We report the case of a 19-year-old female with refractory B-cell acute lymphoblastic leukaemia (ALL), currently undergoing third-line chemotherapy and presenting with prolonged neutropenia. During hospitalization, she developed respiratory symptoms with pulmonary masses unresponsive to broad-spectrum antibiotics. Physical examination revealed a necrotic cutaneous plaque on the thigh, measuring approximately 3 cm. An excisional biopsy and tissue cultures were performed. Initially suspected to be leukaemia cutis, histopathologic analysis revealed angioinvasive hyaline septate hyphae, raising suspicion for invasive fungal infection. Antifungal therapy was promptly initiated, resulting in favourable clinical response and avoiding surgical debridement. SubsequentGomori methenamine silver (GMS) staining confirmed fungal elements, and cultures identified Fusarium spp. Blood cultures remained negative throughout. The patient was discharged in stable condition and is currently awaiting bone marrow transplantation.
Methods: Case report.
Results: This case highlights the diagnostic complexity of necrotic skin lesions in immunocompromised patients and underscores the critical importance of early biopsy and communication of preliminary findings. Differentiating leukemic infiltration from fungal infection is essential to avoid misdiagnosis and therapeutic delay. Histopathologic confirmation enabled timely management despite negative blood cultures. Multidisciplinary collaboration and early antifungal therapy contributed to a favourable outcome.
Conclusion: Cutaneous fusariosis should be considered in neutropenic patients with necrotic skin lesions. Early biopsy and histologic evaluation are essential for diagnosis. Successful management depends on prompt antifungal treatment and immune recovery, with dermatopathology playing a key role.

E-PS-05-058

Non-dermatophytic mold onychomycosis mimicking subungual malignant tumour

D. Koumoundourou[1], G. Kyriakou[2], P. Bosgana[3]
[1]University Hospital of Patras, Rio, Pathology, Patras, Greece, [2]General Hospital of Patras, Dermatology, Patras, Greece, [3]General Hospital of Patras, Pathology, Patras, Greece

Background & Objectives: Onychomycosis, a fungal infection of nails, is primarily caused by dermatophytes and yeasts. Recently, non-dermatophyte molds (NDM), such as Acremonium spp., have also been implicated. These molds are more common in elderly and immunocompromised patients, with prevalence rates ranging from 1.45% to 17.6%. In immunocompetent patients, infections are rare.
Methods: A 34-year-old HIV-negative male presented with a painful subungual mass on his left great toe for three months, following minor trauma. Examination revealed an ulcerated, oozing nodule deforming the nail plate, with surrounding erythema and oedema extending to the second digit. The differential diagnosis included onychomycosis, verruca vulgaris, mycobacterial infection, benign tumours (e.g., pyogenic granuloma, keratoacanthoma), and malignant tumours (e.g., squamous cell carcinoma, melanoma).
Results: Routine haematological, biochemical and immunological investigations were either negative or within normal range. Mantoux test was negative. No significant pathologic findings were detected on X-ray examination and Magnetic Resonance Imaging of the affected limb. Biopsy and tissue cultures obtained from the nail bed revealed infection by Acremonium spp. The patient responded satisfactorily to treatment with i.v. liposomal amphotericin B (4 mg/kg/d) for ten days followed by surgical debulking of the subungual mass and a three-month course of p.o. voriconazole (200 mg b.i.d.). There was no evidence of relapse at his follow-up visit, six months later.
Conclusion: Non-dermatophyte molds may be involved in onychomycosis as primary pathogens in up to 2.3% of all onychomycoses, or as contaminant agents. Acremonium spp. in particular, is an uncommon cause of onychomycosis, especially in immunocompetent individuals. Optimal treatment of Acremonium infections is not well defined due to the rarity of this infection. Based on anecdotal reports, treatment of most invasive infections requires a combination of surgical intervention, when possible, and a regimen of amphotericin B and azoles.

E-PS-05-059

Darier's disease: case series of a rare entity

B.G. Özamrak[1], S. Ekmekci[1], M. Turkmen[2]
[1]Izmir Provincial Health Directorate, Izmir City Hospital, Department of Pathology, Izmir, Turkey, [2]Izmir Provincial Health Directorate, Izmir City Hospital, Department of Dermatology, Izmir, Turkey

Background & Objectives: Darier's disease (DD) is a rare autosomal dominant genodermatosis characterized by a keratinization disorder involving the skin, mucous membranes, and nails. It is characterized by oily, keratotic, yellow-red/brown, crusted papules or plaques. The lesions most commonly affect seborrheic areas. Here we present a case series of 6 patients with DD.
Methods: Six patients (3 females, 3 males; age range 17–67 years) presented with similar clinical manifestations to the dermatology outpatient clinic, including persistent skin eruptions and papules. The localization of the lesions varied, including head and neck/eyelid, trunk, upper extremities, and vulvar regions. Incisional skin biopsies performed on each patient revealed overlapping histomorphological features.
Results: Biopsy findings included focal parakeratosis in the epidermis, marked suprabasal acantholysis, and cleft formation. The retained single layer of basal keratinocytes overlying the dermal papillae protruding into the cavity irregularly formed a villous appearance. Acantholytic "corps ronds" and "grains" cells were observed within the clefts. DIF microscopic examination revealed no IgG, IgA, IgM, C3, or fibrinogen accumulation. Mild perivascular inflammatory cell infiltration was also observed.
Conclusion: DD's estimated prevalence is 1 in 30,000-100,000. Mutations in the ATP2A2 gene on chromosome 12q24.1 are identified in DD cases. Although DD is known to be a hereditary disease, cases can present with no family history of illness or with atypical clinical findings. The disease usually starts around puberty and runs a chronic course. The severity of the manifestations varies with exacerbations induced by sun exposure, heat, friction, infections, and pregnancy. The hallmark histologic feature is focal acantholytic dyskeratosis involving the suprabasal epidermis. DIF examination is essential in the differentiation from other acantholytic dermatitis, as a Darier-like pattern is observed within several acantholytic diseases, such as Hailey-Hailey disease, Grover's disease, warty dyskeratoma, seborrheic dermatitis, pemphigus vegetans, and pityriasis amiantacea. Clinicopathologic correlation is the last word used to arrive at a diagnosis.

E-PS-05-060

Basal acantholytic dyskeratosis as Wolf's isotopic response after herpes zoster infection

V. Díaz Castro[1], J.A. Amat Sánchez[2], J.M. Busto Leis[2], M.A. Abad Vintimilla[1], E. Tornay Mora[1], M. Beato Merino[1]
[1]Hospital Universitario La Paz, Anatomic Pathology, Madrid, Spain, [2]Hospital Universitario La Paz, Dermatology, Madrid, Spain

Background & Objectives: Wolf's isotopic response occurs when a new skin disorder develops at the site of a healed, unrelated skin disease. Herpes zoster (HZ) is the most common preceding condition. Reported disorders are primarily granulomatous and lichenoid reactions.
Methods: Diagnosis was made using a routine staining. We reviewed the medical record to obtain data such as age, site and clinical suspicion. Additionally, we performed a review of the literature in the last ten years.
Results: A 69-year-old female consulted for a linear eruption of asymptomatic hyperpigmented and crusted plaques on her right thoracic region. The lesions were located on the same site where, eighteen months before, she had suffered a HZ, that had completely disappeared after treatment. With the clinical diagnosis of lichen planus, a biopsy was made. This revealed basal acantholytic dyskeratosis along the whole epidermis, with no herpetic changes. These findings were interpreted as a Wolf's isotopic response.
Conclusion: Many disorders have been described as Wolf's isotopic response in healing or healed herpes zoster scars. To our knowledge, this is the first reported case of basal acantholytic dyskeratosis occurring as this reaction after a HZ infection. This finding expands the spectrum of conditions included in this phenomenon.

E-PS-05-061

Mogamulizumab-associated rash and the overlap histopathological features with Cutaneous T cell lymphoma: a case report

C. Faria[1], S. Leocádio[2], M. Sanches[3]
[1]Champalimaud Clinical Centre, Pathology, Lisbon, Portugal, [2]Champalimaud Clinical Centre, Haematology, Lisbon, Portugal, [3]Champalimaud Clinical Centre, Dermatology, Lisbon, Portugal

Background & Objectives: Mogamulizumab is a monoclonal antibody targeting CCR4 used as a therapeutic option for mycosis fungoides (MF) and Sézary syndrome (SS).
Nevertheless, Mogamulizumab-associated rash (MAR) can be defiant to distinguish from MF or SS, clinically and histopathologically, which may result in treatment withdrawal due to severe drug response or incorrect diagnosis of recurrence or disease progression.

Methods: A 60 year-old woman previously diagnosed with Sézary Syndrome has been treated with methotrexate for two months. However due to lack of response, mogamulizumab was initiated.
After three months of treatment, the patient presented a disseminated, monomorphous, and grossly symmetrical dermatosis characterized by lichenoid papules surrounding hair follicles with occasional scale. Erythrodermic lesions were also accentuated in the face.
A recent biopsy was performed.
Results: Histopathological study revealed an epidermis with mild acanthosis, parakeratosis, scattered apoptotic keratinocytes and exocytosis of lymphocytes. In the papillary and superficial dermis, there is a mild to moderate lichenoid inflammatory infiltrate, composed predominantly of lymphocytes and histiocytes, with a focal granulomatous pattern.
Immunohistochemistry showed positivity of the abundant T cell population for CD3, CD2, CD5, CD7, CD8 in the dermal infiltrate but also highlighted alignment of lymphocytes among the basal keratinocytes.
CD4 was negative and CD30 was positive in scattered cells.
Conclusion: The histopathological findings were in favour of MAR, still the alignment of lymphocytes in the basal layer raised concern of disease persistence.
Therefore, the rearrangements study of T cell receptor genes was performed in this biopsy and in the previous where the diagnosis of SS was made.
A polyclonal population of T cells were detected in the current biopsy in contrast to the first one.
Then, the patient was submitted to corticoid therapy but also maintained treatment with mogamulizumab leading to complete response, reinforcing the fact that mogamulizumab therapy continuation or retreatment should be considered for a favourable outcome.

E-PS-05-062
Cutaneous chromomycosis in an elderly agricultural worker. A case report
F. Mundim[1,2], C. Ferreira[3], N. Mundim[3], P. Mundim[3], J.R. Silva[4]
[1]UNIFAL, Pathology, Alfenas, Brazil, [2]UNIVAS, Pathology, Pouso Alegre, Brazil, [3]UNIFENAS, Alfenas, Brazil, [4]UNIVAS, Silvianopolis, Brazil

Background & Objectives: Cutaneous chromomycosis is a chronic fungal infection of the skin caused by various species of dematiaceous fungi found in nature and common in the tropical zone. This report presents a disease that is rare in Europe, which poses difficulty in its diagnosis.
Methods: An 81-year-old woman, residing in the rural area of Silvianópolis, Minas Gerais, Brazil, reports a history of a cutting trauma on her right and left forearms caused by a bird during her work. Following the incident, a vegetating lesion with a central crust appeared.
Results: The patient had a previous history of two skin biopsies with a diagnosis of skin carcinoma and sought treatment after noticing the growth of the lesion. Microscopic analysis, with H.E. staining, revealed skin with pseudoepitheliomatous hyperplasia and granulomatous inflammation with Langhans giant cells, intraepidermal abscesses, and brownish, birefringent membrane structures, consistent with Chromomycosis sp. Grocott's staining was positive for fungi. Treatment with Itraconazole 100mg daily for two months resulted in the complete resolution of symptoms.
Conclusion: Cutaneous inflammatory processes show an important differential diagnosis with skin cancer. It is important to emphasize that fungal lesions, of occupational origin, can also lead to severe infections, and that timely diagnosis and appropriate treatment can lead to successful outcomes.

E-PS-05-063
Molecular profiling of advanced melanoma
M. Khudadad[1,2], M. Carter[1,2], R. DeCoste[1,2]
[1]Queen Elizabeth II Health Science Centre, Department of Pathology and Laboratory Medicine, Halifax, Canada, [2]Dalhousie University, Halifax, Canada

Background & Objectives: Melanoma is the fifth most common cancer worldwide, characterized by a high mutation rate driven by environmental and genetic factors. Next-Generation Sequencing (NGS) has revolutionized cutaneous melanoma (CM) management, particularly in identifying mutations for targeted therapies. This study assesses the frequency of driver mutations in advanced melanoma cases in Nova Scotia and compares these findings with broader literature.
Methods: We analysed data from 799 melanoma patients who underwent NGS and/or BRAF immunohistochemistry (IHC) testing between 2017 and 2023. Associations between mutation types, age, tumour stage, and anatomical location were evaluated.
Results: The mean patient age was 71, with a male-to-female ratio of 1.6. BRAF mutations were found in 297 (37%) cases, NRAS in 211 (26%), KIT in 34 (4%), and GNAQ/GNA11 in 15 (2%). A mutation of clinical significance was not detected in 243 (30%) cases. Among BRAF-positive cases, 201 (68%) had V600E mutations, 69 (23%) had V600K/R/D, and 27 (9%) had non-V600 mutations. BRAF mutations were significantly associated with younger age ($p < 0.00001$), lower T-category ($p = 0.0002$), and were most frequently observed in CM of the torso (54%). NRAS mutations correlated with older age (≥60 years, $p = 0.009$), but not with T-category. NRAS mutations were most frequent in CM of the extremity (38%). KIT mutations were relatively rare in our cohort, but were most frequent in CM of mucosal (25%) and acral (17%) sites.
Conclusion: BRAF mutations, particularly V600E, were the most common but occurred at a lower frequency than often reported in literature. NRAS mutations were relatively frequent in Nova Scotia. Appropriate molecular testing is essential for optimizing management of advanced CM, and knowledge of expected local trends influences resource planning and quality assurance practices.

E-PS-05-064
Calcinocis cutis appearing as a vascular lesion on MRI
A. Sykaras[1], A. Therapontos[2], D. Efthymiou[2], E.-A. Spiteri[2], E. Athanasiou[2], C. Kouvidou[2]
[1]University College Dublin, Department of Pathology, Dublin, Ireland, [2]Evangelismos General Hospital, Department of Pathology, Athens, Greece

Background & Objectives: Calcinosis cutis is a rare disease characterised by calcium salts deposition in the skin and subcutaneous tissue. It is classified as dystrophic (the most common, associated with connective tissue disease), metastatic (associated with abnormal serum levels of calcium and phosphorus), idiopathic, iatrogenic, and calciphylaxis (calcification of blood vessels).
Methods: An 18-year-old female presented with painful swelling in the posterior compartment of the forearm. Clinical examination identified a subcutaneous mass, and MRI suggested the presence of a vascular lesion, possibly a haemangioma. Fine needle aspiration (FNA) was performed in another centre and was compatible with a vascular neoplasm. A wedge-shaped excision of the lesion was performed, and we received a skin specimen measuring 54x47x36mm.
Results: Microscopically, we recognised a lobular and relatively well-demarcated lesion that occupied the reticular dermis and the subcutaneous adipose tissue. Its main characteristic was the extensive presence of basophilic, amorphous, irregular aggregates indicating calcium deposits and establishing the diagnosis of calcinosis cutis. The calcium deposits were separated by fibrotic bundles containing thin-walled blood vessels without calcifications; therefore, we excluded

calciphylaxis. A moderate inflammatory infiltrate was present with occasional lymphoid nodules and focal foreign body reaction with multinucleated giant cells. Despite the classic morphology of the lesion, we performed immunohistochemistry with classic vascular markers to exclude the presence of a vascular neoplasm that was suggested by imaging and FNA.
Conclusion: This is a typical case of calcinosis cutis that was evaluated by imaging and cytopathology as a vascular neoplasm. The typical differential diagnosis of calcinosis cutis includes mycetoma, xanthoma, and gout/pseudogout but not vascular lesions. Clinicopathological correlation is required for determining the aetiology of calcinosis cutis. We suggested that vitamin D, calcium and phosphate levels should be measured and a follow-up investigation was required to rule out autoimmune systemic diseases that cause connective tissue damage.

E-PS-05-065
MYO5A::NTRK3 fusion in Spitz tumours: comparison between a Spitz melanocytoma and a Spitz melanoma
A.-M. Cohn[1,2], C. Pouget[1], A. Cuevas Bourdier[1], F. Jacob[3], C. Florescu[1]
[1]Laboratoire National de Santé, Dudelange, Luxembourg, [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania, [3]Centre Hospitalier du Nord, Ettelbruck, Luxembourg

Background & Objectives: Melanocytic lesions with MYO5A::NTRK3 fusion are a subset of Spitz tumours, associated with a spindle cell morphology and a neuroid appearance.
This presentation highlights the morphological, immunohistochemical and molecular features of a Spitz melanocytoma and a Spitz melanoma, in which a MYO5A::NTRK3 fusion was detected.
Methods: Case 1: A 45-year-old female presented on the left arm an atypical pigmented lesion of 7x8 mm.
Case 2: A 47-year-old male presented a tumour on the ear, measuring 32x12 mm, initially suspected as squamous cell carcinoma.
The two lesions were excised and underwent pathological examination.
Results: Both cases showed a compound melanocytic proliferation with fusiform morphology, focal neuroid pattern and immunohistochemical expression of pan-TRK.
Case 1: Microscopic examination revealed a biphasic melanocytic population: a central fusiform component with desmoplastic stroma, surrounded by a peripheral nevoid component. Focally, the cellularity was increased and some nuclei were hyperchromatic. No dermal mitoses were found.
The expression of p16 and MelanA was diminished in the fusiform component. The diagnosis of Spitz melanocytoma was established.
Case 2: The histological examination showed a densely cellular, ulcerated melanocytic lesion with focal necrosis. The architecture was fascicular, with neuroid appearance. Pseudo-Verrocay bodies were focally noted. In some areas, the spindle cells were monomorphic, while other areas showed significant pleomorphism. Deep dermal mitoses were present (4 mitoses / mm^2).
P16 expression was partially absent. The proliferation index was high.
DNA sequencing revealed a TERT gene mutation. The TMB was 19.8 mutations/Mb.
RNA sequencing was performed in an external reference laboratory and a MYO5A::NTRK3 fusion was detected. A diagnosis of Spitz melanoma was rendered.
Conclusion: The fusiform morphology and the neuroid pattern strongly correlate with the presence of MYO5A::NTRK3 fusion and are consistent with the data described in the literature.
The identification of an NTRK3 fusion could represent a potential therapeutic target for melanoma cases.

E-PS-05-066
Merkel cell carcinoma in a young immunocompetent patient with MCPyV positivity
B. Yeni Erdem[1], M. Artukoglu[1], S. Ozturk Sari[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Pathology, Istanbul, Turkey

Background & Objectives: Merkel cell carcinoma (MCC) is an aggressive neuroendocrine carcinoma of the skin, typically seen in elderly patients. Although extremely rare, MCC can occur in younger individuals. Immunosuppression, especially related to solid organ transplantation, hematologic malignancies, and HIV, is a significant risk factor for younger patients. However, the occurrence of MCC in immunocompetent younger patients remain exceptional. Herein, we present a case of MCC in an immunocompetent young patient diagnosed through Merkel cell polyomavirus (MCPyV) antibody positivity, despite initially negative CK20 staining.
Methods: A 45-year-old male patient presented with a palpable, firm mass in the left gluteal region. Patient had no prior medical history. Diagnostic biopsy revealed a tumour composed of nests and trabecular arrangements of round-shaped, blue cells with narrow cytoplasm, occasionally exhibiting plasmacytoid appearance. Differential diagnoses included small round cell tumours, metastatic carcinoma, and lymphoma.
Results: Immunohistochemically, tumour cells were negative for CK20, positive for pan-cytokeratin, NSE, chromogranin, synaptophysin, INSM1, and MCPyV clone Ab3, with a high Ki-67 proliferation index. Local wide excision revealed a 2.2 cm nodular lesion in deep dermis. Repeat CK20 staining demonstrated focal and weak perinuclear dot-like positivity. Crucially, MCPyV antibody clone Ab3 was positive and MCC was diagnosed.
Conclusion: MCC predominantly affects patients over the seventh decade of life, with only 4% diagnosed below the fifth decade. Our patient's young age, immunocompetent status, and initially negative CK20 biopsy made diagnosis challenging. The identification of MCPyV positivity was crucial for diagnostic confirmation.
Although rare, MCC should be considered in younger immunocompetent patients presenting with atypical skin lesions. In such challenging scenarios, utilizing MCPyV testing can significantly aid in accurate diagnosis. Small number of MCC cases in young, immunocompetent patients have been reported, but MCPyV status is documented in only two cases. To our knowledge, this is the second MCC report with MCPyV positivity in a young, immunocompetent patient.

E-PS-05-067
Cutaneous involvement of extranodal NK/T cell lymphoma, nasal type, a clinical and histopathological presentation of two cases
D. Aloui[1], I. Chelly[1], A. Zehani[1], K. Bellil[1], H. Azouz[1], S. Haouet[1]
[1]Rabta Hospital, Department of Pathology, Tunis, Tunisia

Background & Objectives: Extranodal natural killer/T-cell (ENK/T) lymphoma is a rare Epstein-Barr virus (EBV)-associated neoplasm. The skin is the second most common site of involvment after the upper aerodigestive tract. It has various histopathological findings and numerous differential diagnoses.
Methods: We present two cases of cutaneous involvement of Extranodal NK/T Cell Lymphoma, nasal type, emphasizing its clinical presentation and histopathological findings.
Results: The first case is a 34-year-old man presented with multiple plaques infiltrating the trunk and limbs for 3 months, in the context of weakness and fever. Physical examination revealed the presence of an inguinal lymph node. Microscopic examination showed cutaneous tissue with extensive ulceration and necrosis in the epidermis. The dermis and subcutaneous tissue contained a diffuse lymphoid infiltrate composed of small to medium-sized cells. Angiotropism with angiodestruction and thrombosis was observed. Immunohistochemical study demonstrated intense and diffuse positivity of the tumour cells for CD56 and CD3, with rare lymphocytes expressing CD20.
The second case is a 52-year-old woman presented with a 5 cm erythematous to violaceous nodule on her back, which had been evolving for 6 months, and a similar 1.5 cm nodule on her right leg. Microscopic examination revealed cutaneous tissue with focal epidermal ulceration.

The dermis and subcutaneous tissue showed a dense malignant lymphoid proliferation organized in diffuse sheets. The cells were medium to large. There were areas of tumour necrosis and angiotropism. Immunohistochemical analysis showed positivity of the tumour cells for CD3 and CD56, while they were negative for CD20, ALK, CD4, and CD8. CD30 marked some active lymphocytes. The search for EBV by in situ hybridization showed nuclear positivity.
Conclusion: ENK/T cell lymphoma is characterized by the coexistence of tumour necrosis and angioinvasion. The differential diagnosis includes primary cutaneous Gamma Delta T-cell lymphoma, and peripheral T-cell lymphoma.

E-PS-05-068
Differential diagnosis challenges. Overlapping histological features between IgG4 related desease and EPGA
D. Accalai[1], L. Pilloni[1], A. Canino[1], L. Nonnis[1], M. Vincis[1], E. Noto[1], R. Ambu[1], C. Gerosa[1], D. Fanni[1]
[1]University of Cagliari, Department of Medical Sciences and Public Health, Cagliari, Italy

Background & Objectives: IgG4-related disease (IgG4-RD) is an inflammatory disorder responsible for fibrosing, tumefactive lesions that can involve the lacrimal gland as well as the extraocular muscles, orbital soft tissues, sclera, and local nerves. Eosinophilic granulomatosis with polyangiitis (EGPA) constitutes an unusual disorder which is characterized histopathologically by necrotizing vasculitis, extravascular granulomas and tissue infiltration by eosinophils. The differential diagnosis between these conditions can be complex.
Methods: A 12-year-old patient underwent biopsy sampling for a right orbital neoformation. The main specimen measured 23x8x7 mm and contained two whitish lesions measuring 10x5 mm and 7x4 mm, while a second conjunctival sampling measured 4x3x3 mm. Immunohistochemical analysis showed positivity for CD68++, CD163++, CD38++, CD138+ and IgG4+ (>10/HPF), with mixed infiltration of B (CD20+) and T (CD2+) lymphocytes. The absence of immunoreactivity for BRAF V600E, S100 and CD56 excluded some differential diagnoses of neoplastic nature.
Results: Histological analysis revealed a mixed cellular infiltrate characterized by numerous IgG4+ polytypic plasma cells and a storiform arrangement of fibrous tissue, elements suggestive of IgG4-RD. However, the presence of foci of necrosis and neutrophilic granulocytes made it necessary to consider a differential diagnosis with EGPA. Negativity for BRAF V600E and S100 ruled out a neoplastic process. These histologic findings, although indicative, require clinical and laboratory framing to define with certainty the nature of the lesion, thus guiding therapeutic management.
Conclusion: The case highlights the difficulty in the differential diagnosis between IgG4-RD and EGPA, given the overlapping histological features. The presence of IgG4+ plasma cells points toward IgG4-RD, but the necrosis and mixed infiltrate dictate careful evaluation. A multidisciplinary approach, with clinicopathologic correlation, is essential to establish the definitive diagnosis and set the correct treatment.

E-PS-05-069
Folliculotropic mycosis fungoides: a clinicopathological study of a case series of 12 patients
H. Maaroufi[1], I. Helal[1], S. Ben Cheikh[1], F. Khanchel[1], H. Hammami[2], E. Ben Brahim[1], R. Jouini[1], A. Chadli[1]
[1]Habib Thameur Hospital, Department of Pathology, Tunis, Tunisia, [2]Habib Thameur Hospital, Department of Dermatology, Tunis, Tunisia

Background & Objectives: Folliculotropic mycosis fungoides (FMF) is a rare variant of cutaneous T-cell lymphoma (CTCL), comprising only 10% of all mycosis fungoides cases. Distinct clinical and histological features have been identified in patients with FMF. In this study, our aim was to provide through a case-series additional information regarding its clinicopathological features.
Methods: Twelve patients diagnosed in the department of pathology of Habib Thameur Hospital between 2008 and 2024 were identified. The clinical data and microscopic features of these cases were reviewed and analysed.
Results: Patients mean age was 46.1 years [15–73] with a male-to-female ratio of 1.4:1. The median diagnostic delay was 130 days [65-303]. Clinically, all patients presented with erythematous plaques, 58% of which were infiltrated. One case also exhibited a tumour on the right cheek. Lesions were localized to the trunk and extremities in seven cases, to the face and neck in 4 cases and were generalized in 3 cases. Three cases showed alopecic plaques, with one case associated with eyebrow depilation. A total of 22 biopsies were performed. Histopathological analysis revealed epidermotropism in 20 cases and pilotropism in all cases. Immunohistochemical analysis demonstrated a CD3 positive staining and a high CD4/CD8 ratio in all cases. A CD7 loss was found in 71% of biopsies.
Conclusion: FMF occurs more frequently in male patients and in those in the fifth decade of life. Skin lesions often persist for months before diagnosis, with a diagnostic delay varying between 18. Clinically, FMF presents with plaques, acneiform lesions, follicular keratosis, and alopecia. Lesions primarily affect the head, neck, upper extremities, and torso, distinguishing FMF from classical MF. Histopathologically, FMF is characterized by dense lymphocytic infiltrates around hair follicles, often accompanied by follicular mucinosis. Loss of T-cell antigens like CD7 is common. Multiple biopsies may be necessary before a definitive diagnosis could be rendered.

E-PS-05-070
Melan-A-positive cells in re-excision samples for skin cancer and melanoma: a possible diagnostic trap
C. Cacchi[1], M. Lammert[1], N. Ortiz-Brüchle[1], D. Jonigk[1], S. Büsker[1]
[1]Institute for Pathology RWTH Uniklinik, Aachen, Germany

Background & Objectives: Rutinary diagnostics of malignant melanoma involves the evaluation of skin re-excision specimens.
It is also possible to observe the presence of factors that may complicate the diagnosis such as a dense inflammatory infiltrate and/or the presence of melanophages and/or melanin in the dermis of the observed specimen.
Methods: We retrospectively re-evaluated the malignant melanoma re-excision samples in our database, in which case Melan-A immunohistochemical staining was used to exclude the presence of malignant melanoma.
Results: Of the retrospectively identified cases in which excisional enlargement was performed following the diagnosis of malignant melanoma, immunohistochemical staining with Melan-A was performed in eight cases, Melan-A-positive cells were observed in the dermis without an additional associated melanocytic lesion. These were always single cells in the dermis without cytological atypia or mitotic activity. In those cases where it was performed, immunohistochemical staining for HMB45 did not show aberrant expression.
In two cases subsequent histological processing with serial sections of the specimen showed the presence of an associated melanocytic nevus; in one case, (associated with the presence of inflammatory infiltrate) melanocytes were present in the border zone between dermis or subcutaneous tissue ; the subsequent processing of the sample showed the presence of atypical melanocytes, present in aggregates and not individually, suggestive for malignant melanoma.
Conclusion: The data in our observation suggest that the rare, Melan-A positive dermal cells melanoma could be found in re-excisions specimens due to malignant melanoma diagnosis made earlier.

The absence of cytologic atypia and HMB45 abnormal recation support the diagnosis of benign, melanocytes.
An accurate and careful evaluation of other morphological parameters (such as inflammatory infiltrate or the localization of melanocytes in the vicinity of subcutaneous tissue) requires a thorough examination of the histological sample with serial sections to exclude the presence of melanocytic nevi or malignant melanoma residues.

E-PS-06-001

Bichromatic squamous epithelium: an artifact associated with the use of Lugol's iodine solution in oesophageal endoscopic submucosal dissection specimens

S. Soni[1], T. Wang[1], R. Bechara[2], D. Hurlbut[1]
[1]Queen's University, Department of Diagnostic and Molecular Pathology, Kingston, Canada, [2]Queen's University, Department of Medicine (Gastroenterology), Kingston, Canada

Background & Objectives: Endoscopic Submucosal Dissection (ESD) is a minimally invasive endoscopic technique used for the en bloc resection of precancerous lesions and early-stage cancers in the oesophagus. For squamous neoplasia, Lugol's iodine is used during ESD procedures to better delineate the lesion, enhancing visualization during resection. This study highlights a notable histopathological artifact observed in the squamous epithelium of oesophageal ESD specimens treated with Lugol's iodine.
Methods: This is a retrospective review of nine oesophageal ESD cases performed at our institute between 2018 and 2024. Prior oesophageal biopsies were available in five of these patients. The cohort included individuals diagnosed with squamous dysplasia and/or invasive squamous cell carcinoma. Clinical procedure notes, endoscopic images, histopathology slides, and pathology reports from both biopsy and ESD specimens were reviewed to assess findings related to Lugol's iodine.
Results: Lugol's iodine was applied in all biopsy and ESD procedures. In ESD cases with squamous dysplasia (low and high grade) and/or squamous cell carcinoma, the dysplastic squamous epithelium exhibited a distinctive layered bichromatic (two-toned) appearance with a superficial band-like zone where the cells displayed cytoplasmic eosinophilia and nuclear pyknosis. This distorted histology presented a diagnostic challenge, as the artifact was confined to the superficial layer of the dysplastic epithelium, mimicking a less severe degree of dysplasia. No biopsy specimen exhibited this artifact, likely due to shorter iodine exposure time pre-formalin fixation compared to ESD specimens. This artifact was absent in normal squamous epithelium. The concentration of Lugol's iodine (variable; 1.25-2.5 %) did not affect this artifact development.
Conclusion: As ESD is increasingly used to treat oesophageal squamous neoplasia, recognizing this epithelial artifact associated with Lugol's iodine application is important for the surgical pathologist. The nuclear changes and altered nuclear-cytoplasmic ratio in the superficial squamous epithelium may interfere with accurate histological diagnosis of dysplasia severity.

E-PS-06-002

E-Cadherin and P53 expression in colorectal adenocarcinoma: impact on prognosis and survival

M. Hamdani[1], S. Hidouri[2], K. Belhaj Ali[2], A. Khabir[2]
[1]Regional Hospital Sadok Mkadem of Djerba, Department of Pathology, Djerba, Tunisia, [2]University Hospital of Medenine, Department of Pathology, Medenine, Tunisia

Background & Objectives: Colorectal cancer (CRC) is a major public health concern worldwide, including in Tunisia. Despite therapeutic advances, recurrence and metastasis remain the leading causes of mortality after surgery. We investigated the expression of P53 and E-cadherin and their association with histo-prognostic factors, prognosis, and overall survival.
Methods: We included 100 patients diagnosed with colorectal adenocarcinoma over 88 months. Histopathological data were collected from the University Hospital of Medenine and the private laboratory of Dr. Nejib Ben Yahia in Djerba. Immunohistochemical (IHC) analysis was performed on paraffin-embedded tissues for E-cadherin and P53 antibodies. Immunostaining was semi-quantified based on the percentage of stained cells and staining intensity. A final score was calculated for each case and dichotomized into positive and negative categories based on a predefined threshold. Statistical analyses were performed using SPSS version 22.
Results: IHC analysis was conclusive for both antibodies in 75 patients. Loss of E-cadherin expression was significantly associated with advanced tumour stages (III and IV; $p = 0.047$), lymph node involvement ($p = 0.002$) and lymphatic invasion ($p = 0.035$). P53 expression was significantly linked to the presence of an additional tumour component (e.g., mucinous) ($p = 0.022$) and venous invasion ($p = 0.046$). A positive correlation was found between high E-cadherin and P53 expression ($p = 0.009$). Patients with low E-cadherin expression had better 3-year overall survival ($p = 0.008$). No significant association was found between P53 expression and survival.
Conclusion: Loss of E-cadherin expression is associated with a poorer prognosis. In contrast, the prognostic value of P53 in colorectal adenocarcinoma remains controversial, with our study showing no significant impact of its expression on overall survival. These findings highlight the need for further exploration of biomarkers to refine prognosis and optimize CRC management.

A challenging case of three concomitant tumours in a young woman

M.-G. Tanasă[1,2], A.-M. Trofin[3,4], C.-E. Andriescu[1,2], L. Lozneanu[1,2], S.-M. Tanasă[1,2], B. Toma[1,2], D.-G. Ciobanu-Apostol[1,2]
[1]"Grigore T. Popa" University of Medicine and Pharmacy of Iasi, Pathology, Iași, Romania, [2]County Clinical Emergency Hospital of Iasi "Sf. Spiridon", Pathology, Iași, Romania, [3]"Grigore T. Popa" University of Medicine and Pharmacy of Iasi, General Surgery, Iași, Romania, [4]County Clinical Emergency Hospital of Iasi "Sf. Spiridon", General Surgery, Iași, Romania

Background & Objectives: Primary small bowel adenocarcinoma (SBA) is a rare gastrointestinal cancer with a low incidence among young people. The atypical clinical presentations, the potential to metastasize to the ovary and the association with a primary ovarian cancer constitute a diagnostic and therapeutic challenge.
Methods: We present the case of a 39-year-old female patient which was admitted to the surgical clinic for upper abdominal pain accompanied by vomiting. Imagistic investigations detected the presence of a right ovarian tumour mass and a jejunal stenosing lesion, for which segmental enterectomy and right adnexectomy was performed through laparoscopy. The specimens were processed by classic histopathological methods with additional immunohistochemical tests.
Results: Gross examination of intestinal specimen revealed the presence of an exophytic polypoid and stenosing lesion, the microscopic examination establishing the diagnosis of low-grade adenocarcinoma of the jejunum, invasive to the subserosal layer. Histopathological examination of ovarian specimen revealed the presence of two distinct entities: an ovarian metastasis of intestinal adenocarcinoma and a cystic teratoma with mature tissues with an ovarian strumal carcinoid component. Additional immunohistochemical tests, positive for Villin, CDX2 and CK20 markers in the tumour area, confirmed the diagnosis of ovarian metastasis of intestinal adenocarcinoma. Synaptophysin, chromogranin A and CD56 positivity markers but calcitonin negativity established the diagnosis of ovarian strumal carcinoid. Postoperative

evolution of the patient was favourable, but given the association of these tumours, genetic testing for Lynch syndrome was recommended.
Conclusion: This case highlights an unusual diagnostic association, jejunal adenocarcinoma with ovarian metastasis, being entities rarely reported in the literature to date. The incidental discovery of ovarian strumal carcinoid adds an increased level of complexity to this case, thus emphasizing the importance of histopathological diagnosis with additional immunohistochemical tests for establishing the suitable therapy.

E-PS-06-004
Early gastric cancer specimens resected by endoscopic submucosal dissection – is tumour microenvironment CD10 expression significant?
A. Cibotariu[1], A. Voiosu[2,3], A.E. Bastian[1,3], A. Cioroianu[1], L.E. Stanciu[1], R. Ionescu[1], R. Neagu[1], D.-M. Marinoiu[1], A. Bordea[1], V. Marin[1], C. Popp[1]
[1]Colentina University Hospital, Pathology, Bucharest, Romania, [2]Colentina University Hospital, Gastroenterology, Bucharest, Romania, [3]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background & Objectives: Cancer-associated fibroblasts are a dominant stromal component assisting in tumour development by influencing tumour growth, invasion and metastasis. CD10 is a cell surface type II zinc-dependent metalloprotease structurally similar to MMPs that inactivates various signalling peptides. The role of CD10 positive stromal cells is known in breast and colo-rectal carcinoma, but understudied in gastric carcinoma. This study aims to investigate whether CD10 expression is correlated with other pathological parameters in early gastric carcinoma.
Methods: Twelve patients diagnosed with early gastric carcinoma completely resected by endoscopic submucosal dissection represented the cohort. Most representative paraffin-embedded blocks were selected for analysis. CD 10 and p53 expression were evaluated using immunohistochemistry and correlated with lympho-vascular invasion and degree of local extension.
Results: The study analysed 12 patients, 8 men and 4 women with ages between 62 and 87 (median age 69 years). All cases were intestinal type early gastric carcinoma (pT1a 58.3% and pT1b 41.7%), 5 of which were located in the body (41.7%), 5 in the antrum (41.7%) and 2 in the gastroesophageal junction (16.7%). Stromal CD10 expression was detected in 5 cases (41.7%), while the remaining 7 (58.3%) were negative. CD10-positive cases associated mutant p53 pattern of expression, with complete loss of expression or overexpression. CD10 positivity also had significant correlation with tumour grade and lympho-vascular invasion.
Conclusion: Stromal CD10 expression seems to correlate with other histologic markers of aggressive behaviour. The study has limitations due to cohort size, but it emphasizes the effect tumour microenvironment has on tumour behaviour and potential to invade.

E-PS-06-005
Colorectal adenocarcinoma with regional lymph node metastases from other primary foci of cancer
D. Uzunov[1], B. Ilcheva[1], A. Fakirova[1], D. Dikov[1], S. Ivanova[1]
[1]Military Medical Academy, Pathology, Sofia, Bulgaria

Background & Objectives: Colorectal cancer is one of the commonest malignancies that the pathologist encounters in his daily work. Examination of the lymph nodes in the submitted resected specimen is a basic task, essential for correct staging and subsequent appropriate therapy for the patient. However, lymph node metastases in the colon are not always from a primary focus of colorectal adenocarcinoma.
Methods: A case study is made in which 4 cases of resected specimens of colorectal cancer with regional lymph node metastases with proven origin from other primary foci are examined using histochemical and immunohistochemical methods for period of 2 years.
Results: The results of the immunohistochemistry are the following: in the patient with colorectal and prostatic cancer all metastatic lymph nodes, which are fifteen, show origin from prostatic acinar cancer; in the patient with colorectal and serous cystadenocarcinoma of the ovaries all metastases in the lymph nodes are from the ovarian tumour; in the patient with colorectal and endometrial adenocarcinoma all the metastatic lymph nodes are from the endometrial tumour and in the patient with colorectal and invasive ductal carcinoma of the breast from 15 isolated lymph nodes, 2 of them are metastatic, 1 of which is from the invasive ductal carcinoma of the breast.
Conclusion: This case-report series aims to show that not always metastases in regional lymph nodes originate from the primary foci and to emphasize how important is the connection between the pathologist and the clinician, as well as the immunohistochemistry, so that the patient can receive the most appropriate treatment.

E-PS-06-006
A rare case of tactile corpuscle-like bodies in the rectum mimicking amyloidosis
F. Muresan[1], A.M. Niculae[1], F. Dobritoiu[2]

[1]Carol Davila University of Medicine and Pharmacy, Pathology, Bucharest, Romania, [2]Bucharest Emergency University Hospital, Pathology, Bucharest, Romania
Background & Objectives: Tactile Corpuscle-Like Bodies (TCLB) are benign, neural structures incidentally found in gastrointestinal biopsies. Fewer than 30 cases have been documented, from which only 2 located in the rectal mucosa. Due to their rarity, TCLBs may pose significant diagnostic challenges.
Methods: We present the only case of TCLB in the rectum found in the archive of The Emergency University Hospital, Bucharest. The specimen was obtained by colonoscopy and evaluated histologically with haematoxylin and eosin (H&E) and Congo red stains. Immunohistochemical analysis was performed as part of the diagnostic workup.
Results: A 45-year-old male with a history of bladder cancer underwent routine surveillance colonoscopy, during which a $3 \times 3 \times 2$ mm sessile rectal polyp was identified and resected. Histological examination revealed mucosa with relatively normal epithelium and multiple well-circumscribed, non-encapsulated, eosinophilic nodules in the lamina propria. The nodules were negative on Congo red and presented rare concentrically-arranged spindle cells with eosinophilic cytoplasm and elongated nuclei. Based on these features, a diagnosis of rectal TCLBs was established. At one-year follow-up, the patient remained asymptomatic, with no recurrence or complications.
Conclusion: TCLBs are rare, under-recognized lesions that are increasingly identified with the growing use of endoscopy. Several ethiopathogenical hypothesis have been proposed regarding TCLBs, including reactive, hamartomatous, or early neoplasic process. Few reports of peripheral nerve sheath tumours containing TCLB-like areas raised the possibility of a precursor relationship. Although they have a benign prognosis, their resemblance to other conditions such as amyloidosis or granulomatous lesions may raise diagnostic challenges. Recognizing this entity is essential to prevent misdiagnosis and avoid unnecessary interventions.

E-PS-06-007
Small bowel ganglioneuromatosis in a NF1 patient: a case report
B. Toma[1,2], M.-G. Tanasă[1,2], D.-G. Ciobanu-Apostol[1,2]

[1]"Grigore T Popa" University of Medicine and Pharmacy, Pathology, Iasi, Romania, [2]"Sf. Spiridon" Emergency County Hospital, Pathology, Iasi, Romania

Background & Objectives: Ganglioneuromatosis is a rare benign proliferation of ganglion cells, Schwann cells, and nerve fibres, associated with neurofibromatosis type 1 (NF1), multiple endocrine neoplasia type 2b (MEN2b) and Cowden syndrome. Intestinal involvement can lead to bowel obstruction. We report a case of diffuse small bowel ganglioneuromatosis in a patient with NF1, presenting with intestinal occlusion.
Methods: A 53-year-old man with NF1 presented with acute abdominal pain, distension, and absence of bowel movements. Imaging revealed small bowel obstruction. Exploratory laparotomy with segmental resection was performed. Histopathological analysis and immunohistochemistry (S100, SOX10, Synaptophysin, CD34, CD117, SMA, AE1/AE3, Ki67) were conducted for diagnosis.
Results: The resected bowel segment showed diffuse mural thickening and luminal dilatation. Histologically, there was a dense mesenchymal proliferation predominantly located in the submucosa, with extension into the lamina propria (including ulcerated mucosal areas), the muscularis propria, and the subserosa. The lesion was composed primarily of spindle-shaped Schwannian cells (S100+) and scattered ganglion cell aggregates (SOX10+, Synaptophysin+). It extended to the proximal resection margin and was associated with fibrotic and degenerative nerve changes in the subserosal space. An abundant eosinophilic infiltrate was also noted. Ki67 proliferation index was <1%. Concurrent skin biopsies revealed multiple neurofibromas. The findings established a diagnosis of diffuse intestinal ganglioneuromatosis, associated with NF1.
Conclusion: Ganglioneuromatosis is a rare complication of NF1, with limited reported cases. Diffuse intestinal ganglioneuromatosis in NF1 is unusual, with most cases affecting the large intestine. Reported small bowel cases primarily involve young adults, making our case an uncommon presentation. Beyond its potential to mimic malignancy, it may also point toward an underlying genetic syndrome. Its identification in such scenarios underscores the importance of linking histological findings to potential systemic or genetic implications.

