data. Data on all histopathological features presence and grading listed in the Society for Cardiovascular Pathology and the Association for European Cardiovascular Pathology consensus statement were collected in Microsoft Excel and further analysed with Open Meta-Analyst program.
Results: A total of 871 cases out of 10 studies were analysed. The pooled prevalence of cases diagnosed with moderate overall medial degeneration as moderate among 264 cases of dissection from 5 studies was 47.1% (95% CI from 32.1 to 62.1%, I^2 was 85.34%). Out of all cases of dissection, 46.3% (95% CI from 28.7 to 63.9%, I^2 was 72.44%.) reported overall MEMA as moderate. Interlamellar MEMA was severe in most dissected cases (38.6% (95% CI from -4.5 to 81.6%), I^2 was 98.13%). Translamellar MEMA was moderate in the majority of analysed cases (46.6% (95% CI from 15.2 to 78.1%), I^2 was 94.97%).
Conclusion: The Society for Cardiovascular Pathology and the Association for European Cardiovascular Pathology consensus statement is a practical toolkit for assessment of thoracic dissected aorta samples in everyday practice. Nevertheless, its rigorous application is limited to several centres and the majority of users do not apply the consensus in its extent.

E-PS-03-018
Patterns of fibrosis in secondary dilative cardiomyopathy
O. Tica[1,2], O.A. Tica[3]
[1]Bihor Emergency Clinical County Hospital, Pathology, Oradea, Romania, [2]University Hospitals Birmingham, Cellular Pathology, Birmingham, United Kingdom, [3]University of Birmingham, Cardiovascular Sciences, Birmingham, United Kingdom

Background & Objectives: Secondary dilative cardiomyopathy (S-DCM) is defined by non-familial heart dilation associated with severe left ventricular systolic dysfunction. Myocardial fibrosis is known as the remodelling of extracellular matrix, which leads to increased myocardial stiffness.
Methods: In this retrospective study we included 48 adult patients with postmortem examinations in which, the main morphologically diagnosis was S-DCM and were compared with a control group of 12 patients with non-dilative heart conditions. This study was conducted over four years in a regional emergency clinical hospital.
Results: The pattern of fibrosis in S-DCM may vary, from focal to stellate, diffuse or even scar-like.

Advanced stages of fibrosis have a pro-arrhythmogenic role in these patients because the isolation and exclusion of cardiac fibres by bundles of collagen fibres framed the appearance of so-called "myocyte micronodules", with both clinical and functional implications. These patients underwent severe arrhythmic events as a result of contractility impairment. Several of these sub-endocardial nodules presented with a central area of fibrosis, resembling a scar; this was a result of micro-infarction rather than apoptosis.
Transmural interstitial fibrous scars developed through intricate pathophysiological mechanisms, and the amount of collagen determined was over 4 times higher in S-DCM cohort compared the control group.
The special character of interstitial myocardial fibrosis is highlighted, with the individual fibre dissection which ultimately leads to the diminishing of the vascular nutritional supply necessary for each cardiac cell.
Conclusion: Myocardial fibrosis is an important constituent in the development and progression of S-DCM. Even though magnetic resonance is nowadays a gold standard for the assessment of cardiac fibrosis patterns, histology can help in establishing the cornerstone for single-cell sequencing in identifying the subpopulation of fibroblasts expression.

E-PS-03-019

Hyperacute cardiac allograft rejection with successful early retransplantation by bridging ECMO

R. Skowronek[1,2], J. Nożyński[1], E. Trejnowska[3], J. Śliwka[4]
[1]Silesian Centre for Heart Diseases, Department of Histopathology, Zabrze, Poland, [2]Medical University of Silesia in Katowice, Department of Forensic Medicine and Forensic Toxicology, Katowice, Poland, [3]Silesian Centre for Heart Diseases, Department of Cardioanesthesia and Intensive Care Unit, Zabrze, Poland, [4]Silesian Centre for Heart Diseases, Department of Cardiac Surgery, Transplantology and Vascular Surgery, Zabrze, Poland

Background & Objectives: Hyperacute cardiac allograft rejection starting on the first day or even during transplantation leads to high mortality (approximately 70%). The rejection reaction depends on the presence of antibodies in the recipient and may result from previous hyperimmunization after blood transfusion [1-2].
Methods: Presentation of a rare case of hyperacute cardiac allograft rejection with successful early retransplantation by bridging extracorporeal membrane oxygenation (ECMO).
Results: Hyperacute cardiac allograft rejection was confirmed by examination of the explanted heart. Abundant intramuscular haemorrhages, linear deposits of complement protein C4d in the vessel walls and intravascular margination of CD68+ cells confirmed hyperacute rejection.
Conclusion: Bridging circulatory support using continuous ECMO allowed for successful early retransplantation of the hyperacute rejected organ, so this method can be used in such rare cases. The patient remains under the care of Silesian Centre for Heart Diseases in Zabrze.

E-PS-04-001

Incidence and outcomes of thyroid nodules with Atypia of Undetermined Significance (AUS) cytology in a tertiary government hospital: a ten-year review (2013 to 2022)

A.M. Valle[1], D.T. Argamosa[2]
[1]Philippine General Hospital, Department of Laboratories, Manila, Philippines, [2]UP College of Medicine, Department of Pathology, Manila, Philippines

Background & Objectives: Thyroid cancer is ranked as the ninth most common malignancy in the Philippines. Fine needle aspiration biopsy is the initial diagnostic of choice because it is noninvasive and cost-effective. Aspirates are diagnosed using the Bethesda System, one category of which is Atypia of Undetermined Significance (AUS) which poses a confusion among clinicians due to being a noncommittal diagnosis. This study aims to describe the frequency and outcomes of AUS and the reasons in choosing this category during a 10-year period in the Philippine General Hospital (PGH) and UP College of Medicine Pathology Research Laboratory (UPCM-PRL).
Methods: A records review was conducted using the available medical documents in PGH and UPCM-PRL.
Results: The percentage of Category III cases is 4.23% which is within the recommended standard of less than 7%. The quantity of repeat biopsies (15.38% in PGH, 18.64% in PRL) of Category III is small, and the most frequent diagnosis for benign cases is Thyroid Follicular Nodular Disease. For the malignant category, Papillary carcinoma, conventional/classic subtype occupies the top spot. The risk of malignancy (ROM) is very high (66.7% in PGH, 73.9% in PRL, 68.9% combined) although this is limited by the database available. The top basis of pathologists for choosing Category III remains to be "focal/mild atypia" that is not further elaborated in the histopathology reports.
Conclusion: A more accurate rate of biopsies and risk of malignancy can be achieved by having a larger database that includes registries outside the institution to follow the patients who receive management outside PGH. The application of the newly released 3rd edition of the Bethesda System for Reporting Thyroid Cytopathology in 2023 is also advised to give a better description of the atypia that can be observed in AUS cases.

E-PS-04-002

Unexpected guests on cytologic evaluation of anal Pap tests

P.D. Adolewska[1], S. Quinones[1], M.M. Petrino[1], A.M. Rodríguez García[1], I. de la Peña Navarro[1], J. Iglesias González[1], P. López Ferrer[1]
[1]La Paz University Hospital, Pathology, Madrid, Spain

Background & Objectives: Anal Papanicolaou (Pap) tests are primarily used for detecting squamous intraepithelial lesions and carcinoma. However, the presence of intestinal amoebas is an incidental finding that is not well documented in medical literature. Intestinal amoebas can be transmitted via ingestion of amoebic cysts through contaminated water and food, or via sexual contact. Invasive amoebiasis such as Entamoeba histolytica can cause different clinical symptoms, while other species can be nonpathogenic. Morphologically, they can be indistinguishable. Despite this, there's no consensus on reporting these findings.
Methods: As a result of a incidental finding of scattered amoebic cysts in an anal pap test of a male who was diagnosed with human papillomavirus (HPV) years ago, the cytopathologists at our centre prospectively searched during a six month period for amoebas on cytologic evaluation of ThinPrep® slides. In all cases, quantitative PCR of high-risk HPV (HR-HPV) was performed. For clinical data and follow-up, the patients' medical records were reviewed.
Results: Three cases of amoebic cysts on anal pap tests were found, all belonged to HIV positive males, being the average patient age 47 years old. None exhibited intraepithelial lesions or malignancy, though two had HR-HPV positive results. Revising clinical data, one patient had autolimited diarrhoea, while the others were asymptomatic. *Blastocystis hominis* was detected by PCR in one asymptomatic patient.
Conclusion: Although anal Pap tests are primarily used for detecting dysplasia and carcinoma, recognizing amoebic cysts can provide

clinical benefits. Cytology alone cannot differentiate between different species of amoebas, however, it is important to recognize them and be able to differentiate them from other entities such as pollen, inflammatory cells, or other entities such as flagellate. Thanks to cytological identification of these cysts, microbiological examination and clinical follow-up could be achieved, despite the lack of standardized reporting guidelines.

E-PS-04-003

EUS-guided FNA findings of gastrointestinal subepithelial lesions

S. Erdogan Durmus[1,2], B. Ozcan[3], E. Yarikkaya[4]
[1]Ege University, Institute of Health Sciences, Basic Oncology, Izmir, Turkey, [2]SBU Izmir City Hospital, Pathology, Cytopathology Division, İzmir, Turkey, [3]SBU Istanbul Training and Research Hospital, Pathology, Cytopathology Division, Istanbul, Turkey, [4]SBU Istanbul Training and Research Hospital, Pathology, Istanbul, Turkey

Background & Objectives: Subepithelial lesions (SEL) of gastrointestinal track are difficult to diagnose using imaging alone. Endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) is an effective and safe tissue sampling technique. In this study it was aimed to investigate the cytopathological and demographic features of SELs diagnosed with EUS-FNA.
Methods: This retrospective study examined 18 consecutive SELs cases that sampled by EUS-FNA and histopathologically proven. Demographic data such as age, gender, size, location obtained from pathology report. If ancillary studies were performed, they were noted.
Results: The average age of the patients was 61.7±11.0 (range 28-73). 8 of the cases were female and 10 were male. 14 cases were diagnosed with Gastrointestinal stromal tumour (GIST), 2 cases with leiomyoma, 1 case with Schwannoma, and 1 case with lipoma with sizes of 16-36 mm (median 25 mm). The most common location is stomach-corpus (n:9), followed by stomach-fundus (n:4), duodenum (n:3), stomach-antrum (n:2). Immunohistochemistry (IHC) was used for differential diagnosis in 18 (94.7%) of the cases. The most frequently used markers were CD117 and CD34 (n: 18). CD117 was positive in 85.7% of GIST cases and CD34 was positive in 78.5%. DOG1 was positive in 100% (9/9), SMA was positive in 55.5% (5/9) of GISTs, immunohistochemically. While S100 positivity was observed in schwannoma case, Desmin were positive in leiomyoma cases (n:2).
Conclusion: EUS-FNA is a very useful diagnostic method not only for the diagnosis of pancreatic masses but also for SELs located in the gastrointestinal tract. In sufficient samples, a clear diagnosis can be made with appropriate cytopathological examination and ancillary studies, such as IHC.

E-PS-04-004

Evaluation of p53 and IMP-3 in Pancreatic Adenocarcinomas(PDAC) Diagnosed by Endoscopic ultrasound-guided fine-needle aspiration(EUS-FNA)

S. Gonca Keskin[1], B. Akı[2], S. Erdogan Durmus[3]
[1]Izmir City Hospital, Department of Pathology, Izmir, Turkey, [2]Prof. Dr. Cemil Tascioglu City Hospital, Department of Pathology, Istanbul, Turkey, [3]Izmir City Hospital, Department of Pathology, Cytopathology Division, Izmir, Turkey

Background & Objectives: Endoscopic ultrasound-guided fine-needle aspiration(EUS–FNA) is a safe and effective technique that can be used to diagnose pancreatic tumours, with a pooled sensitivity of 85%–92% and specificity of 96%–98%. Pancreatic ductal adenocarcinoma(PDAC) is one of the most aggressive malignant tumours, with a 5-year survival rate of only 4%.In our study, we aimed to investigate the diagnostic significance of p53 and IMP-3 expression in PDAC diagnosed by EUS-FNA.
Methods: A total of 79 cases diagnosed as PDAC(case group) and 10 cases that Negative for malignancy(control group) were included in the study. The demographic data of the patients were obtained from the electronic data system of the hospital.p53 and IMP-3 expressions were evaluated using immunohistochemical analysis.
Results: The median age of the patients was found to be 69 years. The sex distribution, 49 cases(62.8%) compared to 30 female cases(37.2%). In the analysis of pancreatic biopsy cases, the diagnostic value of the immunohistochemical markers IMP3 and p53 was assessed. The sensitivity of IMP3 positivity was calculated as 76.7%, while its specificity was 100%. p53 null mutant pattern-characterized by complete absence of p53 staining—was observed in 34.2% of the cases, aligning with a calculated sensitivity of 34% and specificity of 100%. IMP-3(+) and p53(+) co-expression was seen in 50.6% of the Case group(40 cases), but in 0% of the control group($p<0.01$).
Conclusion: While IMP-3 can be used as a positive marker, p53 positivity is significant, but its negativity(null-mutant pattern) is also meaningful. The combination of both IMP-3 and p53 expressions proved valuable in improving diagnostic accuracy in suspected malignant cases**.** These findings support the potential of using p53 and IMP-3 as diagnostic tools in EUS-FNA samples for PDAC, offering significant insights into tumour biology and aiding clinical decision-making.

E-PS-04-005

Cytological diagnosis of Langerhans cell histiocytosis: case report series

R. Lekše[1], Ž. Ledinek[2,3], A. Rode[4], V. Kloboves-Prevodnik[4,2]
[1]Institute of Oncology, Ljubljana, Slovenia, [2]Faculty of Medicine, University of Maribor, Maribor, Slovenia, [3]University Medical Centre Maribor, Department of Pathology, Maribor, Slovenia, [4]Institute of Oncology, Department of Cytopathology, Ljubljana, Slovenia

Background & Objectives: Langerhans cell histiocytosis (LCH) is a rare disease, caused by clonal neoplasm of bone marrow-derived myeloid dendritic cells, predominantly affecting paediatric patients. The prognosis varies depending on the stage at presentation, ranging from spontaneous remission to life-threatening complications. Due to its rarity, the diagnosis of LCH can be challenging and often delayed. A precise cytological diagnosis, in conjunction with appropriate clinical evaluation, imaging studies and immunostaining, can reduce the need for unnecessary and invasive biopsies, facilitate a more rapid diagnosis and guide appropriate patient management.
Methods: We report three cases of LCH and one case of Langerhans cell sarcoma (LCS) diagnosed using fine-needle aspiration biopsy (FNAB). Two cases involved paediatric patients: a 26-day-old female neonate with congenital LCH (biopsy performed for diagnostic confirmation) and a 16-year-old male with a temporal skin lesion. Other two cases were adult: a 41-year-old female with a painful, indurated skin lesion on the forehead and a 65-year-old male presenting with cervical lymphadenopathy.
Results: All patients underwent FNAB. In three cases, the diagnosis of LCH was established—one based on cytomorphology and two with the aid of immunocytochemistry (CD1a+, Langerin+). In one patient, a diagnosis of "malignant tumour, cytologically and immunophenotypically consistent with LCS" was made (CD1a+, Langerin-/+, CD100+, CD68 PGM-/+, CD68 KP1+). Biopsy was performed and histopathological confirmation was obtained in one LCH case and the case of LCS. In the other two LCH cases where a biopsy was not performed, clinical presentation was consistent with the cytopathological findings.
Conclusion: Given the potential for life-threatening complications in LCH, timely and accurate diagnosis is essential. In our experience cytological evaluation, particularly in conjunction with immunocytochemistry, can facilitate the early diagnosis of LCH in the appropriate clinical setting, thereby expediting patient management.

E-PS-04-006

Bethesda IV thyroid nodules: malignancy rate and risk factor analysis

H. Maaroufi[1], S. Kamoun[1], S. Ayari[1], I. Bettaieb[1], A. Goucha[1], R. Brahem[1], Y. Houcine[1], M. Driss[1], S. Kedous[2]
[1]Salah Azaiez Institute, Department of Pathology B, Tunis, Tunisia, [2]Salah Azaiez Institute, Department of Otorhinolaryngology and Head and Neck Surgery, Tunis, Tunisia

Background & Objectives: The Bethesda IV cytological category represents a diagnostic gray zone in the classification of thyroid nodules. Lesions in this category exhibit a range of potential outcomes, from benign to malignant, making it challenging to predict malignancy. This study aims to assess the malignancy rate in Bethesda IV thyroid nodules at our institution and to identify associated risk factors.
Methods: A retrospective review of fine needle aspiration (FNA) cytology reports from our institution over a 3-year period (2021-2023) was conducted. All cases diagnosed as Bethesda IV according to the Bethesda System for Reporting Thyroid Cytopathology were included. Histological diagnosis, considered as the gold standard, was used for comparison. We also examined potential risk factors associated with malignant behaviour.
Results: A total of 452 FNA samples were analysed. Of these, 64 cases (14.2%) were classified as Bethesda IV. Histopathological follow-up was available for 34 cases. Among these, 27 cases (79.4%) were benign, including 15 cases of follicular adenoma, 9 cases of multinodular goiter, and 3 cases of lymphocytic thyroiditis. The remaining 7 cases (20.6%) were malignant, with 3 cases of noninvasive follicular thyroid neoplasm with papillary-like nuclear features (NIFTP) and 4 cases of classic papillary thyroid carcinoma. No significant association was found between age, gender or ultrasonography characteristics and malignancy risk (p=0.8, 0.2 and 0.5 respectively).
Conclusion: Bethesda IV thyroid nodules exhibit a heterogeneous risk of malignancy, highlighting the need for careful evaluation. The malignancy rates in this study fall within the threshold suggested by the Bethesda consensus for Bethesda Category IV. NIFTP can be challenging on cytology, sharing cytomorphological characteristics with follicular neoplasms and having nuclear features that can range from mildly atypical to unequivocally suggestive of papillary carcinoma. Further studies are warranted to refine predictive factors for Bethesda IV nodules on larger samples.

E-PS-04-007

Diagnostic value of nipple discharge cytology: reassessment of initially insufficient samples in a single-centre experience

E.B. Balaban Yilmaz[1], B.B. Senay[1], M.G. Gurleyik[2], F. Vardar Aker[1]
[1]University of Health Sciences, Haydarpasa Numune Training and Research Hospital, Pathology, Istanbul, Turkey, [2]University of Health Sciences, Haydarpasa Numune Training and Research Hospital, General Surgery, Istanbul, Turkey

Background & Objectives: Nipple discharge cytology is a commonly used diagnostic tool in evaluating patients with breast discharge; however, its sensitivity remains limited. This study aims to assess its diagnostic performance by comparing cytologic findings with histopathological outcomes and evaluating the effect of re-sampling by trained pathology staff on initially insufficient specimens. We particularly focus on the impact of repeat sampling in reducing the rate of insufficient cytology results.
Methods: A total of 438 nipple discharge cytology samples evaluated between 2011 and 2025 at Haydarpasa Numune Training and Research Hospital were retrospectively analysed. Cytological diagnoses were categorized as benign (n=341), atypical (n=26), malignant (n=12), or insufficient (initially n=76). A subset of 20 cases with initially insufficient cytology results, prepared externally, was recalled for repeat sampling by the pathology department. Histopathological follow-up was available in 80 cases. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and diagnostic accuracy were calculated based on cases with definitive benign or malignant cases.
Results: Among the 80 cases with histopathology, there were 9 true positives, 1 false positive, 38 true negatives, and 8 false negatives. Sensitivity was 52.9%, specificity 97.4%, PPV 90.0%, NPV 82.6%, and accuracy 83.9%. Malignancy was identified in 61.5% of atypical cases and 18.2% of insufficient cases. Remarkably, 17 out of 20 initially insufficient cases (85%) became diagnostically adequate following repeat sampling by the pathology department, which reduced the number of insufficient cases from 76 to 59.
Conclusion: Although nipple discharge cytology demonstrates high specificity, its limited sensitivity may lead to missed diagnoses. Atypical and insufficient samples carry a considerable risk of malignancy and require further evaluation. Notably, re-sampling by trained pathology staff significantly improved the diagnostic adequacy, with a remarkable reduction in the number of insufficient specimens. These findings emphasize the importance of repeat sampling and multidisciplinary collaboration in improving diagnostic accuracy.

E-PS-04-008

***Strongyloides stercoralis* hyperinfection: a case report**

M. Larrubia-Loring[1], A. García-Cosculluela[1], F.M. Pérez-Muñoz[1], S. Calvo-González[1], J. Massó-Castella[1], I. Sánchez-Güerri[1], M. Iglesias[1]
[1]Hospital del Mar, Pathology Department, Barcelona, Spain

Background & Objectives: Strongyloidiasis is a parasitosis caused by the intestinal nematode *Strongyloides stercoralis*, which can manifest from asymptomatic to severe forms in immunocompromised patients. Microscopically, the form we diagnosed is the rhabditiform larvae, measuring approximately 250–300 µm, showing a blunt anterior end, corresponding to the buccal cavity, and a pointed posterior end, coinciding with the anus. These larvae exhibit orangophilic characteristics in cytological extensions processed with the Papanicolaou technique. This case illustrates a clinical case of severe hyperinfestation, highlighting the clinical presentation, cytological and histological findings, and associated complications.
Methods: The case involves a 63-year-old male patient with a medical history of heart failure, Charcot-Marie-Tooth neuropathy type I, chronic obstructive pulmonary disease (COPD), smoking, and alcoholism. He presented with progressive dyspnoea on minimal exertion, productive cough, wheezing, and abdominal pain. Thoracic computed tomography (CT) revealed bilateral pulmonary collapse, pleural effusion, and cavitated pulmonary nodules. Abdominopelvic CT demonstrated jejunal intestinal obstruction with free peritoneal fluid.
An extensive jejunal resection was performed due to intestinal mural necrosis. He subsequently developed abdominal septic shock (positive *Enterococcus faecium* cultures) and respiratory sepsis, prompting fibrobronchoscopy with biopsies, bronchial aspirates (BAS), and bronchoalveolar lavage (BAL).
Results: Cytological evaluation of BAS and BAL revealed abundant mixed inflammation, necrotic material, and numerous elongated, orangophilic rhabditiform larvae, morphologically consistent with *Strongyloides stercoralis*. Bronchial and intestinal biopsies confirmed parasitic infestation.
Clinically, the patient progressed to severe hyperinfestation syndrome complicated by abdominal septic shock (*Enterococcus faecium*), bacteraemia (*Pseudomonas aeruginosa*), systemic sepsis resulting from intestinal bacterial translocation (*Enterococcus faecium* and *Enterococcus faecalis*), as well as gastrointestinal haemorrhage due to refractory intestinal ulcers. Ultimately, the patient succumbed to multi-organ failure.

Conclusion: Hyperinfection with *Strongyloides stercoralis* constitutes a severe clinical condition with significant septic complications, particularly among immunocompromised patients. Early clinical suspicion and timely cytological and histological diagnosis are crucial to improve therapeutic management and reduce mortality.

E-PS-04-009

Two for the price of one effusion: a case report of the cytological diagnosis and biomarker profiling of concurrent breast and lung adenocarcinoma

A. Straus[1,2], J. Mirkovic[1,2], H.H. Wong[3], A. Parmar[4], Z. Ghorab[1,2]
[1]University of Toronto, Department of Laboratory Medicine and Pathobiology, Toronto, Canada, [2]Sunnybrook Health Sciences Centre, Department of Anatomic Pathology, Toronto, Canada, [3]Sunnybrook Health Sciences Centre, Division of Respirology, Department of Medicine, Toronto, Canada, [4]Sunnybrook Health Sciences Centre, Division of Medical Oncology & Haematology, Department of Medicine, Toronto, Canada

Background & Objectives: Diagnosing concurrent primary malignancies within a single pleural effusion is exceedingly rare. Due to their overlapping cytomorphologic features, distinguishing coexisting malignancies in effusion cytology is challenging but has critical implications for diagnosis and treatment.
Methods: We describe the case of a 60-year-old woman with a remote history of breast cancer who presented with progressive dyspnea and large right-sided and small left-sided pleural effusions. Initial cytological analysis of the right-sided pleural fluid at an outside institution yielded a diagnosis of metastatic lung adenocarcinoma. However, evaluation of additional effusion cytology specimens from the left-side revealed two morphologically distinct tumour cell populations, raising suspicion for a second malignancy.
Results: Immunohistochemistry confirmed the presence of both metastatic lung adenocarcinoma (TTF1+, Napsin-A+, GATA3 -, ER-) and metastatic breast adenocarcinoma (GATA3 +, ER+, TTF1-, Napsin-A-). Biomarker analysis was successfully performed for both malignancies, revealing an ER+/PR-/HER2- profile for the breast adenocarcinoma. Meanwhile, the lung adenocarcinoma was negative for any targetable gene mutations (e.g. EGFR, ALK, ROS1 and others) but exhibited a Tumour Proportion Score of 1-49% for PD-L1, suggesting possible benefit from immunotherapy in combination with chemotherapy.
Conclusion: This case underscores the importance of meticulous cytomorphological assessment in effusion cytology, particularly when evaluating specimens with subtle heterogeneity. While pleural effusion metastases typically correlate with a known primary malignancy, the possibility of a second primary tumour should be considered in complex oncologic cases. Furthermore, cytological specimens provide valuable biomarker information for treatment planning, emphasizing the role of immunohistochemistry, in situ hybridization, and next-generation sequencing in precision oncology. To our knowledge, this is the first reported case of concurrent metastatic breast and lung adenocarcinoma diagnosed within a single pleural effusion specimen with successful biomarker analysis. This case highlights the diagnostic and therapeutic value of effusion cytology in detecting and characterizing multiple malignancies.