E-PS-06-008
Comparison of CMV density with serological findings and Nancy Scores in active Ulcerative Colitis
E. Över[1], T.M. Aydin[2], M. Sezak[1], N.G. Ünal[3], S. Erensoy[4], B. Doğanavşargil[1]
[1]Ege University, Pathology, Izmir, Turkey, [2]Ege University, Internal Medicine, Izmir, Turkey, [3]Ege University, Gastroenterology, Izmir, Turkey, [4]Ege University, Medical Microbiology, Izmir, Turkey

Background & Objectives: Ulcerative colitis (UC) is a chronic inflammatory disease characterized by alternating periods of remission and exacerbation. Cytomegalovirus (CMV) infection is known to influence disease severity, contribute to immunosuppressive therapy resistance, and trigger exacerbations. This study aimed to investigate the correlation between CMV density, serological markers, and histological findings in patients with active UC.
Methods: We retrospectively analysed biopsies from hospitalized UC patients with CMV infection at Ege University's Gastroenterology Department between 2018 and 2023. CMV immunohistochemistry was performed in all cases. Histological activity was assessed using the Nancy histological scoring system. CMV density was quantified by counting positively stained nuclei per high-power field (HPF) (Olympus BX50 microscope, 40× objective, r = 0.54 mm). Data were analysed using nonparametric tests.
Results: A total of 47 patients (18 females, 29 males) were included, with a median age of 50 ± 18 years (range: 20–86). CMV infection was detected via serology in 21 cases, tissue PCR in 31, and immunohistochemistry in 24. Among immunohistochemically positive cases, serology was positive in 13, while tissue PCR was positive in 12 ($p = 0.047$, Chi-square test). The mean CMV density was 2.61 ± 2.29 per HPF (range: 1–9). Most patients (78.7%, n = 37) had a Nancy score of 4, indicating severe histological activity. Steroid resistance was observed in 32 cases (70.2%), 27 of whom had a Nancy score of 4. No correlation was found between CMV density, age, gender, and histological scores, serological markers, or PCR results.
Conclusion: CMV infection was more frequent in patients with a Nancy score of 4. Immunohistochemistry correlated better with tissue PCR than with serology. Whether CMV is a bystander or a pathogenic factor in UC remains unclear and requires further investigation

E-PS-06-009
Two rare cases of radiation-induced sarcoma: pleomorphic sarcoma and angiosarcoma
H.F. Ince[1], B.E. Yıldız[1], M. Çıkrıkçıoğlu[1], A. Sürmelioğlu[2], F. Vardar Aker[1]
[1]Haydarpasa Numune Training and Research Hospital, Pathology, İstanbul, Turkey, [2]Haydarpasa Numune Training and Research Hospital, General Surgery, İstanbul, Turkey

Background & Objectives: Radiation-induced sarcoma (RIS) is a rare, aggressive cancer that typically develops 10-15 years after radiation therapy. It occurs in irradiated tissues and is associated with high recurrence rates and poor prognosis due to late diagnosis and chemotherapy resistance. This report presents two cases of radiation-induced sarcoma in patients with a history of radiotherapy.
Methods: First case: A 53-year-old female, diagnosed with oesophageal squamous cell carcinoma in 2016, underwent chemotherapy and radiotherapy but declined surgery. 9 years post-radiotherapy, she presented with dysphagia, and an endoscopic examination revealed a mass. The esophagectomy specimen showed a polypoid tumour (4.5 x 2.3 x 1.3 cm) in the same area as the prior tumour. Histologically, the tumour was composed of pleomorphic spindle cells in fascicles. Immunohistochemistry showed focal smooth muscle actin (SMA) positivity. The diagnosis was radiation-induced pleomorphic sarcoma. Next-generation sequencing (NGS) was performed for further analysis.
Second case: A 61-year-old female, diagnosed with moderately differentiated gastric adenocarcinoma in 2014, underwent total gastrectomy followed by chemotherapy and radiotherapy. 11 years post-radiotherapy, she presented with nausea and vomiting, and ileus was diagnosed. Small bowel resection revealed a haemorrhagic, poorly circumscribed tumour of atypical spindle cells. Immunohistochemical staining was positive for ERG and CD34, confirming the diagnosis of radiation-induced angiosarcoma.
Results: The first case involved radiation-induced pleomorphic sarcoma, diagnosed 9 years after radiotherapy for oesophageal squamous cell carcinoma. The second case involved radiation-induced angiosarcoma, diagnosed 11 years after radiotherapy for gastric adenocarcinoma.
Conclusion: Radiation-induced sarcomas are rare but serious complications of radiation therapy, characterized by aggressive behaviour and poor prognosis. Their development poses a significant challenge in managing patients with a history of radiation exposure.

E-PS-06-010
A 14-year experience with appendiceal mucinous neoplasms: insights from a single-centre case series
S.B. Uran[1], I.E. Cakır[1]
[1]Izmir Katip Celebi University Ataturk Training and Research Hospital, Department of Pathology, Izmir, Turkey

Background & Objectives: Appendiceal mucinous neoplasms (AMNs) are rare epithelial tumours with varying risks of peritoneal dissemination. This study aimed to retrospectively evaluate the clinicopathological features of AMN cases diagnosed at a single centre over 14 years.
Methods: Sixty AMN cases diagnosed between 2010 and 2024 were retrospectively analysed. Patient demographics, histopathological features, pT stage, presence of appendiceal diverticulum, and accompanying neoplastic lesions were evaluated. Haematoxylin-eosin (H&E) stained slides were reviewed for grade of nuclear dysplasia, mucin extrusion, invasion depth, and related pathological findings. All cases were staged according to the 9th edition of the AJCC system.
Results: Among the 60 cases, 18 were male (30%) and 42 female (70%), with a mean age of 58 (35–89) years. Histopathological examination revealed that 56 cases (93.3%) exhibited low-grade appendiceal mucinous neoplasm (LAMN) morphology throughout, while 4 cases (6.7%) displayed high-grade features. pT staging was as follows: pTis in 29 cases (48.3%), pT3 in 4 (6.7%), pT4a in 18 (30%), and pT4b in 9 (15%). High-grade appendiceal mucinous neoplasm (HAMN) cases were all pT4. Appendiceal diverticula were found in 17 cases (28.3%). Accompanying neoplastic lesions were identified in 10 cases (16.7%), including 7 colonic adenocarcinomas (11.7%), 1 malignant mesenchymal tumour (1.7%), and 2 appendiceal neuroendocrine tumours (3.3%).
Conclusion: The analysed cases showed a broad age range, with a mean age in the late 50s, consistent with the literature. Although AMNs are reported to be slightly more frequent in females, the marked female predominance in our series is notable. The distribution of pT stages was generally in line with prior studies; notably, the low number of pT3 cases may reflect a brief or less detectable transitional phase. The relatively high frequency of diverticula and coexisting neoplasms suggests possible associations with AMN development. Further studies and large series are needed to clarify prognostic factors.

E-PS-06-011
Loss of PTEN expression as a poor prognostic marker in colorectal cancer: a Tunisian case series' study
R. Aouadi[1], A. Khemir[2], Z. Abdelkafi[3], G. Sahraoui[2], W. Kachoud[4], R. Mcheri[5], N. Ben hamida[5], R. Doghri[2], L. Charfi[2], K. Mrad[2]
[1]Pathology Department, Salah Azaiez Institute, Tunis, Tunisia, [2]Pathology Department, Salah Azaiez Institute, Faculty of Medicine of Tunis, University of Tunis Al Manar,Precision Medicine and Oncology Investigation Laboratory (LR21SP01), Tunis, Tunisia, [3]Pathology Department, Salah Azaiez Institute, Precision Medicine and Oncology Investigation Laboratory (LR21SP01), Tunis, Tunisia, [4]Higher Institute of Medical Technologies of Tunis, Tunis, Tunisia, [5]Pathology Department, Salah Azaiez Institute, Faculty of Medicine of Tunis, University of Tunis Al Manar, Precision Medicine and Oncology Investigation Laboratory (LR21SP01), Tunis, Tunisia

Background & Objectives: Colorectal cancer (CRC) is one of the most common cancers and the third cause of death by cancer worldwide. Discovering new prognostic markers such as PTEN and developing new targeted therapies could improve patients' care. Loss of PTEN expression in CRC could indicate an aggressive clinical course, impacting patients' prognoses and outcomes.
Methods: This is a retrospective monocentric study at the Pathology department of Salah Azaiez Institute using Tissue micro-array samples and immunohistochemical techniques for studying PTEN expression in CRC in a Tunisian case series.
Results: Our case series included 21 patients (12 males and 9 females). The mean age was 52 years. PTEN expression was retained in 71.43% of cases and lost in 9.52% of cases. Loss of PTEN expression was observed in tumours which size exceeded 10cm in largest diameter. Loss of PTEN expression was also observed in tumours with advanced pT stage (pT3 or pT4) and those with lymph node metastases.
Conclusion: In our series, PTEN expression was lost in 9.52% of cases. These results are consistent with those reported in literature, where loss of PTEN expression in CRCs accounted for nearly 8% of cases in most studies. Loss of PTEN expression was observed in tumours with large size and advanced pT and pN stages. According to literature, loss of PTEN expression in CRC is associated with more advanced stages of the disease, local recurrence and distant metastases, notably liver metastases. Our results are consistent with those reported in the literature.

E-PS-06-012
Expecting the unexpected: a case report of a MiNEN in the ampullary region with a NET G3 component in a patient with BRCA2 mutation
M. D'Arezzo[1,2], M. Pagnanelli[1,2], M. Sollai Pinna[1], S. Uccella[1,2]
[1]Humanitas Research Hospital, Rozzano, Italy, [2]Humanitas University, Department of Biomedical Sciences, Milan, Italy

Background & Objectives: This study describes a rare case of Mixed Neuroendocrine / non-neuroendocrine Neoplasm (MiNEN) of the ampullary region composed of adenocarcinoma and NET G3, along with a systematic review of the few similar cases in literature.
Methods: A 47yo female patient with BRCA2 germinal mutation and breast cancer presented with US-diagnosed bile ducts dilation. Endoscopically, the duodenal papilla was bulging and eroded and a biopsy was diagnosed as "carcinoma, NOS". She underwent duodenocefalopancreatectomy.
Results: Microscopically, an ampullary neoplasms composed of two different cell population was found: one showed glandular adenocarcinoma morphology and the other showed a solid-trabecular growth of polygonal cells with round nuclei and granular cytoplasm. Negative immunostains for GATA3 and Mammaglobin ruled out a metastatic breast carcinoma. CK7 was diffusely positive in the glandular part and negative in the solid-trabecular one. Chromogranin A and Synaptophysin were positive in the solid-trabecular component and negative in the glandular one. Ki67 PI was 25% in the solid-trabecular component and mitotic index was 17 mitoses x2mm^2. p53 and Rb1 showed a wild type pattern at immunohistochemistry. A MiNEN composed of adenocarcinoma (40%) and NET G3 (60%) was diagnosed. A systematic review of the literature retrived only 12 known cases of MiNEN: 11 mixed adenocarcinoma-NEC and only 1 adenocarcinoma-NET.
Conclusion: MiNENs of the ampullary region are exceedingly rare, with only 13 known cases (including ours). Here, we report the second case of mixed adenocarcinoma-NET of this site. Since the symptoms are similar to other types of neoplasia of the same region, and since the gold standard for an optimal diagnosis is an extensive sampling, the final diagnosis could be delayed.

E-PS-06-013
Neoadjuvant chemotherapy combined with cytoreductive surgery (CRS) and hyperthermic intraperitoneal chemotherapy (HIPEC) in patients with peritoneal colorectal carcinomatosis: an observational study of 178 patients
C.-M. Vieru[1], W. Vásques Jiménez[2], E. Sola Vendrell[3], O. Mateo-Sierra[4], M.J. Fernández Aceñero[5]
[1]Hospital Central de la Defensa Gómez Ulla, Surgical Pathology, Madrid, Spain, [2]Hospital General Universitario Gregorio Marañón, General Surgery, Madrid, Spain, [3]Universidad Complutense de Madrid, Facultad de Veterinaria, Madrid, Spain, [4]Hospital General Universitario Gregorio Marañón, Neurosurgery, Madrid, Spain, [5]Hospital Clínico San Carlos, Surgical Pathology, Madrid, Spain

Background & Objectives: Colorectal cancer (CRC) is the second leading cause of cancer-related death worldwide, primarily attributed to metastatic disease. Selected patients with peritoneal colorectal carcinomatosis could be offered a curative-intent strategy based on CRS combined with HIPEC, following neoadjuvant systemic chemotherapy.
Methods: We searched the pathology archives of our department between 2003 and 2019 and retrospectively analysed sociodemographic (age and sex), clinical and surgical (timing of peritoneal carcinomatosis (synchronous vs metachronous), chemotherapy regimens, CRS and HIPEC intervention date, Peritoneal Cancer Index (PCI), Completeness of Cytoreduction (CC) score, relapse date, severe complications, mortality) and histological data (tumour histological subtype, TNM status, immunohistochemical and molecular status and histological response evaluated using Peritoneal Regression Grading Score (PRGS)).
Results: 178 patients were retrospectively studied, 50% males and 50% females, with median age of 60 years. All patients received CRS combined with HIPEC, after neoadjuvant systemic chemotherapy and were divided into two groups based on histological response [complete (18) and incomplete (160)], with 10,1% of complete response, consistent with the literature. The statistical analysis showed that tumour histological subtype, lymph node involvement, KRAS status and PCI are significantly associated with the histological response (p=0.007, 0.006, 0.036 and 0.000, respectively) and consequently with progression-free survival (PFS).
Conclusion: Selected patients with peritoneal colorectal carcinomatosis could be offered a curative-intent strategy based on CRS combined with HIPEC, following a neoadjuvant systemic chemotherapy and some of them can achieve pathological complete response, offering prognostic information. Significant predictor factors of pathological response could be helpful to enable a better selection of patients who are candidates for this treatment, with the aim of optimizing benefits and minimizing risks within the context of personalized medicine.

E-PS-06-014
Mixed neuroendocrine-non-neuroendocrine neoplasms (MiNENs): first case-series in an Oncology Hospital in Portugal
C. Perez Duque[1], A.L. Cunha[1]
[1]Instituto Português de Oncologia do Porto Francisco Gentil, E.P.E. (IPO Porto), Pathology Department, Porto, Portugal

Background & Objectives: Mixed neuroendocrine-non-neuroendocrine neoplasms (MiNEN) are a rare occurrence in the gastrointestinal tract (GI). These tumours have both neuroendocrine and non-neuroendocrine differentiation, each component representing at least 30%. We report the first case-series of MiNEN in an Oncology Hospital in Portugal.
Methods: We performed a retrospective analysis of patients with MiNEN diagnosis from January 2010 to February 2025 at IPO Porto, Portugal. Information regarding clinical data, tumour details, immunohistochemical markers, pathological stage, treatment modalities, clinical and oncological outcomes were collected.
Results: Twelve patients with diagnosis of MiNEN in the GI tract were found in our centre. Four patients were females and the average age at diagnosis was 67,9 (26 - 83) years. The most common tumour location was the stomach in eight patients, two in right colon and two in the oesophagus/gastroesophageal junction. All patients underwent surgery. In the entire patient group, the neuroendocrine component was a poorly differentiated neuroendocrine tumour, small or large cell carcinoma (NEC), and the non-neuroendocrine component was adenocarcinoma. One tumour had amphicrine features. All patients had lymph nodes metastases.
Conclusion: To our knowledge this report details the first case-series of MiNEN of the GI tract diagnosed in a Portuguese Oncology Hospital. The results obtained, which show a NEC component in association with an adenocarcinoma, are consistent with the findings presented in previous studies. This association is linked to poor prognosis, predominantly due to the high grade neuroendocrine tumour. Furthermore, we report an amphicrine tumour diagnosed in the right colon. Overall, this report gathers further insights into knowledge of MiNEN.

E-PS-06-015
BRAF and PD-L1 protein signatures in early colon cancer – correlations with intratumor lymphocytes
V.N. Marin[1], L. Nichita[1], M. Cioplea[1], A. Voiosu[2], D. Marinoiu[1], A. Cibotariu[1], L. Stanciu[1], R. Ionescu[1], R. Neagu[1], A. Bordea[1], C. Popp[1]
[1]Colentina University Hospital, Department of Pathology, Bucharest, Romania, [2]Colentina University Hospital, Department of Gastroenterology, Bucharest, Romania

Background & Objectives: Endoscopic submucosal dissection (ESD) for early colonic cancer (ECC) is an emerging therapeutical option, that allows a curative minimal invasive approach, offering for microscopical assessment full-thickness mucosa malignant lesions. This study evaluates, on a small prospective cohort, the expression of various histopathological and immunohistochemical parameters, correlated with tumour progression: differentiation, desmoplasia, intratumor lymph cells (TILs), BRAF and PD-L1 expression.
Methods: Twenty consecutive patients with ESD fully resected ECC were included in this study. The whole tumour was assessed on multiple sections according to European guidelines. TILs and desmoplasia were evaluated using a four-steps qualitative scale. Immunohistochemical assays were performed on the most representative paraffin blocks. BRAF expression was assessed in tumour cells from the invasive component, while PD-L1 in stromal and inflammatory cells within the invasive tumour.
Results: Ten tumours exhibited submucosal invasion (pT1), while the other 10 invaded only the lamina propria (pTis). Histologic grade was usually high (15 lesions), without any correlation with invasion stage. BRAF was negative in all lesions. PD-L1 was positive in 10 cases, usually in small proportion of cells (median value 10 percent, ranging from 1 to 30 percent). There was a significant positive correlation between PD-L1 expression and number of TILs (two-tailed P value 0.0091), cases with more TILs having a constantly higher expression of PD-L1. Also, PD-L1 expression was higher (without statistical significance) in stromal component of pT1 tumours, than in pTis ones. Tumours with high levels of desmoplasia had, also, higher expression of PD-L1 (but not of TILs).
Conclusion: PDL-1 overexpression, known to correlate with short overall survival in colonic cancer, is also correlated, in ECC, with the presence of TILs, feature that has a positive prognosis value. These interesting data from a small study, are tackling the insides of immune response and effects of immunotherapy in colorectal cancer.

E-PS-06-016
Chondroid metaplasia of peritoneum incidentally detected after total gastrectomy: a case report
G. Ozkaya[1], K. Simsek[1], O.C. Gunizi[1], G.O. Elpek[1]
[1]Akdeniz University, Pathology, Antalya, Turkey

Background & Objectives: Chondroid metaplasia of the peritoneum is a rare condition in which mesothelial or fibroblastic cells transform into chondrocytes, forming cartilage-like tissue without atypia and independent of malignant mesothelial neoplasms, metastatic carcinoma, or foetal implantation. The primary causes are previous abdominal surgeries and trauma. Here, we present a case of chondroid metaplasia of peritoneum in a patient with both trauma and malignancy, suggesting alternative pathogenic mechanisms.
Methods: A 64-year-old woman with a history of rib fractures due to a car accident and Herpes Zoster infection 1.5 years ago presented with stomach pain. Abdominal CT revealed a 27x21 mm irregularly

bordered, heterogeneous contrast-enhancing mass attached to the gastric wall at the hepatogastric ligament. Endoscopy identified an infiltrative tumour mass in the antrum and angulus, and biopsy confirmed gastric adenocarcinoma. The patient received four cycles of neoadjuvant FLOT treatment and showed a nearly complete response according to the PET findings. Total gastrectomy with D2 dissection was performed.
Results: Histopathological examination of the total gastrectomy specimen confirmed the diagnosis of poorly differentiated gastric adenocarcinoma in microscopic foci. Immunohistochemical analysis showed that HER-2 was negative. According to the TNM classification, the case was reported as ypT2 ypN1. Additionally, a firm, single, flesh-coloured nodule, measuring 3 cm, was incidentally found on the peritoneal surface of the perigastric fat tissue. Histopathological evaluation confirmed the presence of mature hyaline cartilage without cytological atypia, leading to the diagnosis of chondroid metaplasia.
Conclusion: Chondroid metaplasia of the peritoneum is rarely reported and is usually found incidentally. Our case is the first in the literature to involve both a history of trauma and a malignant tumour diagnosis. Further research is needed to better understand the various aetiologies of chondroid metaplasia.

E-PS-06-017
A rare tumour of the gallbladder: mixed lymphoepithelioma-like carcinoma and adenocarcinoma
S.D. Turgut[1], S.B. Yolburun[1], Ö.C. Günizi[1], G.Ö. Elpek[1]
[1]Akdeniz University, Pathology, Antalya, Turkey

Background & Objectives: Lymphoepithelioma-like carcinoma (LELC) is a rare malignancy characterized by poorly differentiated epithelial cells with dense lymphoplasmacytic infiltration. Although it is most commonly found in the nasopharynx, lung, and thymus, gallbladder involvement is extremely rare. Due to the limited number of reported cases, its prognosis and optimal treatment approach remain uncertain. We present a rare case of gallbladder carcinoma with mixed histology of LELC and adenocarcinoma, contributing to the scarce literature on this entity.
Methods: An 86-year-old woman presented with abdominal pain and distension in February 2025. Imaging revealed a polypoid lesion with exophytic growth in the gallbladder wall, leading to a cholecystectomy.
Results: Macroscopic examination revealed a 2 cm polypoid tumoral lesion located 1 mm from the surgical margin. Histologic evaluation showed poorly differentiated tumour cells with dense lymphoid infiltration in some areas and glandular structures in others. Immunohistochemistry demonstrated cytokeratin 7 and cytokeratin 19 positivity in both the undifferentiated tumour cells and glandular areas. Vimentin positivity was observed only in the solid areas with undifferentiated tumour cells. Based on these findings, a diagnosis of mixed LELC and adenocarcinoma was made. Epstein-Barr virus (EBV) was negative in immunohistochemical staining. Microsatellite instability (MSI) testing revealed preserved mismatch repair (MMR) proteins.
Conclusion: Gallbladder LELC is an exceptionally rare tumour and should be considered in the differential diagnosis of gallbladder neoplasms. LELC is generally associated with a more favourable prognosis compared to conventional gallbladder carcinoma. Further studies are needed to clarify its biological behaviour and guide treatment strategies.

E-PS-06-018
Imatinib and immunosuppression: an overlooked side effect?
S. Aftab[1], A. Ranjan[1]
[1]All India Institute of Medical Sciences, Lab Oncology, New Delhi, India

Background & Objectives: Gastrointestinal stromal tumours (GIST) are rare malignancies mainly found in the stomach and small intestine, known for their variable malignancy. Here, we present a case involving Tuberculosis (TB) in conjunction with GIST.
Methods: A unique case was retrieved from the hospital record
Results: A 37-year-old male with a history of Gastrointestinal Stromal Tumour (GIST) and prior surgical resection presented with recurrent abdominal pain. Ultrasound revealed a mesenteric mass indicating GIST recurrence, confirmed by biopsy. During exploratory laparotomy, dense adhesions and extensive mesenteric involvement halted the procedure. Six months of Imatinib therapy followed, with partial response seen on CT scans. Treatment continued for two years, but a subsequent scan showed a 28% mass increase with fibrosis and calcified granulomas. An enterocutaneous fistula appeared, leading to a three-month Sunitinib course, but no improvement was observed on follow-up scans. Regorafenib was initiated, but cavitary lung lesions, fibrotic changes, and lymphadenopathy raised suspicion of tuberculosis. Regorafenib was stopped, and Anti-tuberculosis therapy (ATT) was administered. After nine months, continued chest symptoms required a six-month ATT extension. The patient's condition stabilized, but an abdominal mass remained, suggesting old tuberculosis. Follow-up is ongoing.
Conclusion: This case report highlights the challenges posed by the coexistence of recurrent GIST and TB infection in a patient. Imatinib, a cornerstone of GIST therapy, not only targets cancer-specific receptors but also modulates T cell function. While not typically considered a predisposing factor for TB, previous reports have suggested potential associations between Imatinib therapies leading to immune-suppression followed by flaring up of tuberculosis. This raises questions about its impact on immune susceptibility.

E-PS-06-019
Submucosal lipomatosis of the appendix: a rare clinical entity
D.A. Grubišić[1], S. Tomić[1]
[1]University Hospital Centre Split, Clinical Department of Pathology, Forensic Medicine and Cytology, Split, Croatia

Background & Objectives: Submucosal lipomatosis of the appendix was first described histopathologically by Antonci in 1956. It is a rare clinical entity that can sometimes be mistaken for a tumour on clinical and radiological evaluation. This condition is often associated with localized symptoms or acute appendicitis, for which it is frequently the underlying cause. Unlike a true lipoma, submucosal lipomatosis lacks a well-defined capsule.
Methods: We present the case of a 48-year-old patient who arrived at the Emergency Department with severe abdominal pain that initially began in the epigastrium before migrating to the lower right quadrant. Abdominal ultrasound revealed a tubular, aperistaltic structure measuring 1.1 cm in diameter with a "targetoid" appearance in the ileocecal region. Blood tests showed elevated leukocyte and C-reactive protein levels, prompting the surgical team to proceed with an appendectomy.
Results: Macroscopic examination of the resected appendix, which measured 8 cm in length and up to 2 cm in diameter, revealed a markedly thickened, whitish wall forming a tumour-like mass of 1.5 cm in length. The serosa appeared gray, inflamed, and exhibited increased vascularity. Histological analysis demonstrated pronounced lobules and sheets of mature adipocytes within the appendiceal wall. The appendix also showed partial necrosis and dense granulocytic inflammatory infiltrate, which extended into the tumour-like mass, contributing to its characteristic macroscopic appearance.
Conclusion: While some authors argue that small amounts of submucosal fat within the appendiceal wall are common, submucosal lipomatosis is distinguished by its size and mass-like appearance. Recognizing this condition through both radiological and histopathological examinations is crucial, as it can lead to complications such as intussusception, torsion, and inflammation. The main radiological differential diagnoses include isolated acute appendicitis, small and large bowel obstruction, and carcinoma. Furthermore, due to the presence of necrosis and

degenerative changes in the adipocytes at the histopathological level, careful evaluation is necessary to rule out malignancy.

E-PS-06-020

Grossing the Whipple: a tertiary cancer centre's experience with ampullary lesions and a review of major macroscopic features

J.N. Peixoto[1], M. Alzamora[1], A. Varelas[1], A.L. Cunha[1], L.P. Afonso[1]
[1]Portuguese Oncology Institute of Porto (IPO-Porto), Department of Pathology, Porto, Portugal

Background & Objectives: Ampullary adenocarcinomas constitute 6-9% of all periampullary malignancies. These lesions can cause exuberant clinical manifestations, such as obstructive jaundice and weight loss, and thus motivate surgical intervention, representing approximately 15% of pancreaticoduodenectomies. The Whipple procedure remains a cornerstone of treatment for such lesions, although less invasive interventions are preferable when possible. Establishing an intra-or peri-ampullary origin for tumours poses a diagnostic challenge, and proper grossing is crucial in demonstrating the specific localization of these neoplasms. Likewise, adenomyomatous hyperplasia is a rare cause of biliary obstruction and common bile duct dilation, mimicking malignancy and posing a diagnostic challenge prior to surgical intervention, possibly leading to overtreatment. We propose to review ampullary lesions in our institute that motivated surgical intervention, including adenomyomatous hyperplasia centred in the ampulla.
Methods: We performed a review of cases with ampullary lesions treated primarily with cephalic duodenopancreatectomy in our institution over a 15-year period, through a query of internal records. Relevant clinical and pathological information was retrieved and analysed. Histological slide analysis is ongoing.
Results: Preliminary results of our review show that, between January 2010 and December 2024, 47 cases of ampullary lesions were treated with cephalic duodenopancreatectomy, with a slight predominance of intra-ampullary lesions. Notably, 25.3% (12/47) of these cases presented with concurrent or isolated adenomyomatous hyperplasia. Further analysis and review of the histological slides are required to confirm these initial observations.
Conclusion: Our preliminary review underscores the diagnostic difficulties in distinguishing between various types of ampullary lesions, highlighting the need for thorough gross examination, detailed histological assessment, and consideration of clinical presentation. In particular, the presence of adenomyomatous hyperplasia in a subset of cases may have implications for both diagnosis and management. Ultimately, our findings may contribute to refining diagnostic protocols and improving patient outcomes.

E-PS-06-021

Evaluation of non-conventional dysplasias associated with inflammatory bowel disease – a single centre experience

A. Sejben[1], Z. Balajthy[1], Z.K. Török[1], S. Almási[1], T. Lantos[2]
[1]University of Szeged, Department of Pathology, Szeged, Hungary, [2]University of Szeged, Department of Medical Physics and Informatics, Szeged, Hungary

Background & Objectives: Patients with inflammatory bowel disease (IBD) have a higher risk of developing neoplasms, due to chronic inflammatory milieu. In the last couple of years, new, non-conventional entities have been identified, reflecting generally poorer prognosis. Our study aimed to examine and compare all IBD-associated dysplasias, to identify their frequency in a Southern Hungarian population, and to further characterize their clinicopathologic features, as well.
Methods: A consecutive database was built from all IBD patients, who were diagnosed and/or treated in the Albert Szent-Györgyi Clinical Centre of the University of Szeged between 2011 and 2023. Basic clinicopathological data were collected from medical charts, and all neoplastic samples have been reevaluated. Statistical analysis was carried out by using khi-square, Mann-Whitney, and Kruskal-Wallis tests, with SPSS Statistics V 23.0 software (Armonk, USA).
Results: In the examined 13 years, 2397 patients were either diagnosed or treated with IBD, and 176 of them had a neoplastic sample. Non-conventional dysplasia was diagnosed in 50 patients. The most frequent subtype proved to be serrated lesion NOS (n=20; 40%), followed by hypermucinous (n=14; 28%), goblet cell deficient (n=9; 18%), sessile serrated lesion-like (n=6; 12%) and traditional serrated adenoma-like dysplasia (n=1; 2%). Significant association was found between the presence of non-conventional dysplasia and patient's age (p=0.003), IBD subtype (p=0.037), endoscopic appearance (p=0.01), the development (p<0.001), localisation (p<0.001), size (p<0.001), macroscopic appearance (p<0.001), grade (p<0.001), histological subtype (p<0.001), T (p=0.003) and M stage (p=0.012), mismatch repair protein status (p=0.007) of carcinoma, and the presence of lymphovascular invasion (p=0.024).

Conclusion: Based on our results, it can be stated that non-conventional dysplasias are fairly common in IBD-associated neoplastic samples (50/176; 28%). Due to their uncertain behaviour, complete resection needs to be proven, and patients may benefit from a closer follow-up.

Reproducibility examination of histopathological growth patterns of liver metastases in a retrospective, consecutive, single-centre, cohort study

A. Sejben[1], S. Almási[1], B. Pósfai[1], B. Baráth[1], Á.K. Ferenczi[1], P. Abbasi[1], T. Zombori[1], T. Lantos[2]
[1]University of Szeged, Department of Pathology, Szeged, Hungary, [2]University of Szeged, Department of Medical Physics and Informatics, Szeged, Hungary

Background & Objectives: Histopathological growth patterns (HGPs) of liver metastases have been determined to have prognostic value. So far, only 2 studies have analysed the reproducibility of HGPs. Our study aimed to examine the reproducibility of the assessment of HGPs.
Methods: In our retrospective, consecutive, single-centre, cohort study, a database was built from patients who were operated on due to liver metastases at the University of Szeged, between 2011 and 2023. In each case, basic histopathological data were registered. Histological slides were collected and individually evaluated by 5 doctors and 2 medical students, with different years of experience in gastrointestinal pathology. Statistical analysis was carried out, and our methods were intraclass correlation and Fleiss' kappa.
Results: Our study comprised the resection specimens of 205 patients, with altogether 336 metastatic foci, of mostly gastrointestinal origin (n=188). Excellent agreement was reached between both the pathology specialist trainees (ICC score: 0.903) and the board-certified pathologists (ICC score: 0.983). The general agreement between all 7 evaluators proved to be moderate, with an ICC score of 0.738.
Conclusion: Our study proves that HGPs could be reliably determined for those who have at least 2 years of work experience in general pathology. This is the first study that includes the most board-trained pathologists included in the reproducibility examination of HGPs.

Funding: This work was supported by the University of Szeged, Faculty of Medicine Research Fund-Heténi Géza Grant (IV-134-62-1/2024. SZAOK)

Down-regulation of long intergenic non-protein coding RNA 261 confers favourable prognosis and improved response to neoadjuvant CCRT in patient with rectal cancers

I-W. Chang[1,2]
[1]Wan Fang Hospital, Taipei Medical University, Department of Clinical Pathology, Taipei, Taiwan, [2]School of Medicine, College of Medicine, Taipei Medical University, Department of Pathology, Taipei, Taiwan

Background & Objectives: The introduction of neoadjuvant concurrent chemoradiotherapy (CCRT) for patients with resectable rectal cancer not only improves survival rates but also increases the likelihood of curative surgeries. long intergenic non-protein coding RNA 261 (LINC00261), a long non-coding RNA (lncRNA), has been extensively documented as playing diverse roles across various cancer types and participating in numerous cellular processes. However, no comprehensive evaluation has been conducted on the relationship between LINC00261 expression, response to neoadjuvant CCRT, and survival rates in patients with rectal cancer.
Methods: A comparative analysis of gene expression profiles from the transcriptomic dataset (GSE35452) identified LINC00261as the most significantly up-regulated lncRNA. Tumour samples were collected from 343 primary rectal cancer patients who underwent neoadjuvant CCRT followed by surgical resection. The expression level of LINC00261 was semi-quantitatively assessed using in situ hybridization. Subsequently, statistical analyses were conducted to examine the relationship between LINC00261 expression, various clinicopathological features, and survival outcomes. Real-time RT-PCR was used to validate the transcription level between responders and non-responders in an independent cohort ($n = 8$ in each group).
Results: Decreased expression of LINC00261 showed significant correlations with less advanced post-treatment tumour invasiveness, negative post-treatment nodal metastasis, absence of vascular invasion and perineural invasion, and improved response to neoadjuvant CCRT (all $p \leq 0.024$). Diminished expression of LINC00261 was associated not only with favourable disease-specific survival (DSS), local recurrence-free survival (LRFS) and metastasis-free survival (MeFS) (all $p < 0.0001$) in univariate analysis but also functioned as an independent predictor signifying enhanced clinical outcomes, including DSS, LRFS, and MeFS (all $p < 0.001$). In the real-time RT-PCR analysis, the transcriptomic levels were significantly lower in the responder group compared to the non-responder group ($p = 0.007$).
Conclusion: LINC00261 may play a significant role in rectal cancer progression and response to neoadjuvant CCRT, serving as a novel prognostic factor.

E-PS-06-024

Unveiling medullary rectosigmoid carcinoma: a rare clinical presentation and comprehensive review of literature

S. Al Khatib[1], S. Abusini[1], Y. Irshied[2], M. Al Orjani[1], M. Banihani[2]
[1]Jordan University of Science and Technology, Pathology and Microbiology, Irbid, Jordan, [2]Jordan University of Science and Technology, General Surgery and Urology, Irbid, Jordan

Background & Objectives: Medullary carcinoma (MC) of the rectosigmoid is an extremely rare and poorly understood subtype of colorectal cancer, constituting a small percentage of cases. It is characterized by its unique histological features, including solid, syncytial sheets of large eosinophilic cells with abundant lymphocytic infiltration and the absence of glandular differentiation. MC is frequently associated with microsatellite instability (MSI) and mismatch repair (MMR) protein deficiencies, particularly MLH1 and PMS2, and it often demonstrates a favourable prognosis, particularly in the absence of distant metastases. The diagnosis of MC is challenging due to its overlap with other poorly differentiated carcinomas.
Methods: A 50-year-old male with a history of sarcoidosis and chronic steroid use presented with left lower quadrant abdominal pain and altered bowel habits. Imaging studies revealed a rectosigmoid mass with regional lymphadenopathy. A left-sided colectomy, revealed features consistent with MC. IHC demonstrated positivity for calretinin and loss of MLH1 and PMS2, confirming the diagnosis of MC with microsatellite instability. The tumour was staged as pT3N0Mx, with no evidence of lymphovascular space invasion or perineural invasion.
Results: The histological and immunohistochemical findings, combined with the patient's favourable prognosis, underscore the importance of accurate diagnosis. MC, with its unique immune microenvironment and association with MSI, may exhibit a more favourable clinical course compared to other poorly differentiated colorectal carcinomas, making early recognition and surgical resection pivotal for optimal outcomes. This case contributes to the growing body of literature on the diverse clinical presentations of MC and reinforces the need for a comprehensive diagnostic approach to guide management.
Conclusion: Based on a literature review conducted from 2012 to 2023, our case is the first reported instance of a male patient with rectosigmoid medullary carcinoma. This case highlights the clinical and molecular variability of MC, which contrasts with the typical presentation in older females and the proximal colon.

E-PS-06-025

Complete response rate analysis in neoadjuvant therapy with FLOT (Fluorouracil, Leucovorin, Oxaliplatin and Taxol) in adenocarcinoma of oesophagogastric junction

M. Bonfitto[1], V. Silva[2], N. Andreollo[2], V. Junior[2]
[1]State University of Campinas, Laboratório de Anatomia Patológica - Gastrocentro Unicamp, Campinas, Brazil, [2]State University of Campinas, Departamento de Gastrocirurgia - Hospital de Clínicas da Unicamp, Campinas, Brazil

Background & Objectives: The incidence of adenocarcinoma of oesophagogastric junction (AOJ) has increased in recent years due to obesity and gastroesophageal reflux disease. It is the tumour with the highest mortality among gastrointestinal tumours. The rate of increase in incidence over the past four decades is the highest of any cancer, especially in high-income countries.
The aim of this study was to analyse the response of AOJ to the neoadjuvant perioperative chemotherapy regimen FLOT (Fluorouracil, Leucovorin, Oxaliplatin and Taxol) through histopathological analysis of the surgical specimen after esophagectomy.
Methods: Twenty patients who underwent video-assisted thoracoscopic esophagectomy with oesophagogastroplasty after a FLOT neoadjuvant regimen (average of 4 sessions) were analysed and divided into 2 subgroups: complete and incomplete responses.
Results: Surgical specimen analysis showed a complete response to FLOT in 4 patients (20%) (pT0N0M0 – 3 cases and pT0N1M0 – 1 case), including one poorly differentiated tumour with signet ring cells in the preoperative biopsy. The four received four cycles of neoadjuvant FLOT regimen with 100% of the dose calculated by weight. Approximately 40 days after esophagectomy, all 20 patients received other four sessions of FLOT. However, 10 (50%) required reduced doses or postponement of the adjuvant therapy intervals due to toxicity/weakness. The median survival was 19 months, with a maximum of 60 months. Patient pT0N1M0 developed lung metastasis and survived for 13 months. Among the 13 patients who are still alive, 8 are disease-free.

Conclusion: When other modalities of neoadjuvant therapy are considered and similar case series in current literature are analysed, the perioperative FLOT chemotherapy regimen in AOJ is proving to be an effective option. Indeed, it was associated with a disease free status in

almost half of the patients in the present study. Larger case series could be performed in order to place the FLOT regimen among the treatment options with better response in AOJ.

Funding: Educorp - State University of Campinas (UNICAMP)

E-PS-06-026

Systemic sclerosis of colon with severe constipation and colonic pseudo-obstruction

H.J. Choi[1], J.-Y. Moon[2]
[1]St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Department of Pathology, Suwon, Republic of Korea, [2]St. Vincent's Hospital, College of Medicine, The Catholic University of Korea, Department of Surgery, Suwon, Republic of Korea

Background & Objectives: Systemic sclerosis of the digestive tract is very rare and commonly occurs in the oesophagus, large intestine, small intestine and stomach in that order.
Methods: A 72-year-old woman presented with severe constipation and abdominal pain. Right hemicolectomy was performed because the patient did not respond to medical treatment.
Results: Grossly, the specimen showed a dilatation of the lumen of the ascending colon (megacolon) measuring approximately 20cm in length. Histologically, Muscularis propria showed multifocal atrophy with replacement by fibrosis. There was extensive collagenization in the submucosa and fibrosis in small vessels. Immunohistochemically, infiltrating lymphocytes were predominantly CD4 rather than CD8. Congo red staining was negative.
Conclusion: We report a rare case of systemic sclerosis of colon that is histologically difficult to experience.

E-PS-06-027

Human epidermal growth factor receptor 2 (HER2) expression prevalence in gastroesophageal adenocarcinomas in Malaysia

P. Puspanathan[1], S. Armon[2], J.K. Sou[3], C.H. Fong[4], Y.M. Tang[3], M. Thiagarajan[5]
[1]Hospital Pulau Pinang, Department of Pathology, Pulau Pinang, Malaysia, [2]Hospital Kuala Lumpur, Department of Pathology, Kuala Lumpur, Malaysia, [3]Hospital Pulau Pinang, Department of Surgery, Pulau Pinang, Malaysia, [4]Hospital Pulau Pinang, Department of Radiotherapy & Oncology, Pulau Pinang, Malaysia, [5]Hospital Kuala Lumpur, Department of Radiotherapy & Oncology, Kuala Lumpur, Malaysia

Background & Objectives: The 5-year prevalence of gastric and oesophageal adenocarcinomas in Malaysia, are 6.8 and 1.7 per 100 000 population and is a major cause of mortality and morbidity. Gene amplification and overexpression of *HER2* in gastroesophageal adenocarcinomas (GEA) are associated with aggressive disease and the introduction of targeted therapy has demonstrated significant benefit. *HER2* testing in GEA is sporadically performed in Malaysia with limited local data.
Methods: HER2 immunoexpression in 41 biopsies and 13 resection specimens from 54 patients (39 males, 15 females) aged between 23-77 years with advanced GEA from two government hospitals between 2022 to 2025 were studied. Two sample groups were tested with HER2 immunohistochemistry (IHC); patients for an industry driven research (IDR) preliminary screening (28) with confirmatory testing [IHC and Dual-colour dual-hapten in situ hybridization (DDISH)] and the other upon clinical request (26). IHC was interpreted as 0 /1+(negative); 2+(equivocal) and 3+(positive) by two pathologists following 2016 CAP-ASCP-ASCO HER2 testing in gastroesophageal adenocarcinoma guideline and compared with DDISH results when available.
Results: From the 54 samples, 49 were from primary site (Oesophagus, cardio-oesophageal junction[COJ], stomach) and 5 from metastatic sites. 39 (72%) of IHC were interpreted as negative, 10 (19%) as equivocal and 5(9%) as positive. Overall, 10 cases (19%) showed HER-2 DDISH amplification (6) and 3+ IHC (4). Tumour with intestinal differentiation were HER2 amplified/ overexpressed in 7/30 cases (23%) compared to diffuse type 2/21(10%). HER2 positivity was higher in COJ/oesophagus specimens (9/10) and in biopsies (10/10).
Conclusion: 28% of the cases were either equivocal or positive for HER2 IHC with 19% displaying *HER2* amplification or 3+ IHC, in keeping with range of 6.8% to 26.8% described in literature. Most positive samples were COJ/oesophagus biopsies with propensity to GEA with intestinal differentiation. Despite the limited cases, GEA HER2 immunoexpression in Malaysia appears consistent with other countries.