E-PS-04-010

Awareness of the spectrum of presentation of aspergillosis

A. Fatima[1], C. Lobato[2], M. B Casey[1]
[1]Galway University Hospital, Histopathology, Galway, Ireland, [2]Galway University Hospital, Galway, Ireland

Background & Objectives: Aspergillus species are filamentous fungi capable of causing a broad spectrum of infections in humans, primarily infecting the lungs but also involving the sinuses, skin, eye and CNS. Forms of Pulmonary aspergillosis include allergic bronchopulmonary aspergillosis, saprophytic aspergilloma and invasive aspergillus pneumonia, necrotizing tracheobronchitis and necrotizing granulomatous inflammation. Human host reaction depends on immunologic status, underlying lung structure and nature of exposure. We present three different clinical cases of aspergillosis at our hospital, highlighting the diverse manifestations and diagnostic approaches.
Methods: We reviewed the clinical presentations, laboratory investigations, imaging studies and cytohistopathological findings of three patients diagnosed with aspergillosis. Key diagnostic features, risk factors and treatment outcomes were analysed. Bronchoscopy, sputum culture, cytological evaluation and imaging modalities were utilized for diagnosis.
Results: Case 1: A 77 year old male with intermittent haemoptysis was diagnosed with unsuspected aspergillus fumigatus infection after cytological analysis revealed a rare fungal hypha amidst inflammatory cells.
Case 2: A 67 year old female with bronchiectasis and mucus plugging had undiagnosed abundant aspergillus organisms confirmed through cytology and culture.
Case 3: A 60 year old female with a history of septic shock after laparotomy for benign disease developed pulmonary and cerebral aspergillomas and necrotizing tracheobronchitis. Despite treatment with amphotericin, the patient succumbed to the infection.
Conclusion: Aspergillosis presents with a diverse spectrum of clinical manifestations. A high index of clinical suspicion is required for timely intervention. The role of the pathologist in early detection is crucial. Antifungal therapy remains the mainstay of treatment but severe and invasive forms continue to pose significant morbidity and mortality.

E-PS-04-011

Artificial intelligence in the evaluation of urine sediment cytology

A. Korolczuk[1,2], P. Michalak[1]
[1]Alcid, Warsaw, Poland, [2]University Hospital no. 4, Department of Pathomorphology, Lublin, Poland

Background & Objectives: To develop and test an IT tool for assessing urine sediment cytology.
Methods: To train artificial intelligence (AI), scans of slides assessed by experts and the result according to the Paris Classification (PC) for assessing urine cytology were used. Slides were made using the liquid cytology method, stained according to Papanicolaou. The IT tools used were Computer Vision Annotation Tool CVAT (a tool for labelling images and video files) and Digital Slide Archive DSA (a platform providing storage, management, visualization and annotation of image data sets). In addition to the main parameter of N/C assessment, an attempt was made to algorithmically determine other parameters of cell images. Traditional methods of feature extraction were used (colour histograms, textures or shape features). Due to the small number of available slides, additional synthetic images for training AI were generated. We used slides assigned to one of two target classes: HGUC (High Grade Urothelial Carcinoma) and suspected HG cancer (SHGUC). A method for validating the results was developed. To verify the system's operation, samples that did not participate in model training were randomly selected and the results of the AI algorithms were presented. A team of three independent cytopathologists was appointed. They verified the model predictions - confirmed or changed the category of cells marked as positive (HGUC, SHGUC), and made a final diagnosis. The experts' work was aimed at assessing the results of the algorithms.
Results: The result of the work is an application that allows the cytopathologists to view the sample scan, predictive markings (labels), edit them and add new ones. On this basis, the doctor issues a final diagnosis - confirms the initial diagnosis of the system or changes it, issuing his own.

Conclusion: The developed application is an useful auxiliary tool in the process of assessing urine sediment cytology.

Funding: National Centre for Research and Development: project no. POIR.01.01.01-00-0279/22

E-PS-04-012

Bethesda III thyroid cytopathology - un unpopular but necessary category. Cases 2020-2024 revisited

J. Dušková[1], J. Jiskra[2], P. Rosa[3], J. Lukáš[4]
[1]Inst. Pathol., 1st Faculty of Medicine, Charles University, Cytopathology, Prague, Czech Republic, [2]1st Faculty of Medicine, Charles University, 3rd Dept. of Med., Prague, Czech Republic, [3]Intendo, Internal and Endocrinology Outpatient Clinic, Ltd., Kladno, Czech Republic, [4]Na Homolce Hospital, Department of Otolaryngology, Head and Neck Surgery, Prague, Czech Republic

Background & Objectives: The BIII category refined in the new edition of the TBSRTC (2022), allows for easy reclassification of previously diagnosed BIIIs. Our study focused on reviewing the frequency and types of BIII cases over a five-year period (2020-2024) comparing a faculty postgraduate training centre site with two diagnostic laboratories staffed by the same senior pathologist consulting also the training centre cases.
Methods: All FNABs classified as BIII were reviewed and subtyped. Clinical endocrinologists provided follow-up in cases where histopathological examination was not performed. An analysis of preanalytical and analytical factors influencing incidence was performed. Didactically most beneficial cases were included into a postgraduate workshop.
Results: The overall incidence of BIII in the period was 4.6 % (196 cases out of 4263 diagnoses; females 84%) for both compared groups, higher at the faculty workplace 6.1 % (84 cases out of 1370 diagnoses) compared to the private laboratory 3.9 % (112 cases out of 2893 diagnoses). The subtype distribution was BIIIo 58.6%, BIIIn 28.6%, combined BIIIn/o 12.9%. Biopsy was performed in 41 patients (20,9 %), 16 biopsy diagnoses were malignant (ROM 8.2%).
The higher incidence of BIIIs in a training centre with less experienced evaluating cytopathologists leads to a higher incidence even with regular consultation of BIII cases by an experienced consultant compared to laboratories with primary evaluation by a single experienced cytopathologist.
Conclusion: Strict application of diagnostic criteria for individual BIII subtypes and close interdisciplinary communication are tools for maintaining the sensitivity of thyroid FNAB and keeping the incidence of BIII within the range corresponding to the actual limits of the diagnosed sample.

E-PS-04-013

Evaluation of high-fluorescence cells parameter as a screening tool for malignant effusion screening using automated haematology analyser

G. Chhabra[1], M.N. Sable[1]
[1]All India Institute of Medical Sciences, Pathology & Laboratory Medicine, Bhubaneswar, India

Background & Objectives: Effusion cytology plays a crucial role in the diagnostic and prognostic aspects of cancer management, particularly in the advanced stages of the disease. Cell counts by automated haematology analyser are now emerging as a preferred method over the conventional manual cell counting methods in all Body Fluids (BF). This study aimed to evaluate the high-fluorescence (HF)-BF parameter generated by an automated blood cell counter and correlate it with the final microscopic cytological assessment.
Methods: Effusion cytology plays a crucial role in the diagnostic and prognostic aspects of cancer management, particularly in the advanced stages of the disease. Cell counts by automated haematology analyser are now emerging as a preferred method over the conventional manual cell counting methods in all BFs. This study aimed to evaluate the HF-BF parameter generated by an automated blood cell counter and correlate it with the final microscopic cytological assessment.
Results: A total of 604 samples consisting of 43.79% ascitic fluids (AF), 50% pleural fluids (PF), 5.86% peritoneal fluid, and 0.33% pericardial fluid were included in the study. Of all the samples with corresponding cytopathology, malignant cells were found in 59 samples. The HF-BF%/100 WBCs (85.6 ± 347.79) for malignant BF samples were found to be significantly higher than the non-malignant samples (18.9 ± 106.54) (p-<0.01), while HF-BF# (#-absolute counts)was higher in malignant BF compared to non-malignant (24.21 ± 41.78 Vs 20.26 ± 91.55), however it was not significant (p=0.81).

Conclusion: The HF-BF parameter offers potential utility in identifying malignant samples; however, it should not be relied upon exclusively. A more meticulous microscopic examination is warranted when HF-BF% or counts exceed the laboratory's established thresholds. A comprehensive, large-scale validation study of the HF-BF parameter in BF mode is necessary to establish definitive standards for evaluating critical effusions.

E-PS-04-014

3D visualization & assessment with digital Papanicolaou stain on cell block samples

E. Yanagita[1], Y. Yagi[1]
[1]Memorial Sloan Kettering Cancer Centre, Pathology and Laboratory Medicine, New York, USA

Background & Objectives: Cell blocks, formed by embedding cytological specimens in paraffin blocks, preserve tissue architecture in addition to the features of individual cell/cell cluster. Drawing information from the surrounding tissue architecture, combined with visualization of nuclear morphology, can lead to an increased diagnostic specificity. Crucially, cell blocks are compatible with all ancillary and molecular tests.
However, cell block is sectioned with 4 um and sanctions are stained with H&E which makes difficult to distinguish cell boundaries or the separation between the nucleus and cytoplasm that are often useful to discriminate between malignant and benign and determine tumour sub-types.
While H&E stain is useful for examining tissue structure, Papanicolaou (Pap) staining is to focus on cell morphology. Cytologists are familiar to see Pap staining for cell features more than H&E stain. Therefore, we have developed Digital Pap stain on H&E slides and 3D visualization and assessment tools to support diagnostic process on cell blocks.
Methods: Eight pleural effusion cases (adenocarcinoma, squamous cell carcinoma, and malignant mesothelioma) were used. 4 µm H&E stain sections were scanned with 11 layers. (40 × mode: 0.23 µm/pixel, 11 layers 1 um pitch. Hamamatsu Nano Zoomer S60 Digital slide scanner C13210-01).
In-house Digital Pap stain algorithm was run on all cases. Digital Pap stained WSIs and H&E WSIs were then reconstructed in 3D using commercial 3D imaging application.
Results: The 3D Papanicolaou images allowed cells to be observed in three dimensions. Detailed features of the nucleus and cytoplasm, which were not visible in the 2D H&E images, became apparent.

Conclusion: 3D Visualization & Assessment with Digital Papanicolaou stain on Cell Blocks could support pathologists and cytologists during the diagnostic process, such as differentiating between "Adenocarcinoma vs SCC vs malignant mesothelioma", assessing tumour sub type can, and enabling appropriate treatment and drug administration.

E-PS-04-015

The effectiveness of Milan classification in salivary gland fine needle aspiration cytology evaluation

K. Bulut[1], S. Erkilic[1]
[1]Gaziantep University Medical Faculty, Pathology, Gaziantep, Turkey

Background & Objectives: The Milan System for Reporting Salivary Gland Cytopathology (MSRSGC) is a system that aims to standardize salivary gland fine needle aspiration cytology (FNAC) reports between cytopathologs. MSRSGC classifies cytologies into 6 different categories. Each category specifies the risk of malignancy and how it should be managed. This study aimed to determine the utility of the Milan Reporting System (MRS) for salivary gland FNAC.
Methods: Salivary gland FNAC specimens prepared with Thin Prep liquid-based cytology method that were accessed from the archive system of the Pathology Deparment of Gaziantep University Medical Faculty between 2010 and 2024 were retrospectively evaluated and reclassified according to the Milan classification system. Comparison with parotidectomy reports was used to evaluate the effectiveness of the Milan reporting system and malignancy and neoplasm risk for each category.
Results: A total of 722 FNAC and 409 excision specimens were evaluated. Of the total cytologies, 3% were classified as nondiagnostic (ND), 14.7% as nonneoplastic (NN), 13.4% as atypia of undetermined significance (AUS), 41.4% as benign, 5.7% as salivary gland neoplasm of uncertain malignant potential (SUMP), 5.7% as suspicious for malignancy, and 31% as malignant. At histopathologic follow-up, ROM (risk of malignancy) ratios for each category were 13.3%, 16.6%, 24%, 7.7%, 24.2%, 90%, 100%. The Milan classification was 92.93% accurate for malignant neoplasia/benign lesion differentiation, and 91.18% for non-neoplastic lesion/neoplasia.
Conclusion: Our study confirms that MRS helps establish a common language among cytopathologists when interpreting salivary gland FNAC, though the ROM is high in intermediate categories. To detection of malignant neoplasms or non-neoplastic lesions, MRS has a high specificity and accuracy, but a low sensitivity.

E-PS-04-016

Enhancing diagnostic precision: the utility of carbonic anhydrase IX and alpha-inhibin immunoperoxidase staining in fine-needle aspiration cell blocks for accurate diagnosis of pancreatic serous cystadenoma

Q. Gan[1], H. Sun[1]
[1]University of Texas, MD Anderson Cancer Centre, Houston, USA

Background & Objectives: Pancreatic serous cystadenoma (pSCA) presents a diagnostic challenge in fine-needle aspiration (FNA) specimens due to limited cellularity. While molecular testing of cystic fluid can aid in diagnosis, its availability remains limited. Several immunohistochemical markers, including inhibin, CA-IX, and Glut-1, have been studied in histologic specimens, but their utility in cytologic diagnosis is still debated, representing a gap in current diagnostic strategies. In this study, we assessed the staining patterns of three markers—Inhibin, CA-IX, and CEA—in pSCA, cystic mucinous neoplasms, and contaminating gastrointestinal epithelial cells.
Methods: We identified the following pancreatic FNA cases: 1) Cell block is contributory with more than 20 epithelial cells; 2) Ten confirmed pSCA cases; 3) Five cases each of pancreatic mucinous cysts and gastrointestinal contaminants. Immunoperoxidase staining for pan-keratin, CEA, CAIX, and alpha-inhibin was conducted on cytologic cell blocks following standard protocols in our clinic's immunohistochemical laboratory.
Results: 1. Inhibin were positive in the epithelial cells of all the pSCA cases and negative in contaminated gastrointestinal and other mucinous epithelial cells (Figure 1).
2. CA-IX staining is non-specific for pSCA, and could be positive in both neoplastic mucinous epithelial cells and contaminated gastrointestinal epithelial cells (Figure 2).
3. CEA was negative in pSCA but focally positive in gastrointestinal epithelial cells.
Conclusion: 1. A combination of immunostaining markers, including inhibin, CA-IX, and CEA, demonstrates high specificity for diagnosing pSCA on FNA cell block preparations.
2. In the appropriate clinical and radiological context, this panel of markers serves as a supportive tool for the accurate diagnosis of pSCA, and thus potentially improving diagnostic precision and patient management.

Fallopian tube fimbrial carcinoma presenting as a solitary huge omental mass – clinical and cytodiagnostic pitfalls

T. Kawasaki[1,2], A. Yabuno[3], H. Goto[2], M. Fujisawa[2], Y. Seyama[2], H. Ogawa[2], Y. Jouo[2], R. Horibe[2], A. Ando[2], M. Sawada[2], M. Suzuki[2], K. Aita[2], K. Gotoda[4], J. Suzuki[4], Y. Usami[4], Y. Okada[4], H. Tajima[4], Y. Baba[4], I. Kuji[4], H. Yoshida[3], K. Hasegawa[3], S. Takemi[1], Y. Ishimaru[1], M. Suzuki[1], R. Kawamura[1], T. Kondo[5], M. Saitoh[5], J. Ichikawa[5]
[1]Saitama Medical University International Medical Centre, Department of Pathology, Hidaka, Japan, [2]Saitama Sekishinkai Hospital, Department of Pathology, Sayama, Japan, [3]Saitama Medical University International Medical Centre, Department of Gynaecologic Oncology, Hidaka, Japan, [4]Saitama Medical University International Medical Centre, Department of Radiology, Hidaka, Japan, [5]University of Yamanashi, Interdisciplinary Graduate School of Medicine, Chuo, Japan

Background & Objectives: It was recently suggested that a significant majority of so-called ovarian and peritoneal high-grade serous carcinomas (HGSCs) arise from a precursor lesion known as serous tubal intraepithelial carcinoma (STIC) of the fallopian tube, regardless of the tumour's primary location.
Methods: A 74-year-old Japanese woman with an abnormality detected by endometrial screening cytology three years earlier, presented to our hospital. MRI revealed a 53 mm omental mass, but no other suspicious lesions. Based on pathological examinations of the resected specimens, we ultimately diagnosed HGSC with STIC originating from the fimbria of the fallopian tube, which formed a bulky disseminated omental mass.
Results: On cytological smears, mononuclear or multinucleated, large atypical epithelial cells were sporadically observed, mainly forming small clusters, in the background of endometrial tissues with neither proliferative changes nor atypia. The atypical cells exhibited a high nuclear/cytoplasmic ratio and possessed polygonal, foamy cytoplasm and hyperchromatic nuclei with irregularities in size and shape (Papanicolaou classification: class IIIb). Similar atypical cells were also seen in small numbers in cervical smears. Endometrial biopsy and curettage were performed, but no atypical cells were detected, and CT, MRI, and F-18-FDGPET/CT showed no abnormalities. At subsequent follow-up, nine endometrial cytological examinations and two endometrial biopsies were performed, none of which showed abnormalities.
Conclusion: If atypical epithelial cells with the possibility of an extrauterine primary are incidentally found on endometrial cytology, but no abnormalities are identified by diagnostic modalities, periodic (every six or 12 months) imaging examinations can be recommended, considering the potential for these lesions to originate from the fimbria of the

fallopian tube. In our current case, fibrous encapsulation of the omental seeding focus might, fortunately, have prevented further contiguous spread as well as wider dissemination.

Second look ultrasound (US)/fine needle aspiration (FNA) in the breast oncology field - cytopathological analyses

T. Kawasaki[1,2], K. Aita[2], M. Fujisawa[2], H. Goto[2], Y. Seyama[2], H. Ogawa[2], R. Horibe[2], Y. Jouo[2], A. Ando[2], M. Suzuki[2], A. Kondo[3], J. Yanagida[3], M. Nishio[3], H. Tokumitsu[3], R. Sugiura[3], Y. Ishimaru[1], S. Takemi[1], M. Suzuki[1], R. Kawamura[1], T. Tashima[1], M. Hirasaki[1], Y. Ichiki[1], Y. Nakamura[1], K. Kaira[1], J. Ichikawa[4], H. Kodama[3]
[1]Saitama Medical University International Medical Centre, Department of Pathology, Hidaka, Japan, [2]Saitama Sekishinkai Hospital, Department of Pathology, Sayama, Japan, [3]Saitama Sekishinkai Hospital, Department of Surgery, Sayama, Japan, [4]University of Yamanashi, Interdisciplinary Graduate School of Medicine, Chuo, Japan

Background & Objectives: The significance of second look ultrasound (US)/fine needle aspiration (FNA) has recently been drawing attention in the breast oncology field, while vacuum-assisted biopsy is frequently used as an intervention from the viewpoint of research on biomarkers, genomic medicine, and so on. Technologically, 2nd look US/FNA means that a lesion not detectable by the first US might be identified by other modalities such as magnetic resonance imaging and mammography, and re-US followed by FNA cytology would then be performed to evaluate the lesion. This study aimed to clarify the characteristics of mammary lesions detected by 2nd look US/FNA.
Methods: From among the 248 breast cancer cases undergoing surgery at our hospital during the period from January 2019 to March 2021, 13 specimens obtained from 10 cases (4%) undergoing 2nd look US/FNA were cytopathologically analysed.
Results: The patient ages ranged from 41 to 82 (mean 63.2) years, and the puncture site was ipsilateral in 7, contralateral in 2, and bilateral in 1 case. Clinical imaging findings were 6 masses, 4 cystic lesions, 1 low echoic area, 1 duct dilation, and 1 unknown. The cytodiagnostic classification was 'adequate' in 10 samples. Specifically, 5 were "benign", 1 "suspicious of malignancy", and 4 "malignant". The other three samples were 'insufficient' or 'inadequate'. Based on subsequent verification with surgically-resected specimens, all 5 lesions cytologically suggesting malignancy corresponded to ductal carcinoma *in situ*, and 3 of these (60%) were the solid papillary/neuroendocrine variant.
Conclusion: Cytodiagnoses were appropriately made in this investigation, and the utility of 2nd look US/FNA was accordingly verified. The histological cancer subtype was often neuroendocrine (solid papillary), and these tumours tend to occur multicentrically in the background of neuroendocrine cell hyperplasia (*J Clin Pathol*, 2012. *Pathology*, 2018), supporting our current research results.

Funding: JSPS KAKENHI Grants (Nos. 21K06910 and 23K11869), the National Hospital Organization (NHO) Grant (H29-NHO-01), and Joint Research Support Grants based on the Comprehensive Agreement between Saitama University and Saitama Medical University (21-J-14, 22-J-01, 23-J-08 and 24-J-2)

E-PS-04-021

Fine Needle Aspiration (FNA) biopsy from lung metastasis of myxopapillary ependymom

B.U. Durmus[1], A.N. Yüksel[1], Z. Kuş Silav[1]
[1]Kartal Lütfi Kırdar City Hospital, Medical Pathology, Istanbul, Turkey

Background & Objectives: Myxopapillary ependymoma (MPE) is a rare central nervous system tumour, particularly seen in children and young adults. Our patient is a 34-year-old female who presents with complaints of lower back pain and a palpable mass. A firm, fixated mass is palpated during the digital rectal examination. The patient has a surgical history from 3 years ago, but the pathological diagnosis is unknown. MRI imaging shows a 36x20 mm mass located in the midline distal to the coccyx. Upon surgical excision, multiple nodular lesions with smooth, well-defined capsules are observed macroscopically.
Methods: Histopathological examination of the specimen reveals papillary structures characterized by columnar cells located around fibrovascular cores, along with abundant myxoid material. The myxoid material stains positive with Alcian Blue. The immunohistochemistry (IHC) panel of the tumour shows GFAP:+, S100:+, EMA:-, CK(AE1/AE3):- staining. The Ki67 index is found to be 10%. The case is reported as MPE. The patient, who is clinically monitored, experiences a recurrence in the retrorectal region within subcutaneous tissue 4 years later. The tumour has similar IHC results to the previous material, with a Ki67 index of 23% and mitosis of 11/10 HPF. The case is reported as anaplastic transformation of MPE, classified as WHO Grade III.
Results: The patient, who has been clinically monitored, underwent a Chest CT scan 3 years later, which revealed multiple subpleural nodules in the right lung, the largest being 25x20 mm at the basal segment of the lower lobe. An FNA biopsy was performed on the lesion. The cytology material showed a tumour composed of cells with radial arrangement around vascular lumens, exhibiting a monotonous granular chromatin structure, with poorly defined cytoplasmic borders.
Conclusion: In the differential diagnosis, neuroendocrine tumours, including carcinoid tumours, were considered, and after performing IHC, the case was reported as metastasis from MPE.

E-PS-04-022

Cytology-histology correlation in epithelioid angiomyolipoma: diagnostic pitfalls in intraoperative imprint cytology

J.S. Marrero Afonso[1], E. Linares[1], N. Storti[1]
[1]Hospital Universitario Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain

Background & Objectives: Epithelioid angiomyolipoma (EAML) is a rare renal mesenchymal tumour that can closely mimic renal cell carcinoma (RCC) in radiologic and cytologic evaluations. While computed tomography (CT) imaging is often diagnostic for conventional angiomyolipoma due to its fat content, tumours with minimal adipose tissue present a diagnostic challenge. Imprint cytology may be inconclusive or misinterpreted, underscoring the importance of histopathologic confirmation and immunophenotyping.
Methods: A 73-year-old male underwent evaluation for an incidental solid, renal lesion (2.6 cm) in the left interpolar region, classified as an intermediate-probability RCC (group 3, CCLS scoring) based on MRI characteristics. Patient underwent a total nephrectomy and an imprint cytology was performed prior to formalin fixation and a histopathological and immunohistochemical correlation was made.
Results: Imprint cytology revealed an hypercellular smear with hematic background, sheets of round to plump spindle cells with indistinct cell borders, sometimes with displaced eccentric nuclei with a voluminous, frothy cytoplasm and occasional nuclear pseudoinclusions. Histopathological examination of the resected tumour (2.9 × 1.9 cm) demonstrated a proliferation of epithelioid cells with abundant cytoplasm, interspersed blood vessels, fascicles of smooth muscle, and occasional mature adipose tissue. Immunohistochemical staining confirmed positivity for actin and caldesmon, HMB45 and MelanA. The absence of a clear adipose component in the imprint cytology

contributed to initial diagnostic uncertainty, highlighting the difficulty of diagnosing EAML when fat is scarce.
Conclusion: EAML with minimal fat content can be a diagnostic pitfall in both radiology and cytology. Intraoperative imprint cytology, while useful for rapid assessment, may be inconclusive without adipose tissue, leading to potential misclassification as RCC or sarcomatoid tumours. This case underscores the need for histologic confirmation and immunophenotyping to achieve accurate diagnosis, avoiding unnecessary overtreatment.