E-PS-06-028

Perianal ectopic breast fibroadenoma: a rare case report

E. Salmo[1], N. Haboubi[2]
[1]Northern Care Alliance NHS Group, Oldham Care Organization, Histopathology, Oldham, United Kingdom, [2]Spire Manchester Hospital, Histopathology, Manchester, United Kingdom

Background & Objectives: Ectopic breast tissue is an uncommon phenomenon and is situated along the so-called Milk Line that extends from the axilla to the vulva [1]. Various histopathological appearances have been described ranging from normal breast tissue to cancer [2]. We report an unusual case of fibroadenomatous type changes in perineum in a woman who presented with an anal lesion/mass clinically.
Methods: A 43 years old woman complained of persistent perianal lesion causing discomfort. Clinically it appeared a soft cystic mass and an excision biopsy was then undertaken.
Results: Grossly, the specimen was a well-defined firm white nodule measuring 21x15mm. Microscopically, the mass was composed of proliferating ductal tissue showing minimal epithelial hyperplasia embedded in spindle cell breast type stroma resembling fibroadenomatoid hyperplasia (figure 1a). Immunohistochemical stains for CK7 (figure 1b), ER (figure 1c), and GATA3 (figure 1d) were strongly positive confirming breast tissue phenotype.
Conclusion: Ectopic female breast tissue is often seen in the axilla but can be anywhere along the milk line/mammary ridge which extends from the breast to the groin including the vulva and perineum and less commonly reported in the buttock, neck, face, flank, arms, hips, shoulders and back [3, 4, 5]. Ectopic breast tissue may become more pronounced owing to hormonal changes during puberty and pregnancy. In our case, there were focal changes suggestive of fibroadenomatoid hyperplasia but there was no evidence of atypia or malignancy in the tissue examined. This is a rare phenomenon in which the pathologist should be aware of and be included in the differential diagnosis of any perianal mass.

E-PS-06-029

Intracholecystic papillary neoplasm, an incidental finding: report of two cases

I. Butka[1], A. Bombonati[1], Y. Persidsky[1], M. Mollaee[1]
[1]Temple University Hospital, Anatomic and Clinical Pathology, Philadelphia, USA

Background & Objectives: Intracholecystic papillary neoplasm of the gallbladder (ICPN) is a rare, premalignant lesion of the gallbladder, with the potential for progression to invasive gallbladder carcinoma. It was first recognized by the World Health Organization (WHO) in 2010 and proposed in the 2019 WHO classification, as a unique preinvasive neoplasm of gallbladder. Despite its malignant potential, ICPN generally has a better prognosis than invasive carcinoma. This report highlights two cases which were diagnosed after routine cholecystectomy and underlines the importance of early detection and histopathological diagnosis.

Methods: The first case we present is a 57-year-old female, with a history of recurrent right upper quadrant pain and gallstones, who underwent abdominal ultrasound that revealed two non-mobile, echogenic lesions in the gallbladder. Post-cholecystectomy histology confirmed ICPN, with a mixture of gastric pyloric-type epithelium, foveolar, and oncocytic epithelium. The second case is a 62-year-old male, who was referred to general surgery due to a suspicious polypoid mass in the gallbladder fundus on CT imaging. Laparoscopic cholecystectomy revealed a mass measuring 1.6 cm and confirmed on histology as ICPN. None of those lesion showed high-grade dysplasia or invasive carcinoma.
Results: ICPN is often found incidentally during imaging or post-cholecystectomy histological evaluation and it may present with symptoms similar to cholelithiasis. Most cases are non-invasive, however there is potential for malignancy, especially in the presence of high grade dysplasia or papillary growth pattern. This underscores the importance of histopathological examination in confirming the diagnosis and determining the risk of malignancy.
Conclusion: ICPN is a rare gallbladder lesion, but a small fraction can progress into invasive carcinoma. The need for screening guidelines is essential for early detection of the disease to prevent malignant transformation into invasive carcinoma. Pathological study of this type of lesion is important to identify the main characteristics that influence patient prognosis and survival.

E-PS-06-030
A rare case of primary pancreatic ductal adenocarcinoma and synchronous serous carcinoma of the ovary
N. Ntalakos[1], M. Arnaouti[1], E. Arkoumani[1]
[1]Saint Savvas Anticancer Hospital of Athens, Department of Surgical Pathology, Athens, Greece

Background & Objectives: An 82-year-old female patient is diagnosed, via Endoscopic ultrasound-guided fine needle biopsy, with pancreatic ductal adenocarcinoma and subsequently undergoes distal pancreatosplenectomy. During the procedure two additional masses are found in the woman's abdominal and pelvic cavity and are therefore sent in the Pathology Department for evaluation.
Methods: An Intraoperative Frozen Section Consultation of the abdominal mass revealed a tumour with papillary growth and fluid-filled cysts, microscopically suggestive of malignancy with papillary architecture. Following surgery, the rest of the resected specimens, consisting of the pancreas, spleen and pelvic mass, were sent for further studying.
Results: Morphological and immunohistochemical analysis confirmed the two macroscopically similar masses as extraovarian presentations of serous carcinoma of the ovary [WT1(+), ER (+), PR (+), p16 (+), p53(+)]. Specifically, the abdominal mass consisted mostly of a borderline serous component with low-grade and high-grade areas, whereas the pelvic mass consisted solely of a high-grade serous component. Histopathological examination of the pancreas confirmed the diagnosis of pancreatic ductal adenocarcinoma [CK7(+), CK17(+), CK20(+), WT1(-), ER (-), PR (-), p16 (-), p53(-)].
Conclusion: The identification of synchronous ovarian and pancreatic malignancies raises the possibility of an inherited genetic predisposition, including Hereditary Non-Polyposis Colorectal Cancer/Lynch Syndrome, Familial Adenomatous Polyposis (FAP), Hereditary Breast and Ovarian Cancer (BRCA 1 or 2 mutation), Peutz-Jeghers Syndrome and Li-Fraumeni syndromes. Genetic counselling for the patient's immediate family should be considered.

E-PS-06-031
Squamous cell carcinoma following treated oesophageal intramucosal adenocarcinoma: an unusual scenario
A. Elmahs[1,2], M. Hayley[1], K. Robertson[3], M. Elgoweini[1]
[1]University Hospital Crosshouse, Pathology Department, Kilmarnock, United Kingdom, [2]Faculty of Medicine, Helwan University, Pathology Department, Cairo, Egypt, [3]University Hospital Crosshouse, General Surgery Department, Kilmarnock, United Kingdom

Background & Objectives: Radiofrequency ablation (RFA) is an established treatment for high grade dysplasia and intramucosal adenocarcinoma, where it may be used in combination with endoscopic mucosal resection (EMR). Squamous cell carcinoma (SCC) is a very rare complication of these interventions. To our knowledge, this is the first case of SCC arising following combined EMR and RFA for intramucosal adenocarcinoma.
Methods: A 75-year-old male with a history of Barrett's oesophagus (BO) diagnosed in 2002 was lost to follow-up. Upon re-referral in 2017, endoscopy revealed a suspicious lesion at 39cm from the incisors. Biopsy confirmed intramucosal adenocarcinoma on a background of BO with high-grade dysplasia (HGD).
Results: The patient was treated with two rounds of neoadjuvant chemotherapy (carboplatin/capecitabine), followed by EMR. Microscopy confirmed ypT1a (m3) intramucosal adenocarcinoma close to deep margin in the EMR specimen. Follow-up biopsies at 2 and 6 months showed chronic inflammation and intestinal metaplasia without dysplasia or malignancy. He subsequently received RFA. At 12 months follow-up, endoscopy revealed a stricture suspicious for malignancy and repeat biopsies confirmed a poorly differentiated SCC. This was confirmed by immunohistochemistry. Imaging (CT and CT-PET) staged the SCC as T2/T3, with no nodal or distant metastases. The radical curative surgical approach was declined by the patient. Given the recent interventions (EMR & RFA) and risk of worsening dysphagia with radiotherapy, the multidisciplinary team opted for palliative stenting.
Conclusion: This case illustrates a rare but serious complication of combined EMR and RFA for treatment of early adenocarcinoma arising in BO and highlights the necessity of long-term surveillance and repeat biopsies.

E-PS-06-033
Gastroesophageal adenocarcinoma and Human epidermal growth factor receptor 2 (HER2) testing validation in Malaysia
P. Puspanathan[1], S. Armon[2], C.H. Fong[3], J.K. Sou[4], Y.M. Tang[4], M. Thiagarajan[5]
[1]Hospital Pulau Pinang, Department of Pathology, Pulau Pinang, Malaysia, [2]Hospital Kuala Lumpur, Department of Pathology, Kuala Lumpur, Malaysia, [3]Hospital Pulau Pinang, Department of Radiotherapy & Oncology, Pulau Pinang, Malaysia, [4]Hospital Pulau Pinang, Department of Surgery, Pulau Pinang, Malaysia, [5]Hospital Kuala Lumpur, Department of Radiotherapy & Oncology, Kuala Lumpur, Malaysia

Background & Objectives: HER2 immunohistochemistry (IHC) with confirmatory in-situ hybridisation is routinely performed on breast cancers in hospitals in Malaysia but sparsely performed in Gastroesophageal Adenocarcinomas (GEA) despite evidence of targeted therapy benefit in patients with HER2 overexpression and gene amplification. The challenges of staining variability and heterogeneity of HER2 IHC interpretation is recognised worldwide. This study investigates the interobserver variability between two pathologists while validating HER2 immunohistochemistry at respective laboratories.
Methods: HER2 immunoexpression for 54 patients with advanced GEA from two government hospitals between 2022 to 2025 were studied. Two sample groups were tested with HER2 immunohistochemistry (IHC); patients for an industry driven research (IDR) preliminary screening (28) with confirmatory testing [IHC and Dual-colour dual-hapten in situ hybridization (DDISH)]and upon clinical request (26). IHC was interpreted as 0 /1+(negative); 2+(equivocal)

and 3+(positive) by two pathologists, independently following 2016 CAP-ASCP-ASCO HER2 testing in gastroesophageal adenocarcinoma guideline and compared with confirmatory IHC/DDISH. Both pathologists are trained and certified for IHC interpretation. Weighted Kappa was performed for assessment of agreement.
Results: Out of the 54 cases, the pathologists achieved agreement in 52 cases with a weighted Kappa = 0.932 (95% CI). Two discrepant cases were reported as 1+ vs 2+ and 2+ vs 3+. Concordance between the pathologist and IDR confirmatory tests (either IHC or IHC & DDISH, n=28) was substantial with weighted Kappa =0.729 (95%CI). Discrepancies were present in 5 cases.
Conclusion: The interpretation of GEA HER2 IHC requires practise as it is different from breast cancer and the heterogenous nature complicates interpretation. The excellent agreement of HER2 IHC interpretation between both pathologists and good concordance between pathologist and confirmatory tests in an established laboratory is an encouragement for pathologist to perform HER2 IHC testing for GEA confidently in all laboratories within Malaysia.

E-PS-06-034
Value of flow cytometry in the diagnosis of complex celiac disease
I. Sureda Alberti[1], M.A. Martinez Ortega[1], I. Torralba Cloquell[1], V. Cunill Monjo[2], E. Pol Pol[2], C. Garrido Duran[3], N. Chausse Vazquez de Parga[3], I. Amengual Antich[1]
[1]Son Espases University Hospital, Anatomical Pathology, Palma de Mallorca, Spain, [2]Son Espases University Hospital, Immunology, Palma de Mallorca, Spain, [3]Son Espases University Hospital, Gastroenterology, Palma de Mallorca, Spain

Background & Objectives: The analysis of intraepithelial lymphocytes (IELs) in the duodenal mucosa by flow cytometry (lymphogram) identifies a specific lymphocyte profile in celiac disease (CD), serving as a complementary diagnostic tool in borderline or discordant cases and even in the follow-up of suspected refractory CD. It is also useful in patients who have initiated a gluten-free diet (GFD) without prior diagnosis, since certain IELs subpopulations remain elevated. This study describes cytometric and histological findings in various clinical scenarios of suspected CD.
Methods: Thirty-five patients with suspected CD were retrospectively reviewed between August 2023 and February 2025, and classified into five groups: (1) inconclusive serology and intraepithelial lymphocytosis (n=8), (2) villous atrophy with negative serology (n=5), (3) GFD without prior diagnosis (n=16), (4) paediatric patients with borderline serology (anti-TG2: 7–16 AU/mL) (n=4), and (5) suspected refractory CD type II (n=2), defined by >15–20% aberrant T cells ($sCD3^-$, $icCD3^+$). The lymphogram in our series included the evaluation of $TCR\gamma\delta^+$, $CD45^+$, and $CD3^-$ NK-like IELs. A CD-compatible lymphogram was defined by $TCR\gamma\delta^+$ IELs >15%.
Results: The lymphogram was compatible with CD in 14 of 35 patients, distributed among groups 1 (n=2), 2 (n=3), 3 (n=8), and 4 (n=1). Aberrant T cells (<10%) were identified in 1 patient from group 5 and 2 additional patients from group 2.
Conclusion: IELs profiling contributed to the diagnosis of CD in 40% of the patients evaluated, demonstrating its complementary value in complex clinical settings, particularly in patients on a GFD without a confirmed diagnosis. Additionally, it may also help in seronegative cases (regardless of the degree of atrophy), in borderline histology or non-celiac lymphocytosis, and in the early detection and monitoring of refractory CD type II. Nonetheless, this case series is limited, and larger studies are needed to confirm these findings.

E-PS-06-035
Spatial mapping reveals heterogeneous immune microenvironments in the evolution of colitis-associated colorectal cancer
K. Bräutigam[1], S. Mandal[1,2], M. Yalchin[1], H.E. Grant[1], N. Trahearn[1], S. Nowinski[1], I. Al Bakir[1,3], J. Fisher[1,3], H. Sefton[1], K. Smith[1], M. Moorghen[4], M. Rodriguez-Justo[5,6], S.J. Leedham[7,8], A.-M. Baker[1], A. Hart[3], T. Graham[1]
[1]Institute of Cancer Research, Centre for Evolution and Cancer, London, United Kingdom, [2]Institute of Cancer Research, Data Science Team, London, United Kingdom, [3]St Mark's Hospital, Inflammatory Bowel Disease Unit, Harrow, United Kingdom, [4]St Mark's Hospital, Department of Histopathology, Harrow, United Kingdom, [5]University College London Hospital, Department of Pathology, London, United Kingdom, [6]University College London, UCL Cancer Institute, London, United Kingdom, [7]University of Oxford, Wellcome Centre for Human Genetics, Oxford, United Kingdom, [8]University of Oxford, Translational Gastroenterology Unit, Nuffield Department of Medicine, John Radcliffe Hospital, Oxford, United Kingdom

Background & Objectives: Patients with inflammatory bowel disease have a higher risk of colitis-associated colorectal cancer (CA-CRC), but microenvironmental factors driving progression remain unclear. This study explores evolution of the immune microenvironment in two human ulcerative colitis (UC) whole colons through space and time.
Methods: Cellular microenvironments of two total panproctocolectomy specimens (UC1 and UC2), including preoperative biopsies, were digitally analysed using 166 H&E-stained whole slide images (WSI) from tissue sections sampled every 2 cm around the entire bowel. A state-of-the-art convolutional neural network-based cell classifier examined 592 pathologist-annotated regions of interest (ROIs) across non-dysplastic mucosa, dysplasia, and carcinoma to quantify densities of four immune cell types (lymphocyte, neutrophil, eosinophil, and plasma cell), along with epithelium and fibroblasts. T-cell receptor (TCR) sequencing (n=35 UC1; n=76 UC2) profiled T-cell clonal composition and dynamics across colons and through time.
Results: UC1 comprised 124 WSI with 23 dysplasia samples and four cecal adenocarcinomas, while UC2 contained 42 WSI with three foci of "indefinite for dysplasia". The rectosigmoid showed the highest mean lymphocyte density and unique TCR clonotype count in both colons. TCR sequencing revealed diverse clonotype distribution patterns in the UC bowels, ranging from ubiquitous presence throughout to localized patches, with some clonotypes persisting for up to 2 years. Significantly higher neutrophil densities (p=0.04) were observed cancer-near (mean 119.0/mm^2; cecum and ascending) versus -far (71.2/mm^2; transverse and below), but significantly less in dysplasia (53.6/mm^2) compared to non-dysplastic mucosa (76.2/mm^2; p=0.03). In UC1, signet-ring cell type CA-CRC exhibited much lower lymphocyte density (278.75/mm^2) compared to two conventional adenocarcinomas (1095.12/mm^2 and 1276.83/mm^2).
Conclusion: In UC, the immune microenvironment varies regionally, with the distal colon having the highest lymphocyte density and TCR diversity, whereas in CA-CRC it is subtype-dependent, but overall suggestive of an immune-privileged environment during carcinogenesis.

E-PS-06-036
Russell Body Esophagitis in Barrett's oesophagus
D. Kosemetin Dover[1], P. Idaewor[1], K. Osayi[1]
[1]Basildon University Hospital, Cellular Pathology, Basildon, United Kingdom

Background & Objectives: Russell Body Barrett's Esophagitis (RBBE)is a rare and chronic inflammatory condition that has been associated with Barrett's oesophagus and, in some cases, an increased risk of malignancy. It can be linked to various factors HIV, gastric carcinoma, monoclonal gammopathy, and hepatitis C. It is characterized by accumulation of immunoglobulin-filled plasma cells, known as Russell bodies,which can sometimes be mistaken for neoplastic cells.

It has been linked to various conditions, including H. pylori infection, gastric carcinoma, and immunological disorders.
Methods: We report a case of Russell body Barett's Esophagitis in a 82 year-old female who is on Omeprazole 20 mg and endoscopic surveillance for low-grade dysplasia and 12 cm Barrett's oesophagus diagnoses since 2015. The patient has no gastrointestinal or oesophageal symptoms. Endoscopic findings are 12 cm Barrett's mucosa and 4 cm hiatus hernia.
Results: The biopsy from oesophagus showed numerous Russell bodies with excessive plasma cells in lamina propria which are showing positive staining for CD138, kappa and lambda light chains (polyclonal) and negative for pancytokeratin AE1/AE3. Congo red stain for amiloid and Modified Giemsa for H pylori is negative. The mucosa is negative for dysplasia.
Conclusion: The inflammation in RBBE is caused by overstimulation of plasma cells, leading to the accumulation of nondegradable immunoglobulin in the endoplasmic reticulum, forming Russell bodies. Recognizing this pattern is crucial for conducting a thorough workup to exclude associated conditions. Additionally, it can sometimes be mistaken for extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue, plasmacytoma, or signet ring cell carcinoma. Given the risk of chronic inflammation potentially leading to metaplastic or neoplastic changes, patients diagnosed with Russell body gastroenteritis, especially with additional risk factors such as smoking, may require close surveillance. Further research is needed to fully understand the clinical significance of this condition and its possible long-term implications.

E-PS-06-037
Monophasic gastric tumour with MALAT1-GLI1 fusion: another variant of gastroblastoma
P. Kalinina[1], R. Brand[1], B. Mozayani[1]
[1]Medical University of Vienna, Clinical Institute of Pathology, Vienna, Austria

Background & Objectives: Gastroblastoma is an exceptionally rare gastric neoplasm, traditionally characterized as a biphasic lesion composed of epithelial and spindle cell components, originating in the muscularis propria. Most cases exhibit GLI1 gene fusions, with the MALAT1-GLI1 fusion being the most prevalent and serving as a diagnostic biomarker. Here, we present a case of an aggressive, metastasizing gastroblastoma, confirmed to harbour the MALAT1-GLI1 fusion, which exclusively displayed an epithelial pattern, thus demonstrating an atypical monophasic morphology.
Methods: See below
Results: A 50-year-old female patient was diagnosed with a 5 cm submucosal tumour in the pylorus, concomitant with two hepatic metastases. Two months following gastrectomy and liver resection, the patient required a second surgical intervention due to the development of new hepatic lesions. Nine months later, the patient underwent surgery again after multiple distant metastases were identified in the liver and peritoneum.
Histological evaluation of the aforementioned surgical samples revealed relatively uniform epithelioid cells arranged in nests and cords, with occasional microcystic changes and vague glandular formations containing eosinophilic material. The tumour cells exhibited scant to moderate eosinophilic cytoplasm and round, monotonous nuclei with fine, infrequent nucleoli, rare mitotic figures (1/5 mm²), and occasional apoptotic bodies. Tumour cells were strongly positive for keratin cocktail (CK AE1/3), CD56, and CD10. No expression of c-KIT, DOG1, CD34, SMA, desmin, synaptophysin, chromogranin or S100 was detected. Despite extensive examination, the lesions did not show a spindle cell component. The MALAT1-GLI1 gene fusion was identified in the tumour tissue.
Conclusion: Due to their extremely low incidence and the lack of distinct characteristics, gastroblastomas pose a diagnostic challenge. Their biphasic nature, characterized by the presence of both epithelial and spindle cell components, normally serves as a key diagnostic criterion. However, in our case, as well as in two recently published clinical cases, a new variant of GLI1-rearranged gastrointestinal monophasic tumours is described.

E-PS-06-038
Chondrolipoma of the oesophagus-a case report
E. Sayar[1], M. Büyük[1], G. Ünverengil[1], C. Şen[2], Z. Bayramoğlu[3], N. Berker[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Pathology, Istanbul, Turkey, [2]Istanbul University, Istanbul Faculty of Medicine, Otorhinolaryngology, Istanbul, Turkey, [3]Istanbul University, Istanbul Faculty of Medicine, Radiology, Istanbul, Turkey

Background & Objectives: Chondrolipoma is a rare, benign mesenchymal tumour composed of both mature adipose and cartilaginous tissue. It is a subtype of lipoma, a common mesenchymal tumour, distinguished by areas of cartilaginous differentiation. Chondrolipomas can develop in various anatomical sites, including soft tissues, the head and neck region, and, rarely, internal organs such as the intestines and stomach. Here, we present a case of chondrolipoma arising from the oesophagus which appears to be the first reported case in English literature.
Methods: A tumour was incidentally detected in the cervical oesophagus of a 15-year-old male three years ago. Fine needle aspiration via endoscopic ultrasound revealed mature squamous epithelial cells and subepithelial connective tissue fragments. Due to the development of dysphagia, radiologic evaluations were repeated, and magnetic resonance imaging showed a thick-walled tumour, measuring 6x4x3cm, located in the cervical oesophagus, extending into and obliterating the oesophageal lumen. Most of the mass exhibited fat signal intensity, with non-lipomatous soft tissue components. The tumour was in the submucosal layer and displaced the trachea to the right. Submucosal mass excision was performed, and haematoxylin&eosin-stained slides were evaluated.
Results: Macroscopically, a well-circumscribed, yellow-coloured lesion containing patchy white solid areas was observed. Microscopic examination revealed a lesion with mature cartilaginous and adipose tissue. No lipoblasts were identified, and no atypia, mitosis, or necrosis was observed. Focal osseous metaplasia was noted. Chondroid lipoma, hamartoma, and chondrolipoma were included in the differential diagnosis. Histomorphologic findings were consistent with lipoma with chondroid metaplasia, also known as chondrolipoma.
Conclusion: Oesophageal chondrolipoma is a rare tumour. Even though without suspicious radiologic findings for malignancy, causing symptoms may lead surgical intervention. To the best of our knowledge, this is the first reported case of oesophageal chondrolipoma. Awareness of this unusual location is important for accurate diagnosis and management.

E-PS-06-039
Combination of Hirschsprung's disease and Epstein-Barr virus infection in children
A. Drobintseva[1], D. Tonkonog[2], R. Nasyrov[2]
[1]Saint Petersburg State Paediatric Medical University, Histology and Embryology named after A.G. Knorre, Saint Petersburg, Russia, [2]Saint Petersburg State Paediatric Medical University, The Prof. D.D. Lohov Department of Pathological Anatomy with Course of Forensic Medicine, Saint Petersburg, Russia

Background & Objectives: The combination of two conditions - Hirschprung's disease (HD) and Epstein-Barr infection (EBV) create

difficulties in diagnosis and treatment. A novel perspective is the investigation of the role of microcirculatory vessels and glial cells in the pathogenesis of intestinal disorders, as well as the interplay between these components and viral agents. The objective of the study is to conduct a morphological analysis of rectal biopsy samples from children presenting with a combination of Hirschprung's disease and EBV-infection.
Methods: Rectal biopsy specimens of 15 children diagnosed with Hirschprung's disease were used in the study. Histological analysis using haematoxylin and eosin and Van Gieson staining, and immunohistochemical staining with antibodies to calretinin and viral antigens (EBV, HSV, CMV) were performed.
Results: All cases were divided into three groups according to the duration of the disease: less than 2 years, 2 to 3 years, and more than 3 years. In each case, only one ganglion was found in the field of vision. Foci of sclerosis in the intestinal mucosa and muscular layers were detected. HSV and CMV antigens were not detected. In 10 cases EBV antigen was detected in vascular endothelium and ganglion neurons, and in 2 cases - in glial cells. In one case EBV antigen was found in individual nerve trunks. Lymphocytic infiltration and large lymphoid follicles were also observed.
Conclusion: The evidence suggests that EBV affects the endothelial, neuronal, and glial cells, which may influence the morphology of Hirschsprung's disease. This highlights the need to investigate the mechanisms of this pathology. The findings open new perspectives for understanding the role of viral infection in the pathogenesis of Hirschsprung's disease and developing effective treatment strategies.

E-PS-06-040
Diagnostic significance of determining herpes viruses in epithelial tumours of colorectal localization
V. Pechnikova[1], K. Midiber[1,2], N. Shakhpazyan[1], M. Kozlova[1], Z. Gioeva[1], N. Gladyshev[1], A. Buchaka[1], L. Mikhaleva[1]
[1]Avtsyn Research Institute of Human Morphology of Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Moscow, Russia, [2]Peoples' Friendship University of Russia named after Patrice Lumumba, Moscow, Russia

Background & Objectives: Determination of the role of herpes viruses in colorectal carcinogenesis remains controversial and poorly understood, and the study of this issue is an extremely important and urgent problem within the framework of the theory of viral carcinogenesis.
Objective: Comparative assessment of clinical, morphological and molecular genetic features of benign and malignant tumours with and without herpes viruses.
Methods: We studied 134 observations with benign and malignant neoplasms of colorectal localization. The comprehensive analysis included: clinical, morphological, immunohistochemical, molecular genetic methods, as well as the method of transmission electron microscopy. Herpes viruses were determined by real-time PCR.
Results: Among all observations, Epstein-Barr virus (EBV) was detected in 22% of cases, herpes virus type 6 (HHV6) in 19%, and cytomegalovirus (CMV) in 5.2%. Herpes viruses were more often detected in malignant than in benign neoplasms (88% and 12%, respectively; $p=0.004$). In patients with benign neoplasms, infection with one of the analysed viruses was determined in almost all observations, while malignant neoplasms were characterized by a combination of several viruses, and the most common was a combination of EBV and HHV6. We obtained statistically significant data indicating a more frequent lymphovascular ($p=0.002$) and perineural ($p<0.001$) invasion in observations where herpes viruses were detected. We did not find statistically significant differences when comparing the frequency of detection of somatic mutations of *KRAS*, *BRAF* and *NRAS* and the presence of herpes viruses. The study by electron microscopy methods allowed us to identify the presence of viral agents in most samples of malignant epithelial tumours of the colon.
Conclusion: Our study demonstrates the contribution of herpes viruses to the progression of malignant tumours of colorectal localization. Statistically significant results were obtained in relation to lymphovascular and perineural invasion, undoubtedly indicating a more aggressive biological behaviour of the tumour in the presence of herpes viruses.

Funding: The study was carried out within the framework of state budget funding (No 124021600057-0)

E-PS-06-041
Pathomorphological features of eosinophilic esophagitis at presentation and after treatment
V. Pechnikova[1], L. Mikhaleva[1], K. Maslenkina[1], E. Motylev[1], M. Guschin[1], A. Kontorshchikov[1], E. Zentsova[1], A. Konyukova[1]
[1]Avtsyn Research Institute of Human Morphology of Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Moscow, Russia

Background & Objectives: Eosinophilic esophagitis (EoE) is a chronic immune-mediated oesophageal disease, that shows predominantly eosinophilic infiltration of oesophageal mucosa ($\geq$ 15 eos/hpf) and various degree of subepithelial fibrosis. The aim of our study was to analyse histological features of EoE in patient at first biopsy and after treatment with proton pomp inhibitors (PPI).
Methods: Biopsy was performed in 70 patients with endoscopic features of EoE (EREFS $\geq$ 2) and in 25 patients with history of EoE after treatment with PPI. Biopsy specimens were fixed in 10%-neutral buffered formalin and stained with haematoxylin and eosin. Additional Mallory staining was performed for assessment of fibrosis. EoE histology scoring system (EoEHSS) and EoE Histology Remission Score (EoEHRS) were applied for histological evaluation of specimens.
Results: EoE was confirmed in all 70 patients, among them 51 were men (72,86%), median age was 29.5 (21; 42.25). Peak eosinophil count (PEC) ranged from 17 to 222 (Me 52 eos/hpf). Basal zone hyperplasia presented in 100% of cases and varied from 20 to 80%. Dilated intercellular spaces were noticed in 97,14%, surface epithelial alteration – in 60%, eosinophilic abscesses – in 48,57%, surface layering – in 17,14% and dyskeratotic epithelial cells – in 11,42% of patients. Lamina propria of mucosa could be assessed in 71,43% of biopsy specimens, among them various degree of fibrosis was observed. EoEHSS median grade score comprised 12 (8; 14.5), median stage score was 10 (8; 12). After treatment 92% of patients (23 from 25 patients) fulfilled EoEHRS criteria of histological remission.
Conclusion: EoEHSS is a powerful tools to evaluate pathomorphological features of EoE. Assessment of biopsy specimens obtained after treatment with EoEHRS helps to establish histological remission. Treatment with PPI was effective in 92% of patients.

Funding: The study was carried out within the framework of state budget funding (No 123030700111-1)

E-PS-06-042
Histological features and immunohistochemical markers of oesophageal cancer
V. Pechnikova[1], L. Mikhaleva[1], K. Maslenkina[1], M. Naumenko[1], A. Mikhalev[2], M. Guschin[1], E. Zentsova[1], K. Midiber[3,4]
[1]Avtsyn Research Institute of Human Morphology of Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Moscow, Russia, [2]Pirogov Russian National Research Medical University, Moscow, Russia, [3]Avtsyn Research Institute of Human Morphology of Federal State Bugetary Scientific Institution "Petrovsky National Research Centre of Surgery", Moscow, Russia, [4]Peoples' Friendship University of Russia named after Patrice Lumumba, Moscow, Russia

Background & Objectives: Worldwide oesophageal cancer is the eighth most commonly diagnosed cancer and is the sixth leading cause of cancer death. Incidence of adenocarcinoma (EAC) rises more rapidly than squamous cell cancer (ESCC). The aim of our morphological study was to assess histological type, grade and immunohistochemical profile of oesophageal cancer.
Methods: Biopsy was performed in 71 patients with oesophageal cancer. Biopsy specimens were stained with haematoxylin and eosin and combined PAS/Alcian blue. Immunohistochemical evaluation was performed using p53 (D0-7), p16 (SP49), Ki67 (MIB-1). All cases of ESCC expressed CK5/6 and p63. 77% of EAC expressed Muc5AC, 53,84% of EAC expressed Muc6 and 38,46% of EAC expressed Muc2.
Results: Median age of patients comprised 70,5 years (63-78), male-to-female ratio was 2,2:1. 46 patients were diagnosed wih EAC (G1 – 9 patients, G2 – 20 patients, G3 – 17 patients), 18 patients had SSCC (G1 – 5 patients, G2 – 8 patients, G3 – 5 patients) and 7 patients had undifferentiated cancer . Immunohistochemical evaluation was performed in 39 cases (26 patients with EAC and 13 patients with ESCC). Positive p53 expression (mutant-type) presented in 6 patients with ESCC (50%) and in 7 patients with EAC (46,15%). Expression of p16 was negative in all but 1 ESCC case (7,69%) and positive in 14 patients with EAC (53.84%). Positive expression of 16 was associated with positive p53 expression in EAC. Higher Ki67 level was associated with positive p53 expression in both cancer types ($p<0.01$).
Conclusion: Mutant-type expression of p53 was noticed in almost half of patients with ESCC and EAC that highlights the key role of *TP53* in oesophageal carcinogenesis. Moreover, mutant expression of p53 was associated with positive expression of p16 in EAC and with higher level of Ki67 in both cancer types. Further studies are needed to establish the role of immunohistochemical markers expression in prognosis of oesophageal cancer.

Funding: The study was carried out within the framework of state budget funding (No 122032100086-3)

E-PS-06-043
Jejunal perforation by histoplasmosis: case report
N. Olaya[1,2], D.M. Gaviria Delgado[3], L.C. Nocua-Báez[2]
[1]Universidad Nacional de Colombia, Pathology, Bogotá, Colombia, [2]Hospital Universitario Nacional de Colombia, Pathology, Bogotá, Colombia, [3]Universidad Nacional de Colombia, Instituto de Genética, Bogotá, Colombia

Background & Objectives: Histoplasmosis is an opportunistic fungal infection caused by Histoplasma species. Disseminated forms, although rare, often involve the gastrointestinal tract and primarily affect immunocompromised patients. This paper presents an unusual case of gastrointestinal histoplasmosis with jejunal perforation.
Methods: A 57-year-old man presented with chronic abdominal pain, intermittent fever, cough, diaphoresis, nausea, and rapid weight loss.
Results: Findings on CT scans showed thickening and malignant lesions in the intestine, further evaluated through laparotomy, in addition to pulmonary involvement. Jejunal perforation and septic shock were identified and
treated with antibiotics. The clinical course was unfavourable, resulting in death. Peritoneal liquid cultures and haemocultures were negative, but the biopsy histological analysis revealed the presence of Histoplasma yeast.
Conclusion: This case underscores the importance of considering invasive fungal infections in apparently immunocompetent critically ill patients and reassessing the diagnostic methods for timely and effective treatment.

E-PS-06-044
Radiation-induced angiosarcoma of the breast metastatic to the upper gastrointestinal tract
H. Henzinger[1], E. Bruckner[2], R. Gassner[1], B. Liegl-Atzwanger[1], C. Langner[1]
[1]Diagnostic & Research Institute of Pathology, Medical University of Graz, Graz, Austria, [2]LKH Hartberg, Department of Internal Medicine, Hartberg, Austria

Background & Objectives: Radiation-induced angiosarcoma of the breast is a rare and aggressive tumour with poor prognosis and increasing prevalence. Widespread metastasis is common, however secondary involvement of the gastrointestinal tract is exceptionally rare.
Methods: We present the case of a 56-year-old woman who was diagnosed with angiosarcoma of the breast seven years after resection of breast cancer, followed by adjuvant external radiotherapy. Within one year, widespread bone metastasis occurred. The patient was referred to the hospital with severe abdominal pain and iron deficiency anaemia.
Results: Upper endoscopy was performed and showed multiple polypous and ulcerated lesions in stomach and duodenum; corresponding to diffuse thickening of the stomach wall on CT scan. Biopsies were taken and demonstrated highly vascularized nodular infiltrates of atypical spindle cells with marked nuclear pleomorphism and increased mitosis. Upon immunohistochemistry, the atypical spindle cells were negative for pan-keratin and SOX10, yet positive for CD31, ERG and MYC, prompting final diagnosis of radiation-induced angiosarcoma metastatic to stomach and duodenum.
Conclusion: Secondary tumours of the gastrointestinal tract are infrequent and mainly attributable to malignant melanoma, breast and lung cancer, while metastasis of sarcoma is even rarer. Reports of gastrointestinal metastasis due to radiation-induced angiosarcoma are currently lacking in the English literature. Our case highlights the differential diagnosis in separating the lesion from spindle cell carcinoma and other spindle cell malignancies.

E-PS-06-045
Gastric manifestation of cystinosis
H. Geddert[1], B. Hemmerlein[1], H. Bruck[2], D. Müller[3]
[1]Helios Hospital, Institute of Pathology, Krefeld, Germany, [2]Helios Hospital, Department of Nephrology, Krefeld, Germany, [3]Helios Hospital, Department of Endoscopy, Krefeld, Germany

Background & Objectives: A 21-year-old female patient is known to have cystinosis (infantile nephropathic form). As a result, renal insufficiency requiring dialysis, growth retardation and arterial hypertension developed.
Methods: A gastroscopy, which was performed due to recurrent haemoptysis, revealed a leathery gastric mucosa.
Histologically, chronic and highly active HP gastritis can be diagnosed. In addition, rectangular to polygonal birefringent crystals are found intracapillary, which appear light yellow in H&E stain.
Results: These correspond to cystine crystals.
We therefore diagnose a gastrointestinal manifestation of cystinosis.
Conclusion: Cystinosis is a very rare autosomal recessive storage disease that primarily damages the kidneys. As the disease progresses, the eyes, musculoskeletal system, endocrine organs and CNS are particularly affected.

E-PS-06-046

Prognostic value of Epstein–Barr virus and stromal tumour-infiltrating lymphocytes in gastric cancer: a single-institution Polish study

A. Chrzan[1,2], E. Sarnowska[3], M. Suska-Węgier[1,2], A. Grabuś[2], N. Rusetska[3], J. Siedlecki[4], A. Mróz[2]
[1]Institute of Mother and Child, Department of Pathomorpology, Warsaw, Poland, [2]Maria Sklodowska-Curie National Research Institute of Oncology, Department of Cancer Pathomorphology, Warsaw, Poland, [3]Maria Sklodowska-Curie National Research Institute of Oncology, Laboratory of Experimental Immunotherapy, Warsaw, Poland, [4]Maria Sklodowska-Curie National Research Institute of Oncology, Department of Molecular and Translational Oncology, Warsaw, Poland

Background & Objectives: There is still a quest for identifying prognostic factors in gastric cancer (GC). This retrospective single-institution study aimed to analyse overall survival (OS), evaluating the prognostic value of Epstein–Barr virus (EBV) and stromal tumour-infiltrating lymphocytes (sTILs) adjusted for other variables such as neoadjuvant chemotherapy, sex, age, and the parameters (y)pT, (y)pN, (y)pM.
Methods: A total of 262 patients with primary GC, who underwent gastrectomy between 2008 and 2018 at the National Research Institute of Oncology, Warsaw, Poland, were included. The tumour staging was assessed according to the 8th edition of the TNM classification. EBV was detected by chromogenic in situ hybridization with the INFORM EBER Probe. TILs were examined by a semi-quantitative method described by International Immuno-Oncology Biomarker Working Group. All statistical analyses were conducted using R4.1.1 (R Core Team, 2021) package. The Akaike Information Criterion (AIC) model comparison procedure was performed. ΔAIC values <-2 were considered indicative of a significant predictor effect.
Results: Univariate and multivariate Cox regression analyses revealed no significant differences in OS between EBV positive and negative GC. Upon univariate analysis, higher percentage values of sTILs within the invasive margin (p=0.025, ΔAIC=-3.61), and combined central area and invasive margin of tumour (p=0.031, ΔAIC=-3.23), were identified as favourable prognostic factors, though these findings were not statistically significant in multivariate analysis. In multivariate analysis, the most significant independent prognostic predictors were (y)pT (p=0.004, ΔAIC=-6.41), (y)pN (p<0.001, ΔAIC =-33.42), (y)pM (p<0.001, ΔAIC=-8.96) and age (p<0.001, ΔAIC=-17.05).
Conclusion: Multivariate Cox regression analysis has identified (y)pTNM, particularly the (y)pN parameter, and patient age as the independent prognostic factors in GC. Incorporating other covariables into the AIC-based prognostic model did not improve prognostic accuracy. However, univariate analysis revealed statistical significance for sTILs within primary tumour, but not for EBV, indicating sTILs hold a higher prognostic value than EBV for GC.

Funding: The work was co-financed by a donation from Roche company for the purchase of the INFORM EBER probe – donation number 54/D/7/8/2016

SWI/SNF-deficient malignant tumours of the gastrointestinal tract: a case-series of a rare and highly aggressive malignancy

M. Bal[1], G. Chaudhari[1], R.K. Kaushal[1], S. Yadav[1], G. Deshpande[1], K. Deodhar[1], M. Ramadwar[1], S.V. Shrikhande[1], V. Ostwal[1]
[1]Tata Memorial Centre, Pathology, Mumbai, India

Background & Objectives: Switch/sucrose nonfermentable (SWI/SNF) complex-deficient carcinomas are rare, aggressive malignancies recently recognized in the gastrointestinal tract (GIT). They result from *SMARCB1* or *SMARCA4* inactivation, key components of the chromatin-remodelling SWI/SNF complex. Given emerging therapeutic implications (EZH2-inhibitors, immunotherapy), accurate diagnosis is crucial.
Methods: We retrospectively reviewed all SWI/SNF-deficient GIT carcinomas diagnosed at our institution from 2015 to 2025. Tumours were identified by complete loss of SMARCB1 or SMARCA4 protein expression in tumour cells, with intact internal controls.
Results: Six cases were identified: three SMARCB1-deficient and three SMARCA4-deficient carcinomas. Median age was 33.7 years (range: 16–61), with a male-to-female ratio of 1:2. Tumour sites included the stomach (n=3), gallbladder (n=2), and pancreas (n=1). One patient had an unresectable tumour, and three had distant metastases. Three underwent surgery. The median tumour size was 9 cm. Histology revealed high-grade undifferentiated carcinoma, with rhabdoid (n=3), yolk sac-like (n=1), and glandular (n=1) features. One case had multiseptate, empty vacuoles. All tumours expressed keratins, and three each showed complete loss of *SMARCB1* or *SMARCA4*. Mismatch repair proteins were retained; PD-L1 CPS scores were <3. One patient was lost to follow-up. With a median follow-up of 8 months, four progressed on palliative chemotherapy, and one died of disease.
Conclusion: SWI/SNF-deficient GIT carcinomas are rare, aggressive, and have poor outcomes. Key histologic clues include undifferentiated, rhabdoid, and yolk sac-like morphology. Immunohistochemistry is essential for diagnosis and guiding trial enrolment.

Histopathological spectrum and αE-catenin expression of gastric cancers from carriers of germline *CTNNA1* truncating variants: insights from the largest reported cohort

S. Lobo[1,2], I. Gullo[3,1,4], C. Colas[5,6], F. Coulet[7], M. Svrcek[8], P. Bourgoin[9], R. Hueneburg[10,11], L. Moreira[12,13,14], S. Tinschert[15], J. Balmaña[16,17], P. Benusiglio[7], F. Carneiro[3,1,3], C. Oliveira[1]
[1]i3S - Instituto de Investigação e Inovação em Saúde, University of Porto, Portugal, Porto, Portugal, [2]ICBAS - School of Medicine and Biomedical Sciences of the University of Porto, Porto, Portugal, [3]Faculty of Medicine of the University of Porto, Pathology, Porto, Portugal, [4]Unidade Local de Saúde São João, Portoportugal, Portugal, [5]Curie Institute, Genetics, Paris, France, [6]Université de Paris, INSERM U830, Paris, France, [7]Sorbonne Université, Hôpital Pitié-Salpêtrière, Genetics, Paris, France, [8]Sorbonne Université, LIMICS, AP-HP, Paris, France, [9]Sorbonne Université, Laboratoire D'anatomie Et Cytologie Pathologiques, Hôpital Saint-Antoine, Paris, France, [10]University Hospital Bonn, Internal Medicine I, Bonn, Germany, [11]University Hospital Bonn, National Centre for Hereditary Tumour Syndromes, Bonn, Germany, [12]Hospital Clínic de Barcelona, Gastroenterology, Barcelona, Spain, [13]Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain, [14]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas, Madrid, Spain, [15]Medical University Innsbruck, Human Genetics, Innsbruck, Austria, [16]Hospital Vall d'Hebron, Medical Oncology, Barcelona, Spain, [17]Universitat Autònoma de Barcelona, Barcelona, Spain

Background & Objectives: Germline truncating variants in *CTNNA1* gene, encoding αE-catenin, account for approximately 2% of hereditary diffuse gastric cancer (HDGC) cases. Loss of αE-catenin expression has been reported on a case-by-case basis in carriers of germline *CTNNA1*-variants. However, the detailed histological/immunohistochemical features of *CTNNA1*-associated gastric cancer (GC) are not well characterized.
Methods: Eleven tumour samples, including six primary GCs and five (peritoneal and nodal) metastases, from nine *CTNNA1* truncating carriers fulfilling the 2020 HDGC genetic testing criteria [doi:10.1016/S1470-2045(20)30219-9] were studied. According to WHO classification, GC was classified as signet-ring-cell-carcinoma (SRCC) /

poorly-cohesive-carcinoma (PCC) (diffuse-subtype by Laurén). Immunohistochemistry for αE-catenin (clone EP1793Y) was performed on eight samples from seven patients.
Results: Median age at GC diagnosis was 48 years (range:37–75). One case was detected at early stage (pT1a) in a prophylactic-total-gastrectomy, while the remaining eight were diagnosed at advanced stage (≥pT2), five with metastases.
The pT1a carcinoma, adjacent to pagetoid spread of SRCs (pTis), showed classic SRCs. Advanced-stage GCs showed predominantly PCC morphology with variable SRC component: <5% in five cases, 5–10% in two, and 10–50% in three. In two patients, the SRC proportion increased from 10% in primary tumours to 50% in corresponding metastases. All metastatic sites showed pure diffuse morphology with prominent desmoplastic stroma. In contrast, primary tumours displayed additional patterns, including nested, trabecular, rosetoid and true microglandular structures.
In all advanced-stage GCs, aberrant αE-catenin immunoexpression was demonstrated: complete loss in 62.5% (5/8) of samples analysed, and faint/incomplete membranous, paranuclear dotted, and/or cytoplasmic staining in the remaining 37.5% (3/8).
Conclusion: This is the largest cohort to date characterizing histopathological features and αE-catenin expression in *CTNNA1*-associated GCs. The morphological diversity observed in primary tumours may represent a diagnostic pitfall in the recognition of HDGC cases. The utility of αE-catenin expression as a marker for genetic triage in these cases warrants further investigation.