E-PS-04-023
HPV infection and prevalence in a Colombian cohort of patients with cervical cytology abnormalities
K.V. Cruz Ramirez[1], P.C. Castro-Quiroga[1], M.a. Forero-rivera[2], A. Rozo-Cruz[2], P.A. Rodriguez-Urrego[1]
[1]University Hospital Fundacion Santa Fe de Bogota, Pathology, Bogotá, Colombia, [2]University Hospital Fundacion Santa Fe de Bogota, Anatomic Pathology Residency Program, Bogotá, Colombia

Background & Objectives: Cervical cytology (CC) plays a crucial role in detecting HPV-related abnormalities. The integration of molecular testing for High risk HPV (HR-HPV) genotyping improves the screening strategies and complements cytological assessments, providing valuable insights into the progression and prevention of cervical lesions. Vaccination programs aim to reduce HPV prevalence and associated lesions; therefore, correlating vaccination status, cytological findings, and genotype distribution is essential to refining public health strategies.
Methods: This descriptive study analysed 7645 CC samples collected during 2019, that were reported according to the Bethesda system. Positivity was defined as atypical squamous cells of undetermined significance (ASCUS and above). Diagnoses were categorized into low-grade lesions LGL (ASCUS and LSIL) and high-grade lesions HGL (HSIL, glandular atypia and adenocarcinoma). Demographic data, vaccination status, HPV genotyping, and vaccination status underwent statistical analysis.
Results: A total of 334 positive samples (4.3%) were identified and categorized as LGL n=272 (3.5%) , and HGL n=62 (0.8%). HPV-genotyping was positive for HR-HPV in 263 cases (78%), 221 cases from LGL (84%) and 42 cases from HGL (25,9%). HPV 16 and 52 were the most frequent genotypes (20 and 15 patients) .Vaccination information was available only for 14 patients, among this 5 were not vaccinated and 9 were vaccinated, HR-HPV was found on 5/9 of vaccinated patients (serotypes 26,82,30 and 59). Multiple infection (more than one HPV genotype) was found in 42 patients (12,5%)
Conclusion: This study underscores the importance of HPV molecular testing in confirming high-risk genotypes. Although the sample is limited findings indicate a significant prevalence of HPV-related abnormalities with HR-HPV genotypes present in both vaccinated and unvaccinated individuals. In our population multiple-infection is lower than reported in the literature. Despite small representation of vaccinated population in our sample, HR-HPV genotype persistence warrants further research in vaccine efficacy and genotype coverage.

E-PS-04-024
A polarising issue - turnaround times for synovial fluid cytology
H. O'Shea[1], J. Doheny[1], B. Lynch[1], S. Phelan[1]
[1]Galway University Hospital, Galway, Ireland

Background & Objectives: Synovial fluid analysis is the gold standard test for crystal arthropathies. The Royal College of Pathologists (RCPath) recommends a 7-10 day turnaround time (TAT) for cytopathology, and the Irish National Histopathology Quality Improvement Programme advises a similar TAT. There is some ambiguity in terms of expected TAT for synovial fluid - neither guideline mentions a specific TAT, though of note, the RCPath bone and soft tissue pathway does recommend analysis within 12-48 hours. We assessed TAT for these samples in Galway University Hospital, a tertiary hospital with a weekday cytology service.
Methods: Cytology cases tissue coded for crystals, and SNOMED coded gout or pseudogout between July 2023 and January 2024 were reviewed. Evaluated variables included: patient demographics, sampling date and location, date received into laboratory, report authorisation date. Request forms were also reviewed for date received in microbiology prior to receipt in cytology.
Results: Eighty samples were included in the analysis. 57.5% of samples were from inpatients. TAT within the laboratory was 98.75% within 48 hours, with one outlier reported within 72 hours during a public holiday period. The clinical TAT from joint aspiration to authorised report ranged from <24 hours to 6 days, with an average of 60 hours. Longer delays were seen prior to check in for samples taken Friday-Sunday or on public holidays. 51.25% of specimens were not analysed within 12-48 hours. There was no statistically significant difference between inpatient and outpatient TAT.
Conclusion: Though the recommended laboratory TAT was achieved, delays were identified in the overall turnaround, particularly on samples taken on non-working days. These delays may have clinical implications in terms of treatment decisions and length of stay. Potential solutions include a limited weekend cytology service or provisional wet prep reporting by clinicians. A need for greater clarity on TAT for specific cytology specimens has also been identified.

E-PS-04-025
PHOX2B is a reliable marker for diagnosing neuroblastoma in fine needle aspiration material
K. Barklund Palm[1], I. Schliemann[1], S. Wessman[1]
[1]Karolinska University Hospital, Department of Clinical Pathology and Cancer Diagnostics, Stockholm, Sweden

Background & Objectives: Neuroblastoma (NB) is the most common solid extra cranial tumour in children, responsible for around 7 % of childhood cancer cases and 15 % of child cancer mortality. These tumours arise from primitive neural crest cells, most commonly in the adrenal medulla and sympathetic chain ganglia. For diagnosis, fine needle aspiration cytology (FNAC) can be preferred over core needle biopsies for its lower complication rate and quicker route to diagnosis. However, since neuroblastomas belong to the small round blue cell tumour (SRBCT) group they can sometimes be difficult to distinguish from other tumours in this group cytomorphologically without ancillary immunocytochemical staining. PHOX2B is a marker for differentiation of sympathetic and autonomic neurons and has been found effective in differentiating NB from other SRBCT on histologic material.
In this study, we aim to evaluate the sensitivity and specificity of the immunocytochemical marker PHOX2B in differentiating neuroblastomas from other small round blue cell tumours in fine-needle aspirated cytologic material.
Methods: A total of 43 cases of NB and other SRBCT were collected from the archives of the Department of Pathology and Cancer Diagnostics at Karolinska University Hospital between the years 2016 and 2023. All samples either already had been or were stained immunocytochemically (ICC) with PHOX2B, and histologic material from the same patient and tumour was stained with PHOX2B as control. All cases were reviewed by a panel of senior cytopathologists. Nuclear staining of PHOX2B in >5 % of tumour cells was considered positive.
Results: We found a sensitivity of 80 % and a specificity of 100 % on ICC of PHOX2B in diagnosing NB and differentiating it from other SRBCT when used on FNAC material.

Conclusion: We are proposing the use of PHOX2B as a reliable marker to diagnosing and differentiating neuroblastoma among other SRBCTs in FNAC as well as in histologic tissue samples.

E-PS-04-026

Identification of oxidized regenerated cellulose (surgicel) in transbronchial/transthoracic fine needle aspiration of pseudotumoral lesions following pulmonary lobectomy: a case series

S. Çolak[1], O. Kurtulan[1], S. Önder[1], O. Karcıoğlu[2]
[1]Hacettepe University Faculty of Medicine, Department of Pathology, Ankara, Turkey, [2]Hacettepe University Faculty of Medicine, Department of Pulmonary Medicine, Ankara, Turkey

Background & Objectives: Topical hemostatic agents like oxidized regenerated cellulose (e.g., Surgicel) are commonly used during surgical operations. These substances are usually reabsorbed within two weeks at the surgical site; however, incomplete absorption can occasionally lead to foreign body reactions that mimic neoplastic recurrence. Imaging studies may not provide accurate diagnoses in such cases. This study aims to emphasize the role of fine needle aspiration (FNA) in diagnosing these changes in patients with suspected recurrence after lung cancer surgery.
Methods: Fine needle aspiration, either transbronchial or transthoracic, was performed in three patients with imaging findings suspicious for malignancy recurrence following pulmonary lobectomy, and cytological samples were evaluated at the Pathology Department of Hacettepe University.
Results: The clinical details and cytological findings of the three cases were as follows:
Patient 1: A 71-year-old female who had undergone right upper lobectomy for lung adenocarcinoma. Fifteen months after surgery, imaging revealed soft tissue thickening at the distal right main bronchus.
Patient 2: A 68-year-old male with right upper lobectomy for high-grade adenocarcinoma with mediastinal lymph node metastases. Four months post-surgery, PET-CT displayed FDG uptake in the right lower paratracheal and subcarinal regions.
Patient 3: A 55-year-old female who had left lower lobectomy for colloid adenocarcinoma. Three months postoperatively, FDG uptake was observed in an extrapleural mass.
In all cases, FNA revealed the presence of inorganic, elongated, quadrangular foreign body material, exhibiting birefringence under polarized light, in a dense proteinaceous background—findings consistent with oxidized regenerated cellulose (Surgicel). Notably, one case also showed a foreign body giant cell reaction.
Conclusion: FNA is a rapid and minimally invasive technique for identifying oxidized regenerated cellulose causing pseudotumoral reactions. Familiarity with its cytomorphological features is essential for accurate diagnosis and appropriate patient management.

E-PS-04-027

A comprehensive study of alveolar soft tissue sarcoma: five cases with cytology, immunocytochemistry and molecular alterations

I. Schliemann[1,2], J. Wejde[1], E. Tani[1]
[1]Karolinska University Hospital, Department of Pathology and Cancer Diagnostics, Stockholm, Sweden, [2]Karolinska Institute, Department of Oncology-Pathology, Stockholm, Sweden

Background & Objectives: Alveolar soft part sarcoma (ASPS) is a rare tumour of uncertain origin with predilection for the lower extremities. It has an indolent course and often the patient has already metastases when the disease is discovered. ASPS has a specific translocation between the transcription factor TFE3 in Xp11.2 and ASPSCR1/ASPL in chromosome 17. This translocation can be detected by immunocytochemistry with an antibody against TFE3 , FISH or PCR. Here we describe five cases in a period of 12 years from the archives of our institution and compare with publish cases related to cytologic diagnosis of ASPS and importance of immunocytochemistry.
Methods: A total of five cases diagnosed as ASPS between 2012 and 2024 were retrieved from the archives of the Department of Pathology and Clinical Cytology of Karolinska University Hospital, Stockholm, Sweden. Cytologic and histologic material were reviewed by two cytopathologists. Molecular analys were performed in all five cases. Immunocytochemistry for TFE3 was performed in two cases.
Results: All five cases showed typical cytologic features for ASPS. Cellular smears with dominance of bare nuclei and prominent nucleoli. Aggregates of tumour cells were also present, with light fine granulated cytoplasma, with one case showing vacuolated cytoplasm. A granulated material was present in the background. All cases showed TFE3::ASPSCR1 translocation on PCR. Two cases were positive for TFE in immunocytochemistry. Two of our cases were in the lower extremities and two patients had lung metastasis at diagnosis. These features are in accordance with previous published cases of ASPS. Medium age is 38 years, which is a bit higher that expected for ASPS.
Conclusion: ASPS is a rare tumour that must be remembered in young patients with soft tissue tumours. The typical cytomorphology can be wrongly mistaken as carcinoma. Immunocytochemistry is useful for the diagnosis but confirmation with PCR should be mandatory.

E-PS-04-028

Challenges in anal cytology for screening high-grade squamous neoplasia and above lesions in high-risk populations: a single institution's experience over the past three years

C. Brown[1], A. Hull[2], A.G. Neto[1], T. Guo[1]
[1]University of Texas Health Science Centre at Houston, Department of Pathology and Laboratory Medicine, Houston, USA, [2]Harris Health, Department of Laboratory Medicine, Houston, USA

Background & Objectives: Anal high-grade squamous intraepithelial lesions (HSIL) are precursors to anal squamous cell carcinoma, and screening with anal cytology in high-risk populations, such as HIV-positive patients, is recommended. Anal cytology is used alongside digital rectal examination and high-resolution anoscopy. However, the sensitivity of anal pap cytology has historically been low, and its specificity is variable. The aim of this study is to evaluate the correlation between anal cytology and follow-up biopsy results in high-risk patients (HIV-positive), focusing on improving the detection of HSIL.
Methods: Retrospective cohort study conducted at our institution reviewed anal cytology cases with follow-up biopsy results from January 1, 2022, to March 8, 2025, at a level three trauma centre.
Results: A total of 812 anal pap smears were analysed during the 3-year period, with 97 patients meeting the inclusion criteria. Of these, 91.8% (n=89) were classified as abnormal on cytology: 13.4% (n=13) had high-grade cytology (ASC-H/HSIL), 43.3% (n=42) had atypical cytology (ASC-US), and 35.1% (n=34) had low-grade cytology (LSIL). Follow-up biopsies revealed that 49.5% (n=48) were diagnosed with HSIL/AIN2-3, 2.1% (n=2) with squamous cell carcinoma, 47.4% (n=46) with LSIL/AIN1, and 1.0% (n=1) had negative results. Of the cases with high-grade cytology, 92.3% (n=12) had corresponding high-grade or worse histology. Among biopsy-proven high-grade lesions, 92% (n=46) had abnormal cytology: 30% (n=15) ASC-US, 38% (n=19) LSIL, and 24% (n=12) ASC-H/HSIL.
Conclusion: While the specificity of high-grade cytology was high (97.8%) and correlated well with high-grade histology, the sensitivity remains low. A significant portion of patients with high-grade histology and above had preceding low-grade or atypical cytology. Successful cytology sampling is crucial for improving sensitivity, and high-risk patients with any abnormal anal pap screening results should undergo further evaluation by high-resolution anoscopy.

E-PS-04-029

Cytology vs histology in lung cancer diagnosis: a concordance study

V. Almeida[1,2], B. Sepodes[1]
[1]Coimbra University Hospital, Pathology, Coimbra, Portugal, [2]Univ Coimbra, Faculty of Medicine, Coimbra, Portugal

Background & Objectives: Bronchial biopsies and cytological specimens (bronchial brushing, washing and aspiration) are frequently used in parallel to investigate suspected pulmonary neoplasms. While histology is often considered the reference method, cytology with cell-block preparation may also provide relevant diagnostic and molecular information. This study aimed to evaluate the concordance between histology and cytology in terms of malignancy and histological subtype.
Methods: We retrospectively analysed 40 diagnostic episodes in patients with clinical suspicion of lung neoplasm, each comprising both histological and cytological sampling. Cytological specimens were processed using the *cell block* technique, enabling improved cytomorphological assessment and ancillary studies. Each episode was considered independently, reflecting real-life clinical decision-making, including repeated procedures when required. Concordance between methods was evaluated using Cohen's kappa coefficient, and discordant cases were further analysed.
Results: Among the 40 diagnostic episodes with valid results, overall agreement regarding malignancy was 72.5%, with moderate concordance (Cohen's kappa = 0.44). Cytology identified malignancy with specific subtyping in 5 cases where histology was negative. Conversely, histology identified malignancy in 6 cases missed by cytology. Among discordant cases, cytology more frequently diagnosed adenocarcinoma, while histology showed a broader distribution across subtypes. Subtype concordance was evaluated in 9 episodes where both methods provided a specific diagnosis. A perfect agreement was observed in this subgroup (Cohen's kappa = 1.00), which included adenocarcinoma and squamous cell carcinoma.
Conclusion: Cytological assessment with cell-block processing shows high concordance with histology and may provide complementary or even superior diagnostic information in selected cases. Its role in the diagnostic work-up of lung cancer is particularly valuable when histological sampling is limited or inconclusive.

E-PS-04-030

A comprehensive review of sarcoma involvement in fluid cytology with focus on cytomorphology: a 10-year study at an Indian oncology centre

A. Toshniwal[1], S. Mehta[1], M. Shah[1], S. Samanta[1], P. Trivedi[1], S. Shah[1]
[1]The Gujarat Cancer and Research Institute, Ahmedabad, India

Background & Objectives: Malignant effusions are some of the most common specimens evaluated in cytopathology. In comparison with carcinomas, sarcomas are rare, accounting for less than 1% of primary adult malignancies and the presence of sarcomas in effusion specimens evaluated by cytology is extremely rare. This study evaluates cytomorphology of sarcomas in fluids and determines characteristic features for identification and classification.
Description of clinico-pathological landscape in known cases of sarcomas, involving body fluid with emphasis on cytomorphologic details.
Methods: This study is based on a 10-year experience, conducted from January 2014 to February 2025, at a tertiary care oncology institute in India. It includes cases identified as positive for sarcoma involvement through fluid cytology, encompassing pleural, ascitic, and cerebrospinal fluid specimens.
Results: A total of 30 fluid samples/cases were studied, including 6 CSF, 5 ascitic, and 19 pleural fluid. The case spectrum included 11 cases of Ewing Sarcoma, 5 of rhabdomyosarcoma, 4 cases of osteosarcoma, 3 of synovial sarcoma, 2 of malignant peripheral nerve sheath tumour, one case each of chondrosarcoma, leiomyosarcoma, angiosarcoma, extrarenal rhabdoid tumour and desmoplastic small round cell tumour.
Conclusion: Although metastasis of carcinomas of lung and liver occur with relative frequency, the presence of sarcomas in effusion specimens evaluated by cytology is extremely rare. Cytological evaluation of sarcomas in exfoliative cytology specimens are complicated by several factors. They are commonly hypo cellular with altered cytomorphology. The cells tend to round up in fluids and lack tissue arrangement or vascular, stromal pattern as seen in histopathology and fine needle aspiration specimens. This study highlights on the evaluation of fluids for sarcomatous exfoliation with focus on cytomorphology.

E-PS-04-031

Outcome of Bethesda III-V categories thyroid nodules: single institution experience

S. Bracic Tomazic[1], S. Zöch[1], S. Lax[1,2]
[1]Hospital Graz II, Styrian Hospital Corporation, Academic Teaching Hospital of the Medical University of Graz, Department of Pathology, Graz, Austria, [2]School of Medicine, Johannes Kepler University, Linz, Austria

Background & Objectives: Fine Needle Aspiration Biopsy (FNAB) is a widely used diagnostic technique for thyroid nodules. The Bethesda System for Reporting Thyroid Cytopathology (BSRTC) significantly enhances its diagnostic accuracy. The aim of this study is to analyse Bethesda category III, IV and V nodules with emphasis on the final histological diagnosis.
Methods: We retrospectively analysed FNAB diagnosed in our department between January 2005 and December 2023 retrieved from our files (12,670 samples). All thyroid aspiration specimens were stained with haematoxylin and eosin (HE). All cases received a microscopic description and diagnosis including a category comparable to BSRTC. We reclassified all cases using BSRTC 3rd edition.
Results: 565 samples (4.5%) from 508 patients were diagnosed as Bethesda III (139; 27.4%), IV (257; 50.6%), or V (112; 22.0%). Samples were representative in 93%, of limited adequacy in 7%. 71.2% of Bethesda III nodules underwent follow up FNAB (median within 6.4 months), of these, 43.9% were downgraded to Bethesda II, 20.2% remained in Bethesda III-V, 4.3% were inadequate and 2.9% were upgraded to Bethesda VI and histologically confirmed as malignant. 28.8% were lost to follow-up. 73.5% of Bethesda IV nodules underwent surgery (median within 3.4 months), of these 13.6% were malignant, and 56.8% benign. 2.3% received repeat FNAB and were again classified as Bethesda IV, 27.2% were lost to follow-up. 78.6% of Bethesda V nodules underwent surgery (median within 1.9 months), of these were 50.0% malignant and 28.6% benign; 17.0% were lost to follow-up. The frequency of malignancy between the 3 cytological groups was statistically significant ($p<0.001$; chi^2 test).
Conclusion: The study confirms the diagnostic variation across Bethesda categories III - V with respect to underlying histology and endorses the importance of consistent follow-up and optimized patient management. The use of liquid-based cytology would facilitate molecular reflex testing in challenging cases.

E-PS-04-033

Morphological findings in cytology based on HPV types

B.E. Yildiz[1], N. Koç[1]
[1]University of Health Sciences, Haydarpasa Numune Training and Research Hospital, Department of Pathology, Istanbul, Turkey

Background & Objectives: HPV typing has gained importance since the causality relationship between cervical cancer and HPV was determined. The aim of our study is to determine the predictive value of

cytological findings and high-risk HPV type association in cases with PAP smear test and positive high-risk HPV test.
Methods: A total of 490 cases with a positive PAP smear and a single high-risk HPV subtype evaluated between January 2021 and December 2022 in the Department of Medical Pathology of Health Sciences University Haydarpaşa Numune Training and Research Hospital were included in the study. Molecular high-risk HPV subtypes detected by Real Time PCR were obtained from pathology reports. Liquid-based cytology slides were examined microscopically for classical coilocytes, perinuclear halo, multinucleation, nuclear hyperchromasia, nuclear membrane irregularity, naked nucleus, atypical cell pattern, dyskeratosis, parakeratosis, squamous metaplasia and inflammation. The relationship between high-risk HPV subtypes and cytomorphologic findings was evaluated.
Results: There was a statistically significant correlation between the presence of classical coilocytes on liquid-based cytology and positive detection of other high-risk HPV types ($p<0.001$). A statistically significant correlation was found between nuclear hyperchromasia and nuclear membrane irregularity and HPV16 positive detection ($p<0.47$, $p<0.17$, respectively). No statistically significant correlation was found between high-risk HPV types and the presence of perinuclear halo, multinucleation, naked nucleus, atypical cell pattern, dyskeratosis, parakeratosis, squamous metaplasia and inflammation.
Conclusion: In cases where access to HPV testing is limited for various reasons, cytomorphologic findings may be helpful for HPV subtyping.

E-PS-04-034
The impact of COVID-19 on cervical cytology services in the Free State, South Africa
D. Le Grange[1,2], J. Goedhals[3,2], C. van Rooyen[4]
[1]National Health Laboratory Service, Department of Anatomical Pathology, Bloemfontein, South Africa, [2]University of the Free State, Department of Anatomical Pathology, Bloemfontein, South Africa, [3]PathCare, Department of Anatomical Pathology, Bloemfontein, South Africa, [4]University of the Free State, Department of Biostatistics, Bloemfontein, South Africa

Background & Objectives: Cervical cancer is a major global health issue, with the highest rates in low- and middle-income countries. Screening methods such as Papanicolaou (Pap) smears and human papilloma virus (HPV) testing are critical for early detection and treatment. The COVID-19 pandemic disrupted cervical cancer screening services worldwide, raising concerns about an increase in undiagnosed cases. The aim of this study was to investigate the impact of the COVID-19 lockdown on cervical cytology screening in the Free State Province of South Africa.
Methods: In this retrospective, descriptive study, data from the National Health Laboratory Service (NHLS) electronic database spanning from 25 September 2019, to 5 October 2022, were analysed to compare screening rates six months before, during and six months after the pandemic.
Results: This study found a significant decline in cervical screening rates during the pandemic, with regional disparities within the Free State province. The average daily specimen collection rate in the Free State declined by 52.1% during the peak of the pandemic. A slight decrease in the adequacy rates of cervical cytology samples were noted during the lockdown. Differences in the daily rates of premalignant, malignant and normal diagnoses were identified however, these were not statistically significant. A moderate negative correlation was found between the number of positive COVID-19 tests and the number of Pap smears conducted.
Conclusion: The pandemic markedly affected cervical cancer screening rates, which could have long-term public health implications. These results emphasise the need for adaptable screening strategies and resilient healthcare systems to maintain essential preventive and diagnostic services during global health crises.

E-PS-04-035
Application of ROSE (rapid on-site evaluation) in the study of pulmonary nodules by CT (computerized tomography): preliminary analysis in 49 patients
X. Casanovas Rodríguez[1], J. Martínez Luque[1], M. Guijarro Comas[1], R. Viana Silva[2], A. Delgado Pérez[2], R. Leiro Riera[2], P. Rubinstein Aguñín[2], I. Costa Trachsel[1], A. Bueno Remacha[1]
[1]Atrys, Pathology Department, Barcelona, Spain, [2]Hospital El Pilar, Pneumology Department, Barcelona, Spain

Background & Objectives: Rapid on-site evaluation (ROSE) in endoscopic and imaging procedures has been proven useful in obtaining suitable specimens for cytologic or histologic diagnosis. We evaluated the effectiveness of ROSE on specimen adequacy and diagnostic accuracy in pulmonary hard-to-reach nodules, by CT (computerized tomography).
Methods: Forty-nine patients underwent CT-guided biopsy for suspicious pulmonary image with ROSE by cytologic imprint. A diagnosis of negative, representative non-conclusive (RNC), atypia, suspicious of malignancy (SOM) or insufficient was made. For insufficient, three samples or any clinical contraindication were demanded. When a diagnosis of atypia or SOM was made, an extra sample for molecular study was obtained, and for atypia suspicious of lymphoproliferative disease (LPD), material for flow cytometry analysis was separated. ROSE diagnoses were compared with final diagnoses.
Results: We collected 15(30,6%) negative, 7(14,3%) RNC, 9(18,4%) atypia, 17(34,7%) SOM and 1(2%) insufficient ROSE diagnoses. A unique sample for on-site diagnosis was needed in all cases, except for the insufficient. Final definitive diagnosis was made in 95,9% of the cases: 19 negative (14 of ROSE negative and 5 of ROSE RNC); 28 malignant (25 carcinomas and 3 LPD) included all ROSE SOM and atypia and 2 of ROSE RNC. Two definitive diagnoses were insufficient (the ROSE case and one ROSE negative). Correlation with ROSE diagnosis was observed in 46 cases. For atypia cases, 5 were suspicious of LPD, with confirmed diagnosis in three (the remaining two corresponded to small cell carcinoma). No false positive ROSE diagnoses were collected. The diagnostic sensitivity was 80% with a specificity of 100%, concluding a PPV (positive predictive value) of 100% with a NPV (negative predictive value) of 74%.
Conclusion: Our results indicate that ROSE exhibits high diagnostic accuracy when applied in the study of pulmonary hard-to-reach nodules by CT and it optimises the specimen adequacy, avoiding rescheduling the patient.

E-PS-04-036
Bronchial aspirate surprise: cytological diagnosis of amyloidosis!
S. Yurtsever Inan[1], F.S. Pehlivan[1], B.N. Doğan[1]
[1]Manisa Celal Bayar University, Pathology, Manisa, Turkey

Background & Objectives: Amyloidosis encompasses a group of disorders characterized by extracellular deposition of misfolded proteins (amyloid), leading to progressive organ damage. Definitive diagnosis traditionally relies on invasive biopsies for histopathological identification of amyloid deposits. Congo red staining, with its characteristic apple-green birefringence under polarized light, remains the gold standard for confirmation. Minimally invasive cytological specimens, such as bronchial aspirates, present a promising diagnostic alternative but require further systematic validation. This case study aims to: (1) demonstrate the utility of cytological specimens in diagnosing amyloidosis, (2) highlight the role of Congo red staining in differentiating amyloid from mimicking entities in bronchial samples, and (3) emphasize that amyloidosis may be rarely observed in cytology.

Methods: A 51-year-old woman with Sjögren's syndrome presented with dyspnea and cough. Thoracic CT revealed bilateral nodular lesions, central consolidations, bronchiectasis, and a 4 cm thin-walled cavitary lesion in the left lower lobe. Suspecting granulomatous/fungal infection or malignancy, fiberoptic bronchoscopy was performed. Aspirated material was processed using the ThinPrep method for cytology: smears were Papanicolaou-stained, and cell blocks were prepared with haematoxylin-eosin. Congo red staining was performed, and slides were examined under polarized light microscopy to confirm amyloid deposition.
Results: Cytological smears revealed bronchial epithelial cells, histiocytes, and lymphocytes. Cell block analysis identified eosinophilic amorphous material admixed with histiocytes and epithelial cells. Congo red staining demonstrated red-orange positivity under light microscopy, with characteristic apple-green birefringence under polarized light, confirming amyloid. The findings distinguished amyloid from differentials such as mucus, alveolar proteinosis, fibrin, and corpora amylacea.
Conclusion: This case underscores the diagnostic efficacy of Congo red staining in cytological specimens obtained via minimally invasive bronchoscopy. It highlights the critical role of histochemical methods in differentiating amyloid from morphologically similar entities in pulmonary samples. Integrating Congo red into cytopathology workflows enhances diagnostic precision, reducing reliance on invasive biopsies in suspected amyloidosis cases.

E-PS-04-037
Indeterminate thyroid follicular nodule of the Italian classification: other morphological features could drive the risk of malignancy?
B. Fuochi[1], A. Proietti[2], R. Romani[2], M. Anello Poma[3], C. Ugolini[3]
[1]University of Pisa, Department of Translational Research and New Technologies in Medicine, Pisa, Italy, [2]Unit of Pathology, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy, [3]University of Pisa, Surgical, Medical, Molecular, and Critical Care Pathology Department, Pisa, Italy

Background & Objectives: The "Italian consensus for the classification and reporting of thyroid cytology" (ICCRTC), proposed to split the "indeterminate" category (TIR3) in two subcategories with different risk of malignancy: TIR3A and TIR3B. TIR3B nodules frequently undergo surgery even if at final histology only a part (hypothetically 30%) is malignant. This study aim is to identify potential cytological features associated with malignancy in a series of TIR3B nodules.
Methods: We retrospectively evaluated 142 patients who underwent thyroid FNA at the University Hospital of Pisa from 2017 to 2019, and received a cytological diagnosis of TIR3B. Overall, 147 TIR3B nodules were revised. For each nodule, the following features were evaluated: architecture (microfollicular, trabecular, cluster or single cells), the presence and type of colloid, cellularity, follicular cells characteristics (size, elongated form, eosinophilic cytoplasm, nuclear size, chromatin type, presence of nuclear grooves and presence of nucleoli) and background composition (blood, macrophages, lymphocytes, necrosis). According to histology, patients were divided into thyroid cancer (TC) or benign nodules. Chi-square test were used to compare groups, while ROC curves were used to determine the diagnostic performance.
Results: Among the 147 TIR3B nodules, at final histology only 60 (40,8%) were benign and 87 (59,2%) were TC (including PTC, FTC, PDTC and NIFT-P). We found that predictors of thyroid cancer are: elongated cells (p-value: 0,01) and nuclear grooves (p-value: 0,03). Elongated cells had a specificity of 0,80, a sensitivity of 0,41, an accuracy of 0,57, PPV of 0,75 and NPV of 0,48. Nuclear grooves had a specificity of 0,27, a sensitivity of 0,88, an accuracy of 0,63, the PPV of 0,64 and the NPV of 0,62.
Conclusion: Cytological features, such as elongated follicular cells and nuclear grooves, could be very important in TIR3B risk stratification. Further analysis should be carried on to confirm the data.

E-PS-04-038
Anaplastic thyroid carcinoma cytopathology – the good, the bad, and the ugly: a case report
A. Ali[1], H. Joshi[2], B. Mathew[2]
[1]Broomfield Hospital, Histopathology, Chelmsford, United Kingdom, [2]Broomfield Hospital, Chelmsford, United Kingdom

Background & Objectives: Anaplastic Thyroid Carcinoma (ATC) is a rare but highly aggressive malignancy with a poor prognosis. Cytological diagnosis is crucial for early intervention, but it remains challenging because of its overlapping characteristics with other thyroid neoplasms. We present a case of ATC with unique cytomorphological features, emphasizing the associated diagnostic challenges and conducting an extensive literature review highlighting the wide cytomorphological spectrum seen in association with this aggressive tumour.
Methods: Herin, we present a rapidly enlarged thyroid mass in a 61-year-old patient with a fine needle aspiration reported provisionally as unsatisfactory. Case was reviewed at our specialised Head and Neck unit and a diagnosis of ATC was suspected as very spare highly atypical cells with bizarre nuclei were detected and were thought to be degenerate at first sight. Subsequent biopsy confirmed the diagnosis, and the tumour was deemed non-resectable clinically and radiologically.
Results: This case including the detailed literature review have emphasized on the cytological spectrum of ATC—the "good" (high cellularity facilitating diagnosis), the "bad" (sparsely cellular aspirates due to extensive fibrosis, tumour cells mixed with extrathyroidal tissue due to rapid tumour infiltration and overlapping features with other tumours), and the "ugly" (necrotic smears and morphologically features of squamous cell carcinoma, spindled cell neoplasm, and multinucleated giant cell-like tumours posing diagnostic challenges).
Conclusion: Given the wide cytological spectrum of this tumour, the lack of supportive diagnostic ancillary testing such as immunocytochemistry, and the challenge of obtaining a meaningful molecular profile due to the limited number of cells in the aspirates, it is crucial to familiarize oneself with the atypical and rare cell morphology seen in association with this tumour. This will help prevent misinterpretation and ensure timely clinical intervention.

A highly aggressive giant malignant chondroid syringoma of the occipital scalp with rapid tumour recurrence and progression to lymph node and pulmonary metastasis
M.A.V. Laqui[1], P.A.B. Basilio[1], J.P.K.G. Mojica[1], J.A.C. San Juan[1], A.L.B. Valdez[1], H.A. Saguil, Jr[1], R.D.c. Cabudoy[1]
[1]Ospital ng Maynila Medical Centre, Department of Pathology and Laboratory Medicine, Manila, Philippines

Background & Objectives: Malignant chondroid syringoma (MCS) is a rare cutaneous adnexal tumour characterized by its potential for local recurrence and distant metastasis, with only 52 cases reported in published literature to date. It most frequently arises on the trunk and extremities, with involvement of the head and neck being exceptionally uncommon. The median tumour size is approximately 4 cm, and lesions exceeding 5 cm have been associated with increased risk of metastasis and mortality.
Methods: We report a rare and clinically striking case of giant MCS arising on the occipital scalp of a 38-year-old woman who presented with a 15.0 × 10.0 × 10.0 cm ulcerated, exophytic mass that had

remained indolent for ten years before undergoing rapid growth over a two-month period. Wide local excision with partial-thickness skin grafting was performed, yielding negative surgical margins.
Results: However, within six weeks, the patient developed local recurrence followed by rapidly progressive, multilevel, bilateral cervical lymphadenopathy, and subsequent pulmonary metastases.
Conclusion: This case highlights a particularly aggressive clinical course of MCS and illustrates the tumour's capacity for sudden transformation and rapid progression, even after prolonged latency. It underscores the importance of maintaining a high index of suspicion for aggressive transformation in longstanding lesions and reinforces the need for early diagnosis and timely surgical intervention. Additionally, this report contributes to the limited literature on MCS and supports the goal of pursuing a formal subclassification of these lesions into low-grade and high-grade variants to facilitate more consistent prognostication and standardized management approaches.

Basal cell carcinoma invading the humerus: a case report
C.E. Plesa[1], D. Dorobantu[2], S. Gurzu[1,3]
[1]Clinical County Emergency Hospital, Pathology, Târgu-Mureș, Romania, [2]Clinical County Emergency Hospital, Plastic and Reconstructive Surgery, Târgu-Mureș, Romania, [3]George Emil Palade University of Medicine, Pharmacy, Science and Technology, Pathology, Târgu-Mureș, Romania

Background & Objectives: Basal cell carcinoma (BCC) is a common skin cancer, but its invasion into the bone is exceedingly rare. This report highlights a case of BCC with unusual osseous involvement.
Methods: A 72-year-old woman, known with schizophrenia, was hospitalized for progressive right arm and shoulder pain. She related that the pain was progreesively aggravated in the last 7 years. CT-scan revealed an ill-defined mass with soft tissue and bone invasion, osteolysis, and a pathologic humeral fracture. Surgical management included right arm disarticulation, glenoid fossa resection, and partial clavicle removal. The surgical specimen was send for histopathological assesment.
Results: The macroscopic examination revealed a large nodular tumour with extensive ulceration and direct bone invasion. Histopathologic analysis showed proliferation of basaloid cells, arranged in nests, with peripheral palisading, cleft-like spaces, necrotic foci and loose myxoid stroma. Immunohistochemical profile of tumour cells showed positivity for BerEp4, while CK7, EMA and CEA were negative, supporting the diagnosis of BCC with bone invasion. The patient is still alive at five months after surgery.
Conclusion: Although BCC is a slowly growing tumour, in neglected cases it can have aggressive potential with invasion of deep soft tissues and bone. Early recognition and prompt intervention remain of paramount importance in optimizing patient outcome and preventing further progression.

E-PS-05-003
Pathological spectrum and epidemiological trends of skin adnexal tumours: a 6-year retrospective study
A. Sahli[1], M. Boukhenaf[1], L. Beddar[1]
[1]University Hospital Dr Benbadis, Pathology, Constantine, Algeria

Background & Objectives: Skin adnexal tumours (SATs) are rare tumours with a wide spectrum of differentiation, making them a diagnostic challenge. We conducted the first 6-year retrospective study in Algeria to review and shed the light on the most common SATs in the local population.
Methods: We reviewed 146 cases of SATs that we got over a 6-year period (January 2019-December 2024). All relevant data have been collected.
Results: Our study found a prevalence of 0.34%, and a slight male predominance, with a sex ratio of 1.18:1, consistent with findings reported in multiple studies.
An evaluation of clinicopathological features highlighted a predominance of tumours located in the head-and-neck region (69.86%) due to the rich distribution of skin appendages with high sun exposure.
SATs are a wide group that arise from multipotent stem cells into follicular, sebaceous, eccrine and apocrine tumours, with a considerable morphological overlap between individual entities, making histopathology the gold standard for diagnosis. Histopathological analysis of our cohort demonstrated eccrine/apocrine differentiation in 81 cases (55.48%), followed by follicular then sebaceous differentiation, with pilomatricoma being the predominant SAT, and sebaceous carcinoma as the most frequent malignant tumour.
Several studies, such as ours, showed that malignant tumours are rare compared to benign counterparts (7.53% vs. 92.47%). However, they are more aggressive with high potential of metastasis, making accurate diagnosis essential for appropriate therapeutic management. Benign SATs can be a falsely reassuring diagnosis as there may be genetic diagnoses associated with selected SATs, such as Muir-Torre/Lynch syndrome for sebaceous gland tumours, which underlines the importance of emerging molecular markers, genetic counselling and surveillance.
Conclusion: Our study largely aligns with the literature, proving that these tumours are rare, often in the head-and-neck region, and predominantly benign. Their precise diagnosis and correct treatment are crucial for optimal patient care.

E-PS-05-004
Hidradenoma featuring lymph node metastasis: a rare phenomenon
I. Rodrigues[1], C. Costa[1], J. Pinheiro[1], S. Pedrosa[1], M.C. Couto[2], J.M. Lopes[1,3]
[1]Unidade Local de Saúde de São João, Pathology Department, Porto, Portugal, [2]Unidade Local de Saúde de São João, Oncology Department, Porto, Portugal, [3]Faculdade de Medicina da Universidade do Porto, Porto, Portugal

Background & Objectives: Hidradenoma is considered a benign sweat gland tumour. While lymph node metastases are more common in malignant counterparts (hidradenocarcinoma), rare cases of lymph node involvement in so-called benign hidradenomas have been reported. We present a case of hidradenoma with lymph node metastasis.
Methods: A 59-year-old man with a history of previous metachronous gastric (tubular, intestinal-type, pT1a N0 R0) and colorectal (NOS, G2, pT4b N0 R0) adenocarcinomas, 5 and 4 years earlier, respectively, with no further evidence of progression; microinstability testing was negative. He presented with a nodular skin lesion (1.2 cm largest dimension) on the chest, which was excised. Three years later, he developed an enlarged axillary lymph node, which was also excised.
Results: Histopathology of the skin lesion revealed a well-circumscribed dermal solid-cystic neoplasm composed of bland clear (glycogen: PAS/PASD-), eosinophilic, and focally mucinous cells with focal stromal sclerosis. The mitotic index was low (<1/mm²). No significant atypia, necrosis, lymphovascular, or perineural invasion was observed. Immunohistochemistry showed diffuse and strong p40 and p63 expression, ductal differentiation (CEA and EMA), and absence of myoepithelial markers (SMA and S100), confirming hidradenoma. Three years later, histopathology revealed an axillary lymph node with identical neoplastic features, indicating metastasis. Next-generation sequencing (primary tumour and lymph node metastasis) identified a CRCT1::MAML2 fusion gene. No recurrence was observed after one year of follow-up.

Conclusion: We still dispute the aetiology and never reported neoplasm association after excluding known cancer-predisposing syndromes (e.g., Lynch/Muir Torre). Nevertheless, our case highlights the rarely reported lymph node metastasis in tumours with benign hidradenoma features, adding evidence to the exceptional "benign metastasis" phenomenon. Although the long-term prognosis remains unclear, current evidence suggests that surgical excision is the therapeutic modality of choice and extended follow-up may be more suitable than adjuvant treatments, given the seemingly favourable clinical outcomes.

E-PS-05-005

10 year histopathological review of adnexal tumours of the skin in Accra, Ghana

B. Adjei- Mensah[1], P. Pepra- Ameyaw[1], B. Akinkang[1]
[1]Korle Bu Teaching Hospital, Pathology, Accra, Ghana

Background & Objectives: Adnexal tumours of the skin are a wide range of skin neoplasms which arise from the sebaceous glands, hair follicles and sweat glands. Due to the rarity of these neoplasms, there are very limited studies on them in sub- Saharan Africa. This report aims to review the histopathological pattern of adnexal tumours of the skin diagnosed in the Department of Pathology of the Korle Bu Teaching Hospital in Accra, Ghana.
Methods: A retrospective analysis of histopathology records in the Department of Pathology of the Korle Bu Teaching Hospital in Accra, Ghana was conducted. Data was collected over a 10 year period, from 2015- 2024 and analysed using STATA 14.
Results: A total of 69 cases were reported in the period, accounting for 4.7% of the total number of skin lesions reported in the same period. The male-to-female ratio was 1:1.4. The patient ages ranged from 7 months to 90 years with the commonly affected age group being 60-69 years. The head and neck region was the most commonly occurring site, accounting for 63.3%. The sweat gland derived tumours were the most frequently diagnosed, making up 47.8% of reported cases, then follicular derived tumours, accounting for 27.5% and lastly the sebaceous gland tumours, making up 24.6%. Most of the reported cases were benign (95.7%). Chondroid syringoma was the most frequent benign tumour (15.9%), while eccrine porocarcinoma was the most common malignant tumour (66.7%).
Conclusion: Most adnexal tumours of the skin in our setting were benign, with the commonest tumours being of sweat gland origin. The tumours were most frequently located in the head and neck region. This study contributes valuable regional data on the histopathology of adnexal tumours and highlights the need for further research in this area for prognostic and clinical significance.

E-PS-05-006

Unveiling the complexity of cutaneous collision tumours: a rare triad of squamous cell carcinoma, basal cell carcinoma and melanocytic nevus

G.-N. Radu[1], A.C. Tinca[1,2], B. Pastor[1], O.S. Cotoi[1,2]
[1]Mureș County Clinical Hospital, Pathology Department, Târgu Mureș, Romania, [2]University of Medicine, Pharmacy, Science and Technology "George Emil Palade", Pathophysiology, Târgu Mureș, Romania

Background & Objectives: Cutaneous collision tumours (CCT) are rare entities defined as two or more neoplasms that arise in close proximity to each other yet separated by a tumour-free zone. Although the exact pathogenesis remains unclear, it is believed that neoplastic heterogeneity and paracrine effects on the tumour's nearby epithelial and stromal elements play important roles.
Methods: We report the case of an 81-year-old male patient presenting with an ulcered nodular lesion on the nasal area, measuring 9x7mm. Subsequently, the patient underwent surgical excision. The resected specimen was submitted and further processed in our Pathology Department. Tissue paraffin-embedded sections were stained using routine Haematoxylin-Eosin, and complementary immunohistochemical reactions were performed.
Results: Microscopic examination revealed two distinct malignant cell populations separated by a clear transition zone. A squamous-cell carcinoma (SCC) was noted, characterized by plaques of atypical keratinocytes with abundant eosinophilic cytoplasm, marked nuclear pleomorphism, and focal keratin-pearl formation, which exhibited positivity for EMA. A second malignant proliferation was present less than 1 mm from SCC and was composed of basaloid cells with large hyperchromatic nuclei, peripheral palisading, and peritumoral retraction artifacts. The atypical basaloid cells were positive for BCL-2 and Androgen-Receptor. Additionally, a third neoplastic lesion, a melanocytic nevus, was identified nearby SCC. All surgical margins showed residual tumour cells.
Conclusion: Non-melanoma skin cancers (NMSCs) mostly arise on sun-damaged skin, with a particular predominance for head and neck region. CCT is an umbrella term that encompass a wide range of lesions including benign-benign, benign-malignant or malignant-malignant neoplasms. The most frequent CCT occurs between basal-cell carcinoma and a melanocytic nevus. Thus, the association of two distinct NMSCs within the same lesion is particularly rare, it may indicate a more aggressive behaviour. CCT are unique but well documented entities that usually pose diagnostic challenges to both clinicians and dermatopathologists.

E-PS-05-007

Basal cell carcinoma with a mysterious guest: dermal granuloma surrounding uninvited Demodex mites

A. Armega-Anghelescu[1,2], A.-R. Bucur[1,2], R.-M. Closca[1,2], A.-M. Vasile[1], L. Rus[3], D.S. Lupea Chilom[4,5], C.S. Solovan[6], F. Zara[1,2]
[1]Emergency City Hospital, Department of Pathology, Timisoara, Romania, [2]Victor Babes University of Medicine and Pharmacy, Department of Microscopic Morphology, Timisoara, Romania, [3]Emergency City Hospital, Department of General Surgery, Timisoara, Romania, [4]Victor Babes University of Medicine and Pharmacy Timisoara, Department of Dermatology, Timisoara, Romania, [5]Victor Babes University of Medicine and Pharmacy Timisoara, Department of Microscopic Morphology-Genetics, Centre of Genomic Medicine, Timisoara, Romania, [6]Emergency City Hospital, Department of Dermatology, Timisoara, Romania

Background & Objectives: This article presents the case of a 74-year-old male patient previously diagnosed with basal cell carcinoma on the zygomatic region of the face, with a dermal granulomatous foreign body inflammatory reaction suggestive for *Demodex* mites. As studies within the current existing literature suggest a possible correlation between demodicosis and basal cell carcinoma, we present a case of demodicosis gravis in order to raise awareness to a rare histopathological variant.
Methods: After the initial basal cell carcinoma diagnosis, the patient was admitted to the General Surgery Department of Emergency City Hospital in Timisoara, Romania. A surgical excisional skin biopsy was performed with a subsequent histopathological examination using morphological Haematoxylin–Eosin (HE) staining. Microscopic examination revealed incomplete surgical resection margins. Considering the incomplete histological margins, the patient was once again referred to the General Surgery Department of Emergency City Hospital in Timisoara, Romania for further surgical treatment. On this occasion, three excisional skin biopsies were performed on the remaining scar tissue and processed in the manner previously described.
Results: After staining with Haematoxylin–Eosin, microscopic examination of the skin fragments revealed a dermal granulomatous reaction with multinucleated foreign body giant cells surrounding suture material, as well as multinucleated foreign body giant cells, epithelioid cells

and lymphocytes surrounding microorganisms suggestive for *Demodex* spp. Dermal granulomas with phagocytized mite remnants in foreign body giant cells indicate a distinctive variant of demodicosis gravis. No further cancerous cells were identified.
Conclusion: Within the current existing literature, demodicosis is linked to various dermatoses and a possible correlation between demodicosis and basal cell carcinoma is also under inquiry. We present this case of demodicosis gravis in order to improve awareness to a distinctive histopathological variant with dermal granulomatous inflammatory reaction in a patient previously diagnosed with basal cell carcinoma.

E-PS-05-008
An unusual manifestation of extranodal Rosai-Dorfman disease
A.-B. Cutitaru[1,2], D.G. Ciobanu Apostol[3,2], C. Amalinei[1,4]
[1]Grigore T. Popa University of Medicine and Pharmacy, Morpho-Functional Sciences I - Histology, Iasi, Romania, [2]County Emergency Hospital "St. Spiridon", Pathology, Iasi, Romania, [3]Grigore T. Popa University of Medicine and Pharmacy, Morpho-Functional Sciences I - Pathology, Iasi, Romania, [4]Institute of Legal Medicine, Pathology, Iasi, Romania

Background & Objectives: Rosai-Dorfman disease (RDD) is a histiocytic disorder of uncertain aetiology. Though initially described as a lymph node disease, extranodal lesions can be the only manifestation, 10% of cases featuring soft tissue involvement. Multicentric and recurrent disease is exceedingly uncommon. The following case report features an unusual RDD presentation with recurrence.
Methods: We report a case of a 56-year-old man, which showed a loosely delineated subcutaneous occipitocervical mass, measuring 34/81/56 mm, with mobile superjacent skin on clinical examination and involvement of subjacent muscle without bone invasion on computed tomography. Surgical excision was performed. One month later, the patient showed on clinical examination a thoracic cutaneous nodular mass (13/11/7 mm), which was excised.
Results: Histopathology showed in the first (subcutaneous) sample a loosely distributed reactive histiocyte population without atypia, with epithelioid histiocytes with vesicular nuclei, foamy macrophages, some of them with intracytoplasmic lymphocytes (emperipolesis), rare multinucleated giant cells, associated with brisk inflammatory infiltrate. The histiocytic proliferation extended in the peripheral adipose and muscle tissue, without involvement of the lymph node structures. Histopathology showed in the second (cutaneous) sample a nodular, loosely delineated histiocytic proliferation without atypia in the deep dermis, which consisted of foamy macrophages, some with emperipolesis, epithelioid histiocytes, plasma cells, eosinophils, and neutrophils. Immunohistochemistry showed CD68+, CD163+ and SOX10- histiocytic proliferation, frequent S100+ macrophages, and Ki67+ in 15-20% of the lymphoplasmacytic infiltrate.
Conclusion: The samples' histopathology and immunophenotype revealed extranodal soft tissue RDD with cutaneous recurrence. The timeframe between the two lesions' debut was short (five months), but the first clinical and computed tomography examination did not objectify thoracic or other locations anomalies. Considering these findings, multicentric RDD was not a viable hypothesis. The only accurate conclusion pertains to soft tissue RDD recurrence, which is exceedingly rare and, according to our knowledge, with no other literature report of a cutaneous recurrence.

E-PS-05-009
Juvenile Scleroderma: diagnostic challenges and insights in a series case study
L. Nonnis[1], L. Pilloni[2,1], M. Vincis[1], D. Accalai[1], C. Gerosa[2,1], D. Fanni[2,1]
[1]State University of Cagliari, Pathology, Cagliari, Italy, [2]Cagliari University Hospital, Pathology, Cagliari, Italy

Background & Objectives: Juvenile scleroderma represents the third most frequent rheumatic condition in childhood, with an incidence rate of 0.34-0.9 cases every 100,000 children per year, age ≤16 years. JLS has a poorer outcome than LS, with high morbidity due to major disfigurement and functional impairment, while mortality is extremely rare. Histopathologic changes reflect stages of the localized skin disease but are limited by sampling bias, and repeated biopsies are inconvenient and discouraged. Regardless, they can be useful in cases with atypical skin presentation.
Methods: In our archive, we discovered 2 cases in the last 10 years of JLS with different clinical presentations: one presented a 1-year-old atrophic and sclerotic white area, while the second presented a 4-month-old pink patch lesion on the thigh that was slowly spreading to the leg. In both cases, a biopsy was performed for differential diagnosis. The samples, upon arrival, were fixed in formalin, processed, embedded in paraffin, and a traditional slide stained with haematoxylin and eosin was prepared.
Results: The slides showed fibrosis and sclerosis of the reticular and papillary dermis with a mild lympho-histiocytic inflammatory infiltrate with fibroblasts both peri-adnexal and perivascular, and with collagen cords sometimes invading the adipose tissue. The histologic presentation confirmed the diagnosis of JLS in an intermediate phase in both cases.
Conclusion: JLS is a broad disease and, in some cases, a very severe disorder that can become highly disabling. Most JLS patients who receive timely and appropriate treatment have a favourable prognosis, with most achieving remission on treatment. Early diagnosis is crucial, and even if a biopsy is not needed in most cases, when the clinical presentation and history are not decisive, histologic analysis and dialogue between the clinical team and pathology can be the best option for prompt diagnosis and treatment.