E-PS-06-050
Collagenous gastritis: from microscope to clinic, a diagnostic challenge in children and adults
R.d.P. López-Panqueva[1], M.A. Forero Rivera[1], S. Walker Álvarez[1], V. Cruz[1], M. Mejía-Arango[1]
[1]Fundación Santa Fe de Bogotá, Colombia-Universidad de Los Andes, Department of Pathology and Laboratory Medicine, Bogotá, Colombia

Background & Objectives: Collagenous gastritis (CG) is a rare condition defined by subepithelial collagen band deposition in the gastric mucosa. It has two clinical phenotypes: a paediatric form characterized by abdominal pain and microcytic anaemia, and an adult form associated with malabsorption and autoimmune diseases. Histologically, CG shows three main patterns: lymphocytic gastritis-like, eosinophil-rich, and atrophic. Endoscopic findings are non-specific. Differential diagnoses include amyloidosis, autoimmune gastritis, radiation injury, and scleroderma. Treatment includes dietary modifications, proton pump inhibitors (PPIs), sucralfate, corticosteroids, and oral budesonide.
Methods: We describe a case series of two patients one paediatric and one adult highlighting the phenotypic and histopathologic spectrum of CG.
Results: **Case 1:** An 8-year-old girl with atopy and a family history of autoimmunity presented with abdominal pain, anorexia, pallor, abdominal distension, and constipation. Labs revealed severe iron-deficiency anaemia and hepatosplenomegaly. Initial biopsy showed chronic gastritis and duodenitis. Persistent symptoms led to repeat endoscopy showing pangastritis and follicular duodenitis. Histology confirmed CG with >10 μm subepithelial collagen, marked lymphoplasmacytic and eosinophilic infiltrate (>40 eos/hpf), and oxyntic atrophy. Treatment included elemental formula, corticosteroids, PPIs, and dietary restrictions, resulting in clinical improvement.
Case 2: A 65-year-old woman with hypertension and dyslipidemia presented with chronic abdominal pain. Endoscopy revealed fundocorporal nodularity and erythema. Biopsy showed chronic erosive gastritis, severe oxyntic gland atrophy, pseudopyloric metaplasia (gastrin-negative), smooth muscle hyperplasia, and a thickened subepithelial collagen band (10–15 μm, Masson trichrome). Neuroendocrine cell hyperplasia was confirmed by chromogranin stain and reactive antral gastropathy. Findings were consistent with the atrophic pattern of CG. PPI therapy was initiated.
Conclusion: CG demonstrates age-dependent clinical and histologic variability. These cases emphasize its diagnostic complexity and the critical role of histopathology. Early recognition enables targeted treatment and may significantly improve outcomes, especially in paediatric patients with allergic or autoimmune tendencies.

ChatGPT-4o as a pathologist's assistant: a new era in colon polyp classification
E. Musulen[1,2], N. Camacho[2], M.C. Cuevas-Nunez[3], N. Domínguez Agustín[1], M.T. Fernández-Figueras[1]
[1]Hospital Universitari General de Catalunya-Grupo Quiron, Pathology Department, Sant Cugat del Vallès, Spain, [2]Institut de Recerca contra la Leucèmia Josep Carreras, Grup d'Epigenètica del Càncer, Badalona, Spain, [3]Universitat Internacional de Catalunya (UIC), Pathology Department, Sant Cugat del Vallès, Spain

Background & Objectives: Colon polyps represent an enormous number of diagnoses in the daily work of pathologists specialized in Gastrointestinal Pathology. Also, differentiate tubular adenomas (TA) from sessile serrated lesion with low-grade dysplasia (SSL-LGD) in not always easy. Waiting for the advent of AI algorithms that will help us decrease the burden of care, we have explored how adept the tools we now have available are.
Methods: We selected from our files a series of 158 colon polyps including 61 TA, one of them with high-grade dysplasia (TA-HGD), 33 SSL without dysplasia (SSL-ND), 62 SSL-LGD and 1 SSL-HGD. We use ChapGPT-4o of OpenIA as an AI tool. We trained it with the definitions of each type of polyp given in the WHO Classification of Tumours, Tumours of the Digestive Tract, 5th edition, and defined the differences between LGD and HGD. Once this was done, we showed it the images of the polyps so that it could make the diagnosis.
Results: ChatGPT-4o correctly diagnosed all 33 (100%) SSL-ND and the 2 (100%) HGD polyps, one TA and one SSL. It also correctly classified 56 (92%) TA-LGD and 44 (71%) SSL-LGD.
Conclusion: Given the good results obtained with the available AI in classifying colon polyps, we should not have to wait too long for the arrival of better tools to help the pathologist in the daily work of classifying this type of lesions to free him/her from this repetitive and low complexity task.

E-PS-06-054
The "2" faces of gastric carcinoma: a comparative study of early-onset (EOGC) and late-onset gastric carcinoma (LOGC) using MUC2, CDX2, HER2, and MMP2
R. Neagu[1], A. Voiosu[2], G. Micu[1], L. Nichita[1], L.-E. Stanciu[1], I.A. Cibotariu[1], D.M. Marinoiu[1], R.-G. Ionescu[1], C. Popp[1]
[1]Colentina University Hospital, Pathology, Bucharest, Romania, [2]Colentina University Hospital, Gastroenterology, Bucharest, Romania

Background & Objectives: Gastric carcinoma is a heterogeneous disease with distinct clinical, pathological, and molecular characteristics influenced by the age of onset. This study seeks to elucidate mechanisms behind the increased aggressiveness of EOGC and explore potential implications for targeted therapeutic strategies by analysing the expression of key immunomarkers of **tumour differentiation, invasiveness, and therapeutic potential**.
Methods: The most representative paraffin blocks from the gastric resection specimens of 10 EOGC (onset <45 years of age) and 10 LOGC (onset >45 years of age) patients were selected. Immunohistochemical expression of MUC2, CDX2, HER2 and MMP2 was evaluated.

Results: EOGC is known to be more aggressive than LOGC. We found significantly lower MUC2 positivity in EOGC (12.5%) compared to LOGC (37.5%), while CDX2 positivity was similar in both groups (62.5%). This suggests that while both subtypes share a similar rate of intestinal differentiation (CDX2+), EOGC exhibits a more primitive, poorly organized intestinal phenotype, whereas LOGC may represent a more mature, mucin-producing tumour, potentially correlating with a less aggressive course.
HER2 was positive in 25% of LOGC cases but absent in EOGC, indicating that HER2 overexpression may contribute to the aggressiveness of LOGC. This finding shows a decreased opportunity for HER2-targeted therapies in EOGC.
MMP2 was positive in 80% of both subtypes, highlighting its role in tumour invasiveness and metastasis. This suggests that MMP2-targeted therapies could be beneficial for both EOGC and LOGC.
Conclusion: These findings highlight distinct molecular differences between EOGC and LOGC that may inform future treatment strategies. While both subtypes share common features such as CDX2 positivity and MMP2 involvement, HER2 overexpression and mucinous differentiation may be more relevant in LOGC. Further studies are needed to explore the prognostic implications of these markers and their potential in guiding personalized therapeutic approaches in clinical practice.

Molecular testing in colorectal cancer: a single-centre experience
R. Jankovic[1], M. Đuknić[1], N. Stojaković[2], S. Glumac[1], M. Jovanović[1], M. Denčić Fekete[1], J. Jevtić[1]
[1]University of Belgrade-Faculty of Medicine, Institute of Pathology, Belgrade, Serbia, [2]University of Belgrade-Faculty of Medicine, Belgrade, Serbia

Background & Objectives: Colorectal cancer (CRC) is a heterogeneous disease with distinct molecular subtypes that influence prognosis and treatment response.
Methods: The archival material from the Institute of Pathology, Belgrade, was analysed, encompassing all cases of CRC submitted for consultative review, in which predictive immunohistochemical and molecular biomarkers were assessed. Over five years, these analyses were conducted on 89 patients. Exactly half were male and half female. The average age was 60.8 ± 12.77 years, with the youngest 23 and the oldest 84. The majority (40.4%) were in clinical stage 2; one-third in stage 4, and nearly a quarter in stage 3. Only two female patients were in stage 1, both under 40.
Results: Microsatellite instability was evaluated by determining MMR status in 58 cases, using the RT-PCR method in 11 patients, and both methods in 5 patients (with consistent conclusions). A total of 15.9% of the examined tumours were classified as dMMR/MSI-H. The RAS/BRAF status was assessed in 21 cases; 7 patients had no mutations in either of these genes. In one young patient with MLH1 loss, BRAF-wildtype was identified, strongly suggesting Lynch syndrome.
PD-L1 testing is rarely performed in our institution (tested in 13.5% of tumours), with only three tumours exhibiting expression. HER2 testing in CRC was also infrequent (18%), and no cases showed expression of this marker.
Conclusion: These findings highlight the molecular diversity of CRC and reinforce the importance of biomarker testing for personalized treatment strategies. The relatively high proportion of MSI-H tumours underscores the need for routine screening for Lynch syndrome in younger patients. Limited PD-L1 and HER2 expression suggests a low likelihood of response to targeted therapies against these markers in our cohort. Expanding molecular profiling in CRC patients could improve patient stratification and therapeutic decision-making.

E-PS-06-056
Sarcomas involving the digestive system: a single-centre, 10-year experience
R. Sakr[1], L. Lei[1]
[1]University of California San Diego, Pathology, San Diego, USA

Background & Objectives: Sarcomas involving the digestive system are rare and can be challenging to classify, with the major differential diagnoses including sarcomatoid carcinoma and gastrointestinal stromal tumours (GIST). To facilitate diagnosis and management, we present our single-centre experience on the clinicopathologic characteristics of these sarcomas.
Methods: A retrospective review of non-GIST digestive system sarcomas in adults was conducted using an institutional pathology database query of cases received from January 2015 to March 2025 (IRB protocol 812420). The analysed parameters included demographics, clinical presentation, tumour site, histologic type, stage, and outcome.
Results: A total of 72 cases were identified, accounting for approximately 1% of all malignancies involving the digestive system over the 10-year period. There was a male predilection (63.9%) and a wide age range (23–92 years; mean 56.7 ± 17.2 years). The most common tumour type was well-differentiated/dedifferentiated liposarcoma (30.6%), which primarily involved the digestive system through direct extension. This was followed by metastatic sarcoma (19.4%), Kaposi sarcoma (18.0%), leiomyosarcoma (11.1%), desmoplastic small round cell tumour (5.6%), angiosarcoma (4.2%), epithelioid haemangioendothelioma (2.8%), malignant peripheral nerve sheath tumour (2.8%), myeloid sarcoma (2.8%), pleomorphic rhabdomyosarcoma (1.4%), malignant glomus tumour (1.4%), and gastrointestinal neuroendocrine tumour (1.4%). Three primary tumours (4.2%) remained unclassifiable despite extensive workup. Notably, metastatic sarcomas may present following a remote history of sarcoma or as intussusception due to polypoid mucosal involvement, posing a diagnostic challenge and potential delay. Most cases were high stage (pT4 20.8% vs. pT1 8.3%). Two cases exhibited nodal metastasis (3%). Among 40 patients with complete follow-up data, 25 succumbed 1–56 months (mean 14.3 ± 16.2 months) after diagnosis, resulting in a mortality rate of 62.5%.
Conclusion: Non-GIST digestive system sarcomas are associated with high mortality, particularly in cases of high-stage or high-grade disease. Large intra-abdominal or retroperitoneal sarcomas involving the digestive system represent the most common scenario, followed by metastatic sarcomas.

E-PS-06-057
Claudin 18.2: emergin therapeutic target in HER2-negative gastroesophageal adenocarcinoma
G. Vázquez Esteban[1], S.M. Díaz López[1], M.d.l.P. González Gutiérrez[1], M.A. Bermúdez Alarcón[1], L.A. Pérez Pabón[1], S. Junceda Antuña[1], P. Morales Del Burgo[1], G.E. Mendoza Pacas[1], E. Higueras Mora[1], M. Rubiera Valdés[1], C. González Rodríguez[1], S. Merino Baamonde[1], A. Soria Montoya[1], F.J. Pérez Rastrollo[1], M.L. Berríos Hernández[1]
[1]Hospital Universitario Central de Asturias, Pathology, Oviedo, Spain

Background & Objectives: Claudin-18.2 is an intercellular binding molecule that is naturally expressed in non-malignant gastric epithelium. With tumour transformation and loss of cell polarity claudin is exposed allowing it to work as a therapeutic target with encouraging preliminary results in clinical trials. We have evaluated the expression pattern of this marker in a cohort of gastric tumours and its correlation with histological type, epidemiological determinants and the expression of other markers.
Methods: Forty-eight cases of gastroesophageal adenocarcinomas were recorded over a one-year period, 29 of them were HER2 negative. 51% were women and 49% were men. Their ages ranged from 47 to 96 years

with a median of 70 years. 16 were intestinal, 9 were diffuse, 3 were mixed and 1 was poorly differentiated. Those sections with adequate tumour representation were selected and immunohistochemical staining was performed. Subsequently, claudin staining was evaluated in each of them, recording the intensity and distribution of staining.
Results: Claudin 18.2 expression was studied in 27 of these cases. Two, were excluded due to lack of material at the time of the study. 13 cases were positive (48%) and 14 negative (52%). Regarding staining intensity, 77% of positive cases (10) showed 3+ intensity and 23% (3) were 2+. One case showed heterogeneous staining with 3+ at the superficial level of the tumour and 2+ at the deep level. It is important to highlight the need to have an adequate representation to carry out the study.
Conclusion: Given the heterogeneity of the marker expression and the still scarce literature supporting it in this field, further studies are needed to evaluate the need to reduce the positivity cutoff and optimize its usefulness as a biomarker in the diagnosis and treatment of advanced gastroesophageal cancer, allowing for better identification of patients candidates for targeted therapies and increasing clinical efficacy of these interventions.

IL-17-positive immune cells in right-sided, left-sided colon cancer and in rectal cancer.IL-17A-197 A/G single nucleotide polymorphisms in colorectal cancer and their connection with IL-17 cell density in the tumour

M. Gulubova[1], K. Ivanova[1], J. Kozhuharov[1], E. Aleksandrova[1], D. Chonov[2], M.M. Ignatova[3], Y. Yovchev[2]
[1]Trakia University, Medical Faculty, General and Clinical Pathology, Stara Zagora, Bulgaria, [2]Trakia University, Medical Faculty, Surgery, Stara Zagora, Bulgaria, [3]Complex Oncology Centre, General and Clinical Pathology, Stara Zagora, Bulgaria

Background & Objectives: IL-17 supports tumour growth by facilitating angiogenesis and by promoting T cell-mediated tumour rejection. Expression of IL-17 cytokines in colorectal cancer is associated with genetic polymorphisms in the IL17A gene. The rs227S913 SNP has been shown to affect the IL17A gene expression and A allele has been associated with worse prognosis and higher susceptibility for colorectal cancer.
The aim of our study is to reveal IL-17 cell density in RCC, LCC and rectal cancer and to correlate these results with MMR status, survival and genetic polymorphisms of rs227S913 SNP.
Methods: Tissue samples resected from 92 patients with RCC (n=21), LCC (n=32) and rectal cancer (n=39) are investigated by immunohistochemistry for IL-17 in the tumour stroma (TS) and in the invasive front (IF) and for MMR proteins and for the (IL-17A-197 A/G SNP conducting the PCR-RELP method.
Results: IL-17$^+$ immune cells are less in number in RCC (11%) compared to those in LCC (36%) (χ2=2.512; p=0.113). Higher numbers of IL-17$^+$ cells in IF are mostly dMMR in RCC patients (χ2=5.661;p=0.59). On the opposite, higher IL-17 cell density in the IF is associated with pMMR status in LCC patients (χ2=6.967; p=0.008). Patients, who have more IL-17$^+$ cells in TS have pMMR status (χ2=5.333; p=0.25). Respectively, IL-17$^+$ cells are higher in the IF of pMMR status (χ2=7.149; p=0.009). In rectal cancer IL-17$^+$ cells are less in number compared to RCC and LCC. When IL-17$^+$ cells are $\geq$ 12.24 cells/mm2 in the IF, patients have pMMR status. In rectal cancer patients with IL-17$^+$ cells $\geq$ 5.44 cells/mm2 we find tertiary lymphoid structures (TLS). We observed higher density of IL-17$^+$ cells in the carriers of the G-allele genotypes (AG +GG).
Conclusion: In conclusion we confirm the negative effect of the A-allele for the IL-17A-197 A/G SNP for the immune response in the tumour microenvironment.

E-PS-06-059

Differences in mismatch repair protein expression between primary gastric tumours and lymph node metastases: clinicopathological insights

E. Porubayeva[1], A. Zakharkina[1], D. Kalinin[2], N. Danilova[1]
[1]Lomonosov Moscow State University, Moscow, Russia, [2]A.V. Vishnevsky National Medical Research Centre of Surgery, Moscow, Russia

Background & Objectives: Heterogeneity in mismatch repair (MMR) protein expression between primary tumours and metastases remains understudied in gastric cancer (GC). We aimed to assess the prevalence of heterogeneous MMR status (hMMR) in lymph node metastases of GC and explore its associations with clinicopathological features to inform prognosis and therapy.
Methods: We analysed 33 GC patients with confirmed lymph node metastases and no prior neoadjuvant therapy. Full-sized surgical specimens were evaluated immunohistochemically using antibodies against MSH2 (79H11), MSH6 (EP49), MLH1 (ES05), and PMS2 (EP51). hMMR was defined as uneven staining ($\geq$20% variability) of any marker in primary tumours or metastases. We correlated hMMR in metastases with sex, age, tumour site, macroscopic type, size, histologic subtype, differentiation, vascular emboli, TNM stage, and clinical stage. Statistical significance was assessed using χ^2 or Fisher's exact tests in Statistica 12.5.192.7, with $p<0.05$ considered significant.
Results: hMMR in lymph node metastases occurred in 5/33 cases (15.2%): three showed hMMR in both primary tumour and metastases, while two had stable primary tumour staining but hMMR in metastases. One additional case revealed microsatellite instability (MSI) exclusively in metastases, not the primary tumour. The mucinous subtype was significantly enriched in the hMMR-metastases group (p=0.024), contrasting with the intestinal subtype dominating the stable-MMR group. hMMR in metastases strongly correlated with advanced N stages (N3, $p<0.001$) compared to stable MMR (N1-2). No associations with sex, age, or tumour size were observed.
Conclusion: Heterogeneous MMR status in GC lymph node metastases, though uncommon (15.2%), is linked to mucinous histology and advanced nodal spread. This suggests clonal evolution with potential implications for prognosis and immunotherapy responsiveness.

E-PS-06-060

Spatial molecular heterogeneity of small bowel adenocarcinoma: when the metastasis tells a different story

G. De Lisi[1], E. Travaglino[2], P. Parente[3], F. Antoci[2], C. Guerini[1], F. Grillo[4], A. Viglio[2], T. Colella[5], C. Bortolotto[6], E. Quaquarini[7], S. Corallo[7], P. Pedrazzoli[7], C. Antoniacomi[1], L. Mastracci[4], M. Fassan[8], M. Paulli[1], A. Di Sabatino[9], A. Vanoli[2,1]
[1]University of Pavia, Department of Molecular Medicine, Unit of Anatomic Pathology, Pavia, Italy, [2]Fondazione IRCCS San Matteo Hospital, Unit of Anatomic Pathology, Pavia, Italy, [3]Fondazione IRCCS Ospedale Casa Sollievo della Sofferenza, Unit of Pathology, San Giovanni Rotondo (FG), Italy, [4]University of Genoa, Pathology Unit, Department of Surgical and Diagnostic Sciences, Genoa, Italy, [5]University of Pavia, Pavia, Italy, [6]Fondazione IRCCS San Matteo Hospital, Unit of Radiology and Neuroradiology Diagnostics, Pavia, Italy, [7]Fondazione IRCCS San Matteo Hospital, Medical Oncology Unit, Pavia, Italy, [8]University of Padua, Surgical Pathology and Cytopathology Unit, Department of Medicine, DIMED, Padua, Italy, [9]University of Pavia, Department of Internal Medicine and Medical Therapeutics, Pavia, Italy

Background & Objectives: Metastatic small bowel adenocarcinoma (SBA) is a rare and aggressive malignancy with limited therapeutic options. Molecular discrepancies between primary tumours and their distant metastases may impact treatment decisions. This study aims to

evaluate the molecular profile concordance between primary tumour and paired distant metastasis in patients with metastatic SBA.
Methods: Next-generation sequencing (NGS) was performed using the Illumina MiSeq platform. Library preparation was conducted with the AmoyDx HANDLE Classic NGS Panel. Bioinformatic analysis was carried out using the AmoyDx NGS Data System (ANDAS). Immunohistochemistry (IHC) for mismatch repair proteins (BenchMark Ultra system) was performed.
Results: Five patients (all females; median age: 70 years) were included; the primary tumour was duodenal in three cases and jejunoileal in two cases. The distant metastases (four synchronous and one metachronous) were peritoneal in all cases. Molecular differences between the primary tumour and the corresponding metastasis was observed in one patient (20%). This patient, who had a history of Crohn's disease and received adjuvant chemotherapy after surgical resection of a stage II SBA (pT4N0) at the age of 61 years, developed a peritoneal metastasis 5 years later. Both primary tumour and metastasis harboured a TP53 and an IDH2 mutation, whereas an additional KRAS mutation (G12V) was identified in the metastatic tissue. The primary tumour of this patient was MMR-proficient by IHC and microsatellite stable (MSS) by NGS, while the metastasis exhibited MMR-deficiency by IHC (loss of MLH1 and PMS2 expression) and it was MSS by NGS.
Conclusion: Spatial molecular heterogeneity may occur in metastatic SBA, suggesting that adding molecular profiling of metastatic tissue, especially in case of metachronous metastases, may improve selection of patients with advanced SBA for targeted therapies and/or immunotherapy.

Colonical estenosis. a case report
J.A. Costas Fernandez[1], Y. Rey Fanjul[1], E. Mateo Álvarez[1], R. Rodríguez Aguilar[1], M. Poch Arenas[1], D. Rodríguez Villar[1], G. Meijide Santos[1]
[1]Hospital Universitario de Cabueñes, Anatomia Patológica, Gijón, Spain

Background & Objectives: Amoebic colitis is an infection of the large intestine caused by the protozoan parasite Entamoeba histolytica which can spread to the liver and other organs such as the brain or lungs.
This infection is most common in tropical and subtropical regions and rare in developed countries. It is transmitted by ingestion of Entamoeba histolytica cysts via the faecal-oral or oral-anal route.
Methods: A 48-year-old woman with no past history of interest consulted for fever >39-40º for 8 days and non-specific digestive symptoms. Laboratory tests showed leukocytosis of 22,750, increased CRP (352.4) and procalcitonin (3.08), alterations in liver function (ALT=68, ALP=422 and Bilirubin=1.6). Micro-organism studies were negative. CT findings suggested a possible neoplasm in the ascending colon, with inflammatory changes in the abscess phase and large hepatic LOES that could be hepatic abscesses. Right hemicolectomy and drainage of liver abscesses were performed.
Results: We received a 29 cm segment of large bowel with a 10X6 cm ulcerated lesion and nearby millimetric cottony exudates. Samples were not sent to microbiology due to the initial suspicion of neoplasia and not of an infectious process. Microscopic examination showed large flask-shaped ulcerations and transmural abscesses that sometimes reached the serosa without perforating it. Numerous trophozoites (suggestive of Entamoeba) were identified in the mucosa and submucosa, showing intense magenta PAS positivity and CD68 negative (being positive in macrophages). No areas of dysplasia or tumour infiltrates were identified and the final diagnosis was Entamoeba histolytica amoebic colitis.
Conclusion: Amoeboma (amoebic pseudotumour) presents as a firm, well-defined, annular inflammatory thickening of the colon wall, usually in the cecum or ascending colon, which can be confused with a neoplasm, the definitive diagnosis being anatomopathological, with visualisation of trophozoites invading the intestinal mucosa.

E-PS-06-062
A 16-year-old girl with inflammatory bowel disease-associated colorectal cancer
Y.-C. Chang[1], C.-Y. Huang[1], C.-T. Kuo[1], C.-C. Wang[1], J.-H. Tsai[1], Y.-M. Jeng[1]
[1]National Taiwan University Hospital, Department of Pathology, Taipei, Taiwan

Background & Objectives: Inflammatory bowel disease (IBD) increases the risk of colorectal cancer (CRC). Patients with IBD-associated CRC (IBD-CRC) are younger (typically 40s to 60s), more likely to develop right-sided colonic tumours, and have a poorer prognosis. IBD-CRC arises in a background of chronic mucosal inflammation and exhibits an aggressive growth pattern. *TP53* mutations are frequently observed in IBD-CRC.
Methods: We present a 16-year-old girl with a decade-long history of ulcerative colitis and newly diagnosed IBD-CRC. Clinical history, histopathological features, and immunohistochemical findings are described.
Results: Diagnosed with ulcerative colitis at age 5, the patient recently experienced intermittent vomiting, raising suspicion of severe ileus. Contrast-enhanced computed tomography revealed mucosal thickening in the ascending colon. She underwent extended right hemicolectomy, which revealed a 4.5 × 3.5 cm polypoid tumour with adjacent inflammatory ulcerations. Histopathology showed a well-differentiated adenocarcinoma invading the visceral peritoneum, with lymphovascular and perineural invasion. Dense peritumoral lymphocytic infiltration was also noted. The background displayed chronic mucosal inflammation, ulceration, crypt architectural distortion, and focal dysplasia. Immunohistochemistry demonstrated diffuse, strong nuclear p53 staining in the carcinoma, SATB2 loss in the dysplastic foci, and retained mismatch repair protein (PMS2, MSH6) expression.
Conclusion: We report a rare case of IBD-CRC in a very young patient. Despite her age, she had fluctuating ulcerative colitis activity for a decade. IBD-CRC demonstrates distinct histological features, with adenocarcinoma arising from chronic active colitis, crypt architectural distortion, and focal dysplasia. p53 overexpression and MMR proficiency align with previously reported findings. This case highlights the aggressive nature of IBD-CRC, even in young patients, emphasizing the need for vigilant surveillance and timely surgical intervention to improve outcomes.

E-PS-06-063
Morphological heterogeneity in gastric poorly-cohesive carcinoma. Impact on prognosis and on the expression of predictive markers
L. Cardisciani[1,2], A. Boccaccino[3], M. Carroli[1,2], C. Ghirardini[3], D. Anconelli[1], S. Tamberi[3], F. Vasuri[1,4], L. Saragoni[1,4]
[1]Santa Maria delle Croci Hospital, Pathology Unit, Ravenna, Italy, [2]School of Anatomic Pathology - University of Bologna, Department of Biomedical and Neuromotor Sciences, Bologna, Italy, [3]Oncology Unit, Santa Maria delle Croci Hospital, Ravenna, Italy, [4]Bologna University, Department of Medical and Surgical Sciences, Bologna, Italy

Background & Objectives: The WHO Classification drew attention to the distinction between signet-ring cell and poorly cohesive NOS gastric cancer, as a possible indication of different prognosis in these subsets of patients. The high morphological heterogeneity within individual lesions could impact on patients survival, but also on the mutational profile and the expression of markers predictive of response to therapy. The aim of the present study is to analyse the survival and response to therapy on a group of poorly-cohesive gastric carcinomas (PCGC) on biopsy.

Methods: All consecutive patients with a diagnosis of PCGC on biopsy in the last year were enrolled. All clinical and histopathological features were collected, including the percentage of signet-ring and non-signet poorly-cohesive component in each case. After histological revision, immunohistochemistry for MLH1 (clone MI), PMS2 (A16-4), MSH2 (G219-1129), MSH6 (SP93), Claudin-18.2 (43-14A), Her-2 (4B5), and PD-L1 (22C3) was performed.
Results: Sixteen patients (12 males, 4 females; mean age 69,43 years) were enrolled, among which 5 (31.2%) died of disease after a mean follow-up of 229 days.
The presence of a signet-ring component in a heterogeneous PCGC (i.e. signet-ring and non-signet component) was significantly correlated with a better survival, while 3 out of the 5 deceased patients had PCGC with a pure non-signet component (p=0.012, cox regression analysis). No significant differences in the expression of the predictive markers were observed among groups.
Conclusion: We studied a group of patients with poorly cohesive gastric carcinomas, focusing on the different cell subpopulations. The most important finding is that we can confirm that the presence of a not signet-ring cell component is an independent predictor of worse outcome. The case enrolment is ongoing, to confirm this finding, as well as to analyse the role of PCGC heterogeneity in the response to systemic therapy.

E-PS-06-064
Molecular and histopathological features of metastatic gastrointestinal stromal tumours (GISTs)
S. Sakly[1], A. Bdioui[1], M. Krifa[1], R. Badr[1], S. Hmissa[1]
[1]Sahloul University Hospital, Pathology, Sousse, Tunisia

Background & Objectives: Gastrointestinal stromal tumours (GISTs) are rare mesenchymal neoplasms that can metastasize, typically to the liver, peritoneum, and lungs. Metastatic GISTs present significant diagnostic challenges due to their morphological diversity. This study aims to evaluate the clinical and histopathological characteristics of metastatic GISTs.
Methods: We report five cases of metastatic GISTs diagnosed between 2023 and 2025 at our laboratory. Histopathological diagnosis was based on the examination of biopsy and surgical resection specimens. Immunohistochemistry was performed to detect CD117 (c-kit) and DOG-1 expression. The mitotic index was assessed by counting mitoses in 10 high-power fields (400×). Clinical data were collected from patients' medical records.
Results: All five patients were male, with a mean age of 59.4 years (range: 49–75). Clinical symptoms varied: two presented with abdominal pain and epigastric discomfort, one with a palpable abdominal mass, and two with general health deterioration. Primary tumour sites included the stomach (2 cases), small intestine (2 cases), and colon (1 case). The average tumour size was 12.1 cm (range: 10.5–18 cm). Metastases occurred in the peritoneum (3 cases), liver (1 case), and scapula (1 case). Histologically, all tumours showed fascicular or myxoid architecture with spindle cells. Necrosis was observed in 3 cases, and vascular emboli in 1 case. According tothe Miettinen and Lasota classification, 3 cases were classified as high-risk, while 2 were classified as moderate-risk. All tumours were positive for CD117 and DOG-1.
Conclusion: Metastatic GISTs are rare but significant, with primary sites commonly in the stomach and small intestine. Tumour size and mitotic index are key prognostic factors. This study highlights the importance of these factors for predicting disease progression, emphasizing the need for long-term follow-up due to the high recurrence rate, especially in high-risk cases.

E-PS-06-065
Metastasis sequence of gastric carcinomas – involvement of Claudin-7
V. Ianole[1,2], I.-D. Căruntu[1,3], D.G. Ciobanu Apostol[1,4], S.-E. Giușcă[1,3]
[1]"Grigore T. Popa" University of Medicine and Pharmacy Iași, Morpho-Functional Sciences I, Iasi, Romania, [2]"Prof. Dr. Nicolae Oblu" Emergency Clinical Hospital, Pathology, Iasi, Romania, [3]"Dr. C. I. Parhon" Clinical Hospital, Pathology, Iasi, Romania, [4]"Saint Spiridon" County Hospital, Pathology, Iasi, Romania

Background & Objectives: Abnormal Claudin-7 expression has been related to carcinogenesis, progression, and metastasis in different cancers, but only few studies have targeted Claudin-7 in gastric cancer (GC). Our work aims to analyse the pattern of Claudin-7 expression in primary GC, tumour emboli and lymph node metastases, and its relationship with clinicopathological features and survival.
Methods: The study group consists of 33 cases of GC with lymph node metastases. Claudin-7 immunoexpression was evaluated in tumour core, invasive front, tumour emboli and lymph node metastases, and statistically correlated with clinicopathological characteristics (age, gender, tumour grading and TNM pathological staging) and survival extracted from medical records.
Results: The univariate analysis showed a statistically significant correlation between Claudin-7 expression in tumour core and gender, as well between Claudin-7 expression in lymph node metastasis and extramural vascular invasion. Kaplan-Meyer curves showed a statistically significant association between Claudin-7 expression in tumour core and overall survival, a lower expression indicating a poor prognosis. Moreover, multivariable Cox proportional hazard model highlighted that Claudin-7 expression in tumour core, along with prognostic stage group and lymphovascular invasion could serve as an independent prognostic factor, signifying that the hazard rate for death is grater in patients with Claudin-7 low expression as opposed to patients with high Claudin-7 expression.
Conclusion: To our knowledge, a complete assessment of Claudin-7 expression in primary GC, tumour emboli and lymph node metastases, correlated with clinicopathological parameters and survival, has not yet been reported. Our study confirmed the correlation between Claudin-7 expression in lymph node metastasis and extramural vascular invasion in primary GC. Moreover, Claudin-7 low expression in tumour core, along with prognostic stage group and lymphovascular invasion, are independent prognostic factors, being correlated with a poor prognosis. Thus, our data contribute to further the knowledge of the involvement of this molecule in metastasis sequence of GC.

E-PS-06-066
Histopathological and molecular correlation of heterogeneous MMR expression in colorectal cancer
L. Ruiz Estigarribia[1], I. Fernández de los Reyes[1], A. Córdoba Iturriagagoitia[1], I. Amat Villegas[1], A. Panizo Santos[1], A. De Oliveira Gomes[1], V. Giménez Abadia[1], A. González Zuñiga[1], D. Guerrero Setas[1]
[1]Hospital Universitario de Navarra, Pamplona, Spain

Background & Objectives: Immunohistochemical (IHC) staining for mismatch repair (MMR) proteins is essential for detecting deficient MMR (dMMR), which occurs in approximately 15-20% of colorectal carcinomas (CRC) and is often associated with microsatellite instability (MSI). Although dMMR tumours show a uniform loss of nuclear staining, up to 2.2% of CRCs exhibit heterogeneous expression patterns possibly associated with MSI and/or BRAF mutations. The frequency and clinical significance of these patterns are poorly documented due to limited studies.

Methods: We retrospectively analysed all cases of colorectal adenocarcinoma diagnosed in 2024 at the University Hospital of Navarra. Cases with heterogeneous MMR protein staining (MLH1, PMS2, MSH2, and MSH6) were selected and classified according to their heterogeneity patterns (intraglandular, subclonal, or regional). Correlations were made between MMR status determined by PCR (MSS, MSI-low, or MSI-high) and BRAF V600E mutation status assessed by IHC in cases with heterogeneous staining of MLH1 and/or PMS2.
Results: Among the 398 patients with CRC, 10 (2.5%) showed heterogeneous MMR protein expression. MLH1 and PMS2 were altered in four cases; three had intraglandular MLH1 loss and subclonal PMS2 loss, and one had intraglandular loss of both proteins. Isolated PMS2 and MSH6 heterogeneity was observed in two cases each (intraglandular and subclonal patterns). Two cases showed MSH2, MSH6, and PMS2 abnormalities with an intraglandular pattern, one also with a subclonal PMS2 loss. Four cases analysed by PCR revealed MSI-high status in two cases. BRAF V600E IHC was performed in four of the eight cases with MLH1 and/or PMS2 alteration, detecting the mutation in one case. Analysis of the remaining cases is pending.
Conclusion: The heterogeneous expression of MMR proteins in CRC is recognized in daily practice and may be associated with MSI and BRAF mutations. Its identification and reporting are important and recommended, as they may have diagnostic and therapeutic implications.

E-PS-06-067
PD-L1 and PD-1 expression in Right-Sided versus Left-Sided Colon Cancer
S. Kanoun[1], I. Helal[1], F. Khanchel[1], N. Khedhiri[2], N. Dhawedi[3], R. Jouini[1], A. Chadli Debbiche[1]
[1]Habib Thameur University Hospital, Department of Pathology, Tunis, Tunisia, [2]Habib Thameur University Hospital, Department of General Surgery, Tunis, Tunisia, [3]Habib Thameur University Hospital, Department of Preventive and Community Medicine, Tunis, Tunisia

Background & Objectives: Programmed cell death protein-1 (PD-1) and its ligand (PD-L1) pathway has emerged as a key predictor of prognosis and immunotherapy response in various solid tumours. Right-sided colon cancers (RSCC) and left-sided colon cancers (LSCC) exhibit distinct clinicopathological and molecular profiles, which may influence the expression of these markers and, consequently, immunotherapy implications. This study evaluates PD-L1 and PD-1 expression patterns based on tumour laterality in colon cancer.
Methods: A retrospective study was carried out involving cases of colorectal carcinoma diagnosed between 2014 and 2016. Tumour laterality was defined as right (cecum to proximal transverse) or left (distal transverse to descending colon). Tissue microarrays were used for immunohistochemical study. PD-L1 expression was assessed using combined positive score (CPS) with a cutoff of 1%.PD-1 expression was considered high if stained cells represented 10% or more of the stromal surface. Patients with bifocal tumours including both RSCC and LSCC were excluded. Statistical analysis was performed using SPSS.
Results: The study included 91 cases with a mean age of 61.7 years (range 19-89), and 55 (60.4%) were male. There were 35 RSCC (38.5%) and 56 LSCC (61.5%). PD-L1 positivity was observed in 10 cases (5 RSCC, 5 LSCC), corresponding to 14.3% of RSCC vs. 8.9% of LSCC (p=0.499). High PD-1 expression was detected in 25 cases, representing 20% of RSCC vs. 32.1% of LSCC (p=0.207). No significant association was found between tumour laterality and PD-L1/PD-1 expression.
Conclusion: Although RSCC and LSCC are prognostically and molecularly distinct (e.g., higher BRAF/KRAS mutations in RSCC), ourstudyrevealed no significantdifference in PD-L1/PD-1 expression by laterality. The trend toward higher PD-1 in LSCC mayreflectdifferential immune microenvironments.
While our results do not support laterality as a sole predictor of PD-L1/PD-1 expression, they highlight the need for larger studies itegrating molecular and immune profiling.

E-PS-06-068
Cyclin D1 expression in colorectal cancer and its association with clinicopathological features
R. Aouadi[1], A. Khemir[2], Z. Abdelkafi[3], H. Douik[3], G. Sahraoui[2], Y. Zenzri[4], N. Ben Ammar[5], N. Hammadi[1], I. Nasri[1], D. Rabiaa[6], R. Doghri[2], K. Mrad[2]
[1]Salah Azaiez Institute, Pathology, Tunis, Tunisia, [2]Salah Azaiez Institute, Faculty of Medicine of Tunis, University of Tunis Al Manar, Precision Medicine and Oncology Investigation Laboratory (LR21SP01), Pathology, Tunis, Tunisia, [3]Salah Azaiez Institute, Precision Medicine and Oncology Investigation Laboratory (LR21SP01), Pathology, Tunis, Tunisia, [4]Salah Azaiez Institute, Medical Oncology, Tunis, Tunisia, [5]Higher School of Sciences and Health Techniques of Tunis, Tunis, Tunisia, [6]Salah Azaiez Institute, Gastroenterology, Tunis, Tunisia

Background & Objectives: Colorectal cancer (CRC) is a major public health problem due to its high morbidity and mortality worldwide. Understanding the mechanisms of CRCs' carcinogenesis and the signalling pathways, including Cyclin D1, is important for the development of new effective therapies the aim of this study was to evaluate Cyclin D1 expression in CRC in a Tunisian case series and identify its association with clinicopathological features.
Methods: A retrospective study including cases of CRC at Salah Azaiez Institute. An immunohistochemical study with anti-Cyclin D1 antibody using the "Tissue Microarray" technique was carried out.
Results: Our case-series included 33 cases. The mean age was 58 years (38-77). CRCs were mainly located in the left colon and rectum. Tumour size was greater than 50mm in nearly 58% of cases. Cyclin D1 expression was retained in 64% of cases. We found a statistically significant association between Cyclin D1 expression and large tumour size ($p = 0.003$), presence of metastases at diagnosis ($p = 0.022$), and the time to onset of metastases of 1 year ($p = 0.03$). No statistically significant association was found between CyclinD1 expression and other clinicopathological features.
Conclusion: Studies on the expression of Cyclin D1 in CRC and its associations with anatomo-clinical aspects are rare. Understanding the carcinogenesis pathways involving Cyclin D1 in CRC could help develop a prognostic, and/or predictive biomarker of response to certain therapies.

E-PS-06-069
Deciphering the tumour-immune landscape in GISTs: immunotherapy-relevant insights from multiplex immunohistochemistry
M. Grillini[1,2], A. Astolfi[1,3], A. Costa[3], I. Motta[4], L. Gozzellino[1], M.C. Nigro[1], A. De Leo[1,5], M. Nannini[1,6], M.A. Pantaleo[1,6]
[1]University of Bologna, Department of Medical and Surgical Sciences (DIMEC), Bologna, Italy, [2]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Division of Pathology, Bologna, Italy, [3]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, [4]University of Bologna, Alma Mater Institute on Healthy Planet, Bologna, Italy, [5]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Division of Molecular Pathology, Bologna, Italy, [6]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Division of Oncology, Bologna, Italy

Background & Objectives: Gastrointestinal stromal tumours (GISTs) are driven by KIT or PDGFRA mutations and treated with tyrosine kinase inhibitors (TKIs), but responses in the metastatic setting remain suboptimal. Immunotherapy may offer a new frontier, yet its integration requires a precise molecular understanding of the tumour immune microenvironment (TME), still largely unexplored in GISTs. This study

aims to generate immune profiling data to support rational design of future targeted therapy.
Methods: Twenty-eight FFPE GIST surgical samples were selected. Multiplex immunohistochemistry for CD3/CD20/CD163, and PD-L1/CD68 was performed with Ventana Discovery Ultra platform, and digitally quantified using QuPath v0.5.0. Additional markers (Arginase-1, HLA class I) were assessed by manual scoring.
Results: Immune infiltration was detected in all samples, with a dominant presence of CD163+ M2 macrophages (mean 15.5%), and a consistent, albeit lower, CD3+ T cell infiltration (mean 3.6%). Notably, primary tumours harboured a significantly richer immune microenvironment than metastatic lesions, particularly in macrophages ($p<0.05$), but also in T and B cells, suggesting a progressive immune escape during metastasis.
PDGFRA-mutant GISTs showed a trend toward higher CD20+ B cell density and PD-L1 expression compared to KIT-mutant tumours, suggesting potential subtype-specific immunogenicity.
PD-L1 expression was higher in primary tumours than in metastases, reinforcing the idea of dynamic immune modulation during progression.
HLA-I expression was retained in most samples, while Arginase-1 staining was consistently negative, excluding a major role for myeloid-derived suppressor cells and suggesting that immune evasion in GISTs does not rely on classical MHC downregulation or myeloid suppression.
Conclusion: This study unveils a nuanced immune landscape in GISTs, with implications for immunotherapeutic strategies. The presence of immune targets—especially in primary tumours—lays the groundwork for rational combinations of TKIs and immunotherapy in selected patient subsets.