E-PS-05-010
Recurrent eccrine spiradenoma with malignant transformation: a diagnostic pitfall
O. Belhadj[1], I. Guesmi[1], M. Triki[1], M. Bouhamed[1], L. Bouzidi[1], T. Boudaouara[1], M. Mellouli[1]
[1]Habib Bourguiba University Hospital, Pathology, Sfax, Tunisia

Background & Objectives: Eccrine spiradenoma is a rare benign adnexal tumour, but malignant transformation (spiradenocarcinoma) poses significant diagnostic challenges due to overlapping histological features. We report a case of recurrent spiradenoma with malignant progression, emphasizing clinicopathological correlation.
Methods: A 48-year-old female presented with a 5-year history of a recurrent anteromedial right leg mass. Initial biopsy revealed cystic eccrine spiradenoma. Following recurrence, complete excision was performed. Comprehensive pathological evaluation included macroscopic examination, histopathological analysis with haematoxylin and eosin staining, and immunohistochemical studies (SMA, S100, CK7, CK18, Ki67). Diagnostic assessment incorporated WHO criteria for malignant transformation.
Results: Macroscopic evaluation identified two well-circumscribed subcutaneous nodules (2.2 cm and 1.5 cm) showing cystic degeneration and haemorrhagic changes. Histopathological examination demonstrated characteristic benign spiradenoma components juxtaposed with malignant transformation foci featuring tumour necrosis, nuclear atypia, and increased mitotic activity (7 mitoses per 10 high-power fields). Immunohistochemistry confirmed myoepithelial differentiation (SMA+, S100+) and epithelial origin (CK7+, CK18+), with a Ki67 proliferation index of 10% in malignant areas. Notably, the tumour extended to within 1 mm of the deep surgical margin.
Conclusion: This case illustrates several important aspects of spiradenocarcinoma diagnosis. First, the transition from benign to malignant features was abrupt, with distinct areas showing necrosis and increased

mitotic activity. The immunohistochemical profile, particularly the elevated Ki67 index in malignant foci, supported the diagnosis of transformation. Recent studies suggest that molecular markers such as p53 and MYB may provide additional diagnostic value in challenging cases, though these were not assessed in our patient. In conclusion, recurrent spiradenomas require thorough pathological evaluation to exclude malignant transformation. The combination of careful histological examination and targeted immunohistochemistry can facilitate accurate diagnosis. This case contributes to the growing literature on diagnostic criteria for this rare malignancy and highlights the need for long-term follow-up in such patients.

E-PS-05-011

Clinical and histopathological evaluation of urticaria pigmentosa: a retrospective study

G. FİKİR[1], G. Büyükekiz[1], M. Ordu[2], Ü. Türsen[2], Y. Yuyucu Karabulut[1]
[1]Mersin University, Pathology, Mersin, Turkey, [2]Mersin University, Dermatology, Mersin, Turkey

Background & Objectives: Urticaria Pigmentosa (UP) is the most common form of cutaneous mastocytosis, characterized by excessive mast cell accumulation in the skin. It primarily affects infants and young children but can also present in adults, sometimes with systemic involvement. This study aims to evaluate the clinical and histopathological characteristics of UP, emphasizing differential diagnosis and systemic associations.
Methods: A retrospective cohort study was conducted to assess the clinical and demographic characteristics of patients diagnosed with UP in our department between 2015 and 2025. Medical records were reviewed, and demographic, clinical, and histopathological data were collected.
Results: A total of 34 patients (17 males, 17 females) were included, with 80% (n=27) in the paediatric age group and 7 adults. Organ involvement was observed in 7 patients (20%), including 5 paediatric cases. Histopathological analysis revealed characteristic mast cell infiltrates in the dermis, confirmed by tryptase and CD117 immunohistochemistry. Our findings indicate a higher prevalence of systemic involvement in paediatric patients, suggesting a need for careful monitoring in this age group.
Conclusion: Our findings align with recent studies emphasizing that paediatric mastocytosis often presents with a higher likelihood of organ infiltration compared to adult-onset cases. The literature highlights that mutations in the **KIT** gene, particularly **KIT D816V**, play a crucial role in mast cell proliferation and disease progression. Additionally, elevated serum tryptase levels and persistent skin lesions have been correlated with an increased risk of systemic mastocytosis.
Given the chronic nature of the disease, long-term follow-up is essential, particularly in paediatric cases where disease progression may be unpredictable. Current guidelines recommend a multidisciplinary approach, including dermatological, haematological, and genetic evaluations, to ensure accurate diagnosis and timely management. Further studies are warranted to explore novel therapeutic targets and improve patient outcomes.

E-PS-05-012

Cutaneous metastatic lobular carcinoma: a pitfall diagnosis

B. Pastor[1], G.-N. Radu[1], A.C. Tinca[2,1], O.S. Cotoi[2,1]
[1]Mureș Clinical County Hospital, Pathology, Târgu Mureş, Romania, [2]University of Medicine, Pharmacy, Sciences and Technology George Emil Palade of Târgu Mureș, Pathophysiology, Târgu Mureş, Romania

Background & Objectives: Invasive lobular carcinoma (ILC) is a distinctive subtype of breast cancer that possesses unique clinical and pathological characteristics, such as its propensity to metastasize to atypical sites, although skin involvement remains relatively uncommon. When such cases arise, they often exhibit histological ambiguity due to a "single-file" pattern of cell infiltration, which can complicate detection during a biopsy and may lead to misdiagnosis as other dermatological conditions.
Methods: A sixty-eight-year-old female, with a history of invasive lobular carcinoma diagnosed in 2021 was admitted to the hospital for excision of a subcutaneous mass located in the presternal area. This mass had developed over a six-month period and was removed for aesthetic reasons. After the surgical excision, the specimen was sent to the Pathology department of Mureș County Clinical Hospital for further examination.
Results: On section, the received skin flap showed an imprecisely demarcated white area measuring 5x3mm. At microscopy, on usual stain we initially observed an abundant proliferation of collagen fiber bundles with irregular patterns resembling a pseudocicatriceal asppearance. However, after extensive examination, a single focus of tumoral growth was identified, consisting of a few small, discohesive cells with a characteristic “Indian file” arrangement. The tumour cells displayed eosinophillic cytoplasm with nuclear pleomorphism and were positive for CTK AE1/AE3, GATA3, ER and PR immunomarkers and negative for E-Cadherin. Based on morphology, immunohistochemistry and the pacient’s history, a diagnosis of cutaneous ILC metastasis was established.
Conclusion: Diagnosing skin metastasis of ILC presents significant challenges for pathologists due to its rare occurrence, atypical presentation, and unique growth pattern characterized by diffuse infiltration rather than discrete masses. As metastatic skin involvement can indicate advanced disease and impact treatment decisions, awareness remains critical. Future directions should focus on developing standardized diagnostic protocols and enhancing molecular profiling to differentiate ILC metastases from other dermatological conditions.

E-PS-05-013

Epithelioid melanoma of the breast in a male patient: a rare occurrence

S.-A. Vese[1], A.-C. Pop[1], A. Orosz[1], N. Orosz-Bogya[1], A. Vigdorovits[1], M.-M. Mureșan[1], A. Cămărășan[1], A. Pașcalău[1], O.L. Pop[1]
[1]Emergency Clinical County Hospital, Pathology, Oradea, Romania

Background & Objectives: Malignant melanoma is an aggressive neoplasm of melanocytes, primarily affecting the skin. Breast involvement is rare, particularly in male patients. When metastatic to the breast, it may present as a palpable mass or remain asymptomatic. Prognostic factors such as tumour thickness, depth of invasion, and tumour-infiltrating lymphocytes (TILs) play a crucial role in assessing metastatic potential and survival..We present the case of a 76 year-old man with an epithelioid melanoma of the breast.
Methods: A 76-year-old Caucasian male presented with a palpable, ulcerated mass in his right breast, evolving over six months. Initial evaluation included a detailed history, physical examination, and surgical resection of the breast lesion. Morphologic and immunohistochemical analysis was performed on the resected tissue, with staining for S100 and HMB45.
Results: On gross examination, the dark brown-coloured skin lesion, was ulcerated and measured 7 cm in its greatest dimension. On serial sections, the lesion infiltrated the breast parenchyma. On microscopic examination, an atypical melanocytic proliferation with heavy pigmentation and skin ulceration was observed. The tumour cells stained positive for S100 protein and HMB-45. Brisk TILs were identified.
Conclusion: Epithelioid malignant melanoma metastatic to the male breast is an exceptionally rare occurrence. Immunohistochemistry is crucial for diagnosis and prognosis, guiding both local and systemic treatment decisions. In such cases, optimal management includes wide tumour resection with axillary lymph node dissection, followed by

adjuvant systemic therapy. Case reports are essential for sharing diagnostic strategies and informing appropriate management approaches for such uncommon presentations.

E-PS-05-014

Rare and unusual locations of melanoma: a retrospective study

D.M. Marinoiu[1], S. Zurac[1], L. Sticlaru[1,1], C. Socoliuc[1], R. Andrei[1], R. Neagu[1], A. Cibotariu[1], R. Ionescu[1], L. Stanciu[1], A. Bordea[1], V. Marin[1], M. Cioplea[1]
[1]Colentina Hospital Bucharest, Pathology, Bucharest, Romania

Background & Objectives: Melanoma is a highly aggressive malignancy that primarily affects the skin but can also arise in mucosal and visceral locations. These uncommon presentations pose diagnostic challenges due to their rarity and potential for misdiagnosis. Mucosal and visceral melanomas tend to have worse prognoses compared to cutaneous melanomas due to late detection, aggressive histological features, and resistance to conventional therapies. This study aims to analyse melanomas in rare anatomical sites, highlighting clinicopathological features and the role of immunohistochemistry in diagnosis.
Methods: We retrospectively reviewed cases of melanoma diagnosed at the Clinical Hospital Colentina, Bucharest, between 2009 and 2025. From all diagnosed cases, we selected those with the most unusual locations. The study included nine patients (seven males, two females) aged between 57 and 80 years. The identified sites were the small intestine, rectum, anal canal, palatal mucosa, urinary bladder, ocular, vulva, and penis. Histopathological examination and immunohistochemical analysis were performed, utilizing markers such as HMB45, Melan A, PRAME, and AE1/AE3. Clinically, all cases were initially diagnosed as tumours, except for the vulvar melanoma, which was correctly identified as melanoma before histopathological confirmation.
Results: The cases showed morphological and immunohistochemical variability, predominantly epithelioid, with large tumour cells, abundant cytoplasm, vesicular nuclei, and prominent nucleoli. High mitotic activity and deep tissue invasion were observed, indicative of aggressive biological behaviour. Melanomas of the anal canal and small intestine were diagnosed at an advanced stage due to nonspecific symptoms, whereas intraocular and mucosal melanomas showed rapid progression despite early detection.
Conclusion: Melanomas in rare locations pose significant diagnostic and therapeutic challenges. Immunohistochemistry is crucial for accurate diagnosis, especially in tumours mimicking other malignancies. Early recognition, molecular testing, and a multidisciplinary approach are essential for improved outcomes.

E-PS-05-015

A rare tumour of skin: microcystic adnexal carcinoma - combined solid and eccrine epitheliomatous variants

G. Kolak Gözüküçük[1], H. Izol Özmen[1], P. Caşkan[2]
[1]Basaksehir Cam and Sakura City Hospital, Pathology, Istanbul, Turkey, [2]Basaksehir Cam and Sakura City Hospital, Plastic Reconstructive and Aesthetic Surgery, Istanbul, Turkey

Background & Objectives: We present a rare variant of microcystic adnexal carcinoma (MAC) on the scalp from a 66-year-old male patient.
Methods: Histological examination, including Haematoxylin and Eosin (H&E) staining, and immunohistochemical analysis (EMA, CEA, p40, SOX10, CK7, CK20, AR, and Adipophilin), were used to confirm the tumour's origin.
Results: H&E staining revealed a biphasic tumour in a sun-damaged skin. The superficial part of the tumour consisted of solid aggregates of neoplastic cells with nuclear atypia and mitotic figures. The deep part consisted of round ductal structures with bland cytology. The superficial part was positive for EMA and p40, while the luminal cells of the deep part were positive for EMA, CEA and p40. The morphological and immunophenotypical profile suggests a variation on the theme of microcystic adnexal carcinoma - combined solid and eccrine epitheliomatous variants. The alternative diagnosis would be squamous cell carcinoma with underlying syringoma, but the cytology is not obviously that of squamous cell carcinoma.
Conclusion: The solid variant of MAC is a rare skin tumour that usually occurs on the scalp. To our knowledge, this case is the first report of the combined solid and eccrine epitheliomatous variant of MAC. The risk of recurrence is very high in this tumour and Mohs micrographic surgery is the treatment of choice.

E-PS-05-016

Bleeding ulcerated pigmented nodule on the back: a case report

B. Bagoly[1], C. Gyömörei[1], G. Sipos[2], B. Kajtár[1]
[1]University of Pécs, Medical Centre, Department of Pathology, Pécs, Hungary, [2]Pápai Gróf Esterházy Kórház és Rendelőintézeti Szakrendelő, Department of Pathology, Pápa, Hungary

Background & Objectives: Pigmented lesions encompass a wide spectrum of benign and malignant melanocytic and non-melanocytic tumours. One of the latter is malignant melanocytic matricoma, an exceedingly rare adnexal neoplasm, that may mimic melanoma.
Methods: An 88-year-old female presented with an occasionally bleeding pigmented nodule on her back, that had been present for an unknown period of time. It was removed by simple surgical excision. Grossly, the lesion was a well-circumscribed, variably pigmented, ulcerated nodular mass.
Results: Histopathological examination revealed an asymmetrical nodular tumour composed of a mitotically active malignant epithelial component with obvious squamous differentiation and patchy matrical keratinization, intimately admixed with pigmented and dendritic melanocytes without significant nuclear atypia or mitotic activity. The neoplasm immunohistochemically showed the two lineages with appropriate markers. Additionally, there was both cytoplasmic and nuclear expression by beta-catenin. p53 was also strongly expressed. The combined CK AE1/AE3/Ki67 revealed brisk proliferative activity in the epithelial component, while nuclear immunoreactivity in the melanocytes was rare. The overall histologic features were consistent with malignant melanocytic matricoma. The immunohistochemistry results supported the diagnosis, and it was completed with next-generation sequencing (NGS) analysis, which revealed a mutation in the CTNNB1 gene.
Conclusion: Malignant melanocytic matricoma is a unique adnexal tumour. Despite the presence of architectural and cytological features of malignancy, the biological potential and the prognosis of malignant melanocytic matricoma is essentially unknown, with very few cases reported and limited clinical follow-up available. Further research is needed to better understand its biological behaviour and predict the clinical outcome.
Pathologists should be aware of this extremely rare entity when evaluating pigmented skin lesions to avoid misdiagnosis.

E-PS-05-017

Pleomorphic fibroma of he eyelid: a rare and unusual location of a benign entity

T. Kokturk[1], N. Reisli Attar[1], M.B. Hoşal[2], A. Okçu Heper[1]
[1]Ankara University Medical School, Department of Pathology, Ankara, Turkey, [2]Ankara University Medical School, Deparment of Ophtalmology, Ankara, Turkey

Background & Objectives: The pleomorphic fibroma (PF) of skin was first described by Kamino et al. in 1989 as a slow-growing lesion and clinically indistinguishable from a polypoid skin tag. They show loosely arranged spindle cells with large pleomorphic nuclei

but lacking mitotic activity. Herein we present a case in an unusual location.
Methods: Seventy-three-year-old male presented with a 4 mm cystic lesion extending to the conjunctiva in the right lower eyelid. It had appeared 12 years ago and remained the same size throughout. After total excision, the lesion examined by using routine pathological methods.
Results: Macroscopic examination revealed a 4x3x3 mm, nodular, cream-white coloured mass with on cut surface. On H&E; the lesion was polypoid in structure, with relatively well-circumscribed margins, and located immediately beneath the epidermis, extensively filling the dermis. It consisted of spindle cells with lightly swollen, oval nuclei, eosinophilic cytoplasm, and indistinct cytoplasmic borders, arranged in irregular bundles and storiform pattern within a fibrous stroma. There were also some multinucleated cells. Mitotic activity, significant inflammatory cell infiltration, epidermal involvement and ulceration were not observed. On immunohistochemical analysis the tumour cells were CD34 and Factor 13a positive. S100, STAT6, SOX10, CD68, CD163 were negative. The Ki67 proliferation index was 2-3%. Loss of Rb was detected.
Conclusion: PFs are rare, slow-growing tumours showing loosely arranged spindle cells with some large pleomorphic cells. They follow a benign clinical course. Diagnosis of PF requires few immunostains with typical expression CD34. However, it is important to consider that CD34 positivity can be seen in a couple of benign fibroblastic tumours. A PF located on the eyelid, which has been reported very rarely in this localization in the literature. This entity should be considered in any solitary slow-growing spindle cell tumours located even on an eyelid.

E-PS-05-018
Cylindroma arising after a human bite trauma: a case report
K. Şimşek[1], G.A. Ocak[1], I.E. Gurer[1]
[1]Akdeniz University, Pathology, Antalya, Turkey

Background & Objectives: Cylindroma is a rare benign adnexal tumour of eccrine or apocrine origin, typically located on the scalp and face. Although this condition is often associated with genetic mutations, particularly in the CYLD gene, trauma-induced cases have not been previously reported. This case presents the first instance of cylindroma developing following a human bite injury, suggesting that trauma might act as a potential trigger for tumour formation.
Methods: A 61-year-old female patient presented with a 3 × 3 cm mass on her right shoulder, beneath scar tissue from a previous human bite. The lesion was initially considered an epidermoid cyst or lipoma. The patient had a history of smoking, orthopedic knee surgery, and lipoma excision from the chest. The mass was excised without prior radiological evaluation.
Results: Histopathological examination revealed a solid, nodular mass composed of acinar structures with basaloid cell aggregates. Immunohistochemistry showed positive staining for CK7 and CK8, with a Ki-67 proliferative index of 8%. The diagnosis was confirmed as cylindroma.
Conclusion: This case describes the first reported occurrence of cylindroma arising after a human bite trauma. Although trauma is not commonly recognized as a causative factor, it may serve as a trigger for tumorigenesis in genetically predisposed individuals. Chronic inflammation and tissue remodelling following injury could contribute to tumour development. Cylindromas are usually slow-growing and have an excellent prognosis, with surgical excision being the standard treatment. Long-term monitoring is advised, especially in patients with multiple lesions or a genetic predisposition, such as Brooke–Spiegler Syndrome. This case represents the first documented instance of cylindroma arising after a human bite trauma in the literature. Further research is needed to establish a definitive association between trauma and cylindroma development.

E-PS-05-019
Histopathological assessment of fibrin sealants in burn injury treatment: insights from a rat model
E. Koniaris[1], C. Nikolaou[2], M. Frountzas[3], A. Paraskeva[1], D. Schizas[4], S. Kykalos[4], D. Iliopoulos[5], S. Ritsatou[1], E. Tsafa[1], G. Kafiri[1]
[1]Hippocration General Hospital, Pathology, Athens, Greece, [2]General Hospital of Athens "G. Genimatas", Athens, Greece, [3]Hippocration General Hospital, Athens, Greece, [4]Laikon General Hospital, Athens, Greece, [5]Laboratory of Experimental Surgery and Surgical Research "N.S. Christeas", Athens, Greece

Background & Objectives: Burn injuries constitute a significant health issue globally, requiring skilled management by trained plastic surgeons, which however, are not always available, implementing a need for alternative effective treatment methods that non-expert healthcare providers could use. This experimental study aimed to assess the safety and effectiveness of a fibrin sealant (TISSEEL™) compared to traditional treatment with sulfadiazine for partial-thickness burns in a rat model.
Methods: Sprague-Dawley rats underwent partial thickness contact thermal burn wound, divided into three groups: control group (no treatment), silver sulfadiazine cream group and TISSEEL™ group.
Following animal sacrifice, a blinded histopathologic analysis was performed to assess the inflammatory response, healing, and tissue regeneration. Haematoxylin-eosin staining was used as it can distinguish dermal structures. Fibroblastic proliferation was observed through Vimentin staining, known as the most effective marker for identifying fibroblasts. Moreover, neovascularization observed through the use of CD-31, a crucial marker for endothelial cells.
Results: In total, 30 animals were included with a median weight of 236 ± 10 g. Animals in the TISSEEL™ group presented dominant collagen expression compared to animals in the control and silver sulfadiazine cream group ($p = 0.000$). Histopathologic analysis also demonstrated marked leukocyte infiltration ($p = 0.009$), increased neovascularization ($p = 0.000$) and higher fibroblast expression ($p = 0.002$) in the TISSEEL™ group compared to the other two groups
Conclusion: TISSEEL™ appears to be a safe and effective choice for treating partial-thickness burn injuries. Thus, TISSEEL™ could be used in clinical settings for the initial treatment of partial-thickness burn injuries.

E-PS-05-020
Desmoplastic cutaneous squamous cell carcinoma: a scar simulator
A. Córdoba[1], L. Alvarez[1], I. Fernandez[1], G. De Lima[1], A. De Oliveira[1]
[1]Hospital Universitario de Navarra, Pathology, Pamplona, Spain

Background & Objectives: Desmoplastic cutaneous squamous cell carcinomas (DCSCs) are rare neoplasms that usually affect the sun-exposed skin of older people.
Microscopically, they are characterised by atypical and inconspicuous epithelial cells associated with a prominent desmoplastic stroma. To broaden this clinicopathological spectrum, we present 2 cases of an unusual variant of desmoplastic SCC.
Methods: These are two male patients aged 85 and 93 years respectively. They present in periorbital region and scalp with 3 and 2.5 cm crusted plaques.
Results: Both cases are characterised by isolated atypical cells, thin cords and spindle cells. Occasionally the cytoplasm is dense, squamoid. The stroma is very extensive and desmoplastic. The stroma accounts for more than 70 % of the tumour area. One case showed a large ulcer. One case showed associated actinic keratosis. Perineural invasion was observed in both cases. The squamous nature of the tumour was confirmed by p63.
Conclusion: Desmoplastic squamous carcinoma is a very aggressive subtype with extensive local infiltration that must be distinguished from other epidermoid carcinomas.

Confirmation of the squamous nature by immunohistochemistry is essential.
It shows a high proportion of perineural invasion.
It is difficult to diagnose due to the low cellularity in a very large stroma, simulating a scar.

E-PS-05-021
Periscrotal apocrine carcinoma with extensive pagetoid spread and nodal metastasis
C. Yoo[1]
[1]St. Vincent Hospital, The Catholic University of Korea, Department of Pathology, Suwon, Republic of Korea

Background & Objectives: Apocrine carcinoma is a rare and the axilla is the most commonly involved site. In particular, periscrotal occurrence is very rare and according to some reports, it is known to be accompanied by pagetoid spread.
Methods: The patient underwent three operations, and pathologic findings were observed in all of the periscrotal masses, scrotum skin, and inguinal lymph nodes.
Results: A 41-year-old male patient visited the hospital because of various masses around the scrotum. On physical examination, several verruciform masses were observed on the right side of the penis, and skin involvements were also suspected in the left side of scrotum. It is said that the mass grew gradually over the years. The sizes of submitted masses were 4.5x3.0cm, 5.5x4.0cm, and 5.0x1.5cm, respectively. Macroscopically, these masses showed a gravel-shaped surfaces. Histologically, a mass in the form of adenocarcinoma infiltrating the dermis was observed, and it was accompanied by extensive pagetoid spread looking similar to extramammary paget disase in most of the specimens. Dermal adenocarcinoma showed well-differentiated tubular form, and in some tubules decapitation secretions were also observed along with the abundant eosinophilic cytoplasm, leading to the estimation of the origin of apocrine glands. Immunohistochemical staining was positive for CEA, CK7, GCDFP-15, androgen receptor, and EMA. These findings were combined and diagnosed as apocrine carcinoma. Subsequently, part of the scrotum skin was further resected, and only extramammary paget disease-like findings were confirmed here. Radiologically, bilateral inguinal lymph node metastasis was suspected and surgery was performed, and metastatic carcinoma was histologically confirmed.
Conclusion: One report shows a pagetoid spread in about half of this carcinoma. In another report, apocrine carcinoma is cited as an example as the underlying disease of extramammary paget disease. This case is reported to be shared because it shows extensive pagetoid spread and nodal metastasis with apocrine carcinoma.

E-PS-05-022
A rare case of oseteocartiligious differentiation in metastatic melanoma
A. Nolan[1], S. Phelan[1]
[1]Galway University Hospital, Histopathology Department, Galway, Ireland

Background & Objectives: Metastatic melanoma has been called the great mimic, and rightly so. Melanoma can exhibit a wide variety of histological patterns, which can confound diagnosis, and transdifferentiation of melanoma to a variety of sarcomatoid and carcinomatous phenotypes is described. We present a case of a rare variant of sarcomatoid metastatic melanoma post immunotherapy, with osteosarcomatous and chondrosarcomatous components.
Methods: n/a
Results: 51 year old male initially presented with acral melanoma of left little toe. A sentinel lymph node resection of the patient's left groin showed a single 0.5mm deposit of metastatic melanoma. A plan was made for 3 monthly ultrasound follow-up and he was commenced on anti-PD1 therapy (Pembrolizumab). Unfortunately, he re-presented the following year with groin swelling and underwent groin dissection. Five of twelve lymph nodes resected contained metastatic melanoma, along with three dermal in-transit metastases. No histological evidence of response to therapy was seen. The melanoma in the repeat resections showed extensive areas of sarcomatoid changes, with metaplastic chondrosarcoma and osteosarcoma present. These changes were not present in the primary tumour.
Sox-10 and HMB-45 immunohistochemistry (IHC) was positive in the areas of conventional melanoma, but expression was lost in the sarcomatoid areas. No BRAF or NRAS mutations were detected.
Conclusion: This is a case of malignant osteochondroid differentiation within metastatic melanoma. Osteochondroid differentiation is rarely observed in primary and metastatic melanomas, with most lesions arising in acral/subungual and mucosal locations, as in our case.
Transdifferentiation is a well-documented feature of melanoma, which can cause diagnostic difficulty and is often associated with loss of expression of melanocytic markers by immunohistochemisty. Awareness of this unusual morphology is essential to avoid misdiagnoses.
Of note, there was no evidence of treatment effect post-immunotherapy in this case. The role of immunotherapy in sarcomatoid melanoma may warrant further investigation.

E-PS-05-023
Modern aspects of melanoma diagnosis and treatment
A. Barikian[1], N. Khvichia[1], T. Jorbenadze[1], N. Khujadze[1]

[1]Clinical Pathology Centre, Pathology, Tbilisi, Georgia
Background & Objectives: Melanoma of the nail apparatus is a variant of acral lentigo melanoma. This form of melanoma is not associated with exposure to sunlight. It is rare. In 0.7% - 3.5% of cases, the tumour is malignant. It occurs in all racial groups, predominantly in African-Americans and Asians. In particular: in the African population 75%, in China - 25% and in Japan - 10%.
Methods: We report a case of a old female in her 7^{th} decade of life referred to the clinic, purulent surgeon, phlegmon of the first toe of the left ankle. After removing the nail, during examination of the bed, melanoma was suspected, there was a black formation, a biopsy was taken. A digital PET/CT scan was performed. We actively sought clinical information, including medical and family history, to facilitate accurate diagnosis.
Results: H&E sections revealed fragments of stratified squamous epithelium, adjacent fibrous-connective tissue, excessive pigment, as well as proliferation of epithelioid unsaturated cells of round, large cells, nuclear hyperchromasia, dusty pigmented cytoplasm, which are presented diffusely and in the form of nests, mitotic figures. The tumour cells were positive for Melan A, S100, HMB45, Ki67 index was $\geq$ 50%. Examination of mutations in tumour tissue: BRAF - 50%: NRAS – 20%: KIT Mutational analysis 5%.
Conclusion: Acral lentiginous melanoma is rare, accounting for no more than 5% of all types of melanoma. This type of disease is characterized by the appearance of a malignant lesion on closed areas of the skin, under the nail plates, which excludes the usual effect of ultraviolet and ionizing radiation for the appearance of melanoma. Another difference between acrolentiginous melanoma and other forms of pathology is the absence of the influence of nevi. An unfavourable prognosis also depends on the high risk of metastases penetrating the internal organs at the initial stages.

E-PS-05-024
Integrating three-dimensional histopathology with bread loafing and orientation preservation without artificial coloring
N. Zila[1,2], P. Tschandl[2]
[1]University of Applied Sciences FH Campus Wien, Department of Health Sciences, Section Biomedical Science, Vienna, Austria,

[2]Medical University of Vienna, Department of Dermatology, Vienna, Austria

Background & Objectives: Basal cell carcinoma (BCC) is a common form of non-melanoma skin cancer (NMSC) that, despite its rare metastasis, can cause significant morbidity through tissue infiltration. Due to its proximity to critical anatomical structures, precise control of resection margins is essential. However, thorough margin examination in small excisions may compromise the central tumour assessment. We propose a novel method that combines three-dimensional (3D) histopathology with bread loafing to address this challenge and reduce the risk of recurrence.
Methods: In our technique, the specimen is first incised during macroscopic work-up for optimal dehydration, ensuring correct orientation. The excision is then divided during embedding with aligned cutting planes, and the spindle tips are centrally divided. The bread loafing step involves tilting the narrow cutting planes toward the lesion and folding the spindle tips outward for 3D margin assessment. Additionally, we propose preserving orientation without tissue coloring by leaving the sample intact during initial grossing, keeping suture markings, and avoiding dissection during macroscopy.
Results: While established techniques have certain limitations, our approach combines their strengths and mitigates their weaknesses. 3D processing supports margin control in narrow specimens but may overlook central tumour evaluation. Bread loafing facilitates central lesion assessment but doesn't fully capture lateral margins. Our combined method optimizes both, potentially reducing recurrence risk while sparing healthy tissue. Although based on theoretical estimations, follow-up studies comparing techniques are needed to confirm whether the increased tip coverage in our method leads to better clinical outcomes.
Conclusion: Having successfully integrated our technique into routine histology practice, the next step is to retrospectively evaluate its performance, which we are currently in the process of doing.

E-PS-05-025

The prognostic value of PRAME, P16 and Ki-67 for metastatic risk in early stage melanomas in the D-ESMEL study

G. Asri Aghmuni[1], C. Zhou[2], A. Nigg[1], T. van den Bosch[1], S. Aksu[1], T. Kerkour[2], A. Mooyaart[1], L. Hollestein[2]
[1]Erasmus MC Cancer Institute, Pathology, Rotterdam, The Netherlands, [2]Erasmus MC Cancer Institute, Dermatology, Rotterdam, The Netherlands

Background & Objectives: Cutaneous melanoma is an aggressive skin cancer with a high risk of metastasis. Despite early detection, many stage I and II patients remain at risk of recurrence, with a significant proportion experiencing relapse within five years. Traditional prognostic models rely on clinicopathological factors such as Breslow thickness and ulceration, but emerging molecular biomarkers may improve risk assessment. Preferentially Expressed Antigen in Melanoma (PRAME), Ki-67, and p16 have shown potential in refining melanoma prognostication. This study evaluates their prognostic value in predicting metastatic progression, aiming to enhance risk stratification and guide clinical decision-making.
Methods: Formalin-fixed paraffin-embedded tissue blocks from stage I/II melanoma cases were analysed using samples from the Dutch Early-Stage Melanoma Study (D-ESMEL), a population-based matched case-control study. Cases and controls were matched on key prognostic factors. Immunohistochemical staining was performed for PRAME, Ki-67, and p16. PRAME and P16 were assessed by a pathologist and resident, while Ki-67 positivity was detected using a specialized app. Paired analyses was used to explore the relationship between biomarker expression and melanoma progression.
Results: PRAME expression was higher in melanoma cases than controls, with dermal positivity and intensity increasing in metastatic cases (OR=1.82, 95% CI: 0.94–3.93, p=0.129; OR=1.43, 95% CI: 0.59–3.46, p=0.432), though neither was statistically significant. P16 expression was significantly lower in metastatic cases (p=0.012), and clonal loss was associated with increased metastatic risk (OR=2.05, 95% CI: 1.23–3.41, p=0.007). Ki-67 expression showed no significant difference but trended higher in metastasized cases (OR=1.023, 95% CI: 0.99–1.06, p=0.140).
Conclusion: P16, particularly clonal loss, is a significant prognostic marker for melanoma progression and metastatic risk. Further validation and clinical implementation of this biomarker is needed to improve risk stratification and guide clinical decision making in melanoma management. PRAME and Ki-67 did not demonstrate strong predictive value.

E-PS-05-026

Advanced nonscarring alopecia associated with longstanding dermatomyositis, calcinosis cutis and porokeratosis in an elderly female, masked by disease-modifying treatment: a case report and discussion

F. Kubba[1], C. Duhovic[2], I. Wamuo[3]
[1]University College London Hospitals NHS Foundation Trust, Cellular Pathology, London, United Kingdom, [2]Whittington Health NHS Trust, Dermatology, London, United Kingdom, [3]Whittington Health NHS Trust, Rheumatology, London, United Kingdom

Background & Objectives: A 70-year-old Caucasian female with a 30-year history of dermatomyositis (DM) associated with anti-NXP2 antibody, presented with a 4-year history of alopecia starting in the central/parietal scalp. She noticed hair falling in clumps following Methotrexate treatment. She was on Azathioprine, intravenous immunoglobulin (IVIG) and high dose Prednisolone. Examination showed shiny, smooth parietal and frontal scalp with scarring, mild erythema and scaling in the occiput. She had subcutaneous nodules and bilateral eczematous leg lesions, consistent with porokeratosis. She had history of muscle weakness, Whipple procedure for pancreatic intraductal papillary mucinous neoplasm, type 1 diabetes mellitus, dietary iron and zinc deficiency, hypertension and heart failure.
Methods: One scalp 4mm punch biopsy showed three terminal hair follicles, two vellus follicles and two stelae. The epidermis was intact. The other punch was tangentially embedded and showed three terminal hair follicles and seven stelae with one catagen follicle, and severe elastosis in the upper dermis. No significant or inflammation or fibrosis was noted. Alcian blue stain confirmed mucin deposition. The epidermis showed mild hyperkeratosis and the basal layer was intact. The skin nodules showed calcinosis cutis.
Results: Scalp involvement is present in around 12.8% of DM patients, about 30-40% of which have alopecia. DM alopecia is usually a diffuse nonscarring type, with vacuolar interface dermatitis, increased reticular dermal mucin and perivascular lymphocytes. Cases of alopecia areata and universalis have been reported in association with DM. Medications such as steroids, Cytotoxic drugs and IVIG are known to modify the inflammatory process, as in our patient.
Conclusion: We have presented a case of advanced nonscarring alopecia associated with longstanding dermatomyositis severe, showing dermal elastosis and absent basal epidermal vacuolar degeneration. Long term steroid and cytotoxic therapy may have masked the usual interface epidermal findings and it is important to correlate this with the clinical history to reach the correct diagnosis.

E-PS-05-027

Favre-Racouchot syndrome: case report

E. Kuzucular[1], N.E. Kore[1], Ö. Yalçin[1]
[1]Prof. Dr. Cemil Taşcıoğlu Şehir Hastanesi, Pathology, Istanbul, Turkey

Background & Objectives: Favre-Racouchot syndrome is a disease of elderly male that develops due to chronic sun exposure. It is also known

as nodular elastosis with cyst and comedones. The etiopathogenesis is not known but chronic sun exposure, smoking, radiation and physical agents are proposed predisposing factors.
Methods: We report a case of 70 year old male who presented with dark coloured raised lesions along with thickening of facial skin which was increasing progressively.
Results: Physical examination showed the presence of thickened inelastic skin along with deep furrows and wrinkles involving the entire face. Histopathological examination epidermis showed epidermal cyst formation containing laminated keratin and superficial dermis shows follicular infundibular plugging and large nodules filled with keratinous material.
Conclusion: We present an elderly male patient who was diagnosed to have Favre-Racouchot syndrome with typical distribution of the comedones on the face and years of heavy smoking history. Our patient's findings were quite demonstrative of Favre-Racouchot syndrome.

E-PS-05-028
Porokeratosis in skin biopsies: insights and challenges from the experience of university histopathology service
M. Bosic[1], E. Manojlovic Gacic[1], D. Petrovic[1,2], J. Stojkovic FIlipovic[3,4]
[1]Institute of Pathology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia, [2]Institute of Oncology and Radiology of Serbia, Belgrade, Serbia, [3]Faculty of Medicine, University of Belgrade, Department of Dermatology and Venereology, Belgrade, Serbia, [4]University Clinical Centre, Clinic for Dermatology and Venereology, Belgrade, Serbia

Background & Objectives: Porokeratosis is a rare genodermatosis characterized by cornoid lamella on histopathology and an increased risk of malignant transformation, particularly in certain clinical forms, longstanding lesions, and immunosuppressed patients. This study examines the incidence and major characteristics of porokeratosis patients diagnosed at university.
Methods: We retrospectively analysed porokeratosis cases diagnosed at the Institute of Pathology, Faculty of Medicine, University of Belgrade in the period 2016-2024 and evaluated demographics, clinical presentation, and histopathological findings.
Results: Only 27 biopsies from 22 patients were diagnosed as porokeratosis in the examined period, with an annual incidence of $\leq$0.17% in skin biopsies. Porokeratosis was more common in women (68.2%) and older individuals (median age: 70 years, range: 18–86). Clinical misdiagnosis occurred in six patients (27.3%), often as skin tumours. Inflammatory skin diseases were a frequent differential diagnosis (27.3%). Lesions were mostly multiple and regionally restricted (50%), usually on legs, though some were disseminated (27.3%) or focal (on leg, face, chest, or back) (22.7%). Disseminated superficial actinic porokeratosis (DSAP) was the most frequent clinical form (68.1%), followed by porokeratosis of Mibelli (12.5%), with rarer forms (combination of DSAP and Mibelli forms, linear, follicular, palmoplantar) seen in single cases. The two youngest patients (age 18 and 19 years) presented with focal lesions on the face as Mibelli form. Neoplastic transformation was observed in five DSAP cases, with actinic keratosis more common than squamous cell carcinoma (4:1). Retrospective analysis found porokeratosis was suspected but not histologically confirmed in 15 additional patients. One patient diagnosed in 2008 was later found to have porokeratotic eccrine ostial and dermal duct nevus, an entity frequently debated as a form of porokeratosis.
Conclusion: Porokeratosis is exceptionally rare, even in a university setting. DSAP is the most common form, with a risk of neoplastic transformation, mainly into actinic keratosis, highlighting the need for accurate diagnosis.

E-PS-05-029
Molecular profile of cutaneous melanomas in an Algerian population
W. Ouahioune[1], N. Moulai[1]
[1]Faculty of Medicine of Blida 1 University, Medecine Department, Laboratory of Cancer Research, Blida, Algeria

Background & Objectives: In Algeria, cutaneous melanoma remains rare and its molecular profile is poorly understood. This study aims to investigate the molecular profile of cutaneous melanoma in an Algerian population.
Methods: We analysed the molecular profile of 52 cutaneous melanomas. Immunohistochemistry (IHC) was performed in 30 patients using the Ventana VE1 antibody. Real time Polymerase Chain Reaction (RT-PCR) was conducted in 45 cases using the BRAF Threscreen Qiagen kit to detect the V600 allele. Next-generation sequencing (NGS) was performed in 7 patients using the Oncomine^{TM} Focus Panel (ThermoFisher).
Results: Our samples consisted of 41 primary tumours and 11 metastasis from 28 men and 24 women. The mean age was 51.82 years (range: 14-86 years). Histological types included: nodular melanoma NM (15 cases), acral lentiginous melanoma ALM (11 cases), superficial spreading melanoma SSM (11 cases), lentigo maligna melanoma LMM (1 case), unclassifiable melanoma (3 cases). 47 patients presented with locally advanced or metastatic disease. By IHC, 27 patients expressed BRAF. RT- PCR revealed BRAF mutations in 30 patients.
We assessed the concordance between IHC and RT-PCR in 30 patients; results were concordant in 25 cases; Chi2 test: $p < 0.0001$. NGS performed identified one case of BRAF mutation and one case of NRAS mutation. The molecular profile according to histological type: NM: 7 BRAF+; ALM: 6 BRAF+ and 1 NRAS+; SSM: 9 BRAF+, LMM: BRAF-, Unclassifiable melanoma: All BRAF+. Among the 11 metastasis, 6 presented with BRAF mutations.
Conclusion: This study represents the first molecular profiling of cutaneous melanomas in Algeria. Our findings demonstrate a high proportion of patients with locally advanced or metastatic disease at diagnosis. BRAF mutations were identified in 54.54% of ALM, which contrasts with findings in litterature. Statistical analysis revealed significant concordance between immunohistochemistry and RT-PCR results, supporting the utility of immunohistochemical assessment as a primary screening approach for BRAF V600E mutations.

E-PS-05-030
Metastatic porocarcinoma resolved with patient history and molecular analysis – a case report illustrating experience of a university consultation service
M. Bosic[1], M. Jovanovic[1], S. Glumac[1], D. Petrovic[1,2], I. Petrovic[1], M. Dencic Fekete[1], M. Komnenic Radovanovic[1], A. Golubovic[3], F. Markovic[3]
[1]Institute of Pathology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia, [2]Institute of Oncology and Radiology of Serbia, Belgradeserbiase, Serbia, [3]University Clinical Centre of Serbia, Clinic for Pulmonology, Belgrade, Serbia

Background & Objectives: Porocarcinoma is a rare malignant tumour of skin appendages with well-defined genetic features. Up to a third of cases metastasize mostly to regional lymph nodes. The main predictors of metastatic potential are increased mitotic activity (>8 per square millimetre) and high tumour thickness (over 7 mm). Here, we describe

the evolution of metastatic porocarcinoma in a patient and show the importance of patient history in the diagnostic process.
Methods: We described histopathological, immunohistochemical, and molecular features of primary and metastatic porocarcinoma.
Results: An axillary skin tumour in a 58-year-old woman was referred for a consultation from a regional hospital. It was composed of epithelioid solid nests occupying epidermis and dermis, with focal ductal formation and prominent mitotic activity (15 per square millimetre). The final diagnosis of porocarcinoma was based on the expression of CK7, p63, pCEA, and EMA, and on the rearrangement of *WWTR1* gene; no expression of NUT was identified. Tumour thickness was 5 mm (AJCC 8th Ed.; 7.5 mm AJCC 7th Ed.). After 16 months, patient was admitted at University Clinical Centre with tumours in axillary skin and pleura but with a history of cutaneous squamous cell carcinoma; the data on true nature of primary tumour was lost. Samples were received for a consultation, and on both sites, tumour cells with abundant, focally clear cytoplasm were organized in strands and glands. Immunohistochemical features could not exclude triple-negative breast carcinoma (CK7+, GATA3 + focally, GCDFP15+, TRPS1+, Mammaglobin-, ER-, PR-, HER-2-). Access to our digital archive revealed true nature of metastasis, and porocarcinoma metastases were confirmed with WWTR1 rearrangement using FISH in both samples.
Conclusion: Breast carcinoma represents the main diagnostic dilemma in the cases of metastatic porocarcinoma. Preservation of medical history and good clinical communication can prevent excessive use of immunohistochemistry; a simple WWTR1 FISH analysis is enough to confirm porocarcinoma metastasis.

Funding: This research was supported by the Ministry of Science, Technological Development and Innovation of the Republic of Serbia and the Faculty of Medicine, University of Belgrade, project No. 451-03-66/2024-03/200110

E-PS-05-031
Columella nasal isolated cutaneous sarcoidosis mimicking a cancer in phototype 1 caucasian patients: a rare presentation
A.V. Pagliari[1]
[1]U.O. ORL ASST Crema, Dipartimento di Chirurgia ASST Crema, Crema, Italy

Background & Objectives: Sarcoidosis is a chronic inflammatory disorder that occur that occur in all age, sex ethnicity and race with peaks in the third and fourth decades followed by the sixth decades and a high incidence among black women. Although the lower respiratory tract is affected in 90% of cases head and neck location are very uncommon with a prevalence varying between 1 % and 6,5%. Cutaneous locations involving the face and neck are present in 25% to 35% of patients with systemic disease, but may also be isolated
Methods: A caucasian man in his 40s phototype 1 was referred for a firm and nonpainful papulonodular isolated nasal columella skin lesions no associated to endonasal pathology. The lesion was radically excised and columella reconstructed using flip over buccal mucosa flap.
Results: Histological examination showed the presence of granulomas noncaseating characterized by aggregates of epitheliod histiocytes with abundant eosinophilic cytoplasm without lymphocytes or inflammatory cells and absence of necrosis. Multinucleated giant cells were also present with asteroid bodies, eosinophilic starbust lesione, and Schaumann bodies, laminated cytoplasmatic calcification. Periodic acid Shiff, Grocott and Zielh stains were negative. The patient workup including thorax computed tomography, pulmonary function electrocardiogram and ophthalmologic examination were negative.
Conclusion: Sarcoidosis is a multiorgan disease with high levels of cutaneous involvement. Head and neck isolated cutaneous fist manifestation of disease is unusual. This can be challenging for a timely diagnosis to treat those a chronic and progressive disease. It is a diagnosis usually made following the evolving findings of both clinical and investigatory test. In cases of nasal papulonodular lesions the diagnosis remains doubtful and local biopsy is useful. However despite various medical treatments complete disappearance was never obtained.

E-PS-05-032
Botryomycosis in the leg of a farmer: unveiling diagnostic challenges
K.V. Cruz Ramirez[1], A. Rueda Herrera[2], M.C. Rolon Cadena[2], J.D. Serrano Arias[2]
[1]Fundación Santa Fé de Bogotá, Pathology, Bogotá, Colombia, [2]Fundación Santa Fé de Bogotá, Pathology, Bogota, Colombia

Background & Objectives: Botryomycosis is a rare, chronic granulomatous bacterial infection primarily affecting the skin but can occasionally involve visceral organs. The main causative agent is *Staphylococcus aureus*, with less common involvement from other bacteria like *Pseudomonas spp.*, *Escherichia coli*, *Proteus spp.*, and *Streptococcus spp.* It is characterized by granule formation due to the pathogen's low virulence, an intermediate inoculum, and the host's immune status. The condition involves the Splendore-Hoeppli phenomenon, where antigen-antibody reactions cause granuloma formation. Botryomycosis can mimic neoplastic, fungal, or actinomycotic infections. Lesions usually appear as nodular, purulent masses that may develop fistulas. The cutaneous form has a better prognosis than the visceral form. Risk factors include cystic fibrosis, immune disorders, chronic granulomatous disease, diabetes, and HIV, making it a rare opportunistic infection.
Methods: This case report describes the diagnosis, clinical presentation, and management of a patient with botryomycosis, a rare chronic granulomatous bacterial infection. We present a detailed analysis of the clinical, microbiological, and histopathological findings associated with the condition, as well as the treatment approach.
Results: We report the case of a 66-year-old male with a six-month history of a mass in his left leg. Physical examination revealed a 3 cm resilient mass on the anterior thigh, initially suspected to be a lipomatous lesion, which was subsequently resected. Histopathological analysis revealed multiple fragments of skin and soft tissue with pronounced acute abscess formation. The abscesses contained moderate-sized bacterial colonies displaying the Splendore-Hoeppli phenomenon—granules encapsulated within an eosinophilic matrix, as seen in Gram-stained samples. Ziehl-Neelsen, PAS, and Gomori methenamine silver stains did not identify fungal microorganisms or mycobacteria.
Conclusion: Following prophylactic antibiotic therapy and surgical excision, the patient showed favourable progress, with complete resolution of the lesion. This case highlights the clinical challenges in identifying the lesion's nature and underscores the importance of accurate diagnosis.

E-PS-05-033
CR-1 expression of cutaneous melanoma tumour cells and correlation with histopathologic and prognostic parameters
A.M. Önenerk Men[1], A.H. Namal[2], Ö. Aydin Ülgen[1], H. Turna[3]
[1]Istanbul University Cerrahpasa-Cerrahpasa Medical Faculty, Pathology, Istanbul, Turkey, [2]Akşehir State Hospital, Pathology, Konya, Turkey, [3]Istanbul University Cerrahpasa-Cerrahpasa Medical Faculty, Medical Oncology, Istanbul, Turkey

Background & Objectives: Melanoma is a malignant tumour that can be seen in any organ where melanocytes are found, especially in the skin, and has a poor prognosis in advanced stages. Our study aimed to investigate the immunohistochemical expression of CR-1, an oncofoetal protein, and its relationship with clinicopathological parameters in cutaneous melanoma cases.

Methods: Cutaneous melanoma cases diagnosed at Istanbul Cerrahpaşa University-Cerrahpaşa Medical Faculty Hospital between January 2016 and January 2023 were scanned from the system. Immunohistochemical CR-1 stain was applied to all cases and the results were compared with clinicopathological parameters.
Results: 78 cutaneous melanoma cases diagnosed between January 2016 and January 2023 were included in the study. CR-1 expression was observed in melanoma cells in 9% (n=7) of the cases. Although statisticaly insignificant, CR-1 positive tumours were mostly located on the intermittantly sun exposed skin (57.1%; n=4), pT4 (71.4%; n=5), without regression (71.4%; n=5), low density of tumour infiltrating lymphocytes (71.4%; n=5), and wtBRAF p.V600 tumours (85.7%; n=6). While the average survival was 16.5±11.6 months in CR-1 positive cases and 39.4±3.9 months in CR-1 negative cases, this result was not found to be statistically significant.
Conclusion: CR-1 is a candidate protein for targeted therapy because it is an oncofoetal protein and its expression is shown to be increased in malignancies while its expression is low/absent in normal adult tissues. In this study, immunohistochemical expression of CR-1 expression was investigated in cutaneous melanoma cases and it was found to be not associated with clinicopathological parameters.