Funding: The research leading to these results has received funding from AIRC under IG 2021 - ID. 26010 project – P.I. Maria Abbondanza Pantaleo

E-PS-06-070
Peritoneal mesothelioma: a report of two cases
P.D. Adolewska[1], M.M. Petrino[1], P. Pérez-Montero[2], P. Puente-López[1], I. De la Peña Navarro[1]
[1]La Paz University Hospital, Pathology, Madrid, Spain, [2]Health Diagnostics Quiron Salud, Pathology, Madrid, Spain

Background & Objectives: Peritoneal mesothelioma (PeM) is a rare malignant neoplasm with poor survival that accounts for approximately 10% of all mesotheliomas. It is generally diffuse and, compared with pleural mesothelioma; it shows weaker association with asbestos exposure, and involves more frequently women and young patients.
Methods: We studied the histopathological findings of two patients diagnosed with PeM. For clinical data, we reviewed the patients' electronic medical records.
Results: We report two cases of PeM, both belonging to males without asbestos exposure, who presented with multiple nodules involving the serosal lining in the peritoneal cavity. The first patient was a 53-year-old diagnosed in 2022 and treated with chemotherapy that recurred in December 2024. In January 2025, he underwent a procedure combining cytoreductive surgery with hyperthermic intraperitoneal chemotherapy. The second patient was a 72-year-old with nodules affecting the peritoneum and multiple abdominal organs that died without a diagnosis and underwent an autopsy. Histologically, the tumours consisted of a predominant solid proliferation of monotonous, round cells; with eosinophilic cytoplasm; and atypical nuclei with mitosis and necrosis. In the first case, there were focal areas of the tumour with atypical cells lying in a myxoid stroma that showed positivity with Alcian Blue-PAS stain. In both cases, the microscopic examination confirmed the mesothelial nature of the tumour (positivity for WT1, calretinin, and podoplanin) and its invasive nature. The first case showed loss of BAP1. The final diagnosis in both cases was high-grade diffuse epithelioid mesothelioma.
Conclusion: PeM is a rare neoplasm that can represent a diagnostic challenge. Ancillary testing, including immunohistochemical stains, in situ hybridization for CDKN2A or NF2, and molecular studies, in selected cases, allows its correct diagnosis. While the standard TNM staging system is used for pleural mesothelioma, there is not a universally accepted TNM staging system for peritoneal mesothelioma due to its rarity and unique characteristics.

E-PS-06-071
A rare case of an amphicrine tumour in the right colon: case report and literature review
C. Perez Duque[1], P. Rodrigues Veiga[1], A.L. Cunha[1]
[1]Instituto Português de Oncologia do Porto Francisco Gentil, E.P.E. (IPO Porto), Pathology Department, Porto, Portugal

Background & Objectives: Amphicrine tumour exhibits both neuroendocrine and non-neuroendocrine morphological and immunohistochemical (IHC) features in the same neoplastic cells. This rare tumour is by many included in a spectrum of mixed adenoneuroendocrine tumours (MiNEN), a group of neoplasms occurring in the digestive tract.
Methods: We herein report a case of a right colon MiNEN with amphicrine characteristics in a 80-year-old female who presented with diarrhoea and weight loss. She underwent a colonoscopy that revealed an ulcerated lesion in the right colon that was biopsied. The biopsy showed a malignant epithelial neoplasm with high proliferative index and neuroendocrine differentiation.
Results: After appropriate staging with MRI showing multiple images suggestive of hepatic metastasis, she underwent a right colectomy. A gross examination of the surgical specimen showed an ulcerated tumour at the right colon with 3.8cm. The final histopathological examination confirmed a MiNEN diagnosis with a single neoplastic cell population presenting dual differentiation: secretory granules (neuroendocrine) and intra-cellular mucin (adenocarcinoma). On IHC, neoplastic cells showed positivity for CAM5.2, CK7, CDX2, sinaptophysin, chromogranin and INSM1. In addition, PAS-D stain showed intracellular mucin in the same cells. We counted 72 mitotic figures in 2mm2 and the proliferative index (Ki67) was >90%. The final pathological stage was pT4aN1bM1.
Conclusion: This report details a rare subtype of MiNEN originating in the right colon with neoplastic cells presenting simultaneously neuroendocrine and glandular differentiation.
Although, amphicrine tumour is still not acknowledge in the most recent WHO Classification of Endocrine and Neuroendocrine Tumours, it poses a challenge for pathologists and for clinical management of patients. This very rare tumour adds to the scant documented cases and complements the knowledge regarding the clinical presentation, pathology, management and prognosis of MiNEN.

E-PS-06-072
eCura score in early gastric cancer patients – a solid tool for assessing endoscopical curability
A. Cibotariu[1], A. Voiosu[2,3], G. Micu[1], C. Socoliuc[1,3], L. Sticlaru[1,3], L.E. Stanciu[1], R. Ionescu[1], R. Neagu[1], D.-M. Marinoiu[1], A. Bordea[1], V. Marin[1], C. Popp[1]
[1]Colentina University Hospital, Pathology, Bucharest, Romania, [2]Colentina University Hospital, Gastroenterology, Bucharest, Romania, [3]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background & Objectives: Endoscopic submucosal dissection has been widely accepted as a minimally invasive, effective method to

achieve curative treatment for early gastric cancer. The eCura score helps in stratifying patients based on the risk of lymph node metastasis. It represents a good histological tool to quantify endoscopic curability supporting optimal decision regarding further treatment. This study aims to evaluate the reproducibility of the eCura score and system.
Methods: Eleven patients who underwent endoscopic submucosal dissection for early gastric carcinoma were included in the study. Two pathologists with different experience (3, respectively 20 years) used the most representative tumour slides for calculating the eCura score and assessing endoscopic curability.
Results: 11 patients, 7 men and 4 women with ages between 62 and 87 (median age 69 years) represented the analysed cohort. The eCura score varied between 0 and 4, with the majority (63.6%) being 0. The eCura system showed 8 cases classified as eCura A (72.7%), 2 cases as eCura B (18.2%) and 1 as eCura C-2 (9.1%). The majority of the patients showed a low risk of lymph node metastasis risk, while the rest showed an intermediate risk. Comparing between the two pathologists' quantifications showed similar results in cases without lympho-vascular invasion, venous invasion and submucosal invasion depth above 500 microns, while in more advanced cases the results were slightly different. Adding immunohistochemical stains for smooth muscle and lymphatics to better visualize them corrected the score differences, making the scoring system less dependent on the pathologist's experience.
Conclusion: The eCura score and system are reproducible in curative cases, while adding immunohistochemical stains to better assess lympho-vascular invasion and submucosal invasion depth could eliminate interobserver variability.

E-PS-06-073
Histological patterns of anti-PD-1 induced colitis
A. Therapontos[1], C. Kouvidou[1], E. Athanasiou[1], E.-A. Spiteri[1], K. Koniari[1], C. Vourlakou[1]
[1]Evaggelismos General Hospital, Department of Pathology, Athens, Greece

Background & Objectives: Programmed cell death protein 1 (PD-1) blocking agents are novel immunotherapeutics used for treatment of advanced-stage malignancies however toxicity is common and may occur many months after the therapy stopped. Immune related adverse events may affect multiple organs including gastrointestinal system and the most widely reported is colitis as an important complication. There is little information on the pathologic features of anti-PD-1 colitis.
Methods: We describe six patients with a history of lung cancer who developed colitis while on anti-PD-1 monotherapy. The patients presented with acute onset of diarrhoea (+/- blood) 3 to 6 months after the anti–PD-1/PD-L1 therapy. Endoscopy showed oedema, erythema, loss of vascular pattern, granularity, ulcerations and even normal mucosa. The patients did not have a previous history of idiopathic inflammatory bowel disease (IBD) or microscopic colitis.
Results: The colon biopsies showed active colitis with neutrophilic infiltration in the lamina propria, cryptitis, crypt microabscesses, basal plasmacytosis and prominent crypt epithelial cell apoptosis reminiscent of graft-versus-host disease and focal crypt atrophy/dropout as in ischemic colitis. Increased intraepithelial lymphocytes (CD3+),a lymphocytic colitis-like pattern was observed in two cases. A mixed colitis pattern combining features of active colitis and ischemic colitis were found in two cases. Two of the patients showed active colitis IBD-like, especially ulcerative colitis but due to CMV positivity were excluded from our study.
The differential diagnosis includes infectionsinjury by other drugs, graft-versus-host disease, and IBD.
Conclusion: As anti-PD-1 agents are increasingly used in oncology, we present these cases to increase awareness of anti-PD-1 colitis among pathologists, to facilitate its timely diagnosis and treatment. The anti-PDL-1 therapy–induced colonic injury can present in a number of histopathologic patterns that can be an overlap. The loss of epithelial barrier integrity may be implicated in the initiation of the pathogenetic process.

E-PS-06-074
Hematoidin crystals in a vessel wall: a rare peculiar histological finding
A. Therapontos[1], D. Efthymiou[1], S. Avgousti[1], A. Bairamis[1], A. Georgiou[1], C. Kouvidou[1]
[1]Evaggelismos General Hospital, Department of Pathology, Athens, Greece

Background & Objectives: Hematoidin is a product of heme metabolism that is deposited in tissues under low oxygen tension conditions in association with blood extravasation and appears 10 - 12 days postinjury. In contrast to hemosiderin, hematoidin is lacking iron and therefore is not highlighted with histochemical staining for iron. Following erythrocyte degeneration, porphyrin is released from haemoglobin and is converted to biliverdin, which is reduced to crystalline hematoidin. Because hematoidin can be converted back to biliverdin, it is not always seen. This may explain its rarity.
Methods: A 59-year-old man which admitted to surgical department with abdominal pain of three days duration. The CT showed signs of ischemic colitis and the patient underwent partial colectomy of small intestine.
Results: The pathological examination revealed findings of ischemic type colitis with necrosis of the mucosal and vessel dilation with haemorrhage of submucosal and mesenteric fat. In a vessel wall especially in the inner layer of the mesenteric fat observed a golden-brown/yellow-orange crystalline pigment and that is composed of thread-like filaments arranged in star-shaped clusters. The Perl's staining for hemosiderin was negative.
Conclusion: May persist for years within haemorrhagic lesions and organizing hematomas. Hematoidin has been documented in a variety of conditions typically associated with chronic haemorrhage. Hematoidin crystals is non-specific phenomenon that can be seen in variety of conditions, it is a combination of acute lung injury and thrombotic microangiopathy in Covid-19 pneumonia, pulmonary infarcts and necrotizing lung lesions. Hematoidin was also reported in patients with traumatic and spontaneous cerebral haemorrhages, acute gastrointestinal bleeding and in the skin.

E-PS-06-075
Kaposi sarcoma in perinodal adipose tissue without lymph node parenchymal involvement: an unusual presentation. A case report
R.R. Askin[1], N. Berker[1], H. Bakkaloglu[2], M. Buyuk[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Pathology, Istanbul, Turkey, [2]Istanbul University, Istanbul Faculty of Medicine, General Surgery, Istanbul, Turkey

Background & Objectives: Kaposi sarcoma (KS) is an angioproliferative disorder associated with human herpesvirus 8 (HHV-8) infection, primarily affecting immunocompromised patients. The skin is the most affected site, followed by mucosal surfaces, lymph nodes, and visceral organs. Primary lymph node involvement is relatively rare. Here, we present a case of KS involving perinodal adipose tissue without intranodal involvement, which appears to be the first reported case.
Methods: A 70-year-old female with a 12-year history of ulcerative colitis (UC) underwent distal subtotal gastrectomy and D2 lymphadenectomy for gastric adenocarcinoma. Haematoxylin and eosin-stained slides of the tumour, normal gastric mucosa, and regional lymph nodes were evaluated.

Results: The patient was diagnosed with pT1bN2M0 gastric adenocarcinoma. Among the regional lymph nodes, nine exhibited abnormal vascular proliferation in the perinodal adipose tissue. Higher magnification revealed slit-like vascular proliferations, some of which were associated with afferent and efferent vessels of the lymph nodes, with no involvement of the lymph node parenchyma. Immunohistochemical analysis showed positive immunoreactivity for CD34 and HHV-8, confirming the diagnosis of KS. No evidence of KS was detected in the tumour or non-tumour sections of the gastrectomy specimen.
A comprehensive evaluation was conducted to assess potential KS involvement at other sites, revealing no mucocutaneous lesions or colonoscopic abnormalities. The patient had not received any immunosuppressive treatment for UC, and HIV testing was negative. No evidence of immunosuppression was found.
Conclusion: KS can occur in unusual anatomical sites, complicating its recognition and potentially leading to underdiagnosis. To the best of our knowledge this may be the first reported case of KS involving perinodal adipose tissue, associated with lymph node vessels, without affecting the lymph node parenchyma. Pathologists should be aware of this presentation and consider further evaluation for involvement at other sites, as well as an assessment of the patient's immunosuppressive status.

E-PS-06-076
Histopathological characteristics of different types of amyloidosis with gastroduodenal involvement
Z. Gioeva[1], A. Tebenkova[1], A. Tsytsaev[1], D. Samoilova[1], I. Stepanova[1], T. Nataliia[1], A. Stepanov[1], L. Mikhaleva[1]
[1]Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Moscow, Russia

Background & Objectives: Diagnosing gastrointestinal amyloidosis can be challenging, as the symptoms are non-specific. The aim of this study is to describe histoanatomical and immunohistochemical features of the most common types of amyloidosis with gastroduodenal involvement in biopsy and autopsy specimens.
Methods: Histological sections were stained with haematoxylin and eosin and Congo red. Immunohistochemistry with a broad panel of antibodies against various amyloid types was used.
Results: The study included 39 cases of duodenal amyloidosis (24 biopsies and 15 autopsies) and 32 cases of amyloid deposits in the stomach (21 biopsies and 11 autopsies). Patient ages ranged from 32 to 91 years.
Immunophenotyping of amyloid in the duodenum revealed AL lambda type in 17 (44%) cases, AL kappa – in 6 (15%), AA – in 11 (28%), and ATTR – in 5 (13%) of cases.
In the gastric specimens, AL lambda amyloidosis was found in 10 (31%) cases, AL kappa – in 11 (34%), AA – in 7 (22%), ATTR – in 4 (13%) cases.
The analysis of histoanatomical distribution of amyloid deposits in the stomach and duodenum demonstrated that AL kappa amyloidosis often affected the duodenal (83%) and gastric (90%) mucosa. However, in patients with ATTR amyloidosis the submucosal layer was involved in 100% of cases and the lamina propria – only in 11%.
Conclusion: As shown in the study, AL lambda was the most common amyloid type detected in the duodenum, while in the stomach lambda and kappa varieties of AL were found in a similar number of cases.
The most extensive amyloid deposits were determined in cases of AL amyloidosis of kappa type suggesting that such patients may have a more rapid progression of the disease.
As ATTR amyloid is deposited mostly within the submucosal and muscular layers, it is recommended to enclose submucosal tissues in the biopsy specimens in order to avoid false negative histological results.

Relevance of OLGA/OLGIM staging systems revisited: background mucosal changes in a large series of gastric adenomas
E.B. Kutsal[1], B. Savaş[1], S. Bertz-Kalinka[2], M. Vieth[3], A. Ensari[1]
[1]Ankara University Medical School, Department of Pathology, Ankara, Turkey, [2]University Hospital Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg, Institute of Pathology, Nürnberg, Germany, [3]Friedrich-Alexander-Universität Erlangen-Nürnberg, Klinikum Bayreuth, Institute of Pathology, Nürnberg, Germany

Background & Objectives: Gastric adenomas (GAs) are premalignant lesions with a potential to progress to gastric carcinoma. The OLGA/OLGIM staging systems for gastric atrophy and intestinal metaplasia are used to assess neoplasia risk, particularly for the intestinal subtype. We aimed to evaluate whether this is also true for other, rarer types of adenomas in a large cohort from two centres.
Methods: A total of 1,253 GA collected from two centres were retrospectively analysed for subtypes (intestinal type-INT; foveolar type-FOV; pyloric gland adenoma-PGA, oxyntic gland adenoma-OGA and others) in relation to background mucosal changes including H. Pylori (HP), intestinal metaplasia (IM), and atrophy.
Results: INT (80.7%) was the most common adenoma type, followed by PGA (9.2%), FOV (4.2%), and OGA (0.3%). INT was predominantly antral (58.3%), while PGA (73.3%), FOV (77.4%), and OGA (50%) were located in corpus. INT exhibited the highest prior/active HP exposure (antrum: 82.3%, corpus: 83.2%) together with IM in the entire stomach (94.6% antrum, 85.9% corpus), and atrophy (95.7% antrum, 87.3% corpus). While IM and atrophy were much lower in PGA 12.5% and 10.6, respectively for antrum and 35.8% and 30.6, respectively for corpus, FOV exhibited the lowest frequency of IM (8%, 11.5%) and atrophy rates (4%, 6%) in corpus and antrum, respectively compared to other subtypes ($p<0.001$). HP exposure was higher in Turkey (85.1%) compared to Germany (73%) in contrast to IM which was slightly more common in Germany (56.7% vs. 49.7%), while atrophy was similarly distributed (55.9% vs. 56.1%).
Conclusion: IM and atrophy as indicators of higher risk for neoplastic transformation in intestinal adenomas do not seem to be in play in FOV or OGA. Though at a lower rate, PGAs also arise in a background of atrophic mucosa. Taken together, these findings suggest that OLGA and OLGIM are useful only in intestinal adenomas.

E-PS-06-078
Dome carcinoma arising in a colonic tubular adenoma with high-grade dysplasia: a case report
J. Sobreiro Silva[1], J. Pardal[1]
[1]Unidade Local de Saúde de Braga, Pathology, Braga, Portugal

Background & Objectives: Dome carcinoma is a rare variant of colorectal carcinoma, characterized by a distinctive morphological pattern with expansive growth, lymphoid-rich stroma, and cystic glands with eosinophilic debris. We present a case of dome carcinoma arising in a colonic tubular adenoma with high-grade dysplasia, emphasizing diagnostic challenges and clinical management.
Methods: A 50-year-old woman was referred for evaluation of a colonic polyp detected during a colonoscopy. The exam revealed a Paris 0-IIa flat, stellate lesion (25 mm) in the cecum, resected via piecemeal diathermic loop.
The patient had no significant personal history or associated symptoms.
Results: Histopathological examination of the fragments showed a tubular adenoma with high-grade dysplasia and, in deeper sections, an

infiltrative neoplasm within the submucosa surrounded by lymphoid tissue. The tumour consisted of cystically dilated glands with eosinophilic necrotic debris, pushing borders, and a dense lymphoid stroma with germinal centres, consistent with dome carcinoma.
Due to incomplete resection margins, the patient underwent right hemicolectomy, which revealed no residual tumour or lymph node metastases.
The patient remains under surveillance and disease free.
Conclusion: This case highlights the unique clinicopathological features of dome carcinoma, including its association with precursor adenomatous lesions and prominent lymphoid stroma. The characteristic histomorphology—expansile growth, cystic glandular dilatation, and lack of desmoplasia— can pose a diagnostic challenge to differentiate from pseudoinvasion of lymphoglandular complexes of the submucosa. While complete endoscopic resection may be curative for early lesions, surgical management remains essential for cases with incomplete excision or deeper invasion. Further studies are needed to better characterize the biological behaviour and long-term outcomes of this uncommon entity.

E-PS-06-079
Colorectal carcinoma with sarcomatoid components and focal mucinous differentiation: a rare case of isolated BRM (SMARCA2) loss
F. Aknar[1], T. Soylemez-Akkurt[1]
[1]Istanbul Medeniyet University Goztepe Prof. Dr. Suleyman Yalcin City Hospital, Department of Pathology, Istanbul, Turkey

Background & Objectives: Colorectal Carcinoma with Sarcomatoid Components is a rare, aggressive WHO-recognized subtype. While SWI/SNF alterations are documented, isolated BRM (SMARCA2) loss remains poorly characterized. We report a novel case with focal mucinous differentiation, adenoma origin, and isolated BRM loss to explore its clinicopathological implications.
Methods: An 86-year-old female presented with perforated rectosigmoid carcinoma. Histopathological analysis included morphology, SWI/SNF complex proteins (SMARCB1/INI1, SMARCA4/BRG, SMARCA2/BRM), and mismatch repair (MMR) status. Intraoperative findings revealed liver metastasis and peritoneal implants. R2 resection was performed due to critical status.
Results: A 9 cm perforated tumour arose from a high-grade tubulovillous adenoma. Biphasic morphology included mostly sarcomatoid (80%) (rhabdoid and spindle cells) and focal adenocarcinoma (20%) including (5%) mucinous components. IHC revealed intact MMR proteins (MLH1, MSH2, MSH6, PMS2) and retained INI1, BRG, while BRM was lost. OSCAR keratin was negative in sarcomatoid regions. The patient succumbed to rapid disease progression two months postoperatively.
Conclusion: This case highlights isolated BRM loss as a rare, underreported molecular event in sarcomatoid CRC—distinct from the more commonly observed co-alterations involving SMARCA4/INI1. Our findings advocate for systematic evaluation of SWI/SNF proteins in CRC to refine prognostic stratification and to expand the molecular spectrum of sarcomatoid CRC as reported in recent literature.

E-PS-06-080
Interaction of Desmin and mast cells in colorectal cancer
A. Filin[1], E. Priputnevich[1], E. Chupandina[1], V. Shishkina[2], R. Tokmachev[3], K. Sakibaev[4], N. Tashmatova[4]
[1]Voronezh State Medical University, Department of Pathological Anatomy, Voronezh, Russia, [2]Voronezh State Medical University, Department of Histology, Voronezh, Russia, [3]Voronezh State Medical University, Research Institute of Experimental Biology and Medicine, Voronezh, Russia, [4]Osh State University, Department of Anatomy, Histology and Normal Physiology, Osh, Kyrgyzstan

Background & Objectives: Mast Cells (MC) are one of the most common types of cells in tumour microenvironment. They have many different well-studied functions, but their exact role in tumour oncogenesis is still understudied. Desmin is a protein of intermediate filaments that is usually expressed in muscle cells. Sometimes, Desmin expression is detected in tumour cells that were not originally muscular, including colorectal cancer cells. The role of Desmin in tumour morphogenesis is unclear.
Methods: Histological examination of surgical material obtained from 45 patients was performed. MC and Desmin were detected by immunohistochemical method using monoclonal mouse antibodies to Tryptase and Chymase (for MC) and monoclonal mouse antibodies to Desmin. Also, double immunolabeling was used to visualize the colocalization of MC and Desmin. To evaluate the level of functional activity of MC, the degranulation index was calculated using special formula.
Results: Expression of Tryptase-positive and Chymase-positive MC and Desmin was observed almost in all studied samples. The amounts of MC and Desmin in tumour were counted. MC degranulation index was calculated and compared to the amount of Desmin. Cases were divided into two groups: the first one – patients with a high degranulation index of MC, and the second – patients with a low degranulation index of MC. The amount of Desmin in tumour was higher in the group of cases with low degranulation index of MC ($p<0.01$, Mann-Whitney test). Using double immunolabeling, the result obtained was visualized. MC were more active in cases where the expression of Desmin was low.
Conclusion: Expression of MC and Desmin was detected almost in all studied samples. MC degranulated more in the group with low Desmin expression. It is necessary to continue studying their role in the morphogenesis of colorectal cancer.

E-PS-06-082
YAP expression in sporadic and inflammatory bowel disease-associated colorectal cancer
F. Yin[1], X. Liu[2]
[1]The University of Texas MD Anderson Cancer Centre, Department of Pathology, Houston, USA, [2]Washington University in St Louis, Department of Pathology and Immunology, St Louis, USA

Background & Objectives: Yes-associated protein (YAP) plays a critical role in the development and progression of various tumours, demonstrating its potential as a prognostic and therapeutic target. However, there is considerable debate regarding whether YAP acts as an oncogene or tumour suppressor during the tumorigenesis of colorectal cancer (CRC).
Methods: This study collected tumour tissue microarrays from two distinct types of CRC: sporadic CRC and inflammatory bowel disease (IBD)-associated CRC. We assessed YAP expression using immunohistochemical analysis, and its correlation with the clinicopathologic features and the expression pattern of other biomarkers.
Results: In sporadic CRC, YAP expression in tumour was not significantly associated with age, gender, tumour site, and tumour differentiation ($P > 0.05$). CRCs with positive YAP expression frequently demonstrated deep invasion with serosal involvement (20.7%), as compared with the YAP negative cases (3.4%) ($P = 0.041$). CRCs with positive YAP expression were less likely to have nodal metastasis (pN1-2: 44.8%), as compared with the YAP negative cases (65.5%) ($P = 0.105$). YAP expression was not associated with immunoreactivity of other biomarkers including Claudin 18.2, p53, AMACR, and nuclear beta-catenin. In IBD-associated CRC,

the YAP positive expression rate was significantly higher (50.0%, 32/64) compared to the sporadic CRC cohort (33.3%, 29/87) (P = 0.045). However, in IBD-associated CRC, YAP expression was not correlated with the clinicopathological parameters, including depth of invasion and lymph node metastasis, and histological features of IBD-associated CRC, including signet-ring cell features, medullary features, Crohn-like reactions, or dirty necrosis.
Conclusion: YAP expression is associated with deep invasion and serosal involvement in sporadic CRC, supporting its role as an oncogenic factor in the tumorigenesis of sporadic CRC. Its positive expression rate is higher in IBD-associated CRC. However, our study suggest that YAP may involve different pathways between sporadic and IBD-associated CRC.

E-PS-06-083
Colitis cystica profunda mistaken for mucinous adenocarcinoma in a patient with ulcerative colitis - a case report
M. Đuknić[1], Z. Zagorac[2], N. Nikolić[3], N. Miloševic[3], J. Jevtić[4], D. Putniković[1], R. Janković[1]
[1]Institute of Pathology "Prof. dr Đorđe Joannović", Faculty of Medicine, University of Belgrade, Belgrade, Serbia, [2]Clinical Hospital Centre"Dragiša Mišović", Department of Surgery, Belgrade, Serbia, [3]Institute for Oncology and Radiology of Serbia, Belgrade, Serbia, [4]Institute of Pathology "Prof. Dr Đorđe Joannović", Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background & Objectives: Colitis cystica profunda (CCP) is a rare benign lesion of the gastrointestinal tract characterized by submucosal mucin-filled cysts. Depending on the localization, it is called colitis, gastritis, or enteritis cystica profunda. Predominantly polypoid lesions involve the entire colon, mainly in the anterior wall of the rectosigmoid tract . They vary in size, depth, and localization, while the surrounding tissue may show changes consistent with chronic inflammation and fibrosis.
Methods: We present a case of a 56-year-old woman with CCP as a complication of chronic ulcerative colitis.
Results: A 56-year-old female patient with UC was admitted to the hospital with signs and symptoms of pancolitis. An abdominal CT showed a large cecal infiltrative mass, narrowing the colon's lumen. A colonoscopy was performed and a diagnosis of colonic adenocarcinoma was suspected. Total colectomy was performed, and the samples were sent to the pathohistological analysis. Submucosal cystically dilated mucin-filled glands, lined with a single-layered cylindrical epithelium with the nuclei in the basal layer were seen histopathologically. Surrounding these glands there was no connective tissue, apart from small focuses where the gland wall ruptured and a reaction to the spilled mucus was present. The lack of cellular atypia and desmoplastic stroma surrounding the glands dismissed the diagnosis of a neoplastic process. Immunohistochemistry was negative for proliferation (Ki67, p53) and microsatellite instability (MLH-1, MSH-2, MSH-6, and PMS-2). The diagnosis of colitis cystica profunda in background of ulcerative colitis was made.
Conclusion: Clinicians and pathologists must maintain a high index of suspicion and consider a broad differential diagnosis when interpreting biopsies from patients with UC, particularly those with unusual or complex clinical features.

E-PS-06-086
Role of E-cadherin as a surrogate prognostic marker in Colorectal carcinoma and its correlation with stage, grade and other important parameters determining aggressiveness
A. Rai[1], C. Tampi[1]
[1]Lilavati Hospital and Research Centre, Histopathology, Mumbai, India

Background & Objectives: Colorectal carcinoma (CRC) is the second commonest cause of cancer-related deaths worldwide, and its 5-year survival rate ranges from 90% for early stage cancers to 10% for metastatic cancers. Epithelial (E)-cadherin (CDH1 gene) represents the prime mediator of intercellular adhesion. Its downregulation promotes cell dyscohesiveness, migration and invasion which facilitates invasive growth and metastasis. While some researches have shown that CRC cases with loss of E-cadherin expression had lower survival time and suggested ecadherin as a significant independent predictor for poor prognosis, other researches found no significant association. In this study we analysed the expression of E-cadherin in tumour tissue (surface and deeper) of CRC in relation to other clinicopathological features such as cancer stage, grade, permeation into the lymphatics and venous channels and tumour location.
Methods: A total of 124 CRC cases were evaluated with haematoxylin & eosin stain and immunohistochemistry using Student's unpaired t test, Mann Whitney U test, Fisher Exact Probability test and Chi square test, post ethical committee approval.
Results: The cases were ranging from 28 years to 91 years with mean age 61 years. 81 were males and 43 females. 33% were located in rectosigmoid colon, while, 27% in the right-sided colon. Loss of ecadherin expression was seen nearly twice in the deeper portions of the tumour as compared to superficial. Majority of the early stage and low grade tumours (70%-100%) showed moderate to strong ecadherin expression but did not show a significant pattern in higher stage/ grade tumours or with permeation into the lymphovascular channels.
Conclusion: Our study was unable to demonstrate a significant positive correlation between loss of ecadherin and tumour aggressiveness, but found some interesting results in various related domains. However, this association remains largely unexplored and necessitates greater attention with a larger sample size to identify a significant surrogate prognostic marker in CRC.

E-PS-06-087
Endoscopic submucosal dissection for upper gastrointestinal tract lesions: a single centre experience
D. Myoteri[1], I. Vlachos[1], K. Papadopoulos[1], P. Zormpas[2], G. Tribonias[2], D. Tiniakos[1]
[1]Aretaieion Hospital, Medical School, National and Kapodistrian University of Athens, Department of Pathology, Athens, Greece, [2]General Hospital of Nikaia-Piraeus Agios Panteleimon, Department of Gastroenterology, Athens, Greece

Background & Objectives: Endoscopic submucosal dissections (ESD) are increasingly performed for the removal of superficial lesions of the gastrointestinal (GI) tract as an alternative to surgical resection. This poster summarizes a single centre's experience in the diagnostic workup of 15 cases of ESD for GI tract lesions received from October 2024 to March 2025.
Methods: ESD specimens (n=15, 4 colonic, 6 rectal, 5 gastric) were received in our Department pinned on styrofoam sheets in a 4% neutral buffered formalin solution, fixed for a minimum of 12 hours, inked in the lateral (mucosal) and deep (submucosal/muscularis propria) margins and submitted for histological examination. Histopathological characteristics of the tumours and margin status were analysed.
Results: Specimens from 15 patients (7 female, 8 male) with median age 67.5 years (range: 41-78 years) were processed. Mean maximum diameter of ESD specimens was 57.6 mm (range: 30-110 mm), while the lesion size averaged 38.6 mm (range: 12-80 mm). Specimens included ESD of 8 invasive (4 gastric adenocarcinomas, tubular subtype, 4 colorectal adenocarcinomas NOS) and 7 of non-invasive tumours (3 colonic adenomas with high-grade dysplasia without

lamina propria invasion and 1 with low-grade dysplasia, 2 traditional serrated adenoma of colon (TSA) and 1 gastric inflammatory fibroid polyp). The lateral margin was involved in 1 case of colonic adenoma with low-grade dysplasia and the deep margin in 2 cases (1 rectal adenocarcinoma and 1 gastric inflammatory fibroid polyp).
Conclusion: ESD is a satisfactory method of invasive treatment for superficial GI tract lesions. Histopathological specimen handling and microscopic examination are of paramount importance in the accurate diagnosis of the resected lesions and margin status assessment, as well as identifying characteristics of prognostic and predictive value, guiding subsequent treatment decisions.

E-PS-06-088

Clear cell features in Colorectal adenocarcinoma: a case series with histopathological and molecular characterization

A. Cioce[1], I. Panarese[1], G. Zannini[1], F. Zito Marino[1], R. Franco[1]
[1]Università degli Studi della Campania "Luigi Vanvitelli", Pathology Unit, Napoli, Italy

Background & Objectives: Colorectal cancer (CRC) is the most common gastrointestinal malignancy, with an annual incidence of 1.9 million cases and over 930,000 deaths. Prognostic factors include histological subtype, differentiation grade, invasion depth, lymphovascular invasion, perineural growth, tumour budding, and metastatic spread. Among adenocarcinomas, clear cell modifications are rare and associated with enteroblastic differentiation, resembling foetal gut epithelium and expressing markers such as Alpfa-fetoprotein (AFP), Sal-like protein 4 (SALL4), and Glypican-3. This study aims to compare a case series of CRCs with clear cell features to existing literature and evaluate whether a percentage cutoff can define a distinct histotype, similar to gastric adenocarcinoma with enteroblastic differentiation.
Methods: Eleven cases of CRC with clear cell features were analysed. Histological examination was conducted on formalin-fixed, paraffin-embedded samples using PAS and Alcian Blue staining. Immunohistochemical analysis was performed for AFP, SALL4 and Glypican-3. Molecular testing assessed microsatellite status and mutations in KRAS, BRAF, PIK3CA, HER2, and NTRK.
Results: The cohort included six males and five females (M:F ratio = 1.2:1), with a mean age of 69.8 years. Tumours were located in the cecum (1), ascending colon (3), sigmoid colon (3), and rectum (4). Ten cases were low-grade, while one was high-grade. Most tumours extended beyond the muscularis propria (pT2: 2 cases, pT3: 7 cases, pT4: 2 cases). Lymph node involvement was observed in 9 cases (pN1: 5, pN2: 4), and distant metastases were present in 2 cases. All tumours were microsatellite stable. AFP was positive in 5 cases, Glypican-3 in 2, and SALL4 in 1. KRAS mutations were identified in 3 cases and PIK3CA mutations in 2.
Conclusion: Clear cell modifications in CRCs are rare but potentially aggressive. Their identification and classification are crucial for accurate prognosis and management. Standardized criteria should be developed to enhance recognition, stratification, and treatment approaches tailored to these tumours.

E-PS-06-089

Clinicopathological analysis of appendiceal neoplasms: a single institution study

H. Kini[1], D. Kumar[1], J. Kini[1], P. K Suresh[1]
[1]Kasturba Medical College, Manipal Academy of Higher Education, Pathology, Mangalore, India

Background & Objectives: Appendiceal neoplasms are rare with an incidence of 0.9-1.4%. They present unique diagnostic and therapeutic challenges due to the varied histological subtypes and common clinical presentation as acute appendicitis. The objective of this study was to analyse the clinicopathological characteristics of the spectrum of appendiceal neoplasms.
Methods: A retrospective and prospective study of appendiceal neoplasms, both primary and secondary, was conducted. Cases diagnosed between January 2017 and December 2023 at the Department of Pathology, Kasturba Medical College, Mangalore were included. Cases were analysed for demographics, presenting symptoms, radiological features, type of surgical interventions, and histopathology.
Results: Out of 3529 appendectomy specimens, 58 (1.07%) were identified as neoplastic. Of these, 26 were appendiceal mucinous neoplasms (AMNs), 10 neuroendocrine tumours (NETs), 2 goblet cell adenocarcinomas, and 20 secondary tumours. Age ranged from 13 to 86 years, with a mean of 51.4 years. Women (63.79%) were more often affected than men. The majority (63.79%) presented with right iliac fossa pain, mimicking acute appendicitis.
Conclusion: Appendiceal neoplasms are rare and often present diagnostic challenges, as most present as acute appendicitis. They are incidentally identified on radiology, intra-operatively or histopathologically. Currently, mucinous neoplasms, especially low-grade AMNs, are the commonest primary tumours, followed by NETs. In adult patients undergoing appendicectomy for acute appendicitis, a high index of suspicion for neoplasms is required. Meticulous grossing of the appendix clinches the diagnosis.

E-PS-06-090

Medullary carcinoma of the colon: an uncommon subtype of colorectal cancer. Clinical, histopathological and molecular profile of 19 cases

V. Cristóbal Redondo[1], P.A. Chilito Paredes[1], N. Calle Peñaranda[1], J.M. Molina López[1], G. Peiró Cabrera[1], A. Payá Romá[1], C. Alenda González[1]
[1]Dr.Balmis General Universitary Hospital of Alicante. Institute for Health and Biomedical Research of Alicante., Pathology, Alicante, Spain

Background & Objectives: Medullary carcinoma of the colon is a rare subtype of colorectal adenocarcinoma, accounting for approximately 0.03% of cases. It is frequently associated with microsatellite instability (MSI) and BRAF mutations. Despite its high-grade morphology, most series report a favourable prognosis. We aimed to describe the clinical, histopathological and molecular features of a series of cases diagnosed in our institution.
Methods: A retrospective review was performed on cases diagnosed between 2000 and 2024. Inclusion criteria were the availability of a surgical specimen and a medullary pattern representing >50% of the tumour, according to the 5th WHO criteria (solid/trabecular growth, expansive borders, and dense intraepithelial lymphocytic infiltrate). Clinical data and histological parameters were collected. MSI was analysed by immunohistochemistry, while BRAF and KRAS mutations by PCR.
Results: We identified 19 cases: 11 females (57.9%) and 8 males (42.1%), mean age of 70 years (range, 45–91). Symptoms were present in 17/19 patients (89.5%), including abdominal pain (47.4%), altered bowel habits (21.1%), rectal bleeding (21.1%), and constitutional syndrome (31.6%). Most tumours were located in the right colon (89.5%) with a mean size of 6.62 cm. Fourteen cases (73.7%) were pure medullary carcinomas. The majority were locally advanced (pT3: 57.9%; pT4: 26.3%) with low budding (68.4%) and frequent extramural venous invasion (52.6%). Lymph node metastases were encountered in 31.6%, and distant metastases in 11.5%. MSI was confirmed in all cases, with loss of MLH1 and PMS2. BRAF mutations were detected in 42.1%, and no KRAS mutations were identified. The mean follow-up was 45.8 months, with 31.6% mortality, half of which occurred within the first 7 months.
Conclusion: Medullary carcinoma is an infrequent subtype of colorectal carcinoma, predominantly affecting women and located in the right colon. Despite high-grade morphology, its prognosis is relatively

favourable. Recognition of this entity is essential, and MSI evaluation is helpful for its diagnosis.

E-PS-06-091

Mesenchymal tumours of the stomach after endoscopic resection

E. Chupyatova[1,2], G. Setdikova[1], A. Verbovskiy[3], A. Semenkov[3]
[1]Regional Research and Clinical Institute ("MONIKI"), Pathological Anatomy (with a Prosector's Office), Moscow, Russia, [2]Russian University of Medical Sciences (RUDN), Pathological Anatomy of the Patrice Lumumba Medical Institute, Moscow, Russia, [3]Regional Research and Clinical Institute ("MONIKI"), Moscow, Russia

Background & Objectives: Mesenchymal tumours (MT) are not typical for the GIT and range from reactive tumour lesions and benign neoplasms to aggressive sarcomas. The most typical mesenchymal tumour of the stomach is GIST, followed in descending order by smooth muscle and neurogenic tumours. The main problem is the differential diagnosis of these neoplasms both at the preoperative stage and during further morphological examination. On the other hand, the problem of benign tumours is the correct terminology, which will help to avoid diagnostic ambiguity and prognostic uncertainty, and therefore the need for subsequent treatment.
Aim: correct differential diagnostic criteria for gastric MT after endoscopic resection (EFTR, STER,ESD).
Methods: The study based on material obtained after endoscopic resection in MONIKI, and the group was 20 patients (age range 45-80) during 2021-2024yy.
Results: MT were presented: 4/20 – leiomyoma, 10/20 – GIST, 3/20 – inflammatory fibrous polyp (IFP); 1/20 – schwannoma (ScW); 2/20 – calcifying fibromatous pseudotumor (CFP). It should be noted that only GISTs had a clear picture during EUS, in other cases the final diagnosis was made only after morphological examination with IHC. Gross, the tumour size varied from 0.5 to 7.0 cm. With the exception of ScW and CFP, the tumours were whitish in colour, fibrous, homogeneous in appearance, and dense-elastic consistency. ScW had a yellowish tint, soft-elastic consistency; CFP - with areas of microcalcifications. Microscopically, MT are localized in the submucosal layer and represented by multidirectional spindle-shaped, stellate cells with ovoid hyperchromatic nuclei and noticeable nucleoli. The stromal component varies depending on the MT. The minimal IHC panel - CD34, CD117, S-100, DOG-1, Vim, PanCK, SMA.
Conclusion: GISTs remain the most common mesenchymal tumours of the stomach, but other rare mesenchymal neoplasms should be remembered. Currently, endoscopic methods of tumour resection are increasingly used as a minimally invasive intervention and replace open surgery.

E-PS-06-092

Clinical and morphological features of patients with autoimmune gastritis for diagnosis approach in advance

A. Krasnova[1], S. Mozgovoi[1], O. Gaus[2], V. Rubtsov[1], S. Ivanova[1], A. Gubanova[2], M. Livzan[2]
[1]Omsk State Medical University, Pathology, Omsk, Russia, [2]Omsk State Medical University, Department of Internal Medicine and Gastroenterology, Omsk, Russia

Background & Objectives: Autoimmune gastritis (AIG) associates with a high risk of gastric atrophy, stomach cancer and neuroendocrine tumours. To improve the diagnosis of AIG in individuals with different H. pylori infection status, an open, cross-sectional cohort study was conducted to identify the most informative clinical, endoscopic, and morphologic features of the disease.
Methods: 124 patients with chronic gastritis were examined. The main group included 35 patients with AIG, comparison group 1 - 38 patients with H. pylori-associated and AIG, comparison group 2 - 51 patients with H. pylori-associated gastritis. The examination included clinical and laboratory tests, endoscopy with histopathological examination.
Results: In 40% patients with AIG without H. pylori infection, endoscopic signs of atrophy in the antral region were observed, but only in 11.4% patients there was evidence of weak atrophy and focal complete intestinal metaplasia according to pathomorphological investigation. In the group of AIG patients associated with H. pylori, the prevalence of endoscopic signs of multifocal atrophic gastritis was statistically significantly higher (p=0.007) when compared to the main group, and without statistical significance when compared to the group of patients with H. pylori associated gastritis (p=0.064). Pseudopyloric metaplasia (p=0.001) and complete intestinal intestinal metaplasia (p=0.001) were statistically significantly more frequent in the gastric corpus. Additionally, with the involvement of the stomach body in the pathologic process, changes in the antral region were also found in patients with AIG in combination with H. pylori infection.
Conclusion: Diagnosis of AIG in patients with different H. pylori infection status requires a comprehensive approach, assessing the presence and severity of inflammation and atrophy, mainly in the body. In patients with AIG and absence of H. pylori infection in anamnesis, it is possible to detect signs of inflammation and atrophy of the antral region, probably due to the modulation of gastric microbiota on the background of hypochlorhydria.