E-PS-05-034
Lichen Sclerosus mimicking clinical atrophic variant of mycosis fungoides in persistent 2-year evolution dermatosis: a case report
C. Faria[1], M.F. Estrela[1], V. Carneiro[1], J.C. Cardoso[2]
[1]Hospital do Divino Espírito Santo de Ponta Delgada, Pathology, Ponta Delgada, Portugal, [2]Centro Hospitalar e Universitário de Coimbra, Dermatology, Coimbra, Portugal

Background & Objectives: Lichen sclerosus (LS) is a chronic skin condition predominantly located in the anogenital area, although 15-20% of cases may present in the extragenital form.
The latter is a challening diagnosis due to clinical overlap with other dermatoses, including cutaneous T-cell lymphoma.
Methods: A 45 year-old woman presents a persistent and progressive dermatosis, with approximately 2 years of evolution. Clinically, it shows a cephalo-caudal distribution, consisting of erythematous-brown reticulated spots, with occasional confluence and bright surface.
No associated symptoms were described. Several biopsies were performed during this period without a definitive diagnosis.
Results: Mixed connective tissue disorder and atrophic variant of mycosis fungoides were the main clinical differential diagnosis. However, histopathological examination revealed a slightly atrophic epidermis with foci of acanthosis. The papillary dermis is partially occupied by a band of hyaline, sclerotic tissue, with some dilated capillaries. In the reticular dermis, there is a perivascular and interstitial inflammatory infiltrate, predominantly composed by lymphocytes and histiocytes.
The immunohistochemical study confirms the predominance of T cells in the infiltrate as shown by CD3, which also highlights mild exocytosis between the basal keratinocytes of the epidermis. CD20 reveals few B cells, exclusively in the dermal infiltrate.
Conclusion: Lichen Sclerosus was the final diagnosis, even with this unusual clinical presentation. Despite the mild exocytosis, there were not histopathological findings that could confirm the suspicion of mycosis fungoides.
The aetiology of LS remains unclear, however, some Borrelia species have been detected in lesional skin. This can also lead to controversial association with morphea, as the diagnosis of LS has also been reported in patients with coexisting autoimmunediseases.
Therefore, clinical and histopathological correlation remain essential for the correct diagnosis.

E-PS-05-035
PRP and hyaluronic acid in treatment of vulval lichen sclerosus et atrophicus – a case report
M. Bosanac[1], M. Kilibarda[2], J. Amidžić[1,3], B. Andrejić Višnjić[1], D. Biro[4]
[1]Faculty of Medicine, University of Novi Sad, Histology and Embryology, Novi Sad, Serbia, [2]General Hospital Vrbas, Gynaecology and Obstetrics with Neonatology, Vrbas, Serbia, [3]General Hospital Vrbas, Pathology and Cytology, Vrbas, Serbia, [4]Clinic Elpida Derm Belgrade, Belgrade, Serbia

Background & Objectives: Lichen sclerosus et atrophicus (LSA) is a rare condition whose incidence in genital area is 1.5% to 2.5%.
Methods: A 62-year-old female patient complained of itching and pricking in the vulva area. After the initial biopsy and diagnosis of LSA, the indicated therapy is a combination of injections of platelet-rich plasma (PRP) and 1 ml of hyaluronic acid given once a month for a period of 3 months, and after three months (6 months from the first therapy) a control biopsy is performed. Initial and control biopsies were histologically processed using haematoxylin and eosin (HE), Mallory's and Orcein staining.
Results: Before treatment, perianal sclerotic-atrophic plaques were present, while the vulva had circular, erythematous and mildly atrophic plaques. Histopathological examination of initial biopsy showed hyalinization of the papillary dermis with vacuolar alteration of epidermis basal cells. Also, fragmented collagen fibres are observed, as well as the lack of elastic fibres and blood vessels in the papillary dermis. After treatment, we observed a pale erythema around the vulva, while perianally erythematous plaques with lesser degree of atrophy were predominant. On the control biopsy the absence of hyalinization of the papillary dermis and vacuolar alteration of epidermal basal cells were observed. Collagen fibres are arranged in a honeycomb pattern, while elastic fibres and blood vessels appear in the papillary dermis.
Conclusion: Therapy with a combination of PRP and hyaluronic acid after only 6 months led to a significant reduction of both macroscopically and pathohistologically verified changes.

E-PS-05-036
Sarcomatoid carcinoma associated with a poroid neoplasm (Sarcomatoid porocarcinoma): an extraordinary case report
L. Moscoso[1], A. Orellana[1], M. Pozo[1], J.C. Garcés[1]
[1]National Oncology Institute Dr. Juan Tanca Marengo, Pathology Department, Guayaquil, Ecuador

Background & Objectives: Primary cutaneous sarcomatoid carcinomas are rare tumours, mostly arising in association with basal cell carcinoma or squamous cell carcinoma. Adnexal associations are exceedingly rare, with only nine cases reported in the English literature. We present a case of cutaneous sarcomatoid carcinoma arising in association with a poroma.
Methods: An 89-year-old female who presented for evaluation of a pink, exophytic, polypoid and ulcerated tumour measuring 4 x 4 x 3 cm located on skin surface of the left lower leg. The patient underwent an excisional biopsy, and the specimen was submitted for histopathological evaluation.
Results: Microscopic examination revealed an ulcerated polypoid tumour composed predominantly of a high-grade spindle cell proliferation arranged in fascicles with focal myxoid changes. At the periphery of the lesion, the epidermis and superficial dermis exhibited a proliferation of small, ovoid, and monotonous poroid cells with areas of ductal differentiation. In several areas, the poroid component merged with the high-grade spindle cell component. The mitotic rate was 10 mitoses per 10 high-power fields. No lymphovascular invasion or necrosis was observed.

Immunohistochemical analysis demonstrated diffuse positivity for cytokeratin AE1/AE3, CK5/6, and p63 in both the high-grade spindle cell and poroid components, supporting an epithelial origin. CEA was positive in the ductal areas of the poroid component. These findings confirmed the diagnosis of sarcomatoid porocarcinoma.
Conclusion: Porocarcinoma is a rare malignant adnexal tumour, and sarcomatoid transformation within these neoplasms is exceptionally uncommon. This case highlights the importance of recognizing this entity and contributes to the limited pool of reported cases in the English literature.

E-PS-05-037
Mycobacterium Chelonae on a skin biopsy associated with peritoneal dialysis catheter - case report and review of the literature
M.A. Abad Vintimilla[1], J.Á. Amat Sanchez[2], E. Tornay Mora[1], V. Diaz Castro[1], C. Gonzalez Garcia[1]
[1]Hospital Universitario La Paz, Pathology, Madrid, Spain, [2]Hospital Universitario La Paz, Dermatology, Madrid, Spain

Background & Objectives: Cutaneous infections by Mycobacterium Chelonae present heterogeneously, including papules, pustules, and deep lesions. It commonly affects immuno-compromised patients. Histopathological findings show granulomatous inflammation depending on immune status and vacuoles. They are frequently associated with trauma and medical procedures, including catheter use.
Methods: A biopsy was performed and processed for histological examination using H&E staining, along with specific histochemical techniques such as Ziehl-Neelsen for mycobacteria, PAS and methenamine silver for fungi. Additionally, microbiological cultures were conducted to isolate microorganisms. These methods allowed for both histological evaluation and identification of the infectious aetiology. Furthermore, we performed a review of the literature.
Results: A 75-year-old man who was taking immunosuppressant drugs including corticosteroids presented with a painful ulcerated nodule with suppuration in the area of the dialysis catheter with an evolution of 5 months. The patient had been treated with several antibiotics with only partial resolution. A sample was sent to microbiology. Histological examination revealed in the deep dermis a mixed inflammatory reaction with neutrophils and abscessed areas, histiocytes, some of them foamy, steatonecrosis and cicatricial fibrosis. Extracellular vacuoles were seen in the dermis with filamentous structures forming clumps within the spaces. The Ziehl-Neelsen stained the filamentous structures, being consistent with mycobacteria. PAS and methenamine silver stains were positive. The culture was positive for Mycobacterium chelonae.
Conclusion: This case emphasizes the importance of recognizing the histopathological features of Mycobacterium Chelonae, a rare cause of cutaneous infections, especially in immuno-compromised patients. A mixed inflammatory reaction, especially with extracellular vacuoles, provides crucial diagnostic clues. The Ziehl-Neelsen stain and microbiological cultures are essential for confirming mycobacterial aetiology. Early diagnosis and appropriate treatment are vital for improving outcomes, particularly in patients with underlying conditions or recent medical procedures, such as catheter placement.

E-PS-05-038
Primary cutaneous apocrine carcinoma of the foot carrying *WWTR1::ANKUB1 f*usion: two exceptional findings
J. Sorino[1], M. Della Mura[1], A. Colagrande[1], E. Cascardi[1], G. Ingravallo[1], G. Cazzato[1]
[1]University of Bari "Aldo Moro", Pathology, Bari, Italy

Background & Objectives: Primary cutaneous apocrine carcinoma (PCAC) is a rare malignant adnexal neoplasm arising from apocrine sweat glands, characterized by definitive features of apocrine differentiation, in absence of distinctive histopathological features seen in other apocrine well-defined tumours. To date, knowledge about its histogenesis, molecular biology and clinical aspects is scarce and needs further investigation.
Methods: Clinical history of the patient was retrieved. Tissue samples were formalin-fixed and paraffin-embedded, then haematoxylin-eosin and immunohistochemical staining were performed. RNA-based NGS was employed for molecular evaluation.
Results: A 68-year-old male presented with a slowly enlarging nodule of 1.5 cm, located on the second digit of the right foot. Surgical excision was performed. Histologically, the tumour was made up of highly atypical cells with round to oval large nuclei, abundant granular eosinophilic cytoplasm, and decapitation secretion, arranged in tubules and solid sheets. Mitotic activity was brisk. Neoplastic cells were positive for CK7, GCDFP-15, ER and AR, while HER2 was negative. RNA-based NGS revealed *WWTR1::ANKUB1* gene fusion. Further clinical workup excluded the possibility of a metastasis.
Conclusion: We report a rare case of PCAC with two unusual features: foot location and *WWTR1::ANKUB1* gene fusion. The anatomical site is very uncommon for PCAC, which usually presents in the axillary or head-neck area. Moreover, the reported fusion has never been described in PCAC, thus representing a novel genomic finding. *WWTR1* gene rearrangement has been occasionally reported in poromas, exerting an oncogenic role through the disruption of Hippo pathway/YAP-signalling (Sekine et al., 2019). *WWTR1* encodes a proto-oncogene whose activity is normally suppressed by the Hippo pathway *via* phosphorylation at a serine residue in the C-terminal region, which prevents its nuclear translocation. As a consequence of the fusion, the loss of this regulatory domain may allow the constitutive nuclear localization of the chimeric protein, thereby promoting transcription of genes involved in cellular proliferation and survival.

E-PS-05-039
Clinicopathologic features of enfortumab vedotin–induced cutaneous toxicity: a case series and review of the literature
F. Repetto[1], S. Jobbagy[1], E.E. Russell-Goldman[1], M.P. Hoang[1], R.M. Nazarian[1]
[1]Mass General Brigham and Harvard Medical School, Department of Pathology, Boston, USA

Background & Objectives: Enfortumab vedotin (EV) is an anti-Nectin-4– monomethyl auristatin E (MMAE) antibody–drug conjugate which has significantly improved progression-free and overall survival for patients with advanced urothelial carcinoma. While cutaneous adverse events have been recognized in nearly half of patients receiving EV, the histopathology of EV-induced cutaneous toxicity (EVICT) remains incompletely characterized. We sought to provide a comprehensive understanding of EVICT by integrating clinical and histopathologic features and correlating with a detailed review of the literature in the largest series of biopsy-proven EVICT.
Methods: Retrospective review of hospital records identified 10 patients who developed cutaneous eruptions during EV therapy, from whom thirteen skin biopsies were obtained during the course of care. Clinical presentations and histopathologic features were studied for each case. A literature review was conducted to identify all published, biopsy-confirmed cases of EVICT through March 2025.
Results: Fewer than 30 cases of biopsy-confirmed EVICT have been published. In our cohort, patients typically presented with diffuse, erythematous, maculopapular eruptions, though a subset exhibited lichenoid or eczematous features. Pruritus was common (>80%), and mucosal involvement was rare (1 case). Histopathologically, 10 of 13 specimens (77%) exhibited vacuolar interface dermatitis with basal cell damage and dyskeratotic keratinocytes. The remaining specimens showed a lichenoid interface pattern with a band-like lymphocytic infiltrate at the dermoepidermal junction, and 2 demonstrated

focal full-thickness epidermal necrosis. All cases featured superficial perivascular lymphocytic inflammation (with eosinophils in roughly half of the cases). In 11 of 13 (85%) specimens, abnormal keratinocyte mitoses (including ring-shaped and "starburst" forms) were identified.
Conclusion: EV-induced cutaneous eruptions exhibit a consistent pattern of interface dermatitis with significant keratinocyte injury, highlighted by distinctive ring mitoses, consistent with MMAE inhibition of microtubule polymerization. This study represents the largest series of EVICT correlating clinical and histopathologic findings. Recognizing these features is crucial for accurate diagnosis and management.

E-PS-05-040

Correlation between ex vivo fusion confocal microscopy and conventional haematoxylin-eosin for the diagnosis of cutaneous squamous cell carcinoma

S. Lopez-Prades[1,2], N. Lobos-Guede[2,3], C. Toloza Salech[2,3], P. Castillo Fernandez[1,2], L. Alós Hernández[1,2], A. Garcia Herrera[1,2], J. Perez-Anker[2,3], R. Albero-Gonzalez[1,2]
[1]Hospital Clinic de Barcelona, University of Barcelona, Pathology Department, Biomedical Diagnostic Centre (CDB), Barcelona, Spain, [2]August Pi i Sunyer Biomedical Research Institute (IDIBAPS-FCRB), Barcelona, Spain, [3]Hospital Clinic de Barcelona, Dermatology Department, Barcelona, Spain

Background & Objectives: Cutaneous squamous cell carcinoma (cSCC) is a highly prevalent skin cancer, second only to basal cell carcinoma, originating from the keratinocytes of the epidermal spinous layer. Although histological examination remains the gold standard, some cases present diagnostic challenges. Ex vivo fusion confocal microscopy (eFuCM) integrates reflectance and fluorescence signals via an advanced algorithm to produce high-resolution, real-time digital Haematoxylin-eosin (H&E) like images, comparables to conventional histology. This study aimed to evaluate the diagnostic performance of eFuCM for cSCC and to assess its concordance with conventional H&E histology.
Methods: A total of 59 fresh lesions suspicious for cSCC were biopsied and analysed using the VivaScope 2500 (MAVIG Gmgh, Munich) from January to May 2019. Digital images obtained by eFuCM were evaluated by two dermatopathologists with no previous experience in this technology. Diagnostic performance metrics, including sensitivity, specificity, positive predictive value, and negative predictive value, were calculated alongside Cohen's kappa to determine concordance with conventional H&E histology.
Results: The study included 59 cSCC lesions from 51 patients and 7 benign/premalignant lesions from 16 patients. For cSCC diagnosis, eFuCM achieved a sensitivity of 91%, specificity of 85%, positive predictive value of 95%, and negative predictive value of 75%, with a substantial concordance (κ=0.733; $p<0.001$) compared to H&E. Regarding invasive staging, sensitivity was 88%, specificity 94%, positive predictive value 92%, and negative predictive value 91%, with almost perfect concordance (κ=0.839; $p<0.001$). Histological features such as desmoplasia and mitosis showed high specificity (93% and 92%, respectively).
Conclusion: Ex vivo fusion confocal microscopy with digital H&E offers reliable diagnostic accuracy for cSCC and its invasive features, producing images comparable to conventional H&E. The good diagnostic concordance achieved by dermatopathologists without prior eFuCM training supports its potential use as a rapid alternative in urgent cSCC diagnostics.

E-PS-05-041

Primary cutaneous CD8+ aggressive epidermotropic cytotoxic T cell lymphoma (AECTCL): a case report

S. Diaz Lopez[1], G. Vazquez Esteban[1], S. Merino Baamonde[1], A. Soria Montoya[1], F.J. Pérez Rastrollo[1], C. Gonzalez Rodriguez[1], M. Rubiera Valdés[1], E. Higueras Mora[1], B. Vivanco Allende[1], G.E. Mendoza Pacas[1]
[1]Hospital Universitario Central de Asturias, Anatomic Pathology, Oviedo, Spain

Background & Objectives: AECTCL is a rare cutaneous lymphoma characterized by proliferation of epidermotropic CD8+ cytotoxic T cells, aggressive clinical behaviour, and poor prognosis. In WHO classification (5th edition) is recognized as a distinct entity. Represents <1% of cutaneous T cell lymphomas (CTCL). Most patients are adults, presenting localized/disseminated eruptive papules-nodules showing central ulceration-necrosis or superficial hyperkeratosis. Progresses rapidly (weeks-months) with propensity to disseminate to visceral sites, lymph nodes are often spared.
Methods: A 57-year-old man was admitted to hospital for multiple cutaneous lesions in different evolution stages that appeared one week ago. He presented body disseminated lesions not affecting face, palms and soles. Initially were maculo-papular, later ulcerated with raised edges, and necrotic background, others were hyperkeratotic. In addition unquantified weight loss over months with no other symptoms. Oncologic PET/CT showed multiple hypermetabolic cutaneous thickening, bilateral axillary and inguinal hypermetabolic lymphadenopathy and a hypermetabolic focus in the cavum associated with a left IIb adenopathy suggestive of malignancy.
A 10 cm diameter scapular skin lesion was biopsied.
Results: A 0.9x0.4x0.4 cm cutaneous punch is received. Microscopically epidermis showed pronounced rete ridges, abundant lymphocytic infiltrate with marked epidermotropism, spongiosis and reactive changes. Lymphocytes were atypical, with coarse chromatin and frequent mitoses, forming microabscesses. In dermis an inflammatory infiltrate with similar characteristics. It does not affect deep dermis or subcutaneous tissue and is accompanied by adnexal structures destruction. The IHC studies showed intraepidermal tumour lymphocytes: CD8+;CD3+;CD7+;CD5+;focal TIA1+;diffuse CD56+; CD45RO-; CD2-; CD4-; CD30-;TCR beta -; TCR delta -; TOX-; high Ki67.
A TCRG rearrangement study on fresh sample showed presence of T lymphocytes with monoclonal rearrangement.
A FISH study on deparaffinized tissue sections showed JAK2 monosomy 75%.
Conclusion: Diagnosis of $CD8^+$ AECTCL is based upon combination of clinical, histopathologic, and immunophenotypic findings. Since several types of primary CTCLs express $CD8^+$ T cell phenotype, careful clinicopathologic correlation is key.

E-PS-05-042

Two studies confirm superior diagnostic accuracy of molecular PCR over dermatopathology for differential diagnosis of psoriasis and eczema

S. Proksch[1], M. Engler[1], S. Roth[1], J. Rüdiger[1], C.S.L. Müller[2,3], A. Volz[4], A. Arnold[4], D. Kacerovska[5], M. Sedivcova[5], L. Gutzweiler[1], K. Eyerich[6], N. Garzorz-Stark[6,1], K. Technau-Hafsi[6]
[1]Dermagnostix GmbH, Freiburg, Germany, [2]MVZ für Histologie, Zytologie und Molekulare Diagnostik Trier GmbH, Trier, Germany, [3]Saarland University, Medical Faculty, Homburg/Saar, Germany, [4]Dermpath Basel GmbH, Basel, Switzerland, [5]Biopticka Laborator s.r.o., Pilsen, Czech Republic, [6]University Freiburg Medical Centre, Department of Dermatology, Freiburg, Germany

Background & Objectives: Targeted treatments for non-communicable chronic inflammatory skin diseases offer significant potential for effective therapy. However, therapeutic success requires an accurate diagnosis, which is challenging due to overlapping clinical and histological features. We aimed at assessing the diagnostic accuracy of the molecular classifier (MC), a novel test designed to assist in the differential diagnosis of psoriasis and eczema.

Methods: In two studies, FFPE samples (n_1=54 and n_2=94) from suspected psoriasis and/or eczema cases were evaluated by 3 and 4 independent dermatopathologists, respectively. MC was performed using the fully automated qPCR system (PsorX©, Dermagnostix, Germany). Diagnostic performance of PsorX© was compared to the reference diagnosis which in study 1 was based on suspected clinical diagnose and histopathology while in study 2 it was based on clinical presentation and course of disease supported by photo documentation, histopathology, blood parameters, and treatment response. Inter-examiner variability in histopathology was assessed using Cohen's and Fleiss' Kappa tests.
Results: There was only moderate diagnostic agreement among dermatopathologists (Fleiss Kappa = 0.22 in study 1 and 0.45 in study 2) in distinguishing eczema from psoriasis. Compared to the respective reference diagnosis, the performance of PsorX© was as follows: sensitivity 85.0% (study 1) and 90.7% (study 2); specificity 87.1% (study 1) and 86.3% (study 2); and accuracy 85.8% (study 1) and 88.3% (study 2). In comparison, histopathological analysis showed a mean sensitivity of 89.7% (75.9-100%, study 1) and 72.0% (62.5-86.0%, study 2), specificity of 61.3% (44.0-92.0%, study 1) and 86.7% (79.5-92.2%, study 2) and accuracy of 76.5% (70.4-83.3%, study 1) and 79.7% (71.4-89.4%, study 2) compared to the respective reference diagnosis.
Conclusion: High interrater variability in histopathology highlights the challenge of distinguishing between psoriasis from eczema, despite expert assessment. This underscores the need for reliable, objective diagnostics like PsorX, which enable precise examiner-independent diagnoses and improve clinical decision-making.

E-PS-05-043
Recurrent skin tumour with mixed features of microcystic adnexal carcinoma, squamous cell carcinoma, and basal cell carcinoma in a renal transplant recipient; a very rare case report
I. Logan[1], E. Nigar[2], A. Qasim[1], A. Martinez[2], F. Kubba[1]
[1]Ealing Hospital, Dermatopathology, London, United Kingdom, [2]Northwick Park Hospital, Dermatopathology, London, United Kingdom

Background & Objectives: Microcystic adnexal carcinoma (MAC) is a rare malignant sweat gland tumour with central face predilection. Perineural invasion (PNI) is present in around 80% of cases. Risk factors include UV radiation, immunosuppression, and previous radiotherapy. Herein we report a case with each of these risk factors and a rare triple mixed tumour morphology.
Methods: A 69-year-old Caucasian male renal transplant recipient (RTR) presented with a clinical squamous cell carcinoma (SCC) on the right cheek. He had been immunosuppressed for 7 years. The primary lesion was treated by wide local excision (WLE) and reported as a pT3 high-risk SCC. He underwent adjuvant radiotherapy with 45Gy in 10 fractions and was started on Acitretin. At 16 months follow-up there was clinical evidence of tumour recurrence reported as MAC on biopsy and subsequently treated by Mohs surgery.
Results: The primary lesion was a 27mm SCC of no specific type, expressing moderate and poorly differentiated areas and a superficial focal basal cell carcinoma-like area 3.5mm from nearest margin, with deep PNI, 1mm from margin. The clinically recurrent 15mm lesion was within the scar. Diagnostic punch biopsy showed MAC. Mohs surgery was completed requiring 4 stages to excise an ulcerated tumour invading deeply into the facial musculature and parotid duct, with widespread PNI. The recurrent tumour had mixed features of MAC and moderately-differentiated SCC, both expressing strong CK5 immunohistochemistry. There was extensive ductal differentiation in the deeper component comprising small/elongated microacini lined by single cell layers, highlighted widely by EMA and focally by CK7, CK19, Cam5.2 and CEA.
Conclusion: Few cases of MAC have ever been reported in transplant recipients. Post-transplant SCC can show divergent differentiation. Two confirmed cases of MAC in RTRs were locally aggressive requiring extensive surgical resection due to bone invasion. More studies are required to confirm the optimal approach for management to minimise recurrence/metastatic risk.

E-PS-05-044
Carcinoma Erysipeloides: a rare entity
S.Y. Çelik[1], Ö. Ilhan Çelik[1], Y. Dere[1], E.T. Alataş[2]
[1]Mugla Sitki Kocman University, Faculty of Medicine, Department of Pathology, Mugla, Turkey, [2]Mugla Sitki Kocman University, Faculty of Medicine, Department of Dermatology, Mugla, Turkey

Background & Objectives: Carcinoma erysipeloides (CE) is an uncommon type of cutaneous metastasis in which malignant cells spread to the skin via superficial dermal lymphatic vessels. The lesions present as ill-circumscribed erythematous plaques resembling cellulitis or erysipelas. Although it is most commonly seen in breast cancer, it can also occur in melanoma, lung, ovarian, colonic and pancreatic carcinomas.
Methods: A 42-year-old woman suffering from red cutaneous lesions on her right chest skin applied to Dermatology Clinic. In her physical examination, there were many ill-defined erythematous macules and plaques resembling cellulitis or erysipelas on her right chest and breast skin. There was no evident crusting or scaling. She had left mastectomy surgery 3 years ago because of breast carcinoma. A punch biopsy with formaldehyde fixation and a fresh punch biopsy for immunofluorescence examination were sent to the Pathology Laboratory.
Results: In the microscopic evaluation of the formaldehyde fixed, paraffine embedded biopsy, under the orthokeratotic and acanthotic epidermis, there were many atypical cells with pleomorphic, hyperchromatic nuclei, large eosinophilic cytoplasm filling the dermal lymphatics. These cells expressed GATA3, oestrogen receptors (ER), progesterone receptors (PR), Keratin7 and they were not stained positive with p40, Keratin20, CD34, Vimentin immunohistochemically. Dermal extravascular invasion of these cells was not present. Inflammatory cells were present in the dermis.
No Immunoglobulin, Compleman and Fibrinogen accumulation was detected in the direct immunofluorescence application to the fresh biopsy.
The lesion was diagnosed as CE.
Conclusion: CE manifests clinically as a fixed erythematous patch or plaque resembling cellulitis or erysipelas without fever. The inflamed area may show a distinct raised periphery and oedema secondary to lymphatic obstruction.
Malignant cells predominantly locate within the dermal lymphatic vessels and malignant thrombi-induced lymphatic obstructions cause the erysipeloid induration.
CE is associated with a poor prognosis and the average life expectancy is 2 years from the diagnosis of CE.