E-PS-06-093

Cronkhite-Canada syndrome: a rare cause of diffuse gastrointestinal polyposis

J. Fallas[1], E. Besseghaier[1], N. Claeys[2], A. Van Gossum[3], M. Gómez Galdón[1]
[1]Hôpital Universitaire de Bruxelles, Centre d'Anatomie Pathologique, Brussels, Belgium, [2]Hôpital Universitaire de Bruxelles, Department of Colorectal Surgery, Brussels, Belgium, [3]Hôpital Universitaire de Bruxelles, Gastroenterology, Hepatopancreatology and Digestive Oncology Department, Brussels, Belgium

Background & Objectives: Cronkhite-Canada Syndrome (CCS) is a rare, non-hereditary, gastrointestinal disorder first described in 1955. It is characterised by diffuse gastrointestinal polyposis, protein-losing enteropathy, and ectodermal abnormalities, including alopecia, onychodystrophy, skin hyperpigmentation, and a fissured tongue. CCS primarily affects adults in their sixties and has no clear aetiology. Fewer than 500 cases have been reported, predominantly in Japan. The disease is relentlessly progressive, leading to severe malnutrition, gastrointestinal bleeding, and infections. Historically, mortality reached 50%, but advancements in treatment—including corticosteroids, immunosuppressants, and nutritional support—have significantly improved outcomes, with 5-year survival now exceeding 90%.
We report a case of CCS in which diagnosis was delayed due to non-specific early endoscopic and histological findings, highlighting the importance of multidisciplinary discussion in rare disease diagnosis.
Methods:.
Results: A 61-year-old man with no prior medical history developed severe digestive symptoms following a Covid-19 infection. He experienced fatigue, ageusia, nausea, and persistent diarrhoea, resulting in a 35 kg weight loss. Endoscopy revealed giant gastric folds, numerous gastric polyps, and few inflammatory polyps in the duodenum and colon. Gastric biopsies showed foveolar hyperplasia and lamina propria oedema, initially suggesting Ménétrier's disease.
The patient deteriorated with severe protein-losing enteropathy, recurrent gastrointestinal bleeding requiring transfusions, and skin and nail abnormalities. Subtotal colectomy was performed for uncontrolled colonic bleeding, revealing hundreds of polyps.
Microscopically, the polyps resembled inflammatory juvenile-type polyps. The glands were hyperplastic, sometimes dilated and cystic,

overlying a prominent oedematous stroma with a dense inflammatory infiltrate of plasmocytes and eosinophils. The inter-polypoid mucosa exhibited glandular dilation and inflammation.
Conclusion: Diagnosing Cronkhite-Canada syndrome requires a multidisciplinary approach and cannot rely on biopsies alone, given the non-specific nature of the lesions. Clinical suspicion should be high when abnormal inter-polypoid mucosa is present, particularly in the colon. Ectodermal manifestations may have a delayed onset and should not be misattributed solely to malnutrition.

E-PS-06-094
Comprehensive evaluation of PD-L1, MMR and HER2 Status in gastroesophageal cancer biopsies: a 15-month consecutive cohort study
J.P. Maldonado[1], V. Almeida[1,2]
[1]ULS Coimbra, Pathology, Coimbra, Portugal, [2]Universidade de Coimbra, Faculdade de Medicina, Coimbra, Portugal

Background & Objectives: PD-L1 expression is a key biomarker in gastroesophageal cancers, guiding decisions around immunotherapy. This study aimed to evaluate the frequency of PD-L1 positivity in biopsy samples and investigate its association with mismatch repair (MMR) status, HER2 expression, and various clinicopathological features.
Methods: A retrospective analysis was conducted on 33 consecutive gastric and oesophageal biopsy specimens over a 15-month period. PD-L1 expression was assessed using the Combined Positive Score (CPS), with a CPS >1 considered positive. MMR status and HER2 expression were evaluated via immunohistochemistry. Associations were analysed using Fisher's exact test or chi-square test, and the PD-L1 positivity rate was compared with published data using a z-test for proportions.
Results: PD-L1 positivity (CPS >1) was observed in 48.5% of cases. Although not statistically significant, PD-L1 positivity was more frequent in dMMR cases (37.5% vs. 12.5% in MSS, $p = 0.217$), in patients over 70 years old ($p = 0.139$), and in HER2-positive tumours (18.8% vs. 12.5%, $p = 0.793$). No significant associations were found with sex, histological subtype, nodal status, or metastatic status. A statistically significant association was identified between MMR status and age ($p = 0.012$), with dMMR more common in older patients. A non-significant trend was also observed between HER2 expression and age ($p = 0.084$). Compared to the KEYNOTE-059 trial (PD-L1 positivity: 57.1%), the difference was not statistically significant ($p = 0.388$), indicating good concordance with published international data.
Conclusion: Nearly half of the gastroesophageal biopsy specimens demonstrated PD-L1 expression above the therapeutic threshold. While most associations were not statistically significant, trends suggested higher PD-L1 expression in dMMR cases and older patients. The significant association between MMR status and age, along with alignment with international studies, underscores the importance of PD-L1 testing in gastric and oesophageal cancer biopsies.

E-PS-06-095
Sevelamer-induced gastrointestinal injury: a hidden threat in chronic kidney disease patients
M. Mexia Leitão[1], M. Zbronska[1], S. Neves[1], X. Wen[1]
[1]Unidade Local de Saúde de Santo António (ULSSA), Pathology Department, Porto, Portugal

Background & Objectives: Sevelamer is a widely used phosphate binder in patients with chronic kidney disease (CKD), but it may be associated with gastrointestinal (GI) mucosal injury, often presenting as crystal deposition and ulceration. Diagnosing sevelamer-induced injury can be challenging due to similarities with other medication-induced injuries.
Methods: A 71-year-old male with chronic kidney disease (CKD) on long-term hemodialysis underwent a routine colonoscopy. Incidentally, a sessile polyp was detected in the distal rectum and removed for histopathological examination. Routine haematoxylin and eosin (H&E) staining, along with special stains, were performed to assess mucosal changes and characterize the crystal deposits.
Results: Histological analysis revealed ulceration and granulation tissue proliferation, accompanied by amorphous, basophilic crystal deposits with "fish scales" like stripes. The differential diagnosis included injuries associated with sevelamer, kayexalate, bile acid sequestrants, and iron supplementation. Special stains such as PAS diastase resistant (PAS-D), Ziel-Nissen, and Perl's were used to characterize the deposits, revealing PAS-D positivity. These histological findings were most consistent with sevelamer-associated mucosal injury. The diagnosis was further supported by the confirmation of the patient´s use of sevelamer for hyperphosphatemia management.
Conclusion: Sevelamer-induced GI injury should be considered in CKD patients who present with gastrointestinal symptoms. In this case, the findings were incidental, but this is not always the case, as sevelamer-associated lesions can include ulceration, erosions, inflammation (such as colitis, gastritis, and duodenitis), and in more severe cases, intestinal necrosis. Recognizing the characteristic histopathological features is essential for accurate diagnosis, preventing unnecessary interventions, and ensuring appropriate treatment. Importantly, sevelamer crystal deposition can extend throughout the entire gastrointestinal tract, highlighting the need for increased clinical and histopathological awareness to prevent misdiagnosis and optimize patient care.

E-PS-06-096
Resection margins in colorectal cancer carry clinical significance with regard to disease
D. Sakiz[1], Y. Akbal[1], A. Sürek[2], T. Dönmez[2]
[1]TC Saglik Bilimleri University Dr. Sadi Konuk Training and Research Hospital, Pathology, Istanbul, Turkey, [2]TC Saglik Bilimleri University Dr. Sadi Konuk Training and Research Hospital, General Surgery, Istanbul, Turkey

Background & Objectives: Resection margins in colorectal cancer carry clinical significance with regard to disease recurrence risk and selection for multimodal adjuvant therapy. Specimen shrinkage during tissue fixation and its retractile properties is well known. However, few studies support this for colorectal specimen. However, the effects of shrinkage have not traditionally been taken into account when analysing tumour-free margins. In this study, the evaluation of the amount of shrinkage in excised colorectal cancer specimens and determination of the relation between surgical margins and tumour diameters were aimed.
Methods: In this prospective study, 35 colorectal cancer specimens were measured in the fresh state and subsequently after 24 hours of formalin fixation for total specimen length, tumour size, proximal and distal resection margin for colorectal cancer. Additional information such as age, gender, stage of the disease, type of surgery, and type and grade of tumour were recorded.
Tumour specimens were measured immediate post-resection and at 15 minutes and 24 hours after formalin fixation. Tumour was measured in two dimensions and proximal and distal margins was measured.
Results: Eleven of the patients are women. 24 were male. Their ages ranged between 42 and 80 years. After formalin fixation, we found 23.5% reduction in proximal surgical margins, 29.5% reduction in distal surgical margins and 17% reduction in tumour size. In 14 cases, there was no change in tumour size before and after fixation. No variation in shrinkage was noted owing to patient or tumour related factors.
Conclusion: Considerable shrinkage of tumour-free surgical margins of colorectal cancer specimen was noted after formalin fixation, whilst the tumour itself does not shrink substantially. It demonstrates that

shrinkage from formalin fixation should be a consideration in decision making where the magnitude of tumour-free margins is small. This inference can have implications on the postoperative management plan.

E-PS-06-097

Prevalence and distribution of KRAS, NRAS and BRAF mutations in metastatic colorectal cancer: a single-centre study

A. Dahmane[1], N. Abdessayed[1], S. Frini[1], Z. Nfikha[1], S. Yacoub[1], M. Mokni[1]
[1]Farhat Hached University Hospital, Pathology, Sousse, Tunisia

Background & Objectives: KRAS, NRAS, and BRAF are well-established biomarkers for metastatic colorectal cancer (mCRC). Various techniques are used to identify mutations in these oncogenes. This study aims to analyse the mutational profile of a cohort of mCRC patients over a one-year period at a single centre.
Methods: The oncogenes KRAS, NRAS, and BRAF were investigated in 255 mCRC patients. Molecular testing was performed using the Idylla automated system (Biocartis) with the KRAS and NRAS-BRAF cartridges (IVD).
Results: Among the 255 metastatic CRC patients (107 female, 148 male; median age: 58 years, range: 20–84), 127 (49.8%) samples were biopsy specimens, and 128 (50.2%) were surgical specimens, with an average tumour cell percentage of 46%. The Idylla system provided results in an average time of 5.2 days. KRAS mutations were identified in 127 patients (50%), NRAS mutations in 6 patients (2.3%), and BRAF mutations in 11 patients (4.3%). The distribution of KRAS mutations was as follows: codon 12 (74.0%), codon 13 (14.2%), codon 61 (6.3%), codon 146 (4.7%), and codon 59 (0.8%). NRAS mutations were distributed as follows : codon 12 (33.3%), codon 61 (50.0%), and codon 146 (16.7%).
Patients with mutations had a mean age of 57 years (range: 27–84). Mutations were more frequent in men (53.5%) than in women (46.5%), but this difference was not statistically significant ($p \geq 0.05$).
Conclusion: Our results highlight the high prevalence of KRAS mutations in mCRC patients, consistent with findings in the literature.

E-PS-06-098

Crawling to a diagnosis: a case of gastric adenocarcinoma

M. de Uribe Viloria[1], E.P. Sánchez-López[2], S. Quinones[2], E. Palacios[3], L. G-Pastrián[3]
[1]Clínico de Valladolid University Hospital, Pathology, Valladolid, Spain, [2]La Paz University Hospital, Pathology, Madrid, Spain, [3]Fundación Jiménez Díaz University Hospital, Pathology, Madrid, Spain

Background & Objectives: We present the case of a 34-year-old woman with a recent history of nonsteroidal anti-inflammatory drug (NSAID) use, who presented to the emergency department with melena and asthenia.
Methods: The patient's clinical history was thoroughly reviewed, encompassing personal and familial background, gastroendoscopic examinations, and anatomopathological findings.
Results: An urgent gastroscopy was performed, which revealed a 6 mm bleeding ulcer on the posterior aspect of the lower gastric body. The ulcer was treated endoscopically and proton pump inhibitors (PPIs) were prescribed. A follow-up gastroscopy performed several weeks later to re-evaluate the ulcer revealed progressive healing without any signs of bleeding, and biopsies were obtained. Microscopy showed very focal, irregularly anastomosed glands and isolated cells with PAS-positive eosinophilic cytoplasm, embedded in an inflammatory stroma. CKAE1/AE3 immunohistochemistry yielded inconclusive results, whereas CDX2 staining was positive. These findings were highly suggestive of malignancy, but were insufficient for a definitive diagnosis, so new biopsies were recommended. Subsequent gastroscopy identified two benign looking 2-3 mm raised mucosal areas. Histological analysis confirmed a diagnosis of diffuse/poorly cohesive adenocarcinoma with a crawling-type pattern.
Conclusion: Crawling-type gastric adenocarcinoma is characterized by irregularly fused glands that recreate the shapes of the letters W, H, Y and X, often with a poorly cohesive component that leads to more aggressive behaviour. It commonly occurs in the middle third of the stomach and typically presents as a superficial depressed or flat type lesion on endoscopy. Some studies suggest it is a distinct adenocarcinoma subtype characterized by RHOA mutations and CLDN18-ARHGAP fusions, which may underlie its unique morphology and frequent progression to poorly differentiated adenocarcinoma. However, it remains unrecognized in the WHO classification. Identifying this pattern in small biopsies is crucial to avoid misdiagnosis with a benign lesion such as intestinal metaplasia. In cases of doubt, repeat biopsy is recommended to confirm or exclude adenocarcinoma infiltration.

E-PS-06-099

Inflammatory fibroid polyp: a series of 99 cases and a systematic review of the literature

I. Guvendir Bakkaloglu[1], S. Sengiz Erhan[1], D. Dogan[1], S. Hallac Keser[1], S. Sensu[2], A. Ege Gul[1], N. Ozdemir Barisik[1]
[1]Kartal Dr. Lutfi Kirdar City Hospital, Pathology, Istanbul, Turkey, [2]Istinye University, Medical Faculty, Pathology, Istanbul, Turkey

Background & Objectives: Inflammatory fibroid polyp is a rare benign mesenchymal lesion of the gastrointestinal tract, primarily located in the stomach, and originates from the submucosa. The onion-skin-shaped arrangement of spindle-shaped cells around the vessels and inflammatory infiltrate dominated by eosinophil leukocytes is typical. In this study, the clinicopathologic features of the inflammatory fibroid polyps are evaluated in light of the literature.
Methods: The patients with inflammatory fibroid polyps included in the study were examined in addition to age, gender, and location, histopathologically, for growth pattern, fascicular and onion-skin pattern, cellularity, collagenization, eosinophil leukocyte infiltration, lymphoid aggregates, and giant cells.
Results: Of the 99 patients included in the study, 40 were male and 59 were female. The mean age was 58.2 years (28-84 years). Eghty-three of the cases were located in the stomach, 8 in the small intestine, 7 in the colon, and 1 in the gallbladder. Sixty-five of the cases were below 1 cm (0.1-5.5 cm). Most cases were of submucosal origin, and 65 showed infiltrative growth. Fascicular pattern was observed in 65 and onion-skin pattern in 60 cases. Collagenization was observed in 75, and lymphoid aggregates in 61 cases. Eosinophil leukocytes were ≥30 in one high-power field in 70 cases. Floret-like giant cells were detected in 15 cases, mostly with gastric localization.
Conclusion: Infiltrative growth pattern, fascicular pattern, collagenization, and lymphoid aggregates were among the common findings, in addition to onion-skin appearance and eosinophil leukocyte infiltration. Floret-like giant cells were especially remarkable in cases with the onion-skin pattern. One of the cases was detected in the gallbladder, a rather rare location. As a conclusion, besides immunohistochemical studies, infiltrative growth pattern, fascicular pattern, collagenization, and presence of lymphoid aggregates can be used as supportive findings in the differential diagnosis of inflammatory fibroid polyp.

E-PS-06-101

Clinicopathological features of Russell Body-associated gastrointestinal lesions

A. Erbağci[1], A.N. Toksöz Yildirim[2], H. Karatay[3], B.E. Yildiz[4], G. Ayranci[5], T. Söylemez Akkurt[2]
[1]GOZTEPE PROF.DR. SULEYMAN YALCIN CITY HOSPITAL, Istanbul Medeniyet University, Pathology, Istanbul, Turkey, [2]Istanbul Medeniyet University, Pathology, Istanbul, Turkey, [3]Başakşehir Çam and Sakura City Hospital, Pathology, Istanbul, Turkey, [4]Haydarpasa

Numune Training and Research Hospital, Pathology, Istanbul, Turkey, [5]Umraniye Training and Research Hospital, Pathology, Istanbul, Turkey

Background & Objectives: Russell body (RB)-associated gastrointestinal lesions are rare plasma cell-rich inflammatory conditions characterized by the accumulation of eosinophilic immunoglobulin inclusions within Mott cells. While often associated with *Helicobacter pylori* (HP) infection, their biological behaviour and potential association with neoplastic processes remain poorly understood. This study aims to describe the clinicopathological features of ten RB-containing lesions and to compare findings with existing literature.
Methods: We retrospectively analysed ten patients with histologically confirmed RB-associated lesions in the gastrointestinal tract. Clinical parameters, localization, immune status, HP presence, clonality status, and accompanying neoplasms were recorded. Follow-up endoscopic and histological evaluations following HP eradication were documented when available. Observations were interpreted in light of current literature.
Results: The patients (mean age: 55.4 years) presented with lesions predominantly located in the stomach (n=9) and rectum (n=1). All patients were initially HP-positive. Immunohistochemistry revealed polyclonal light chain expression in nine cases and monoclonal kappa restriction in one. Three patients had synchronous adenocarcinoma (two gastric, one rectal). In six patients who underwent post-treatment endoscopy, complete histological resolution of RBs was observed following HP eradication. No hematologic malignancy developed during follow-up, including the monoclonal case.
Conclusion: RB-associated gastrointestinal lesions are typically benign and strongly linked to HP infection, with significant regression following eradication therapy. However, their potential coexistence with malignancies and occasional monoclonal light chain expression necessitate careful histopathological assessment. Awareness of this entity is crucial to avoid misdiagnosis, particularly in cases mimicking signet ring carcinoma or plasma cell neoplasia.

E-PS-06-102
The prognostic role of systemic inflammatory markers in gastric cancer
S. Gurzu[1]
[1]George Emil Palade University of Medicine, Pharmacy, Science and Technology, Targu-Mures, Romania

Background & Objectives: Despite the new therapeutic approaches, gastric cancer (GC) remains in the first places of cancer-related deaths. In a large cohort a patients, the inflammatory markers were tested, to check if their supposed prognostic value is indeed valuable.
Methods: In 197 consecutive cases of patients with GC, without prior chemotehrapy, the neutrophil to lymphocyte ratio (NLR), platelet to lymphocyte (PLR) ratio, neutrophil to monocyte (NMR) and lymphocyte to monocyte ratio (LMR) were checked and correlated with the classic clinic-pathological parameters. In all patients the above-mentioned markers were checked one day before surgery. In all the cases emergency surgery was done for hematemesis or occlusion.
Results: The cutoff values for NLR, PLR, LMR, and NMR were 3.95,136.98, 1.33, and 6.2, respectively. The tumour stage was associated with the NLR value (p=0.01); a higher ratio was seen in patients diagnosed in T3/4 stage. PLR was correlated with the depth of tumour infiltration (n=0.04). All of the examined markers proved to have independent prognsotic value. A shorter survival rate was proved for patients with high NLR ($p = 0.002$), PLR ($p = 0.014$), and NMR ($p = 0.009$), respectively low LMR ($p = 0.001$).
Conclusion: In clinical practice, the inflammatory profile of the patient might be checked and be therapeutically modulated, for prognostic purposes. As the geographic-related differences might be seen, an internal validation of the cut-off values is necessary.

E-PS-06-103
Prognostic significance of tumour budding Bd0 category in pT1 colorectal carcinoma with immunohistochemistry confirmation
K. Saez de Gordoa[1,2], E. Musulen[3,4], M. Rodrigo[1,2], I. Archilla[1,2], S. Lopez-Prades[1,2], M. Ramonda[1], M. Daca-Alvarez[5], I. Jurado[6], C. Martínez-Ciarpaglini[7,8,9], Ò. Rosiñol[10], J.J. [1]Hospital Clínic, Pathology Department, Barcelona, Spain, [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, [3]Hospital Universitari General de Catalunya-Grupo QuirónSalud, Pathology Department, Sant Cugat del Vallès, Spain, [4]Josep Carreras Leukaemia Research Institute (IJC), Cancer Epigenetics Group, Badalona, Spain, [5]Hospital Clínic, Gastroenterology Department, Barcelona, Spain, [6]Hospital Universitari Consorsi Sanitari de Terrassa, Pathology Department, Terrassa, Spain, [7]Hospital Clínico Universitario of Valencia, Pathology Department, Valencia, Spain, [8]Biomedical Research Institute INCLIVA, Valencia, Spain, [9]University of Valencia, Valencia, Spain, [10]Althaia Xarxa Assistencial Universitària, Pathology Department, Manresa, Spain, [11]Hospital Universitario Araba, Pathology Department, Vitoria-Gasteiz, Spain, [12]Bioaraba HRI, Vitoria-Gasteiz, Spain, [13]Corporació Sanitària Parc Taulí, Pathology Department, Sabadell, Spain, [14]Hospital Universitario Puerta de Hierro, Pathology Department, Majadahonda, Spain, [15]Hospital Universitario Vall d'Hebron, Pathology Department, Barcelona, Spain, [16]Hospital Universitario Virgen del Rocío, Pathology Department, Sevilla, Spain, [17]Hospital Universitario 12 de Octubre, Pathology Department, Madrid, Spain, [18]Instituto Valenciano de Oncologia, Pathology Department, Valencia, Spain, [19]Hospital QuirónSalud, Pathology Laboratory, Valencia, Spain, [20]Universitat de Barcelona, Barcelona, Spain

Background & Objectives: pT1 colorectal carcinoma (CRC) can be treated locally by endoscopy. The decision on additional surgery is based on the presence of histological features that confer risk of lymph node metastasis (LNM), including tumour budding (TB). A new scoring category with zero buds, namely Bd0, has recently been described, in which immunohistochemistry (IHC) may be a useful tool to determine the absence of TB. The aim of this study is to identify Bd0 pT1 CRC, explore the need of IHC and evaluate its implication in patient prognosis.
Methods: A retrospective multicentre study was designed including 1,543 endoscopically treated pT1 CRCs, of which 714 underwent subsequent surgery. Haematoxylin-eosin (H&E) slides were scanned and twenty gastrointestinal pathologists assessed TB on H&E. Additionally, cytokeratin IHC was performed on Bd0 cases.
Results: On H&E, 60.3% (931 cases) had zero buds (Bd0); 28.5% (440 cases) had 1-4 buds (Bd1); 7.3% (112 cases) had 5-9 buds (Bd2); and 3.9% (60 cases) had ≥10 buds (Bd3). Cases classified as Bd0 using H&E were significantly associated to a lower risk of LNM ($p = 0.001$), while no association was found with the risk of recurrence ($p = 0.549$). IHC was performed on 800 Bd0 cases (86%), of which, 50.25% (402 cases) were confirmed Bd0 by IHC, and 398 tumours (49.75%) had any grade of TB. Only 5 Bd0 cases by IHC had LNM (3%), while 8.2% of Bd0 on H&E but presence of TB on IHC had LNM, although the difference was not significant ($p = 0.097$). IHC analysis was neither associated with the risk of recurrence ($p = 0.641$).
Conclusion: The presence of any grade of TB is associated with an increased risk of LNM in pT1 stage CRC. The addition of IHC to confirm Bd0 grading enables to identify patients with better outcomes.

E-PS-06-105
A retrospective analysis of gastrointestinal malignant melanoma, with special emphasis on anorectal malignant melanoma

C.A. Gomez Gonzalez[1], B. Yaman[1], M. Sezak[1], T. Akalin[1], B. Karaca[2], C. Caliskan[3], I. Karaarslan[4], B. Doganavsargil Yakut[1]
[1]Ege University Faculty of Medicine, Department of Pathology, Izmir, Turkey, [2]Ege University Faculty of Medicine, Department of Medical Oncology, Izmir, Turkey, [3]Ege University Faculty of Medicine, Department of General Surgery, Izmir, Turkey, [4]Ege University Faculty of Medicine, Department of Dermatology, Izmir, Turkey

Background & Objectives: Malignant melanoma (MM) of the gastrointestinal system (GIS) is divided into primary mucosal MM and metastatic MM, with or without a detectable primary tumour. Both forms are linked to high morbidity and substantial disease burden. This study focused on GIS MMs, placing particular emphasis on the molecular characteristics of the cases.
Methods: Sixty-three cases diagnosed between 2000 and 2024 at Ege University Pathology Department were analysed, comprising 81 biopsies and resection specimens. Histopathological evaluation included tumour localization, size, pTNM staging, immunohistochemical profiles, molecular studies, presence of primary or metastatic disease, and patient survival. Statistical analyses were conducted using SPSS 20.0, with variables summarized by mean and median values. Associations and age correlations were examined using Chi-square and ANOVA analyses.
Results: Among the 63 cases, 35 were male (55.6%) and 28 female (44.4%), with a median age of 62 years (range: 26–89 years). Tumours were localized to anorectal (AMM) (n=26), colon (n=10), small intestine (n=12), stomach (n=11), and multiple GIS sites (n=4). Mucosal involvement was significantly more common in anorectal and colon tumours compared to stomach and small intestine tumours (21 versus 9 cases, p=0.020). The median age was higher in anorectal MM cases compared to other sites (65 versus 58 years, p=0.031). Known primary MM was frequently observed in cases involving the small intestine (41.7%), stomach (36.4%), and colon (20%), but not in anorectal cases (p=0.007), indicating AMM as possible primary mucosal MM.
BRAF PCR assessment was performed in 29 cases, with no positive results among AMM cases (p=0.01). Eight of 15 tumours showed CD117 positivity, with C-KIT exon 11 mutation in two cases.
Conclusion: AMM's biology and behavioural patterns differ from non-AMM GIS MMs, and the genomic landscape of GIS MM might differ from cutaneous MM. Therefore, a comprehensive molecular assessment is recommended for these cases.

E-PS-06-107
Multiple gastrointestinal stromal tumours: a series of 27 patients
I. Amat Villegas[1], A. Panizo Santos[1], D. Guerrero Setas[1], L. Ruiz Estigarribia[1], V. Gimenez Abadia[1], A. Gonzalez Zuñiga[1], A. De Oliveira[1]
[1]Hospital Universitario de Navarra, Pathology, Pamplona, Spain

Background & Objectives: Multiple gastrointestinal stromal tumours (GIST) are rare. They can be sporadic or assocciated to neurofibromatosis. Most of gastrointestinal stromal tumours (GIST) arise in the gastrointestinal tract (GIT) mainly in the stomach and small intestine but ocasionally they are found outside the GIT, in the mesentery and omentun (extraGIST). Our objective is investigate the clinicopathologic features and prognosis of multiple GIST patients, taking into account their location.
Methods: Between 2000 and 2025, patients who underwent surgery for multiple GIST at Hospital Universitario de Navarra were selected for the study and their clinicopathological features were analysed. Molecular test to detect KIT/PDGFRA mutations were performed in some of them.
Results: A total of 27 patients with multiple GIST were enrolled, 16 males and 11 females. Patients age ranged from 24 to 78 years old. Twenty-six cases were sporadic and one patient was associated with neurofibromatosis type 1. Seventeen cases were synchronous tumours and 10 metachronous (the interval between the primary tumour and subsequent tumours ranged from 1 to 10 years). Sixteen patients have all the tumours within the gastrointestinal tract whereas 11 have at least one ExtraGIST. The follow-up period varied between 4 months and 20 years. Overall survival was worse in the ExtraGIST cases, were 61% expired due to disease whereas only 31% of GIST gastrointestinal tract associated expired. The follow-up period oscillated from 4 months to 20 years.
Conclusion: There is no criteria to differenciate primary versus metastatic cases in the setting of multiple synchronous or metachronic GIST. The prognosis of Extra-GIST patients is worse than gastrointestinal GIST.
Molecular analysis is recomended in multiple GIST to evaluate the presence and type of mutation and therefore the different sensitivity to imatinib

E-PS-06-108
The number of Langerhans cells is unchanged in untreated and treated eosinophilic oesophagitis
A. Sykaras[1], C. Kouvidou[2], I. Kalliakmanis[3], D. Efthymiou[2], A. Therapontos[2], C. Vourlakou[2]
[1]University College Dublin, Department of Pathology, Dublin, Ireland, [2]Evangelismos General Hospital, Department of Pathology, Athens, Greece, [3]IASO Hospital, Endoscopy Department, Athens, Greece

Background & Objectives: Eosinophilic oesophagitis (EoE) is a relatively rare, chronic, immune-mediated disease of the oesophagus characterised by eosinophil-dominant inflammation, morphological changes to the epithelium and oesophageal dysfunction. Langerhans cells are antigen-presenting cells (APCs) found in the oesophageal epithelium and may have a role in EoE pathogenesis by stimulating an antigen-driven T-cell mediated hypersensitivity reaction.
Methods: We performed immunohistochemistry using an antibody against the CD1a antigen, a specific marker for Langerhans cells, on formalin-fixed paraffin-embedded sections of oesophageal biopsies obtained from patients (n=11) diagnosed with EoE, based on clinical and histological criteria. For four of EoE patients, we compared CD1a staining in tissue sections obtained pre- and post-treatment. We used as normal controls tissue sections of patients (n=5) with suspected EoE that was not confirmed histologically. In each tissue section, we identified the five high power fields (HPF-objective x400) with the higher density of CD1a-positive cells, and we counted the average number of immunopositive cells per HPF. Statistical analysis was performed by GraphPad Prism 10, using unpaired and paired t-test.
Results: We observed CD1a-positive cells with the typical morphology of dendritic cells, mainly in the suprabasal area of the oesophageal epithelium. We found an increased number of CD1a-positive cells in EoE patients (11.56/HPF) compared to normal controls (10.2/HPF); however, this increase was not statistically significant. Similarly, we observed a non-significant increase of CD1a-positive cells in EoE patients pre-treatment (13.25/HPF) compared to post-treatment biopsies (10/HPF).
Conclusion: Our analysis suggests that the number of oesophageal APCs remains unchanged in normal controls and adults with EoE, treated or untreated. Our data agree with prior studies in adult patients that revealed a stable number of oesophageal Langerhans cells in health and disease and are in contrast with reports of an increased population of Langerhans cells, that decreased significantly after treatment, in children with EoE.

E-PS-06-109

Clinicopathological study of squamoid morules in colorectal neoplasms

A. Panizo[1], G. Aisa[1], M.C. Llanos[1], L.M. Ruiz-Estigarribia[1], A.S. De Oliveira Gomes[1], M. García-Martos[2]
[1]Hospital Universitario de Navarra, Pathology, Pamplona, Spain, [2]Hospital General Universitario Gregorio Marañon, Pathology, Madrid, Spain

Background & Objectives: Colorectal adenomas with squamoid morules (SM) are rare; however, colorectal adenocarcinomas are even rarer. The aim was to study the clinicopathological features and immunohistochemical analysis of SM in colorectal neoplasms.
Methods: This was a multicentre retrospective study. We identified 25 colorectal neoplasms with SM and collected clinicopathological data. For IHC, the expression of CDX2, p40, CK5/6, CK20, beta-catenin, LEF1, CD10, synaptophysin, chromogranin, and Ki-67 were examined.
Results: We identified 25 colorectal neoplasms with SM in twenty-three patients: eighteen males (72%) and seven females (28%) ranging from 35 to 88 years (average: 61,8 years). Fourteen neoplasms were found in the rectosigmoid, 3 in the descending, and 8 in the right colon. Fifteen tumours were removed by endoscopic, and ten by surgical resection. The type of colorectal tumours with SM were tubulovillous adenomas (n=17; six with adenocarcinoma), tubular adenoma (n=5), and intestinal adenocarcinoma (n=3). The average size of the adenomas was 3,7 cm (range: 0,8-10 cm). The number of SM in each tumour varied ranging from a few foci (52% cases) to extensive foci (48%). Three neoplasms showed foci of SM not only in adenoma but also in adenocarcinoma. All cases showed CDX2, CK5/6, beta-catenin (nuclear and cytoplasmic), LEF1 and CD10 positivity. SM were focally positive for p40 and synaptophysin in six cases respectively (24%), and in four cases (16%) CK20 was focally positive. SM from all 25 neoplasms were completely negative for Ki-67.
Conclusion: To our knowledge, our study reports the highest number of cases of colorectal neoplasia with SM. SM are a rare but problematic finding in colorectal tumours. SM are characterized by male predominance, large adenoma size, beta-catenin and CK5/6 positivity, and no Ki-67 expression. Pathologists should be aware of rare occurrence of SM in colorectal adenomas to prevent a misinterpretation as foci of invasive carcinoma.

E-PS-06-111

Study of the mutational profile of KRAS and BRAF status in non-metastatic versus metastatic colorectal adenocarcinomas

G. Sahraoui[1], M. Alaya[1], H. Douik[1], E. Khemir[1], H. Guizani[1], H. Mansour[2], R. Doghri[1], L. Charfi[1], K. Mrad[1]
[1]Salah Azaiez Institute, Pathology Department A, Tunis, Tunisia, [2]Salah Azaiez Institute, Medical Oncology Department, Tunis, Tunisia

Background & Objectives: Colorectal cancer ranks third in Tunisia in terms of cancer incidence and mortality, whose dominant histological subtype is adenocarcinoma (ADK). Its treatment has been recently revolutionized with the introduction of immunotherapy. It is therefore essential to study the mutational profile of the RAS and BRAF genes today to elucidate on one hand their interference with the response to immunotherapy and on the other hand their prognostic value, in particular the progression of the disease and the occurrence of distant metastases.
Methods: Our study was retrospective, about 496 cases of metastatic and non-metastatic colorectal adenocarcinomas collected at the Pathology Department A of the Salah Azaïez Institute between April 2021 and December 2022. The molecular study was performed using Biocartis' IdyllaTM.
Results: Our series included 299 men and 197 women with a gender ratio of 1.52. Patients presented with colonic tumours in 73.3% of cases and rectal tumours in 26.7% of cases. Histologically, 92.7% of tumours corresponded to common-shaped ADKs. The other subtypes noted were, in order of frequency, mucinous ADKs (5%), signet-ring ADKs (1.5%), scalloped ADKs (0.6%), and micropapillary ADKs (0.2%). ADKs were moderately differentiated in 45% of cases, well differentiated in 38.5% of cases, and poorly differentiated in 6.5% of cases.
Vascular emboli were found in 13.7% of cases. Perineural sheathing was observed in 10.3% of cases. Distant metastases were confirmed in 25,2 % of cases. A KRAS mutation was found in 48.8% and 49.4% of cases with and without metastases respectively (p=0.999). A BRAF mutation was found in 5.6% and 3.4% of cases with and without metastases respectively (p=0.360).
Conclusion: Our study did not demonstrate a significant association between KRAS BRAF status and the occurrence of distant metastasis. However, to highlight the prognostic value of KRAS and BRAF mutations, it would also be essential to elucidate their association with overall survival.

E-PS-06-112

Three-in-one: a curious case of intra-ampullary adenocarcinoma

J.N. Peixoto[1], M. Alzamora[1], A. Varelas[1], A.L. Cunha[1], L.P. Afonso[1]
[1]Portuguese Oncology Institute of Porto (IPO-Porto), Department of Pathology, Porto, Portugal

Background & Objectives: Ampullary adenocarcinomas constitute 6-9% of all periampullary malignancies, representing approximately 15% of pancreaticoduodenectomies. Likewise, adenomyomatous hyperplasia is a rare cause of biliary obstruction and common bile duct dilation, mimicking malignancy and posing a diagnostic challenge prior to surgical intervention. We present a curious synchronous intra-ampullary adenocarcinoma arising from intra-ampullary papillary-tubular neoplasm and adenomyomatous hyperplasia.
Methods: A 78-year-old male with a previous laparoscopic cholecystectomy presented with acute pancreatitis and associated acute cholangitis. Follow-up imaging studies and upper endoscopy showing an oedematous papilla raised a suspicion for ampullary carcinoma and consequent bile duct ectasia, and the patient underwent cephalic duodenopancreatectomy.
Results: Grossing revealed the main lesion to be a subepithelial nodular lesion with well-defined borders confined to the ampulla of Vater. Additionally, there was another subepithelial lesion which, when cut, did not appear to be related. Microscopically, the main lesion was consistent with intra-ampullary adenocarcinoma of pancreatic-biliary type, developed in an intra-ampullary papillary-tubular neoplasm with both low- and high-grade dysplasia. The additional lesion was histologically consistent with adenomyomatous hyperplasia.
Conclusion: Ampullary lesions can cause exuberant clinical manifestations whether of a benign or malignant nature and thus motivate surgical intervention. The synchronicity of entities in this case may have contributed to a more florid clinical presentation leading to an earlier diagnosis and management. This case also highlights the diagnostic difficulties associated with ampullary lesions which can be surpassed by a thorough gross examination.

E-PS-06-113

Mutational status of KRAS, NRAS and BRAF in metastatic colorectal cancer: correlation with metastatic sites

G. Sahraoui[1], I. Mallek[1], D. Hayet[1], E. Khemir[1], M. Bouhani[2], D. Ben Ghezala[1], L. Charfi[1], R. Doghri[1], K. Mrad[1]
[1]Salah Azaiez Institute, Pathology, Tunis, Tunisia, [2]Salah Azaiez Institute, Surgical Oncology, Tunis, Tunisia

Background & Objectives: Metastatic colorectal cancer (CRC) represents an advanced stage of the disease with a poor prognosis. KRAS, NRAS, and BRAF gene mutations are routinely analysed to

guide treatment decisions, but their association with distant metastases and metastatic sites remains unclear. This study aimed to evaluate the mutational profiles of these genes and analyse the distribution of metastatic sites in CRC patients with distant spread.
Methods: We conducted a monocentric, longitudinal, and retrospective study in the Department of Pathology and Cytology at the Salah Azaïez Institute in Tunis. It included colorectal adenocarcinomas referred for RAS (KRAS and NRAS) and BRAF mutation testing between April 1, 2023, and December 31, 2024. Only patients classified as M1 according to the TNM system were included in the analysis.
Results: Among 496 CRC cases, 125 (25.2%) had distant metastases. These included 89 M1a cases (71.2%), 25 M1c (20%), 9 M1x (7.2%), and 2 M1b (1.6%). The most frequent metastatic sites were the liver (49.6%), peritoneum (15.2%), and lungs (9.6%). Other sites included unspecified locations (8.8%), ovaries (5.6%), dual sites (5.6%), vagina (1.6%), and miscellaneous (4.0%). KRAS mutations were found in 48.8% of M1 patients, NRAS in 4.8%, and BRAF in 5.6%. Compared to non-metastatic patients, there was no statistically significant difference: KRAS (49.4%, p=0.999), NRAS (5.7%, p=0.800), and BRAF (3.4%, p=0.360).
Conclusion: Liver metastases were the most common, followed by peritoneal and pulmonary sites. Most patients were classified M1a, indicating single-organ involvement. The lack of significant association between RAS/BRAF mutations and the presence or location of metastases suggests these mutations may not predict metastatic spread. Further studies are needed to identify novel biomarkers involved in metastatic behaviour in CRC.

E-PS-06-114
On the issue of clinical and epidemiological features of oesophageal cancer in pre-pandemic conditions at the regional level
A. Filin[1], I. Sertakov[1], G. Grebenkov[1], E. Verbitskaya[1], E. Ulitina[1], A. Goryacheva[1]
[1]Voronezh State Medical University, Department of Pathological Anatomy, Voronezh, Russia

Background & Objectives: According to world statistics, oesophageal cancer (EC) is an aggressive tumour and ranks 8th in the structure of tumour diseases in the world. The aim of the study was to study the dynamic changes in some indicators of the incidence of EC in the Voronezh region of Russia.
Methods: Cases of histologically verified diagnosis of EC from 2008 to 2018 were selected. The annual rates of EC verification, age of patients, gender, stage of the disease, number of deaths from this disease (including under 1 year), as well as the division into urban and rural populations were taken into account.
Results: 827 cases of histologically verified EC were registered. The highest incidence rates were observed in the age group of 40-50 years. Over the years, EC has been diagnosed in 735 men (88.8%), and 92 women (11.2%). The share of the urban population was 39.9%, while the share of the rural population was 60.1%. The most common stage of the disease is stage II, which is 657 people (79.4%). The total death rate from EC 589 people (71.2%), while 121 people died within a year of diagnosis (20.5%), which is lower than the national annual mortality rate. There has been a decrease in mortality from EC from 85 people in 2008 to 53 people in 2018.
Conclusion: There is a decrease in mortality from EDC in the Voronezh region and the detection of the disease at an early stage, which reflects a policy aimed at preventive measures. At the same time, more than half of the patients died from the EC, a quarter of whom died within the first year after diagnosis. Obviously, further development of new morphological criteria for predicting the course of this disease is necessary, based not on the relationship between the stage of the disease and the clinical prognosis.

E-PS-06-115
Primary mucosal melanoma of the gastrointestinal tract: a rare case with multisite metastasis
B.N. Doğan[1], Ö. Atmiş[1], S. Yurtsever Inan[1], S. Ayhan[1], H.S. Mavili[1], T. Coşkun[2], P. Temiz[1]
[1]Celal Bayar University, Pathology, Manisa, Turkey, [2]Celal Bayar University, General Surgery, Manisa, Turkey

Background & Objectives: Primary mucosal melanoma of the gastrointestinal (GI) tract is rare, constituting <1% of GI malignancies and 25-50% of melanomas in dark-skinned populations. Despite multimodal therapies, survival remains poor due to delayed diagnosis. This case highlights clinicopathological features to underscore diagnostic challenges and aggressive behaviour.
Methods: A 63-year-old male presented with abdominal pain. Imaging revealed a 6x6.5 cm contrast-enhancing ileal mass. Surgical resection (segmental small bowel resection, right hemicolectomy, cholecystectomy) was performed. Specimens underwent macroscopic evaluation, histopathological analysis including immunohistochemistry.
Results: Gross examination revealed an 8.6x6.2 cm polypoid tumour penetrating to serosa, multifocal brown lesions in the small intestine and distal colon. The gallbladder exhibited a 1.8 cm pigmented fundal lesion with adjacent 'cat's tongue' mucosal changes, while the cystic duct contained a 0.3 cm brown intraluminal lesion contiguous with a 1 cm serosal pigmented focus. Microscopy revealed pleomorphic epithelioid/spindle melanocytic cells with vesicular nuclei, prominent nucleoli, and heavy pigmentation. Immunohistochemistry confirmed melanocytic differentiation (MelanA+, S100+, HMB45+). Tumour foci involved mucosa, submucosa, and subserosa of the small intestine, colon, and gallbladder, with lymphovascular invasion and nodal metastasis. The largest lesion (8.6 cm polypoid mass) originated in the small intestine. Since no other primary focus was found in the patient's dermatological examination and whole body scan, the largest polypoid mass in the small intestine was accepted as the primary lesion.
Conclusion: This case exemplifies the aggressive nature of GI mucosal melanomas, often diagnosed at advanced stages due to nonspecific symptoms and occult anatomical sites. Histopathological and immunohistochemical confirmation is critical, as seen in this multifocal, metastatic presentation. Early detection remains challenging, contributing to poor prognosis. Increased clinical suspicion and recognition of morphological diversity, including pigmented lesions and spindle-cell morphology, may facilitate timely intervention. Further research into molecular drivers (e.g., NRAS mutations) and targeted therapies is essential to improve outcomes in this lethal malignancy.

E-PS-06-117
Crohn's disease-a mycobacterial infection
A. Tie[1], J. Aitken[2]
[1]Wellington School of Medicine, Pathology, Wellington, New Zealand, [2]Awanui Laboratories, Microbiology, Christchurch, New Zealand

Background & Objectives: Demonstration of cell wall deficient mycobacteria (CWDM) in resected tissue from patients with Crohn's disease.
Methods: Wellington Hospital archives (2015-2019) were searched for resections for Crohn's disease (18 cases).
Tissue blocks were stained with the standard Ziehl-Neelsen stain (optimised for Mycobacterium tuberculosis) but with a change in the decolourising step, substituting 30% HCl in isopropyl alcohol for 3% HCl in 97% ethanol.
15 controls (noninflammatory colon) were similarly analysed.
Results: All 18 Crohn's cases contained spherical brightly staining red structures 6-10 microns in diameter, located deep in the intestine wall, in areas of chronic inflammation and fibrosis, not consistently

related to granulomata, some associated with macrophages. Multiple or loosely grouped forms were present. A thin blue halo, possibly biofilm, surrounded some.
We believe these to be CWDM, in particular Mycobacterium avium paratuberculosis (MAP). Loss of the outer membrane/cell wall permits osmotic swelling of the normally bacillary organism, and reduces its antigenicity. The bacillary form of MAP is readily seen with conventional stains in ruminants with Johne's disease, which has otherwise similar clinical and pathological features to Crohn's disease (wasting enteritis, lymphadenopathy, granulomatous tissue reactions).
None of 15 control cases contained the organisms.
Conclusion: Our findings require independent confirmation. The study fulfils Koch's first postulate for causation. In one unrelated case we were able to cultivate CWDM from ileocaecal tissue of a Crohn's patient, but were unable to maintain growth. One author (JA) has regularly cultured CWDM from blood of Crohn's disease patients.
Mycobacteria are difficult to eradicate. The effects of absence of the cell wall are poorly understood. Novel theories of pathogenesis arise, such as direct chemical toxicity (mycolic acid), rather than antigenically driven.
These organisms may cause other systemic disorders, particularly sarcoidosis. The author (AT) has seen them in tissue biopsies from such patients.

E-PS-06-118
Small bowel, small bacilli, big stenosis – *Mycobacterium genavense* in the origin of jejunal stenosis
A. Santos[1], R. Sampaio[1], R. Mendes[2]
[1]ULS Lisboa Ocidental, Serviço de Anatomia Patológica, Lisboa, Portugal, [2]ULS Lisboa Ocidental, Serviço de Gastroenterologia, Lisboa, Portugal

Background & Objectives: Small bowel obstruction is a fairly common cause of ED admissions, especially due to adhesions (in patients with previous abdominal surgery or abdominal trauma), hernias and neoplasms. However, there are other aetiologies of stenosis and obstruction that should be kept in mind. In patients with immunosuppression infectious agents should always be remembered. In this case report we relate a clinical case with an unusual cause of jejunal obstruction.
Methods: We report a case of a 40 year old woman recipient of kidney transplantation 23 years prior, with four episodes of gastroenteritis with no causative agent identified in the previous 6 months, who was admitted to the emergency department with abdominal pain, fever, vomiting and weight loss. Laboratory results showed increased inflammatory parameters; cultures were negative. The CT scan revealed circumferential thickening of the jejunum in a length of 70mm, with mesenteric adenopathy and ascites. An enteroscopy was performed, permitting visualization of a jejunal stenosis, with small mucosal ulcers. Biopsies were obtained.
Results: The fragments obtained consisted of intestinal mucosa with multiple foamy histiocytes in the lamina propria. The Ziehl-Neelsen stain revealed multiple intracytoplasmic acid-fast bacilli within the histiocytes. No granulomas were observed. These findings were consistent with infection by nontuberculous mycobacteria. The patient started a multidrug regimen, with clinical improvement. Three months later the PCR assay done in the formalin-fixed, paraffin-embedded biopsy samples was positive for *Mycobacterium genavense.*
Conclusion: *M. genavense* a nontuberculous mycobacteria that in rare cases can infect immunocompromised patients, with poor prognosis. The treatment is similar to other nontuberculous mycobacteria, with a prolonged multidrug regimen and close monitoring. *M. genavense* is difficult to culture, and most cases require molecular assays for diagnosis. This case highlights the importance of surgical pathologists in the timely diagnosis and treatment of infectious diseases.

E-PS-06-119
Mucinous neoplasms of the vermiform appendix: a clinicopathological study of 95 cases
H. Maaroufi[1], R. Jouini[1], I. Helal[1], F. Khanchel[1], I. Ben Ismail[2], S. Rebii[2], N. Khedhiri[3], E. Ben Brahim[1], H. Zaafouri[3], A. Chadli[1]
[1]Habib Thameur Hospital, Department of Pathology, Tunis, Tunisia, [2]Ben Arous Trauma and Burn Centre, Department of Surgery, Ben Arous, Tunisia, [3]Habib Thameur Hospital, Department of Surgery, Tunis, Tunisia

Background & Objectives: Appendiceal mucinous neoplasms are rare lesions that range from low-grade neoplasms to invasive mucinous carcinoma. Even low-grade lesions can exhibit aggressive behaviour. The recent World Health Organization (WHO) classification has provided a consensus on the nomenclature, facilitating communication between pathologists and clinicians and improving patient care. This study aims to describe these lesions in a large sample and reclassify older cases according to the updated WHO classification.
Methods: Patient records from two tertiary care centres were reviewed for cases diagnosed with a mucinous appendiceal tumour over a 25-year period (2000–2024). Discordant cases were reclassified according to the latest WHO classification of tumours of the appendix.
Results: Ninety-five cases were identified. The mean age of the patients was 57 years [13-89], with a male-to-female ratio of 0.48. Upon gross examination, mucocele was identified in 51 cases (53.6%). Lesions were classified as low-grade appendiceal mucinous neoplasm (LAMN) in 83 cases (87.3%), high-grade appendiceal mucinous neoplasm (HAMN) in 2 cases (2.1%), and invasive mucinous adenocarcinoma in 10 cases (10.5%). Associated pseudomyxoma peritonei (PMP) was found in 5 cases (5.2%), of which 4 were low-grade and 1 was high-grade. Pseudomyxoma peritonei was associated with ruptured LAMN in 4 cases and mucinous adenocarcinoma in one case.
Conclusion: Mucinous neoplasms of the appendix are rare, and recognizing the histological patterns of these lesions is crucial for diagnosis and management. LAMNs have relatively bland histological features but can be associated with pseudomyxoma peritonei, which worsens prognosis. This series represents the largest Tunisian cohort of theses uncommon neoplasms.

E-PS-06-120
MMR deficiency in chronic gastritis as gastric cancer prediction marker
A. Krasnova[1], S. Mozgovoi[1], M. Parygina[1], V. Rubtsov[1], A. Shimanskaya[1], E. Pomorgailo[1], A. Kononov[1]
[1]Omsk State Medical University, Pathology, Omsk, Russia

Background & Objectives: The DNA mismatch repair (MMR) system deficiency causing microsatellite instability (MSI) is common in cancers including gastric adenocarcinoma. There is controversy about whether MSI occurs in established gastric tumours or precancerous lesions, particularly intestinal metaplasia.
Methods: The MMR status was assessed in gastric mucosa specimens with chronic gastritis (n=150) and mucosa specimens of stomachs resected for cancer (≥1 cm from a border of tumour growth, distant zone group, n=155) using immunohistochemical (IHC) staining with anti-MSH2, DBM15.82; anti-MSH6, 44; anti-MLH-1, G168-15; anti-PMS2, A16-4 (Diagnostic BioSystems, USA). Fisher's exact test was used for comparing groups, p<0,05 considered significant.
Results: All cases of the first group (gastric mucosa specimens with chronic gastritis) turned out to be MMR-proficient, regaining MLH1, MSH2, MSH6, PMS2 proteins IHC expression. In the distant zone specimens there were 8 MMR-deficient cases. In five of them loss in the MSH2/MSH6 pair was noted, one case each accounted for a loss in the MLH1/PMS2 pair, an isolated loss of MSH6 protein expression in a focus of intestinal metaplasia, and a combined loss of expression

in the MLH1/PMS2 pair and MSH6 protein. The presence of MMR deficiency cases in the distant zone group demonstrated statistically significant differences compared to the gastric mucosa specimens with chronic gastritis group, p=0.007).
Conclusion: The presence of MMR deficiency in the distant tumour growth zone associated with gastric cancer according to the field cancerization theory and its absence in morphologically similar gastric mucosa specimens with chronic gastritis may indicate that the MSI develops in the early stages of carcinogenesis. It indicates the potential use of the MMR status as a component of a decision support system for assessing the MSI-associated gastric cancer development risk.

E-PS-06-121
Concept of immunohistochemical markers panel in differential diagnostics of dysplasia and gastric cancer
A. Krasnova[1], V. Rubtsov[1], M. Parygina[1], S. Ivanova[1], E. Pomorgailo[1], A. Kononov[1], S. Mozgovoi[1], A. Shimanskaya[1]
[1]Omsk State Medical University, Pathology, Omsk, Russia

Background & Objectives: According to the GLOBOCAN data for 2022, gastric cancer (GC) is among the top ten leading causes of cancer morbidity and mortality, ranking seventh and sixth, respectively. There are inconsistent suggestions that marker panels can be useful tools for early/differential diagnostics at the stage of early, severe precancerous lesions.
Methods: Immunohistochemical staining using anti-Ki-67 (monoclonal antibody, clone SP6, Cell Marque, USA), anti-p53, (monoclonal antibody, clone DO7, Cell Marque, USA), anti-β-catenin, (monoclonal antibody, clone 14, Cell Marque, USA), were performed in gastric cancer specimens (n=150), gastric mucosa biopsy indefinite for dysplasia (n=75) and gastric mucosa biopsy with low/high grade dysplasia (n=75).
Results: Immunohistochemical verification of the proliferative compartment and generative zone orientation loss, vertical and horizontal gradient violation using Ki-67 indicate presence of low/high grade dysplasia and allow to exclude indefinite dysplasia. P53 protein expression exceeding first threshold level 30% indicated presence of low/high grade dysplasia, level <30% suggest reactive nature of the process and label case as indefinite for dysplasia. Exceeding the second threshold of 70%, or complete absence of P53 protein expression indicate gastric carcinoma. Disappearance of the membrane mark and aberrant nuclear expression of the β-catenin protein indicate gastric carcinoma with high specificity, which, despite low sensitivity, can be used in differential diagnosis with dysplasia.
Conclusion: The proposed concept of immunohistochemical markers panel, that include Ki-67, P53, β-catenin, potentially can be useful tool as a component of a decision support system by complement each other's capabilities in the differential diagnosis in cases of indefinite for dysplasia, low/high grade dysplasia and intramucosal gastric cancer.

E-PS-07 E-Posters Digestive Diseases Pathology (Liver/Pancreas)

E-PS-07-001
The expression spectrum of Claudins and Carbonic Anhydrase IX in neoplastic and pre-neoplastic lesions of the gallbladder: new diagnostic horizons
M. Carroli[1,2], J. Todorovic Barbuscia[3,2], L. Cardisciani[1,2], D. Anconelli[1], L. Saragoni[4,1], F. Vasuri[4,1]
[1]Santa Maria delle Croci Hospital, Pathology Unit, Ravenna, Italy, [2]School of Anatomic Pathology - University of Bologna, Department of Biomedical and Neuromotor Sciences, Bologna, Italy, [3]Infermi Hospital, Pathology Unit, Rimini, Italy, [4]Univeristy of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy

Background & Objectives: The use of immunohistochemical markers such as Claudin-4, Claudin-18.2, Carbonic Anhydrase IX (CA-IX), markers of intestinal, pancreatico-biliary and both, respectively, is gaining momentum in refining the diagnoses of pancreatico-biliary and gastro-enteric tract lesions; especially Claudin18.2 has major therapeutic implications. This study aims to understand how the change in differentiation of pre-neoplastic and neoplastic lesions also changes the immunohistochemical expression of Claudins and CA-IX.
Methods: Twenty-five gallbladder lesions from 12 resected patients (8 females, 4 males; mean age 73.25±7.3 years) were selected: 8 low-grade BilIN (LG-BilIN), 8 high-grade BilIN (HG-BilIN), 2 intestinal-type IPMN, and 7 infiltrative adenocarcinomas. Immunohistochemistry (IHC) for CA-IX (clone NCL-L), CLDN4 (clone 3E2C1) and CLDN18.2 (clone 43-14A) was automatically performed.
Results: CA-IX was positive in 20 (80.0%) lesions, 6 LG-BilIN, 7 HG-BilIN, 1 IPMN, and 6 adenocarcinomas. CLDN4 was positive in 22 (88.0%) lesions, 7 LG-BilIN, 7 HG-BilIN, 2 IPMN, and 6 adenocarcinomas. CLDN18.2 was performed in 15 cases so far, and it was positive in 8 (53.3%) lesions, 2/5 LG-BilIN, 3/5 HG-BilIN, 1 IPMN, and 2/4 adenocarcinomas.
Furthermore, the concomitant positivity of CA-IX and CLDN4 was the commonest, being observed in the 72.0% of all lesions. The concomitant expression of CA-IX and CLDN18.2 was observed in 40.0% of lesions. The expression of both CLDN4 and CLDN18.2 was observed in 60.0%.
Conclusion: In gallbladder pre-invasive and invasive neoplastic lesions, CLDN4 is the most positive marker, regardless the presence of intestinal differentiation, and often together with CA-IX positivity. CLDN18.2, as expected, seems to be more related to gastric differentiation. The expression of all examined markers is observed across all types of lesions, regardless the dysplasia grade.
It is appropriate, to confirm this study, to expand the number of cases and to perform multicentre studies, including mutational analyses to understand any biological changes in pre-neoplastic and neoplastic gallbladder lesions.

E-PS-07-002
Cancer's journey to the pancreas: a case series of metastatic disease
V. Rangacheva[1], R. Hristoskova[1], A. Fakirova[1], B. Ilcheva[1], S. Ivanova[1]
[1]Military Medical Academy, Department of General and Clinical Pathology, Sofia, Bulgaria

Background & Objectives: The pancreas is a rare target for metastatic lesions, accounting for approximately 2% of pancreatic malignancies, so therefore, whenever a formation in the pancreas is detected, usually a primary tumour is suspected. But we have encountered a series of secondary tumours to this location which remind us to think twice.
Methods: A case study is made in which 16 cases of pancreatic lesions with proven origin from other primaries are examined with regard to the diagnostic methods used, incidence of the different tumours of origin, synchronous or metachronous manifestation of the metastases, disease-free interval for the latter, as well as the pathological aspects of histology and much needed differential diagnosis with the help of immunohistochemistry.
Results: We present 16 cases: 1 is from a malignant melanoma, 1 from high grade ovarian carcinoma, 2 from colorectal carcinoma, 2 from invasive ductal breast carcinoma, 3 with lung origins and 7 from a renal cell carcinoma. 10 diagnosed on small biopsy specimens and 6 on surgical specimens.
Conclusion: In case of abnormal morphology of a primary pancreatic tumour, it is necessary to discuss the likelihood of metastatic disease and actively seek clinical information about a previous oncological

disease. Because as we have demonstrated there is a diversity of neoplastic malignancies which do show such prospects, some more than others.

E-PS-07-003

Radiofrequency ablation for inoperable cholangiocarcinoma: unraveling the CD4/CD8 ratio and its link to survival outcomes

C.-A. Sora[1], S.A. Zurac[1], A. Ariton[1], A. Zeca[1], L. Nichita[1], I. Tudor[1], M. Cioplea[1], C. Popp[1]
[1]Colentina University Clinical Hospital, Pathology, Bucharest, Romania

Background & Objectives: Cholangiocarcinoma is a rare and aggressive bile duct malignancy often advanced at diagnosis. In inoperable cases, palliative treatments like radiofrequency ablation (RFA) help control tumour growth and improve quality of life. Recent studies suggest that the CD4/CD8 T-cell ratio may influence cancer outcomes, but the effect of RFA on this ratio and its link to survival in cholangiocarcinoma is unclear. This study aims to explore how RFA impacts the CD4/CD8 ratio and its correlation with survival in these patients.
Methods: We retrospectively examined available data in 27 cases of cholangiocarcinoma diagnosed by endoscopic retrograde cholangiopancreatography (ERCP) followed by biopsy, in our department. All patients received palliative treatment through RFA. Biopsies were performed both before and after the RFA procedure, and the following elements were analysed: histopathological diagnosis, specimen volume, percentage of CD3 positive T cells, CD4+ T cell/HPF and CD8+ T-cell/HPF.
Results: The results showed a survival rate of 18.51%, with 10 cases of patients who survived for more than one year, of which only 5 cases of long-term survivors (LTS). The average duration of survival was 7 months. All LTS patients experienced a decrease in CD4/CD8 ratio after RFA and 55% of the analysed cases showed an increase in the percentage of CD3 positive T cells.
Conclusion: Even though it is a malignant pathology with a low survival rate, inoperable cholangiocarcinoma palliatively treated by RFA may show cases of LTS patients who have a decrease in the CD4/CD8 ratio at repeated pre- and post-procedural biopsies. Although the cohort studied was small, these findings could serve as a foundation for future research into immune responses and survival outcomes.

E-PS-07-004

Long survivors versus short survivors in inoperable cholangiocarcinoma – is there the key in the lymph cells?

A. Ariton[1], A. Zeca[1], C. Sora[1], S.A. Zurac[1], M. Cioplea[1], M. Birligea[1], T. Voiosu[1], C. Popp[1]
[1]Colentina University Hospital, Department of Pathology, Bucharest, Romania

Background & Objectives: Extrahepatic cholangiocarcinoma (eCCA) is an aggressive tumour, frequently diagnosed in advanced stages, that rarely beneficiates of proper biopsies. Multiple lines of chemotherapy and immunotherapy are studied in these patients with insufficient data about histologic parameters and their evolution under therapy. Radiofrequency ablation (RFA) is a palliative method of treatment that can induce changes in tumoral microenvironment, changes that are involved in modulating therapeutical response (especially at immunotherapy) and overall survival.
Methods: This study is part of o pilot prospective study including patients with inoperable eCCA that underwent a diagnosis biopsy followed by RFA and clinical surveillance with repeated biopsies at each stenting endoscopic intervention. We comparatively evaluated the proportion of T cells and their subtypes in tumoral microenvironment on pre-RFA and post-RFA biopsies.
Results: We included in this study 22 patients that had at least two biopsies (one at diagnosis, before RFA, and the second after approximately 6-8 weeks). Patients were separated in two sub-groups: long survivors (over one year from diagnosis, 10 patients, median survival minimum 21 months, since 5 patient are still alive) and short survivors (less than an year, 12 patients median survival 5 months).
While long survivors registered a significant decrease (two-tailed P=0.0388) in T cell ratio in intratumoral lymph cells (43 versus 54%), short survivors had an increase of the T cell ratio (63 versus 51%).
Conclusion: A strong T cell-based immune response after RFA seems to corelate with a poor survival. Although the study included a small number of cases, these data are important since there are very few studies including repeated biopsies in eCCA. Since conventional chemotherapy has limited results, there is an increased need for studies about the immune local response in CCA evolution.

E-PS-07-005

Intestinal Metaplasia of the gallbladder: when is additional sampling justified?

S.K. Dursun[1], S. Bagbudar[2], H. Karatay[1], N. Dursun[1]

[1]Basaksehir Cam ve Sakura City Hospital, Department of Pathology, Istanbul, Turkey, [2]Istanbul University, Istanbul Faculty of Medicine, Department of Pathology, Istanbul, Turkey

Background & Objectives: Intestinal metaplasia (IM) is a complication of chronic cholecystitis and thought to be a precursor of neoplasia. Since gallbladder neoplasias are often unrecognizable macroscopically, data on sampling gallbladders with IM is conflicting. In this study, we aimed to evaluate whether additional sampling is necessary in each IM case.
Methods: A total of 1,720 cholecystectomy cases were sampled by taking longitudinal full-thickness slices, including the fundus, corpus, neck, and cystic duct margin. IM was identified in 314 cases (18.3%). Cases with incidental invasive carcinoma, convincing/extensive high-grade dysplasia (HGD), or those in which the "roll method" could not be applied methodologically (e.g., thick gallbladder wall, acute cholecystitis) were excluded. The remaining 211 cases underwent total sampling (TS) using the "roll method."
Results: Cases with IM in the initial/standard sample (IS) were categorized as:
(i) no atypia (n=145),
(ii) reactive/regenerative atypia (RA) (n=22),
(iii) suspicious for dysplasia (n=14), and (iv) dysplasia (low-grade dysplasia (LGD) or focal HGD suspicion) (n=30).
After TS, the final diagnoses were: no atypia (n=125), RA (n=31), LGD (n=48), and HGD (n=7).
Among IM cases without atypia at IS, 86.2% (125/145) remained without atypia, 10.3% (15/145) had RA, 3.4% (5/145) had LGD, and none had HGD after TS.
IM cases with RA in IS showed 72.7% (16/22) RA and 27.3% (6/22) LGD after TS.
The final diagnosis of all IM cases suspected of dysplasia in IS was interpreted as LGD.
Among IM cases with dysplasia at IS, 76.7% (23/30) were diagnosed as LGD, while 23.3% (7/30) had HGD.
Conclusion: According to our results, if there was "no atypia" or "RA" with IM in the initial samples, the worst final diagnosis was LGD (7% of cases). Hence, our findings indicate that additional sampling should only be considered when dysplasia is suspected or confirmed in IS.

E-PS-07-006

CD4+ and CD8 + T cells in cholangiocarcinoma - radiofrequency ablation induced changes with prognosis significance

A. Zeca[1], A. Ariton[1], C.A. Sora[1], R. Ionescu[1], L. Sticlaru[1], O. Stefan[1], A. Cioroianu[1], C. Popp[1]
[1]Colentina University Hospital, Pathology, Bucharest, Romania

Background & Objectives: Radiofrequency ablation (RFA) has emerged as a minimally invasive treatment option for unresectable extrahepatic colangiocarcinoma (CCA). RFA also induces stromal and cellular changes with prognosis significance.
This study aims to evaluate the relationship between CD4+ and CD8+ T cells in biopsies from patients with cholangiocarcinoma before and after RFA.
Methods: This prospective cohort study enrolled 27 patients diagnosed with cholangiocarcinoma who underwent radiofrequency ablation (RFA) with a least one biopsy before RFA and another one after minimum 4 weeks from RFA. 21 cases had complete data to assess outcome following RFA treatment.
The presence and number of CD4+ and CD8+ T lymph cell were evaluated in tissue samples harvested before and after RFA (numbered on high power fiels in hot-spot).
Results: Post-RFA biopsies showed an increased medium number of CD4+ and CD8+ cells, comparing with their pre-RFA counterparts. Regardless of this trend, there are some cases with lower level of CD4+ cells and CD8+ cells on the biopsy performed after RFA (6 cases for each marker, 4 of them having concomitant decrease of both subtypes). The median survival was 7 months, with a significant higher survival in the subgroup that underwent decrease of CD4+ cells (19 vs 7.8 months, two-tailed P value 0,0079). Also, the number of CD4+ cells was significant lower on pre-RFA biopsies of long survivors.
Conclusion: RFA induces changes in the composition of inflammatory infiltrate, some of them influencing the outcome of patients with advanced cholangiocarcinoma. T helper lymph cells are especially correlated with survival.

E-PS-07-007
Retrospective analysis of frozen section and permanent diagnosis concordance in hepatobiliary system pathology: a single-centre experience
B.N. Simsek[1], S.K. Dursun[1], M.B. Yilmaz Özgüven[1], N. Dursun[1]
[1]Basaksehir Cam ve Sakura City Hospital, Department of Pathology, Istanbul, Turkey

Background & Objectives: Intraoperative consultations play an important role in hepato-pancreatobiliary surgeries and they are often difficult and challenging. Therefore evaluating the diagnostic accuracy of intraoperative frozen section analysis is essential.
Methods: A total of 200 frozen section samples from 166 patients were analysed, including 37 bile duct margins (BDM), 47 pancreatic neck/retroperitoneal margins (PRM), 21 liver parenchymal margins (LPM), and 95 cases with suspected malignancy. The concordance between intraoperative frozen section and permanent diagnoses was statistically analysed based on parameters such as localization (liver, pancreas, gallbladder), malignancy status, age, gender, and pathologist experience.
Results: The study cohort comprised 91 male and 75 female patients, with a median age of 50 years. The permanent diagnosis was concordant in 191 cases, while discrepancies were observed in 9 cases. In all but one of these discrepancies, the FS results were negative, but carcinoma was detected in the permanent sections. Among these, in two cases of PRM, no tumour was observed in FS slides, but malignancy was detected in deeper sections of the permanent samples. In one gallbladder case, a polyp within the debris was overlooked during macroscopic examination. The other cases with discrepancy were 1 BDM, 1 LPM, 1 PRM and 3 focal carcinoma focus which missed in FS. The only case with a false-positive FS result was due to misdiagnosis of reactive ductal structures in chronic pancreatitis.
When evaluated based on tissue type, the accuracy rates were 94.87% for liver specimens, 97.22% for gallbladder specimens, 94.64% for pancreas specimens, and 96.67% for ductal specimens, with an overall accuracy of 95.5%. Additionally, frozen sections evaluated by gastrointestinal pathologists had an accuracy rate of 96.03% (121/126), whereas those assessed by non-GI pathologists had an accuracy rate of 94.59% (70/74).
Conclusion: Frozen section permanent section incompatibility was mostly found as false negativity.

E-PS-07-008
Liver explants: histological experience in end stage liver disease
T.S. Driva[1], A. Pergaris[1], S. Kykalos[2], N. Machairas[2], G. Sotiropoulos[3], S. Sakellariou[1]
[1]General Hospital of Athens "Laiko", Medical School, National and Kapodistrian University of Athens, 1st Department of Pathology, Athens, Greece, [2]General Hospital of Athens "Laiko", Medical School, National and Kapodistrian University of Athens, 2nd Department of Propaedeutic Surgery, Athens, Greece, [3]General Hospital of Athens "Laiko", Medical School, National and Kapodistrian University of Athens, Department of Liver Transplantation and Hepatobiliary Surgery, Athens, Greece

Background & Objectives: Histology of liver explants is a field of Pathology which needs further enrichment with the experience from different geographical regions. The present study aims to explore common and distinct histological features in liver explants from the transplantation centre in "Laiko" Athens General Hospital. The investigation focuses on the modifications of primary liver diseases in late-stage cirrhosis.
Methods: Thirty-two explants received between 2022 and 2024 were re-evaluated histologically on histochemical stains H&E, Masson-trichrome, Gomori, Orcein Shikata and Perls and on K7 immunostain regarding Laennec stage, disease-related features (DRF), necroinflammatory activity, cholestasis, steatosis, siderosis, and vein thrombosis/obstruction (VTHR/OBSTR). Twenty-two patients were men and 10 women with a mean age 51.5 years (range 21 to 67 years). Histological and/or clinical diagnosis were steatohepatitis-related cirrhosis (SRC) (ALD, Metabolic Dysfunction or both) (11 cases), chronic hepatitis (CH) (5) [HBV (2), HBV/HDV (2), autoimmune (1)], primary sclerosing cholangitis (PSC) (10), primary biliary cholangitis (PBC) (3), cystic fibrosis (1), fibropolycystic (1) and Wolman disease (1). Hepatocellular carcinoma (HCC) was found in 3 cases and combined HCC-Cholangiocarcinoma in 1.
Results: VTHR/OBSTR was found in 16 and venous stasis in 16 cases. DRF loss was observed in 10 SRC and attenuation of necroinflammatory activity in 2 HBV, 1 HBV/HDV, 1 autoimmune hepatitis-related cirrhosis and in one PBC case. Fibrosis regression was encountered in 4 SRC cases. Moderate and severe siderosis was detected in 3 SRC cases and 1 PSC. Steatosis ranged between 0 and 10% in the examined explants. In all biliary cholestatic cases copper-binding protein was conspicuous and K7-expression extensive. In 3 PSC explants segmental cirrhosis was diagnosed.
Conclusion: Common findings, irrespective of aetiology, were vascular complications and absent or mild steatosis. Attenuation of inflammatory activity in CH-cirrhosis and loss of DRF in SRC may be ascribed to progressive exhaustion of the immune system, alcohol abstinence and malnutrition.

E-PS-07-009
High cellular prion protein expression in cholangiocarcinoma: a marker for early postoperative recurrence and unfavourable prognosis
C.K. Park[1], Y.A. Cho[2], D.W. Shin[3], S.-E. Kim[3]
[1]Seegene Medical Foundation, Seoul, Republic of Korea, [2]Samsung Medical Centre, Seoul, Republic of Korea, [3]Hallym University Sacred Heart Hospital, Anyang, Republic of Korea

Background & Objectives: The cellular prion protein (PrP^C), traditionally associated with neurodegenerative disorders, plays an

important role in cancer progression and metastasis by inhibiting apoptosis. To investigate the influence of PrP^C expression in cholangiocarcinoma (CCA) on patient outcomes following surgical resection.
Methods: Patients who underwent curative surgical resection for either intrahepatic or hilar CCA were enrolled in this retrospective study. Based on the immunohistochemical staining results of the surgical specimens, patients were categorized into two groups: The low PrP^C group (negative or 1+) and the high PrP^C group (2+ or 3+). Survival analyses, including overall survival and recurrence-free survival, were conducted using the Kaplan-Meier method and compared using the log-rank test.
Results: In total, seventy-six patients diagnosed with CCA (39 with intrahepatic and 37 with hilar CCA) underwent curative hepatectomy from January 2011 to November 2021. Among these patients, 38 (50%) demonstrated high PrP^C expression, whereas the remaining 38 (50%) showed low expression of PrP^C. During a median follow-up period of 31.2 months (range: 1 to 137 months), the high PrP^C group had a significantly shorter median overall survival than the low PrP^C group (40.4 months *vs* 137.9 months, respectively; $P = 0.041$). Moreover, the high PrP^C group had a significantly shorter median recurrence-free survival than the low PrP^C group (13.3 months *vs* 23.8 months, respectively; $P = 0.026$).
Conclusion: PrP^C expression is significantly associated with early recurrence and decreased survival period in CCA patients following surgical resection. Thus, PrP^C may be used as a prognostic factor in treatment planning.

E-PS-07-010

Immune-related pathologic response (irPR) features and immunotherapeutic response score (ITRS) predict survival following neoadjuvant combined immunotherapy in intrahepatic cholangiocarcinoma

R. Shi[1], Y. Sang[2], W.X.P. Loh[1], H. Xia[2], J. Zhou[3], K. Zhu[3]
[1]Kandang Kerbau Women's and Children's Hospital, Department of Pathology and Laboratory Medicine, Singapore, Singapore, [2]Zhongda Hospital, School of Medicine & Advanced Institute for Life and Health, Southeast University, Nanjing, China, [3]Liver Cancer Institute, Zhongshan Hospital, Fudan University, Department of Liver Surgery and Transplantation, Shanghai, China

Background & Objectives: Immune checkpoint inhibitor (ICI) based combined neoadjuvant therapy (NAT) is increasingly utilized in the management of initially unresectable intrahepatic cholangiocarcinoma (iCCA). However, immune-related pathologic response (irPR) features and immunotherapeutic response score (ITRS) remain poorly understood in iCCA.
Methods: This study enrolled 147 iCCA patients who received NAT. irPR features (tumour infiltrating lymphocyte, tertiary lymphoid structure, lymphoid aggregate, plasma cell infiltration, granuloma, neutrophil, foamy macrophage, cholesterol cleft, hemosiderin macrophage, giant cell, neovascularization and mature fibrosis) were accessed on routinely processed haematoxylin-eosin stained post-NAT surgical resection specimen tumour bed slides. Kaplan-Meier and Cox regression analyses were used to investigate irPR features and ITRS correlations with recurrence-free survival (RFS) and overall survival (OS).
Results: The irPR features were identified in the post-NAT surgical resection specimen of iCCA. Six selected irPR features (tumour infiltrating lymphocyte, lymphoid aggregate, cholesterol cleft, tertiary lymphoid structure and neutrophil) were included in ITRS. A binary ITRS scheme was developed, wherein patients classified as ITRS-low exhibited significantly better OS (hazard ratio [HR]:3.03; 95% confidence interval [CI]: 1.55-5.89, P<0.01) and RFS (HR:1.94; CI: 1.24-3.03, P=0.03) compared to those in the ITRS-high group, based on univariate analysis. In a multivariate analysis including lymphovascular invasion, perineural invasion and major pathologic response. ITRS scheme was also found to be an independent prognostic factor for OS (HR: 1.95; 95% CI: 1.02-4.27, P = 0.04).
Conclusion: This study proposed an irPR features-based ITRS scheme that significantly predicts OS and RFS in iCCA patients receiving ICI-based combined NAT. The ITRS is feasible for implementation in routine diagnostic pathology practice and offers novel insights into resistance mechanisms associated with immunotherapy. Further validation in future prospective multicentre clinical trials is warranted.

E-PS-07-011

The histopathological diagnosis of hepatic graft-versus-host disease: insights toward an improved diagnostic workup

A. Gambella[1], J. Ferro[2], S. Pistolesi[1], G. Ferrando[3], M. Faraci[3], M. Gambella[4,5], A.M. Raiola[5], F. Grillo[1,6]
[1]University of Genoa, Department of Surgical Sciences and Integrated Diagnostics, Genoa, Italy, [2]IRCCS Istituto Giannina Gaslini, Pathology Unit, Genoa, Italy, [3]IRCSS Istituto Giannina Gaslini, Hematopoietic Stem Cell Transplantation Unit, Genoa, Italy, [4]University of Genoa, Department of Experimental Medicine (DIMES), Genoa, Italy, [5]IRCCS Ospedale Policlinico San Martino, Unit of Haematology and Cellular Therapy, Genoa, Italy, [6]IRCCS Ospedale Policlinico San Martino, Pathology Unit, Genoa, Italy

Background & Objectives: The histopathological diagnosis of hepatic graft-versus-host disease (hGVHD) is challenging due to the broad differentials, subtle features, and significant implications on patient therapeutic management and clinical outcomes. A histopathological algorithm (HA) has been published to facilitate hGVHD diagnostic workup on liver biopsy (Stueck AE et al. Mod Pathol. 2018), but focused on differentiating hGVHD from hepatic disease of non-transplanted patients and has yet to be fully validated. In this study, we aimed to critically evaluate the diagnostic performance of the HA, as well as additional histopathological features, in a series of adult and paediatric patients with a clinical suspicion of hGVHD.
Methods: Thirty-four liver biopsies, performed for clinically suspected hGVHD in adult (n=24) and paediatric (n=10) patients who underwent hematopoietic stem cell transplant (January 2000 - January 2024), were retrieved together with corresponding clinical, therapeutic, and follow-up data. Three pathologists, blinded to clinical data and original diagnosis, independently assessed several histopathological features and applied the HA. Diagnostic performances and interobserver concordance rates of histopathological features and HA were then analysed and compared with post-biopsy clinico-therapeutic management.
Results: Clinico-serological data collection is ongoing, but preliminary findings from 26/34 cases – 21/26 with clinically confirmed hGVHD (cc-hGVHD) – align with the literature and were used for this preliminary study. HA-based diagnosis did not identify 8/14 and 2/7 of adult and paediatric cc-hGVHD, respectively. Implementing granular histopathological characterization – such as detailed portal tract distribution of bile duct injury – improved these metrics, reducing misdiagnosed adult (3/14) and paediatric (0/7) cc-hGVHD, and associated with a correct clinical diagnosis of adult hGVHD (p=0.020). Excellent agreement among pathologists (ICC, range: 0.79-1) was observed for all histopathological variables, including HA.
Conclusion: Our preliminary study revealed critical aspects of the HA and identified new features that may improve hGVHD histopathological diagnosis. We endeavor to validate our findings with complete data collection and multi-institutional cohorts.

E-PS-07-012

Coexisting hepatic actinomycosis and IgG4-related disease mimicry: a diagnostic challenge

R. Kazemimood[1], V. Chavez[1], A. Galvao Neto[1]
[1]University of Texas Health Science Centre at Houston, Pathology, Houston, USA

Background & Objectives: Hepatic actinomycosis is a rare condition usually secondary to abdominal or pelvic infections, while IgG4-related disease (IgG4-RD) of the liver is also uncommon. The overlap of these two conditions can complicate diagnosis, as IgG4-positive plasma cells may be a reactive response to infection rather than indicative of true IgG4-RD.
Methods: We present the case of a 71-year-old Hispanic male who was admitted multiple times over six months due to weight loss, nausea, and poor oral intake. His past medical history includes hypothyroidism, iron deficiency anaemia, and right hepatic vein thrombosis. Imaging consistently revealed multiple hepatic lesions, raising concerns of abscesses or malignancy.
Results: A liver biopsy revealed mixed inflammation, with a predominant presence of plasma cells, hepatic necrosis, extensive fibrosis, and sulfur granules. Microbial sequencing from the FFPE block confirmed the presence of *Actinomyces israelii* and *Fusobacterium nucleatum*. *A. israelii* is an anaerobic Gram-positive branching rod, while *F. nucleatum* is an anaerobic, Gram-negative bacillus that can both colonize various human environments. Prior published case reports indicate that coaggregation of bacterial species in the actinomycosis microenvironment conditions can facilitate anaerobic bacterial growth.
Additionally, immunohistochemistry showed an elevated number of IgG4-positive plasma cells (>50/HPF), suggesting the possibility of concomitant IgG4-RD. Despite elevated serum IgG4 and IgG, clinical and imaging findings did not align with typical IgG4-RD. A multidisciplinary team agreed to treat the patient with amoxicillin/clavulanate.
Conclusion: This unique case highlights the diagnostic complexity of hepatic lesions with IgG4 positivity in the context of infection and emphasizes the importance of differentiating between IgG4-RD and conditions that mimic it. Although persistent IgG4 elevation may be misleading, microbiological studies confirmed *Actinomyces* and *Fusobacterium* co-infection, allowing appropriate treatment without unnecessary intervention for IgG4-RD. At the most recent follow-up, there was a marked clinical improvement and a significant reduction in the size of the liver mass.

Morphometric analysis in metabolic dysfunction-associated steatotic liver disease: toward augmented biopsy in type 2 diabetes

O. Fourati[1], P. Manchon[2], P. Garteiser[3], L. Castera[4], M. Dioguardi Burgio[5], B. Van Beers[5], P. Bedossa[3], M. Albuquerque[1], T. Poynard[6], C. Laouenan[2], D. Valla[3], V. Paradis[1]
[1]Beaujon Hospital, Pathology, Clichy-la-Garenne, France, [2]Bichat Hospital, Department of Epidemiology, Biostatistics and Clinical Research (DEBRC), Paris, France, [3]Paris Cité University, Inflammation Research Centre, INSERM, U 1149, Paris, France, [4]Beaujon Hospital, Hepatology, Clichy-la-Garenne, France, [5]Beaujon Hospital, Radiology, Clichy-la-Garenne, France, [6]Sorbonne University, UMR 938 Institute of Cardiometabolism and Nutrition, INSERM, 14, Paris, France

Background & Objectives: Although liver biopsy remains the reference standard for the diagnosis of steato-hepatitis with metabolic dysfunction-associated steatotic liver disease (MASLD), its utility is challenged by limitations, particularly inter-observer variability. Morphometric analysis of biopsy and imaging techniques that provide continuous and objective assessment of steatosis and fibrosis, may overcome this limitation.
Methods: This study compared the performance of morphometric analysis of steatosis and fibrosis to non-invasive imaging in patients with type 2 diabetes mellitus (T2DM) enrolled in the QUID-NASH project. Among 223 T2DM patients with MASLD, steatosis was assessed by MRI–proton-density fat fraction (MRI-PDFF), for fibrosis, liver stiffness measurement (LSM) by magnetic resonance elastography (MRE) and vibration-controlled transient elastography (VCTE). Morphometric analysis examine steatosis and fibrosis in biopsy slides, assessing steatosis proportionate area (SPA) and collagen proportionate area (CPA), respectively. We assessed the relationship between semiquantitative histological grading and morphometry, as well as the correlation between quantitative morphometric data and non invasive techniques.
Results: Steatosis grade was related to SPA ($p<0.0001$), which was significantly correlated with %PDFF (rho: 0.88 [95% CI: 0.84 to 0.92],). Fibrosis stage was related to CPA and weakly correlated with LSM by MRE (rho: 0.26 [0.12 to 0.39]), and moderately with LSM by VCTE (rho: 0.52 [0.42 to 0.61]).
Conclusion: Our study demonstrates the relevance of quantitative morphometric assessment of steatosis and fibrosis in T2DM patients with MASLD. Such an easily applicable approach could be used in routine practice to better characterize two cardinal features of the disease and to improve monitoring.

E-PS-07-015

Clinicopathological and immunprofiles of three cases of SMARCA4-deficient tumour of different presentation

V. Elibol[1], P. Aşkin[1], M.S. Temizkan[1], S. Çetinkaya[1], D. Yavuzer[1]
[1]Sancaktepe Sehit Prof. Dr. Ilhan Varank Training and Research Hospital, Pathology, Istanbul, Turkey

Background & Objectives: SMARCA4-deficient tumours are aggressive malignancies characterized by inactivation of the SMARCA4 gene, leading to the loss of BRG1 protein expression. These tumours exhibit diverse morphologies and can present in various anatomical locations, often mimicking other malignancies. Due to their rarity and aggressive nature, accurate diagnosis is crucial for clinical management. This study presents three cases of SMARCA4-deficient tumours with distinct clinicopathological and immunohistochemical profiles, illustrating the heterogeneous nature of this entity.
Methods: Three patients diagnosed with SMARCA4-deficient tumours were analysed retrospectively. Clinical history, imaging findings, histopathology, and immunohistochemical markers were evaluated to establish a comprehensive clinicopathological correlation. SMARCA4 (BRG1) loss was confirmed in all cases by immunohistochemistry (IHC).The broad immunohistochemical panel used reveals similarities and differences.
Results: Case 1: 70-year-old man with Horner's Syndrome and lung mass, supraclavicular lymph node biopsy performed.
Case 2: 62-year-old man with lung parenchymal mass and inguinal lymph node metastasis, both biopsied.
Case 3: The most challenging clinical presentation with symptoms including cholecystitis and ascites. A 72-year-old woman with a mass in the liver and mesothelioma-like involvement of the peritoneal cavity was noted in imaging studies. Histopathologically, the first tumour, like the third one, exhibited plasmacytoid morphology consisting of loosely cohesive round cells with eccentric nuclei and abundant eosinophilic cytoplasm, latter showed a more myxoid stroma. CK, claudin 4, and EMA were focally expressed and both were CD138 positive. Case 2 showed spindle cell morphology arranged in fascicles resembling sarcomatoid carcinoma and unlike the others, claudin 4 was significantly positive
Conclusion: SMARCA4-deficient tumours can exhibit diverse morphologies and occur in multiple anatomical sites, making diagnosis challenging. These cases illustrate the varied histological appearances, from plasmacytoid to spindle cell and myxoid stroma with discohesive

cells. Immunohistochemical analysis, including SMARCA4 loss, is crucial for accurate diagnosis. The prognosis remains poor, highlighting the need for further research into potential targeted therapies.

E-PS-07-016

Prognostic impact of T cell markers, expression of immune checkpoint proteins and microsatellite instability in pancreatic ductal adenocarcinoma

N. Tezel[1], T. Unek[2], H. Ellidokuz[3], O. Sagol[1], Y. Baskin[3], A. Aysal Agalar[1], I.T. Unek[4], T. Egeli[2], I.K. Astarcioglu[2]
[1]Dokuz Eylul University, Pathology Depatment, Izmır, Turkey, [2]Dokuz Eylul University, General Surgery Department, Izmır, Turkey, [3]Dokuz Eylul University, Oncology Institute, Izmır, Turkey, [4]Dokuz Eylul University, Internal Medicine Department, Izmır, Turkey

Background & Objectives: Pancreatic ductal adenocarcinoma (PDAC) has low survival rate. The importance of immune checkpoint markers mediating immune tolerance,such as programmed cell death-1 (PD-1) and programmed cell death ligand-1 (PD-L1) is increasingly recognized in PDAC. Additionally,the investigation of microsatellite instability (MSI), which occurs at a low rate (1%) in PDAC,is necessary for the development of future treatments.
Methods: In this study, the association between the expression of following markers:PD-1, PD-L1, CTLA-4, CD3, CD4, MLH1, MSH6, MSH2 and PMS2,along with clinicopathologic characteristics such as age, gender, tumour grade, tumour T stage, tumour size, tumour N stage, number of metastatic lymph nodes, retroperitoneal surgical margin, pancreatic surgical margin, perineural and lymphovascular invasion and also their relation to overall and disease-free survival were examined in PDAC.
Results: The study included 98 patients who underwent proximal pancreaticoduodenectomy due to PDAC. 57% of the patients were male. The incidence of MMR defficiency was very low(1.02%), consistent with the literature. The estimated 1,3 and 5-year disease-free survival (DFS) was 47.6%,3.7% and 3.7% in the PD-1 negative/+ <1% positive group and 68.4%,34.0% and 22.7% in the positive group. In the analysis based on the cut-off value of 7.5 for the CPS of PD-L1,DFS was statistically significantly higher in patients with CPS>7.5 compared to patients with CPS≤7.5. Patients with both PD-1 and PD-L1 positivity had longer overall and disease-free survival. The Cox Regression Analysis showed that PD-1 positivity increased overall survival by 2.409 times while PD-1 positivity increased DFS by 2.88 times.
Conclusion: The positive impact of high PD-1 and PD-L1 levels on survival suggests that additional mechanisms affecting survival in PDAC,such as LAG-3,TIM-3 and TIGIT,require further investigation. This information may also contribute to explaining why immune checkpoint inhibitors are less effective in PDAC. In this context,developing combination strategies,inducing PD-1+ tumour-specific T cells could be a promising approach to enhancing antitumor responses.