E-PS-05-045
The impact of BRAF mutational status on survival in our group of patients with advance melanoma
L. Kovač[1], N. Jonjić[1], D. Vučinić[2], I. Hadžisejdić[1]
[1]KBC Rijeka, Pathology & Cytology, Rijeka, Croatia, [2]KBC Rijeka, Oncology, Rijeka, Croatia

Background & Objectives: Melanoma accounts for less than 2% of all cancers worldwide but is responsible for 80% of skin cancer-related deaths. Among the various genetic alterations in melanoma, BRAF and NRAS mutations are among the most common. While multiple studies have confirmed the involvement of BRAF in melanoma, its role as a prognostic marker remains debated. However,

the BRAF V600E mutation is clinically significant, as its presence determines eligibility for targeted therapy with BRAF inhibitors. This retrospective study aimed to correlate BRAF mutation status with the clinicopathological characteristics of primary skin melanoma, assess the impact of BRAF-mutated versus BRAF wild-type melanoma on disease progression and overall survival, and to evaluate the influence of BRAF inhibitor therapy on survival outcomes.
Methods: A total of 152 patients with advanced melanoma along with available clinical data were included in this study. BRAF mutational status was determined by allele specific real-time PCR between 2013 and 2020 at the Clinical Hospital Centre Rijeka.
Results: Of the 152 patients, 80 (52%) had BRAF-mutated melanoma, which showed a slight predilection for the trunk. Histologically, nodular melanoma was the most commonly associated subtype. No significant difference was observed in terms of disease progression and overall survival between BRAF-mutated and BRAF wild-type patients. However, in patients with BRAF-mutated melanomas, those who received BRAF inhibitors exhibited improved survival outcomes in advanced disease stages.
Conclusion: Overall, this study shows that BRAF inhibition therapy is a proper way for combating melanomas with distant metastases, at least until new and more efficient form of therapy is discovered.

E-PS-05-046
Epithelial hyperplasia with serrated appearance and other reactive changes of eccrine glands
C. Leblebici[1], A. Başkan[1], E. Yarikkaya[1], B. Özcan[1], M. Cin[1]
[1]University of Health Sciences, Istanbul Training and Research Hospital, Pathology, Istanbul, Turkey

Background & Objectives: The existing literature contains a paucity of studies that specifically investigate reactive changes in the eccrine glands. To the best of our knowledge, the occurrence of epithelial hyperplasia within the eccrine unit has not been previously documented. The objective of this study was to ascertain the prevalence of various reactive changes observed in eccrine glands and the accompanying entities.
Methods: During a 6-month period, a total of 2215 skin samples from 2190 patients were examined during routine examination. Epithelial hyperplasia was defined as the presence of at least three cell layers in the eccrine duct and four or more cell layers in the coil.
Results: Epithelial hyperplasia of eccrine coil (cEH) was detected in 19 cases and manifested as serrated appearance, epithelial bridges or slit-like irregular fenestrations. The lower extremity was the most affected area. Epithelial hyperplasia of the eccrine ductus (dEH) was identified in 14 cases and was frequently associated with marked desmoplasia or dermal fibroblastic proliferation.
Clear cell change in eccrine coil (cCCC) was observed in 39 cases and was not associated with diabetes mellitus. Clear cell change of the basal epithelium of the eccrine sweat duct (CCCBESD) was found in 25 cases and was frequently observed in biopsies sampled from the face and trunk. Syringofibroadenomatous hyperplasia (SFAH) was observed in 20 cases.
Conclusion: cEH is typically detected in glands exhibiting a serrated appearance. It was suggested that cEH and dEH may be caused by conditions that impede sweat excretion, such as thick keratin layer, sclerotic/desmoplastic changes. SFAH, cCCC and CCCBED are observed with greater frequency than expected and in various pathologies, some of which are not documented in the literature. This study represents the most extensive series reported in the literature examining the association between reactive eccrine gland changes and various parameters.

E-PS-05-047
Syringocystadenoma papilliferum arising on background sebaceoma: a case report
A. Al-Omari[1]
[1]Sheffield Teaching Hospitals NHS Foundation Trust, Histopathology, Sheffield, United Kingdom

Background & Objectives: Syringocystadenoma papilliferum (SCAP) is a rare benign adnexal tumour that typically arises in the context of other skin conditions, particularly in individuals with basal cell nevus syndrome. SCAP presents as a papule or plaque on the skin and is characterized by the proliferation of sweat gland ductal epithelium. Sebaceoma, a tumour of the sebaceous gland, is also a rare, benign neoplasm, often associated with nevoid basal cell carcinoma syndrome (Gorlin-Goltz syndrome). We present a rare case of SCAP arising on a background of sebaceoma, highlighting the importance of recognizing this unusual histopathological finding. The patient, a 56-year-old male, presented with a solitary, asymptomatic lesion on the scalp that had been growing for several years. Histopathological examination revealed the presence of both SCAP and sebaceoma, with the SCAP component showing the characteristic cystic structures and papilliferous projections, while the sebaceoma component exhibited sebaceous differentiation and characteristic features of basal cell nevi. This case underscores the importance of considering multiple adnexal tumours in the differential diagnosis of cutaneous lesions and emphasizes the need for thorough histopathological evaluation.
Methods: N/A
Results: Histopathological examination plays a crucial role in the diagnosis of such rare associations. The identification of both SCAP and sebaceoma components in a single lesion requires careful consideration of their respective features and immunohistochemical markers.
Conclusion: This case demonstrates the rare occurrence of SCAP arising on a background sebaceoma, emphasizing the need for thorough histopathological evaluation when diagnosing adnexal tumours. The presence of both SCAP and sebaceoma in the same lesion underscores the importance of considering multiple adnexal tumours in the differential diagnosis, particularly in patients with genetic predispositions such as basal cell nevus syndrome. Further research is needed to better understand the pathogenesis and potential genetic underpinnings of such rare tumour associations.

E-PS-05-048
Spindle cell variant of epithelioid fibrous histiocytoma with aneurysmal changes: a case report
C. Leblebici[1], A. Başkan[1]
[1]University of Health Sciences, İstanbul Training and Research Hospital, İstanbul, Turkey., Pathology, Istanbul, Turkey

Background & Objectives: Epithelioid fibrous histiocytoma is a rare mesenchymal neoplasm with cutaneous ALK rearrangement. The spindle cell variant has recently been described. However, intralesional diffuse bleeding (aneurysmal change) has not been reported to date.
Methods: We report on a case of Epithelioid Fibrous Histiocytoma, Spindle Cell Variant (EFH-SP-v) with Aneurysmal Changes, diagnosed in dermatopathology department of University of Health Sciences, Istanbul Training and Research Hospital.
Results: An 18-year-old woman presented with a 1 cm painless purple papule located on the anterior aspect of the right thigh with a halo formation on the periphery. The lesion was excised with the prediagnoses of haemangioma, angiokeratoma and melanoma. Microscopic

examination revealed a tumoral formation consisting of spindle cells with large cytoplasm, and bland uniform oval shaped nucleus, forming short bundles crossing each other, located in a smoothly circumscribed-rounded area in the superficial and mid dermis. Aneurysmal areas containing pools of erythrocytes were observed in the centre of the tumour. In immunohistochemical study, tumour cells expressed ALK (clone D5F3) and Factor XIIIa, while epithelial, smooth muscle, melanocytic and vascular markers were negative. These findings were consistent with the diagnosis of Epithelioid Fibrous Histiocytoma, spindle cell variant (EFH-SP-v).
Conclusion: In the differential diagnosis of EFH-SP-v, there are ALK-expressing and ALK-negative mimics. ALK-expressing mimics include some Spitz lesions, inflammatory myofibroblastic tumour, "ALK-rearranged CD34-positive spindle cell neoplasms resembling dermatofibrosarcoma protuberans". Although considered as a differential diagnosis, there is a morphologic spectrum between Epithelioid Fibrous Histiocytoma and "Superficial ALK-Rearranged Myxoid Spindle Cell Neoplasm". Cutaneous Syncytial Myoepithelioma, Cellular Neurothekeoma, Reticulohistiocytoma may show morphologic similarities with EFH-SP-v, although they do not express ALK.
In order to arrive at an accurate diagnosis, it is imperative to integrate morphologic, immunophenotypic and, in select cases, molecular data. It is also crucial to bear in mind EFH-SP-v.

E-PS-05-049
Porocarcinoma of the scalp a rare cutaneous cancer: a case report
M. Boukhenaf[1,2,3], A. Sahli[1,3], L. Beddar[1,3]
[1]University Salah Boubnider Constantine 3 Algeria, Pathology, Constantine, Algeria, [2]Research Laboratory for Cancer Diseases, University Constantine 3 Salah Boubnider, Constantine, Algeria, [3]University Hospital, Constantine, Algeria

Background & Objectives: Eccrine porocarcinoma is a malignant tumour of eccrine sweat glands, it represents 0.005% of malignant skin epithelial tumours.
The first case was described by Pinkus and Mehregan in 1963 as "epidermotropic eccrine carcinoma".
Methods: We reported the case of a 61 years (3)old woman, who had a skin mass of the right parieto-occipital scalp measuring 6 cm in long axis, largely ulcerated, evolving for 5 months, she had a surgical excision.
Results: ***Macroscopic examination:*** we received a 9x7cm skin sample with an ulcerated lesion of 6x6cm and 5cm thick, The tumour was polypoid, granular and heterogenous coloured with necrotic and haemorrhagic changes.
The microscopic examination : reveals an infiltrating carcinomatous proliferation connected to the epidermis and extended to the reticular dermis, associated to foci of benign eccrine poroma.
An immunohistochemical study was carried out, revealing a positivity of the cells to the anti CD117, EMA and ER antibodies.
Discusson: Porocarcinoma is a very rare tumour. It most often occurs in the elderly, the age at diagnosis being between 60 and 80 years. Tumour size varies widely from < 1 cm to 10 cm. It commonly affects the lower limbs followed by the trunk. Rare locations such as the scalp have been reported in the literature. Ours is similar to that of *Masamatti and Al*, observed in a woman and occurring in the right parieto-occipital region. Most frequently porocarcinoma occurs on a pre-existing poroma as in our case.
Conclusion: Porocarcinoma is an aggressive and rare skin cancer. Surgery is the main modality of treatment.

E-PS-05-050
Mycosis fungoides in Algeria: a 3-year retrospective study
M. Boukhenaf[1,2,3], A. Sahli[1,2], L. Beddar[1,2]
[1]University Salah Boubnider Constantine 3 Algeria, Pathology, Constantine, Algeria, [2]University Hospital, Constantine, Algeria, [3]Research Laboratory for Cancer Diseases, University Constantine 3 Salah Boubnider, Constantine, Algeria

Background & Objectives: Mycosis fungoides (MF) is the most common cutaneous T-cell lymphoma (CTCL) , with an incidence of 2 to 4 cases per 1,000,000 individuals, and well-documented epidemiological patterns.[1] However, data from North Africa remain scarce. This study presents the first Algerian analysis of MF, examining its prevalence, sex distribution, histological subtypes, and immunophenotypic characteristics.
Methods: This retrospective study reviewed 20 cases of MF that we got in the Pathology department of the University Hospital of Constantine-Algeria, over a period of 3 years (February 2022 to February 2025). All relevant data such as sex, histological aspect and immunophenotypes were collected and reviewed.
Results: Among the 42,382 pathological specimens received during the study period, MF accounted for 20 cases (0.04%). The study cohort included 10 male and 10 female patients, yielding a sex ratio of 1:1.
Histopathological analysis highlighted a marked predominance of classic MF, comprising 15 cases (75%) followed by 3 cases of folliculotropic variant MF (15%), and only 2 granulomatous MF cases (10%).
Immunohistochemical analysis found a typical CD4+ phenotype in 16 cases of MF, while 4 cases (20%) exhibited a CD8+ cytotoxic phenotype.
Conclusion: Our study provides the first Algerian data on mycosis fungoides, revealing a balanced sex distribution and a higher-than-expected prevalence of CD8+ cases. These findings challenge established epidemiological patterns and emphasize the need for further research to understand MF's characteristics in North African populations.

E-PS-05-051
Clear-cell atypical fibroxanthoma: a rare subtype in a 25-year case analysis
L. Hato Salmón[1], V. Hincapié Baena[1], V. Macarrón[1], E. Ruiz-Bravo[1]
[1]La Paz University Hospital, Pathology, Madrid, Spain

Background & Objectives: Atypical fibroxanthoma (AFX) is a rare, low-grade malignant neoplasm of dermal fibroblastic-histiocytic origin, primarily affecting sun-exposed skin in elderly individuals. Its histopathological variability and similarities with other skin tumours make diagnosis challenging. This study reviews AFX cases diagnosed at Hospital Universitario La Paz (HULP) over 25 years, focusing on a rare clear-cell subtype case to assess epidemiological, clinical, and histopathological characteristics and highlight diagnostic challenges.
Methods: A retrospective review was conducted on all AFX cases diagnosed at HULP between 2000 and 2024. Data were extracted from pathology reports, including patient demographics (sex, age), lesion location, initial clinical diagnosis, histopathological findings, immunohistochemistry (IHC) profiles, and revision diagnoses. Cases were analysed to determine patterns in diagnosis and misclassification rates.
Results: Over 25 years, 85 AFX cases were identified. The mean age was 78.76 years, with a median of 80. Of these, 66 were male and 19 were female. The most common location was the scalp, followed by the ear, forehead, and cheek. The predominant clinical suspicion was basal cell carcinoma or squamous cell carcinoma, with only four cases correctly identified as AFX before histopathological evaluation. The spindle-cell subtype was the most frequent histological variant, while the clear-cell variant appeared in just one case, highlighting its exceptional rarity and the diagnostic challenges associated with it. This case underscores the importance of considering other differential diagnoses, such as clear cell renal cell carcinoma, to avoid misclassification.

Conclusion: AFX remains a diagnostic challenge due to its clinical and histopathological overlap with other neoplasms, particularly when uncommon histological subtypes are present. A thorough histopathological evaluation, supported by IHC (positive staining for CD10 and vimentin, and negative for keratins, S100, and CD34), is essential for accurate diagnosis and to avoid misclassification. Increased awareness and recognition of AFX features can improve diagnostic accuracy and patient management.

E-PS-05-052

Unna's papillomatous nevi with nuclear atypia trap for young pathologists

B. Lazarova[1,2], G. Petrushevska[3]
[1]Department of Pathology, Clinical Hospital, Shtip, North Macedonia, The Republic of, [2]Faculty of Medical Sciences, Goce Delcev University, Shtip, North Macedonia, The Republic of, [3]Institute of Pathology, Faculty of Medicine, Ss. Cyril and Methodius University in Skopje, Skopje, North Macedonia, The Republic of

Background & Objectives: Unna's papillomatous nevi are exophytic intradermal or compound melanocytic proliferations, whose dimensions are often larger than 1 cm, rarely described in the literature. Additional signs of regression and senescence can be a trap for young pathologists.
Methods: We present a case of a papillomatous Unna's nevi from the neck of a 39 year women, which persisted for about ten years, until just before the excision when signs of discomfort appeared in the patient. A skin excision measuring 0.8x0.7x0.1 cm, with a papillomatous brownish lesion measuring 2.3x1.x1.3 cm present on the surface, was submitted to our department. The material was serially dissected and completely embedded for microscopic analysis, and the sections were stained with haematoxylin and eosin, and additionally one of them was stained with Alcian blue - PAS.
Results: Microscopic analysis showed a compound nevus with prominent papillomatous proliferated epidermis, presence of intraepidermal keratin cysts, and hyperkeratosis on the surface. Prominent blood vessels, stromal oedema, periadnexal growth, pseudotubular and pseudolacunar structures, and signs of neuritization were found. However, the presence of nuclear atypia was puzzling, but we termed senescent, because no mitoses were found. Stromal mucin deposits and corneal Malessezia furfur have been seen on the special stain.
Conclusion: Large size од papillomatous nevi, nuclear atypia, and signs of natural regression can be confusing in the routine work of general young pathologists. So, excluding the presence of mitoses on a series of sections, on basic staining, may be the only way to exclude nevoid melanoma, where the use of artificial intelligence can save a lot of time.

E-PS-05-053

Spotlight on Spitz: unravelling the spectrum of Spitz tumours in a Romanian county hospital

Background & Objectives: Spitz nevus was firstly described by Sophie Spitz as the „benign nevus of childhood" in 1947 and further transformed in the category of Spitz tumours. Spitz tumours are represented by the Spitz nevi, Spitz melanocytoma, Atypical Spitz tumour and Spitz melanoma. The objective of our study was to emphasize the epidemiological and histopathological characteristics of Spitz nevi and atypical Spitz tumours in a county hospital in Romania.
Methods: A retrospective study was performed based on the histopathological diagnosis of Spitz nevi or Atypical Spitz Tumour (AST), including 10 cases of Spitz tumours which were diagnosed in the Clinical Pathology Department of the Mures Clinical County Hospital, Romania, between 2018-2024. The tissue samples were received from either the General Surgery or Plastic Surgery ward from patients diagnosed with a skin tumoral proliferation.
Results: Out of 10 Spitz tumours the highest incidence of 30%(n=3) were diagnosed in 2022, with a mean age of 20.2 years-old (maximum 40 years-old). Grossing revelled plane or elevated lesions on the tegument, with different localizations (arm, calf, forearm, thorax) and variations of colour from white-grey to brown. Histopathological, 100% (n=10) of cases presented fusiform cells, in combination with 70%(n=7) with epithelioid and rhomboid cells. 10%(n=1) of cases showed cytological atypia, 30%(n=3) presented pagetoid migration and 20%(n=2) presented mitoses. Immunohistochemically, the tumoral cells where positive for S100 in 70%(n=7) cases, for SOX10 in 30%, melanA in 40%(n=4) and Ki67 was under 5% in 100%(n=10) cases. The final histopathological diagnostic was Spitz nevus in 90% cases (intradermic or compound) and ATS in 10%(n=1) cases.
Conclusion: Even though Spitz tumours are rare, they represent a challenge in diagnosis especially when the age is higher, with different histopathological appearance, but with a high importance of differentiation between benign and malignant with direct impact on the prognostic of the patient.

Paediatric spiradenoma with adenomyoepithelial hyperplasia and high mitotic activity: a diagnostic challenge in the benign-malignant spectrum

D. Gül[1], S.S. Ozkanli[1], B. Çobanoğlu Şimşek[1], O. Erdem[2]
[1]Istanbul Medeniyet University Goztepe Prof. Dr. Suleyman Yalcin City Hospital, Department of Pathology, Istanbul, Turkey, [2]Istanbul Medeniyet University Goztepe Prof. Dr. Suleyman Yalcin City Hospital, Department of Dermatology, Istanbul, Turkey

Background & Objectives: Spiradenoma is typically a benign adnexal tumour seen in adults, with a predilection for the head and neck. In paediatric patients, this tumour is exceedingly rare. The concurrent presence of adenomyoepithelial hyperplasia and a high mitotic rate further complicates the differentiation between a benign process and potential malignant transformation. This case report presents a 12-year-old male with an unusual toe lesion, highlighting the diagnostic dilemma posed by overlapping histopathological features.
Methods: A 12-year-old male presented with a progressively enlarging nodular lesion on the dorsum of the toe, which had been subject to repeated trauma. An excisional biopsy was performed on a 2.5 cm firm, cream-brown nodule, resulting in the achievement of clear surgical margins. The specimen underwent comprehensive histopathological evaluation, with special emphasis on p63 immunohistochemistry and assessment of the Ki-67 proliferation index.
Results: Microscopic analysis revealed solid nests and glandular structures composed of dual cell populations, including ductal and myoepithelial elements. Myoepithelial differentiation was confirmed by strong p63 positivity. Despite the absence of significant cytologic atypia, necrosis, or infiltrative growth, an elevated mitotic rate (5 mitoses/HPF) and a high Ki-67 index (%70) were observed.
Conclusion: This case emphasizes the diagnostic challenge encountered in paediatric spiradenomas exhibiting adenomyoepithelial hyperplasia and high mitotic activity. The overlap between benign and malignant features necessitates cautious interpretation and underscores the importance of meticulous histopathological evaluation. Moreover, to

the best of our knowledge, such a paediatric case with these specific histopathological features has not been previously reported in the literature. Long-term clinical follow-up is imperative to monitor for any signs of progression, and further studies are required to clarify the prognostic implications of these atypical features.

Folliculotropic mycosis fungoides: about 4 cases

S. Charfi[1], M. Mellouli[1], F. Hammami[2], M. Zghal[1], S. Graja[1], R. Kallel[1], L. Ayadi[1], T. Sellami Boudawara[1], M. Bouhamed[1]
[1]CHU Habib Bourguiba, Pathology, Sfax, Tunisia, [2]CHU Hedi Chaker, Dermatology, Sfax, Tunisia

Background & Objectives: Folliculotropic mycosis fungoides (FMF) is a particular subtype of mycosis fungoides (MF), characterized by invasion of hair follicles, sebaceous glands, and/or sweat glands by atypical T-cells.
Methods: A retrospective descriptive study of all cases with histological diagnosis of FMF between January 2005 and December 2024.
Results: During the study period, 4.8% of cases of MF attended our institute were folliculotropic (4/84). Three patients were male and one was female. The age at the time of diagnosis ranged between 7 to 78 years. FMF presented as ill-defined plaques with follicular papules (n=3,75%), nodular lesions (n=2, 50%), and patchy-plaque alopecia affecting the scalp (n=3, 75%) or the eyebrows (n=1, 25%). The majority of patients had lesions in the limbs (100%), followed by the trunk (75%) and the scalp (50%). The skin biopsies of all FMF patients showed perifollicular or intrafollicular infiltration with atypical T cells. Follicular mucinosis was not noted in any case. Large cell transformation was observed in one case (25%). Lymph node metastasis was present in one case. Three patients showed early-stage (stage IA–IIA) and one showed advanced-stage (IVA–IVB) disease at the time of diagnosis. All patients survived after a follow-up period of 2 years. The treatments used were topical corticosteroids, UVB therapy, and retinoids.
Conclusion: FMF represents 4.8% in our study which is a lower frequency than reported in other series (10%). It can affect the paediatric population and accounts for 3 to 36% of all paediatric MF. The head and neck are usually reported to be the predilection site of the lesions, unlike our patients. It is commonly believed that FMF has a more aggressive clinical course than classical MF.

Primary cutaneous Ewing sarcoma of the distal fifth finger: a rare paediatric presentation

G. Carrola[1], N. Chiote[1], A. Coelho[1]
[1]Unidade Local de Saúde de Santo António, Anatomic Pathology Service, Genetics and Pathology Clinic, Porto, Portugal

Background & Objectives: Ewing sarcoma is the second most common paediatric malignant bone tumour, primarily occurring in long bones. Nevertheless, extraskeletal locations are uncommon, with primary cutaneous Ewing sarcoma being exceedingly rare.
Methods: We report the case of a previously healthy 12-year-old boy who presented with a cutaneous lesion on the palmar aspect of the fifth digit of his left hand. The lesion had been present for several months and had recently exhibited accelerated growth. Clinically, a pyogenic granuloma was suspected and the lesion was ressected. The specimen was submitted to our department for histopathological evaluation.
Results: Macroscopic examination revealed multiple irregular tan to white fragments, the largest measuring 2.1 cm. Microscopic analysis demonstrated skin infiltrated by a high-grade neoplasm composed of uniform, small round blue cells exhibiting mild nuclear irregularity and scant cytoplasm, arranged in a solid architectural pattern. No bone was identified. Immunohistochemistry showed positivity for CD99 (diffuse and membranous), NKX2.2 (multifocal) and CAM5.2 (focal). There was also unusual immunoreactivity for S100, SATB2 and p63, that promped challenging differential diagnosis. No immunoreactivity was observed for TLE1, WT1, SOX10, SMA, Desmin, Myogenin, MyoD1, CD45, HMB45, CD34, or ERG. Fluorescence in situ hybridisation (FISH) revealed rearrangement of the EWSR1 gene and no rearrangement of SS18. Next-generation sequencing (NGS) identified a EWSR1-FLI1 fusion (QIAseq RNA Fusion XP Sarcoma Panel). A diagnosis of Ewing sarcoma was established.
Conclusion: Cutaneous Ewing sarcoma presents a diagnostic challenge in paediatric tumours, due to its rarity and unique histologic and clinical characteristics, besides relatively better prognosis compared with skeletal Ewing sarcoma. A high index of suspicion and comprehensive histopathological evaluation, in conjunction with cytogenetic and molecular studies, are essential for timely diagnosis and adequate management of these patients.

A race against time: cutaneous angioinvasive mycosis in an immunocompromised patient – a diagnostic and therapeutic challenge

L. Chacon Zambrano[1], P.A. Vega[2], S. Cárdenas[2], R. Rodríguez[3], B. Díaz-Gómez[1]
[1]School of Medicine - Universidad de Los Andes - Fundación Santa Fe de Bogotá, Department of Pathology and Laboratories, Bogotá, Colombia, [2]School of Medicine, Universidad de Los Andes, Bogota, Colombia, [3]Clínica Vida, Fundación de Cancerología, Department of Pathology, Bogotá, Colombia

Background & Objectives: Angioinvasive fungal infections are life-threatening complications in immunocompromised individuals, particularly in patients with hematologic malignancies and prolonged neutropenia. Fusarium spp. is an emerging opportunistic pathogen with intrinsic resistance to multiple antifungal agents and high mortality in disseminateddisease. Cutaneous involvement—often mimicking ecthyma gangrenosum or leukaemia cutis, is common and may delay accurate diagnosis and timely intervention.