E-PS-07-017

Clear views, intact tissue: a non-destructive nano-CT pipeline for liver histology

K. Skok[1,2], L. Činč Ćurić[2], J. Vajda[2], B. Vihar[2], K. Panzitt[1], S. Schauer[1], R. Stauber[3], M. Wagner[3], U. Maver[2], C. Lackner[1,4]
[1]Diagnostic and Research Institute of Pathology, Medical University of Graz, Graz, Austria, [2]Institute of Biomedical Sciences, Faculty of Medicine, University of Maribor, Maribor, Slovenia, [3]Division of Gastroenterology and Hepatology, Department of Internal Medicine, Graz, Austria, [4]ZLP - Zentrum für Leber- und Pankreaspathologie, ADK Diagnostics, Vienna, Austria

Background & Objectives: Nanotomography (nano-CT) is a type of non-destructive 3D x-ray microscopy that enables is a non-destructive imaging technique that enables high-resolution visualisation of tissue microarchitecture. Conventional contrast-enhancing stains used in radiology often compromise tissue integrity, limiting subsequent histological evaluation. Liver fibrosis, characterised by an intricate fibrous network, is particularly challenging to assess at the 3D cellular level. Current approaches are labour-intensive and require a complete assessment and sectioning of the whole tissue block.
Methods: We developed an optimised preparation workflow for high-resolution nano CT imaging using the Xradia Versa 620 (Zeiss, Germany), which achieves from micron to sub-micron resolution through geometric and optical magnification. Healthy and cirrhotic liver tissue samples (0.5 cm cubes) were fixed in formaldehyde/acetic acid, washed, stirred in water, stepwise ethanol-dehydrated, snap-frozen in liquid nitrogen, and freeze-dried. Nano-CT imaging was performed using 4x and 20x objectives. After nano-CT imaging, samples were rehydrated in formaldehyde, paraffin-embedded, and stained (H&E, Sirius Red, and Hepar immunohistochemistry) to evaluate antigenic and morphological integrity. qPCR was conducted to assess genetic stability, and morphological measurements were analysed using the 3D visualization and analysis software Dragonfly (Object Research Systems, Canada).
Results: The nano-CT protocol provided excellent structural contrast and allowed detailed volumetric measurements of liver fibrosis in 3D. Importantly, tissue integrity was preserved, enabling high-quality histological evaluation comparable to conventional methods even after rehydration. Furthermore, RNA levels and housekeeping gene expression were detected in all samples. The combined results reveal a novel approach to tissue reuse and visualization.
Conclusion: This non-destructive nano-CT workflow allows detailed 3D visualisation of liver microarchitecture, including fibrosis, while preserving tissue for downstream analysis on a morphological and molecular level. It offers a robust preclinical and translational research tool, facilitating integrated morphological and molecular assessment of liver disease.

E-PS-07-018

First case of primary pancreatic gastrointestinal stromal tumour in our Pathology Department: a rare diagnostic encounter

D.-G. Nicolcea[1], A. Dema[1,2], R. Cornea[1,2], S. Tăban[1,2]
[1]"Pius Brînzeu" County Clinical Emergency Hospital, Department of Pathology, Timișoara, Romania, [2]"Victor Babeș" University of Medicine and Pharmacy, Department of Microscopic Morphology – Anatomic Pathology, ANAPATMOL Research Centre, Timișoara, Romania

Background & Objectives: Gastrointestinal stromal tumours (GISTs) are the most common mesenchymal tumours of the gastrointestinal tract; however, primary GISTs arising outside the gastrointestinal system, such as in the pancreas, are extremely rare. We present the case of a 66-year-old Caucasian male diagnosed with a primary GIST of the pancreas, highlighting the rarity of this condition.
Methods: Initial examination of the patient revealed tenderness in the epigastric and left hypochondrial regions. Preoperative imaging identified a tumour located in the tail of the pancreas with no other visceral lesions. Therefore, a splenopancreatectomy was performed, and the resection specimen was sent to the Department of Pathology. Histological and immunohistochemical analyses were performed to characterize the tumour.
Results: Gross examination of the specimen revealed a 17×15×8 cm tumour in the tail of the pancreas with both cystic and solid components. Histologically, the tumour was a well-circumscribed, multinodular mesenchymal proliferation composed of predominantly spindle cells. The immunohistochemistry panel included S100, desmin, CD34 and CD117. There have been fewer than 70 cases reported in literature, therefore, a primary gastrointestinal stromal tumour of the pancreas was unlikely, and CD117 was performed for exclusion purposes only. The tumour cells were diffusely and intensely positive for CD117 and

CD34, negative for S100 and desmin, thus confirming the diagnosis of a gastrointestinal stromal tumour. The patient had no other tumours involving the gastrointestinal system, so the final diagnosis was a primary gastrointestinal stromal tumour of the pancreas.
Conclusion: This case represents the first reported primary pancreatic GIST diagnosed in our department. The rarity of extragastrointestinal GISTs, particularly in the pancreas, underscores the importance of considering such entities in the differential diagnosis of abdominal masses. The distinct histopathological and immunohistochemical features were crucial in establishing the diagnosis, and this case contributes valuable insight to the growing body of knowledge on primary pancreatic GISTs.

E-PS-07-019
RhoV is a basal-like pancreatic cancer marker and is associated with poor prognosis
S. Lu[1], S. Wu[2], Y. Xiao[1], J. Feng[3], X. Zhou[1], S. Kao[4], K. Hwa[1], Y. Liu[3], C.-K. Huang[2]
[1]Alpert Medical School of Brown University, Pathology and Laboratory Medicine, Providence, USA, [2]Tulane University School of Medicine, Pathology and Laboratory Medicine, New Orleans, USA, [3]Affiliated Hospital of Nantong University, Pathology, Naitong, China, [4]Wheeler School, Providence, USA

Background & Objectives: Pancreatic ductal adenocarcinoma (PDAC) is the third leading cause of cancer-related mortality, with a dismal five-year survival rate of just 11.5%. Genomic profiling has categorized PDAC into two principal subtypes—basal-like and classical—of which the basal-like subtype is associated with significantly worse clinical outcomes. It is critical to identify therapeutic targets for the basal-like PDACs. We have identified RhoV as a tissue-specific Rho GTPase promoting PDAC progression, particularly within the basal-like subtype. However, a systemic evaluation of RhoV expression in PDACs and its association with other putative basal markers is still lacking.
Methods: A total of 160 PDAC specimens resulting from the Whipple procedure were collected from Brown University Health's pathology archive. RhoV, p63, and CK5/6 were stained in sequential tumour resection slides. H-scores were obtained by multiplying staining intensity (0, 1, 2, or 3) and the percentage of stained tumour cells (0-300). Positivity was defined as an H-score of 5 or greater. The patient's recurrent and overall survival data and relevant tumour information were extracted from the medical chart and pathology report.
Results: RhoV, p63, and CK5/6 were positive in 60.3%, 31.3%, and 64.9% of PDACs, respectively. 70.8% of RhoV-positive and 94.5% of p63-positive tumours were also CK5/6-positive. The expression of three markers was not associated with tumour cellularity or small/large duct types. RhoV expression was related to poor histologic grade (P=0.0029), while p63 and CK5/6 were not. RhoV expression was associated with significantly worse overall and recurrent survival (P=0.0324 and P=0.0410, respectively), while there was no significant association between p63 and CK5/6 expression and prognosis.
Conclusion: RhoV is a basal-like marker that coexpresses with putative basal markers p63 and CK5/6. While p63 and CK5/6 have limited prognostic implications, RhoV is confirmed as a useful prognostic marker for PDAC and can be a potential therapeutic target.

E-PS-07-020
Insights in the epidemiological trend of hepatic tumours: a single-centre, 5-year retrospective analysis
G.-N. Radu[1], O.S. Cotoi[1,2], E.-A. Szász[1,3]
[1]Mureș County Clinical Hospital, Pathology Department, Târgu Mureș, Romania, [2]University of Medicine, Pharmacy, Science and Technology "George Emil Palade", Pathophysiology, Târgu Mureș, Romania, [3]University of Medicine, Pharmacy, Science and Technology "George Emil Palade", Histology, Târgu Mureș, Romania

Background & Objectives: Hepatic tumours(HTs) are heterogenous neoplasms that cover a wide spectrum of histologic lesions. The liver is a common site for metastasis due to its dual vascular supply and fenestrated sinusoidal endothelium, which create a favourable microenvironment for metastatic cell infiltration. The aim of our study was to assess the epidemiological trends by clinicopathological factors of HTs, with a special focus on liver metastases(LM), diagnosed over the last 5 years in an university hospital in Romania.
Methods: A retrospective observational study was performed, including all pathological reports of patients with HTs registered in our Department of Pathology, between 2020-2024. Patients were divided into three groups: G1-metastases, G2-primary malignancies and G3-benign tumours. We assessed the frequency of diagnoses throughout the study period, patients' demographic characteristics and primary site of origin in LM.
Results: This retrospective study included 142 patients (92 males;50 females) diagnosed with HTs between 2020-2024 in our Department of Pathology. Out of these, 99 were positive for a diagnosis of LM. The median age(MA) was comparable between G1 and G2, however patients in G3 had a significantly lower MA compared to G1 and G2 patients (59.50 years-old vs. 67.58 years-old vs. 66.76 years-old; p=0,014/p=0,015). During the study period we observed a 13.79% increase in HTs cases number in 2022 which was followed by a descending trend in the subsequent years. The most common primary site of origin among our patients was the gastrointestinal tract(n=26), followed by pancreato-biliary tract(n=16), lung(n=7), genito-urinary system(n=4), skin(n=4) and breast(n=1), while in 43 cases the primary origin remained undetermined.
Conclusion: In our study, patients with benign HTs had a significant lower MA, while LM remained the most diagnosed HT overall, with gastrointestinal tract being the most frequent primary site of origin. LM carry a very poor prognosis in oncologic patients, due to increased treatment resistance and impaired organ function.

E-PS-07-021
Characterising the nature of intraparenchymal lesions identified in liver explants - a study of macroscopic, microscopic, an dradiological correlation
S. Al-Dujaili[1], S. Khwaja[2], M. Hoare[3], G. Webb[3], A. Paterson[1]
[1]Cambridge University Hospitals NHS Foundation Trust, Histopathology, Cambridge, United Kingdom, [2]Cambridge University Hospitals NHS Foundation Trust, Radiology, Cambridge, United Kingdom, [3]Cambridge University Hospitals NHS Foundation Trust, Hepatology, Cambridge, United Kingdom

Background & Objectives: Accurate liver explant assessment is key for characterising known and identifying unsuspected solid lesions.
Methods: A single-centre retrospective evaluation of intraparenchymal lesions identified in consecutive liver explants from first-time recipients with chronic liver disease over 18 months, and correlated with pre-transplant radiological findings.
Results: 48/134 (36%) explants had ≥1 lesion on histological examination; of these15 (31%) had >1 lesion type. 18% of explants contained hepatocellular carcinoma(s) (HCC) (median size 14mm, range 3-55mm); 18% macroregenerative nodule(s) (MRN) (8mm, 1-36mm); 6% necrotic nodule(s) (26mm, 6-58mm); 1.5% haemangioma (10 and 25mm); 1.5% dysplastic nodule(s) (9 and 12mm); 1.5% a bile duct adenoma (7 and 13mm), and 0.7% intrahepatic cholangiocarcinoma (45mm).
≥1 lesion was identified in 33/75 (44%) explants with steatotic liver disease (SLD) including 18/33 (55%) HCCs; 6/16 (38%) explants with alpha-1-antitrypsin deficiency including 3/6 (50%) HCCs; 10/13

(77%) with viral hepatitis including 6/10 (60%) HCCs; and 4/7 (57%) containing siderosis including 2/4 (50%) HCCs. No HCCs were identified in explants with cholangiopathy, vascular abnormalities, autoimmune hepatitis, or acute necrosis.
26/134 (19%) explants had ≥1 solid radiological observation pre-transplant and ≥1 histological lesion. In 24, microscopic assessment confirmed the most significant radiological diagnosis: 19 HCCs, 2 necrotic nodules, 1 MRNs, 1 haemangioma, and 1 intrahepatic cholangiocarcinoma. 9/134 (6.7%) had a radiological observation pre-transplant, comprising 7 LI-RADS-3 observations, 1 suspected cyst/haemangioma, and 1 porto-systemic fistula, without a histological correlate in the explant. 22/134 (16%) had ≥1 histological lesion, although no concerning pre-transplant radiological observation; most were MRNs, however, 15 HCCs, size range 4-17mm, including one with lymphovascular invasion, were identified across 5 explants, all with SLD. Three were stage pT2N0, and 2 pT1a.
Conclusion: HCCs in liver explant can be small and unsuspected from pre-transplant imaging, highlighting the need for thin slicing and detailed assessment. Reviewing the radiological findings before histological evaluation facilitates macroscopic assessment.

E-PS-07-022
Hepatic carcinossarcoma versus collision tumour: a challenging diagnosis
J.L. Amaral[1], J.M. Dias[2], J.P. Maldonado[1], G. Nogueira Fontinha[1,3], M.A. Cipriano[1]
[1]Unidade Local de Saúde de Coimbra, Anatomical Pathology, Coimbra, Portugal, [2]Instituto Português de Oncologia de Coimbra Francisco Gentil, E.P.E., Anatomical Pathology, Coimbra, Portugal, [3]University of Coimbra, Faculty of Medicine, Coimbra, Portugal

Background & Objectives: Primary hepatic carcinossarcoma is extremely rare and contains a mixture of carcinomatous and sarcomatous components, described in literature with possible extrahepatic exophitic growth. Due to its rarity, there is no known aetiology or estabilished treatment protocols. Collision tumours are lesions with two or more distinct cell populations that maintain distinct borders.
Methods: We present a case of a sixty year old man previously diagnosed with two renal cell carcinomas, one in each kidney that underwent surgery. The patient was further submitted to liver transplantation due to multiple hepatocellular carcinomas, one of which was treated with chemoembolization, one cholangiocarcinoma and one combined hepatocellular-cholangiocarcinoma, developed in cirrhotic alcoholic liver disease. One year after transplant, on CT-scan, there was evidence of a 34 mm nodule adjacent to the liver/right nephrectomy loca, which was submitted to biopsy.
Results: On biopsy examination we found a neoplasm with two admixed components, one with spindle-to-ovoid mesenchymal cells and another with epithelial tubular pattern. Both components had marked pleomorphism, with bizarre nuclei and a high mitotic rate. On immuno-histochemistry the epithelial component had expression of CK7, CK19, MNF16, EMA and BerEP4, while the mesenchymal component had expression of ERG and CD31, with negativity for CAMTA-1 and a mutated p53 phenotype. There was negativity in both components for PAX8, HepPar-1, Desmin and Calretinin. Separated by bland connective tissue there was evidence of hepatic tissue on the periphery of one fragment.
Conclusion: Hepatic carcinossarcomas are rare, usually without differentiation of the sarcomatous component, however there are cases described with osteosarcoma, fibrosarcoma and chondrosarcoma, while none with angiosarcoma. In our case the sarcomatous component has vascular differentiation, but the presence of an intermixed epithelial and sarcomatous components abides with the diagnosis of a carcinossarcoma, as collision tumours are characterized by having distinct borders. Definite diagnosis is only possible on resection specimen.

E-PS-07-023
Hepatic epithelioid haemangioendothelioma: a rare vascular tumour revealed by liver biopsy- pathological insights and diagnostic challenges
E.-A. Szasz[1], A. Raicea[1], S. Turdean[1], O.S. Cotoi[1]
[1]George Emil Palade University of Medicine, Pharmacy, Science and Technology of Târgu Mureș, Târgu Mureș, Romania

Background & Objectives: Hepatic epithelioid haemangioendothelioma (HEHE) is a rare, low-to-intermediate-grade malignant vascular tumour of the liver with a variable clinical course. Due to its nonspecific presentation and imaging findings, histopathological examination remains the gold standard for diagnosis. This case report aims to describe the histopathological and immunohistochemical features of HEHE in a biopsy specimen, contributing to the diagnostic approach of this rare entity.
Methods: A percutaneous liver biopsy was performed on a 55-year-old woman presenting with abdominal discomfort and multiple hepatic lesions on imaging. Haematoxylin-eosin (H&E) staining was used for histpathological assessment, and immunohistochemistry (IHC) was performed to confirm vascular differentiation and rule out other hepatic neoplasms.
Results: Histopathological examination revealed scattered cords and nests of epithelioid endothelial cells within a myxohyaline stroma, accompanied by mild cellular atypia. Occasional intracytoplasmic vacuoles suggesting primitive vascular lumina were observed. Immunohistochemical staining showed strong positivity for endothelial markers CD31, CD34, and Factor VIII, supporting the vascular origin of the neoplasm. Tumour cells were also positive for vimentin, while negative for hepatocellular markers (HepPar-1, glypican-3) and biliary markers (CK7, CK19), ruling out hepatocellular carcinoma and cholangiocarcinoma.
Conclusion: HEHE remains a diagnostic challenge due to its rarity and overlapping histological features with other hepatic tumours. The combination of histopathological evaluation and a specific IHC panel is crucial for accurate diagnosis. Given the unpredictable clinical course of HEHE, histopathological confirmation is essential for guiding patient management, including consideration of surgical resection, liver transplantation, or targeted therapies.

E-PS-07-024
Unveiling the potential role of SATB2 as a diagnostic biomarker in a cohort study of patients diagnosed with cholangiocarcinoma
C. Yfanti[1], G. Katsanos[2], K. Mpallas[3], P. Petras[3], I. Gkoutziotis[3], E. Sakellariou[1], E. Katsiki[1]
[1]Ippokrateio General Hospital of Thessaloniki, Department of Pathology, Thessaloniki, Greece, [2]Medical School, Aristotle University of Thessaloniki, Ippokrateio General Hospital, Department of Transplantation, Thessaloniki, Greece, [3]Medical School, Aristotle University of Thessaloniki, Ippokrateio General Hospital, Fifth Surgical Department, Thessaloniki, Greece

Background & Objectives: SATB2, a transcriptional co-factor and gene regulator, involved in stem cell pluripotency and tumorigenesis, is a specific biomarker in colorectal adenocarcinomas. Although research on SATB2 in cholangiocarcinoma, the second most common liver tumour, is limited, this study aims at evaluating the potential utility of SATB2 in cholangiocarcinoma diagnosis beyond cytokeratin 7 and 19.
Methods: Archival formalin-fixed and paraffin-embedded tissue from 34 patients, comprising 19 women and 15 men, aged 49 to 85 years, with cholangiocarcinomas resected between 2020 and 2025 were retrieved. Immunohistochemical staining was performed and SATB2 nuclear expression was evaluated using an h-score system. The h-score (0-5) was calculated using the sum of the staining intensity

(0=negative, 1=weak, 2=moderate, 3=strong) and the percentage of positive cells (<5%=0, 5-49%=1, >50%=2).
Cases were categorized into groups based on histomorphological and immunohistochemical features, including WHO histological subtype of cholangiocarcinomas, degree of differentiation, histological pattern, presence of necrosis, perineural and vascular/lymphatic invasion, intratumoral inflammatory cell infiltrations and coexpression with cytokeratin 20 and CDX2.
Results: The vast majority of patients (73.53%) was immunohistochemically negative (h-score 0) whereas positive nuclear expression of SATB2 was detected in only 9 cases (26.47%). Among the positive cases, h-scores were: 1 (14.71%), 3 (5.88%), 4 (2.94%) and 5 (2.94%). No cases had an h-score of 2.
Statistical analysis showed no significant correlation between SATB2 immnunohistochemical expression (h-score) and any of the histomorphological and immunohistochemical parameters examined (Pearson chi-square test, p>0.05).
Conclusion: Further studies are required to clarify the potential role of SATB2 and other molecules as diagnostic, prognostic and predictive biomarkers in cholangiocarcinomas. These studies may offer promising targeted treatment options.

E-PS-07-025
Molecular classification of neuroendocrine neoplasms in small biopsies
U. Klopčič[1], A. Matjašič[1], M. Strojan Fležar[1]
[1]University of Ljubljana, Medical Faculty, Institute of Pathology, Ljubljana, Slovenia

Background & Objectives: To evaluate the role of molecular genetic analysis using next generation sequencing (NGS) in small biopsies, e.g. core biopsies (CB) and fine needle biopsies (FNB) to differentiate between neuroendocrine tumour grade 3 (G3 NET) and neuroendocrine carcinoma (NEC), to determine the origin of NEC in liver metastases and to provide information on potential molecular targets for therapy.
Methods: In the period from 2019 and 2024 a total of six cases met the entry criteria: 3 pancreatic neuroendocrine neoplasms (NEN) (two CB, one FNB) and three liver NEN metastases (two CB, one FNB). NGS was performed with Oncomine Comprehensive Assay v3 (Thermo Fisher Scientific) on tissue blocks in four cases and on cell suspension in two cases.
Results: In two of three pancreatic NENs, the presence of TP53 and RB1 mutations confirmed NEC, since these genetic aberrations are generally lacking in G3 NET. Both tumours also harboured KRAS gene mutations, confirming their pancreatic origin. In the remaining pancreatic tumour, mutations in KRAS, TP53 and RNF43 genes, but not in RB1 gene suggested the possibility of mixed endocrine non-endocrine tumour or a precursor cystic neoplasm of pancreas.
Two of three metastatic NEN in the liver harboured mutations in TP53, RB1 and TERT (promoter region) genes confirming the metastatic NEC from known bladder primaries. In the remaining liver NEN metastasis no mutations in the tested genes were confirmed, including TP53 and RB1. The tumour was, therefore regarded as a metastatic G3 NET of unknown primary.
No therapeutically relevant genetic alterations were found in any of the cases.
Conclusion: NGS can be successfully performed on small biopsies and on cell suspension obtained by FNB, thus enabling clear distinction between G3 NET and NEC, providing information on potentially targetable genetic aberrations and establishing the origin of metastatic liver NEC.

E-PS-07-026
EBV-related adenocarcinoma of the ampulla of Vater: a rare tumour or an underrecognized entity?
I. Bomfim[1], B. Nascimento Santana[2], L.A. de Lima[2], S.D. Morales Andrade[2], É.A.S.S. Santos Silva[2], V. Segatelli[1], E. Sobroza de Mello[2], R. Teixeira[1]
[1]Instituto do Cancer do Estado de São Paulo, Pathology, São Paulo, Brazil, [2]Universidade de São Paulo, Pathology, São Paulo, Brazil

Background & Objectives: Molecular classification for ampullary tumours is not as well established as it is for gastric carcinoma. However, genetic alterations like Kras mutations and MSI status are linked to ampullary neoplasia and have some correlation with prognosis and therapy. In gastric carcinoma, EBV detection is associated with a better prognosis, but it remains uncertain whether this applies to ampullary adenocarcinoma. Our case report suggests that routine detection of medullary morphology and EBV should be considered in the diagnosis of ampullary adenocarcinoma.
Methods: We present the case of a 72-year-old female patient diagnosed with ampullary carcinoma after the onset of jaundice, who subsequently underwent pancreaticoduodenectomy. Histopathological analysis of the surgical specimen revealed a neoplasia with mixed features, including a predominantly solid-syncytial pattern interspersed with inflammatory cells at the tumour base, along with a superficial tubular morphology.
Results: Given the morphological findings, we investigated the presence of Epstein-Barr virus (EBV) antigens using EBER-1 probe in situ hybridization (ISH), which demonstrated strong and diffuse positivity. Immunohistochemical analysis disclosed proficient mismatch repair (pMMR) protein expression and complete loss of CK7 expression. The stromal tumour infiltrating-lymphocytes was evaluated in 10%.
Conclusion: Ampullary adenocarcinoma lacks a well-defined molecular classification, and only a few cases of EBV-positive tumours have been previously reported. Recognizing medullary morphology in ampullary carcinoma and assessing EBV status may have significant clinical implications, as it could be associated with improved survival and an increased likelihood of response to PD-1 blockade therapy.

E-PS-07-027
Clinicopathological and immunohistochemical characteristics of solid pseudopapillary neoplasms of the pancreas
D. Hellal[1,2], S. Merouche[3,2], M. Boudaoud[4], K. Boulmezair[1], O. Mekentichi[1], N. Boutahir[1], I. Houichi[1], H. Khadraoui[5]
[1]Anti-Cancer Centre of Batna, Pathology, Batna, Algeria, [2]University of Batna 2, Medical Sciences, Batna, Algeria, [3]Anti-Cancer Centre of Batna, Oncology, Batna, Algeria, [4]Anti-Cancer Centre of Batna, Surgery, Batna, Algeria, [5]University of Batna 2, Department of Medical Sciences, Batna, Algeria

Background & Objectives: Solid pseudopapillary tumours (SPTs) of the pancreas are rare, low-grade malignant neoplasms that primarily affect young women. While their clinicopathological features are well-defined, the underlying molecular mechanisms and prognostic factors remain insufficiently elucidated. This study aims to analyse the clinicopathological and immunohistochemical characteristics of SPTs to refine diagnostic criteria and improve prognostic stratification in the anatomic pathology department of CLCC Batna in 2024.
Methods: We conducted a retrospective descriptive study of eight cases of SPT diagnosed at the anatomic pathology department of CLCC Batna in 2024. Data collected included patient demographics, tumour location and size, histological architecture (proportion of papillary and solid components), presence of necrosis, capsule status, invasion,

metastatic potential, surgical margin status, and immunohistochemical markers (β-catenin, CD10, progesterone receptor [PR], synaptophysin [SYNAPTO], and chromogranin [CHROM]). Statistical analysis was performed to correlate histopathological characteristics with clinical outcomes.

Results: The study included eight female patients with a median age of 28 years. Tumour size ranged from 4.5 to 8 cm, with a predominantly papillary architecture (60–90%). Necrosis was observed in only one case. Capsular invasion was identified in 5/6 resected cases, but no metastases were reported. All tumours showed strong nuclear positivity for β-catenin and were also positive for CD10, PR, and SYNAPTO, while CHROM was consistently negative. Surgical margins were clear in 5/6 cases, whereas one case exhibited tumour infiltration, requiring adjuvant chemotherapy.

Conclusion: Our findings confirm the low malignant potential of SPTs, characterized by a distinctive immunohistochemical profile (β-catenin+, CD10+, PR+, SYNAPTO+) and favourable clinical outcomes despite frequent capsular invasion. The consistent expression of PR may be associated with a less aggressive phenotype, highlighting its potential role as a prognostic marker. Furthermore, although surgical resection is generally curative, the tumour infiltration observed in one case necessitated adjuvant treatment, emphasizing the importance of complete tumour excision.

E-PS-07-028

A rare case of cholangiocarcinoma developing from a biliary adenofibroma

A. Alves[1], J. Madeira[1], M. Silva[1], M. Cipriano[1]
[1]ULS Coimbra, Coimbra, Portugal

Background & Objectives: Biliary adenofibroma is a rarely described entity with even rarer reports of malignant transformation. Its recognition, as well as the aspects that might suggest malignancy, is of extreme importance, as it can alter patient follow-up.

Methods: We report a case of a female patient in her 70's, with prior history of left hepatectomy for hepatocellular carcinoma, recurrence and subsequent thermoablation. A 5.6 cm hepatic lesion was discovered during follow-up, biopsied and the patient underwent hepatic segmentectomy.

Results: Macroscopically, the lesion had well-defined, lobulated borders and a biphasic appearance, with a solid, yellowish area and another translucent multicystic component.

Histologically, the tumour was composed of dilated, irregular tubular structures, lined by bland-looking cells and embedded in a fibrous, smooth muscle actin-positive stroma. The macroscopically solid areas corresponded to a denser architectural pattern, with cribriform and back to back tubuloacinar structures lined by cuboidal cells, with eosinophilic cytoplasm, round nuclei and occasional small nucleoli, sometimes with luminal, PAS-D positive secretion. This area had minimal to no intervening stroma and showed atypical mitoses.

All epithelial cells throughout the lesion were CK7 and CK19 positive with SMAD4 and BAP1 retention. The cystically dilated areas also showed EMA positivity. Most neuroendocrine markers (except synaptophysin) were negative, as were hepatocellular markers, GATA3, PAX8, TTF1 and thyroglobulin. P53 had a wild-type staining pattern. Ki67 was about 10%.

Due to the architectural pattern, we considered the tumour to be a malignant transformation of a biliary adenofibroma into a cholangiocarcinoma with a microcystic/cribriform pattern. The patient eventually developed lung metastasis.

Conclusion: Although rare, the malignant transformation of biliary adenofibromas, as reported in the literature and in our case, highlights the preneoplastic nature of this entity and the importance of close follow-up.

E-PS-07-029

Hepatocellular carcinoma: when morphology and immunohistochemistry reveal the keys to prognosis

D. Hellal[1,2], S. Merouche[3,2], M. Boudaoud[4], W. Aissi[5], N. Boutahir[1], I. Houichi[1], H. Khadraoui[1,2]
[1]Anti-Cancer Centre of Batna, Pathology, Batna, Algeria, [2]University of Batna 2, Medical Sciences, Batna, Algeria, [3]Anti-Cancer Centre of Batna, Oncology, Batna, Algeria, [4]Anti-Cancer Centre of Batna, Surgery, Batna, Algeria, [5]Anti-Cancer Centre of Batna, Gastroenterology, Batna, Algeria

Background & Objectives: Hepatocellular carcinoma (HCC) is a malignant liver tumour characterized by diverse morphological and clinical features, which complicate its diagnosis and management. The prognosis of HCC is influenced by various factors, including tumour differentiation, vascular invasion, and the presence of cirrhosis. This study aims to investigate the morphological and immunohistochemical characteristics of HCC in patients who underwent hepatectomy, in order to identify key prognostic factors.

Methods: This retrospective study analysed the pathological reports of 10 patients who underwent hepatectomy for HCC at the Cancer Control Centre (CLCC) of Batna in 2024. The parameters examined included tumour differentiation, inflammatory infiltrates, tumour size, vascular invasion, perineural invasion, surgical margins, liver condition, and capsular status. The diagnosis of HCC was confirmed using immunohistochemical markers HepPar-1, Glypican-3, and Arginase-1, while markers CK7, CK19, and CD10 were used to exclude differential diagnoses.

Results: The study population had an equal sex ratio of 1:1. The tumours were predominantly moderately differentiated (Grade II), with sizes ranging from 2 cm to 6 cm. Encapsulation was observed in 70% of cases, while 30% of the tumours were non-encapsulated, potentially indicating more aggressive behaviour. Most tumours developed in a cirrhotic liver background. The immunohistochemical analysis confirmed HCC with positive staining for HepPar-1, Glypican-3, and Arginase-1, and negative staining for CK7, CK19, and CD10. Vascular and perineural invasion, although rare, were associated with a poorer prognosis.

Conclusion: The absence of encapsulation, lower tumour differentiation, and the presence of vascular and perineural invasion are key factors associated with a poor prognosis in HCC. These findings underscore the importance of a comprehensive morphological and immunohistochemical evaluation to improve risk stratification and guide the management of HCC patients.

E-PS-07-030

A rare case of signet ring cell hilar adenocarcinoma of the extrahepatic bile duct

S.-L. Vasilescu[1], A. Csanadi[1], J. Kalla[1]
[1]Schwarzwald-Baar Klinikum, Department of Pathology, Villingen-Schwenningen, Germany

Background & Objectives: Signet ring cell carcinoma (SRCC) is a rare and aggressive subtype of adenocarcinoma, typically arising in the stomach. Its occurrence in the extrahepatic bile duct is exceptionally rare, with fewer than 20 cases reported in the English literature. Due to its aggressive nature and diagnostic challenges, awareness and reporting of such cases are crucial.

Methods: We present the case of a 71-year-old woman who was admitted with obstructive jaundice and pruritus. Imaging studies revealed a 3 cm hilar mass in the common hepatic duct, obstructing and infiltrating both the left and right hepatic ducts. The patient underwent a right hemihepatectomy. The resected specimen was examined macroscopically and microscopically, and staged according to current TNM guidelines.

Results: Grossly, a 3.7 cm firm, gray-white tumour was identified at the bifurcation of the common hepatic duct, with infiltration into adjacent hepatic tissue. Microscopic examination showed a polymorphous adenocarcinoma with a predominant (>50%) signet ring cell component. Tumour cells exhibited solid and infiltrative growth with abundant intracytoplasmic mucin and eccentrically displaced nuclei. The stroma was desmoplastic with a mixed inflammatory infiltrate. Three of seven lymph nodes showed metastasis with extranodal extension. Infiltration extended to the coagulation zone of the hepatic resection margin. The patient unfortunately died shortly after surgery due to postoperative complications.
Conclusion: This case highlights the importance of recognizing signet ring cell carcinoma in rare anatomical locations such as the extrahepatic bile ducts. Despite surgical resection, prognosis remains poor. Accurate histopathological diagnosis and reporting are essential for improving understanding of this rare malignancy.

CD55 as a potential biomarker for high-grade pancreatic cancer precursor lesions
R. Vesce[1], H. Blomstrand[2], K.C. Vieth[1], A. Yavas[1], I. Esposito[1]
[1]University Clinic of Düsseldorf, Institute of Pathology, Düsseldorf, Germany, [2]Linköping University, Department of Clinical Pathology, and Department of Biomedical and Clinical Sciences, Linköping, Sweden

Background & Objectives: Pancreatic cancer, a leading cause of cancer-related mortality, arises from precursor lesions such as pancreatic intraepithelial neoplasia (PanIN), intraductal papillary-mucinous neoplasms (IPMN), and mucinous cystic neoplasms (MCN). Detecting microscopic high-grade precursor lesions remains a challenge, with limited biomarkers available. Previous research suggests that CD55, a membrane-bound glycoprotein involved in complement system regulation, may be elevated in high-grade lesions. This study aims to investigate CD55 expression in pancreatic cancer precursor lesions and its potential as a biomarker.
Methods: A cohort of 161 precursor lesions (130 IPMN, 12 MCN, and 72 PanIN) from 85 patients was assessed for CD55 expression using immunohistochemistry (IHC). Of these, 32 IPMN, 3 MCN, and 5 PanIN were classified as high-grade. Additionally, CD55 levels were analysed in cyst fluids from 46 patients using ELISA, including samples from 6 low-grade, 12 high-grade, 5 ungraded neoplastic cysts, and 23 non-neoplastic cysts.
Results: CD55 IHC showed high interrater concordance (Kappa 0.66–0.84) by three observers. The two observed staining patterns, luminal and cytoplasmic, were significantly increased in high-grade lesions compared to low-grade ($p=0.0011$ and $p<0.0001$, respectively). ELISA analysis revealed significantly higher CD55 levels in low-grade mucin-producing neoplasms than in non-neoplastic cysts (1444.7 ng/ml vs. 284.4 ng/ml, $p<0.001$). Although high-grade cystic neoplasms exhibited even higher mean CD55 levels (5044 ng/ml), the difference between high- and low-grade lesions was not statistically significant.
Conclusion: CD55 expression is significantly elevated in high-grade pancreatic precursor lesions, reinforcing its role in pancreatic cancer development. Furthermore, IHC-based CD55 scoring is reproducible. With further validation, CD55 could serve as a biomarker for identifying high-risk pancreatic precursor lesions.

E-PS-07-032
Tumour mimickers in the pancreas and spleen; accessory spleen and perisplenitis cartilaginea
A.N. Yuksel[1], B.U. Durmus[1], S. Gulmez[2], I. Guvendir Bakkaloglu[1]
[1]Kartal Dr. Lutfi Kirdar City Hospital, Medical Pathology, Istanbul, Turkey, [2]Kartal Kosuyolu Education And Research Hospital, Gastroenterology Surgery, Istanbul, Turkey

Background & Objectives: Tumour-mimicking lesions in the pancreas and spleen are of significant importance for both clinicians and pathologists. In this case, two tumour-like conditions occurring simultaneously are presented.
Methods: Our case, 75 year old male patient was clinically investigated for malignancy for a lesion 3 cm in its biggest diameter on computer tomography (CT) and localised in pancreatic tail. Fine Needle Aspiration(FNA) Biopsy revealed acinar cell groups that cannot be distinguished from malignancy and it was reported as "Suspicious for Malignancy". The patient underwent a distal pancreatectomy and splenectomy. During the surgery on the surface of the splenic capsule white solid lesions of variable size resembling metastatic nodules were observed and intraoperative pathology consultation was requested.
Results: In the macroscopic examination, 2 well circumscribed brown lesions were observed in the pancreas parenchyma and spleen hilum fat tissue. On the surface of the splenic capsule largest being 1.5 cm in diameter multiple white coloured solid implant-like lesions were observed. No tumour was detected in the intraoperative pathology consultation for the pancreatic lesion and the nodules on the splenic capsule. After detailed inspection and examination with light microscopy, pancreatic lesion was reported as accessory spleen in the tail and hilus fat tissue. The white solid lesions which encovered spleen capsule revealed thick, dense, hyalinized fibrous tissue; along with cartilage-like areas within the fibrous stroma and occasional foci of dystrophic calcification was observed microscopically and reported as "Perisplenitis Cartilaginea".
Conclusion: Pancreatic accessory spleen may show atypical findings in FNA and mimic malignancy. Perisplenitis cartilaginea (also known as "Hyaline Perisplenitis" or "Icing Sugar Spleen) is an infrequent benign finding that accompanies intraabdominal inflammatory conditions and may raise the suspicion for metastatic nodules. It is important for the clinician and pathologist to be aware of this entity in order to distinguish it from metastatic lesions and its malignant masqueraders.

E-PS-07-033
SEL1L-NTRK1 is a recurrent gene fusion in pancreatic acinar cell carcinoma with potential therapeutic significance
F. Yin[1], H. Wang[1], R. Yang[1]
[1]The University of Texas MD Anderson Cancer Centre, Department of Pathology, Houston, USA

Background & Objectives: Pancreatic acinar cell carcinoma (PACC) is a rare malignant exocrine epithelial neoplasm. It does not share the common mutations found in pancreatic ductal adenocarcinoma, and it is of clinical relevance to characterize its molecular signature.
Methods: A retrospective search for PACC patients with genomic alterations was performed in our pathology database from 2020 to 2024. The clinicodemographic and histopathologic information were collected. The findings were analysed in conjunction with a review of the current literature.
Results: We identified one case of PACC with SEL1L-NTRK1 gene fusion through database search and two additional such cases through literature review (published in 2021 and 2024). These 3 patients were all male with age of 65, 71, and 81 years old. The patients' medical history included hypertension, hyperlipidemia, chronic kidney disease, and ulcerative colitis. Radiographically, the PACCs measured 2.0 cm, 2.2 cm, and 4.2 cm, respectively. The tumour involved pancreatic head, neck, and body. All PACC cases demonstrated distant metastasis including liver (3/3) and lymph nodes (3/3). Two patients underwent surgical resection. These patients received gemcitabine-based adjuvant treatment, and the treatment were all discontinued due to further disease progression or adverse effects. The genomic analysis revealed all 3 cases had SEL1L-NTRK1 gene fusion (which has not been reported in any other tumour types), a low tumour mutational

burden and microsatellite-stable status. Additional somatic mutations were found in MEN1, NBN, RB1, ASXL1, and PBRM1 genes. Two patients subsequently received NTRK inhibitors (entrectinib and larotrectinib). One patient demonstrated exceptional radiographic response with near complete liver lesions disappearance. However, another patient discontinued Larotrectinib treatment because of rapid disease progression.
Conclusion: Our study suggests that the SEL1L-NTRK1 gene fusion is a unique and recurrent genomic alteration in PACC. Further study is warranted to determine its frequency and routine testing for such fusion in PACC may provide potential therapeutic benefits.

E-PS-07-034
Neonatal giant cell hepatitis (NGCH) associated to a currently rare cause: haemolysis
Y. Rodriguez-Gil[1], E. Ortega[1], S. Rubio-Roger[2], C. Bueno-Suarez[2], E. Medina[2]
[1]University Hospital 12 de Octubre, Pathology, Madrid, Spain, [2]University Hospital 12 de Octubre, Paediatrics, Madrid, Spain

Background & Objectives: Neonatal giant cell hepatitis (NGCH) is a common histologic finding to a wide variety of liver insults, therefore, the differential diagnosis is broad. The most common causes are perinatal infections, congenital malformations, metabolic disorders and hepatobiliary abnormalities. Identification of aetiology is essential because some of these causes need early treatment or even surgery.
We present an infrequent case of severe neonatal cholestasis associated with morphological findings of NGCH caused by haemolytic disease (HDN).
With improving of prenatal care and the use of anti-D prophylaxis the frequency of liver injury in haemolytic disease has become rare. Currently there is small knowledge about patterns of presentation. Traditionally it was associated to "inspissated bile syndrome" which may need surgical intervention. NGCH is another possible finding that could be caused by neonatal haemolysis. This association has to be known and has some special characteristics and clues.
Methods: Four-month girl, born at 33+1 due to Rh (anti-D, anti-E) incompatibility. Appropriate prenatal care included 3 Red Blood Cell transfusions.Liver enzymes were elevated with higher AST elevation, **AST 235 U/L,** GPT 66 U/L, GGT 70 U/L, ALP 568U/L.Bilirubin 10,2 with high direct Bb.Ferritin 8474ng/m.
Ultrasound showed hepatosplenomegaly. Cholangiography excluded biliary tree abnormalities.
Results: Biopsy showed a diffuse, **panlobular multinucleated giant cell transformation and ballooning of hepatocytes**. Inflammation was scarce and mixed with haematopoiesis. There´s mild ductular reaction, that excluded obstruction and moderate canalicular cholestasis. Characteristically,there´s **hemosiderosis** in giant cell hepatocytes and reticuloendothelial cells. Other diseases were excluded (normal BSEP, TJP2 expression, c5b-9 negative, no infections, etc).
Conclusion: Up to 13% of neonates with alloimmune HDN develop cholestasis which needs biopsy. In the past most cases were attributed to "inspissated bile syndrome".
NGCH has been documented in cases of HDN with cholestasis rarely, but its clinicopathologic features have not been sufficiently described. We present a characteristic case.

E-PS-07-035
Chromophobe variant of hepatocellular carcinoma: a rare histopathological entity with diagnostic challenges – a case report
H.İ. Saribiyik[1], G. Akyol[1]
[1]Gazi University Faculty of Medicine, Pathology, Ankara, Turkey

Background & Objectives: The chromophobe variant of Hepatocellular carcinoma (HCC) is a rare histological subtype of HCC. Due to its distinct morphological features, this variant poses significant diagnostic challenges, potentially leading to misclassification. Increased awareness among pathologists is essential for accurate identification and differentiation from other hepatic neoplasms and metastasis.
Methods: A 69-year-old woman with acute renal failure who was found to have elevated liver function tests on blood tests. Ultrasonographic evaluation revealed a 12 cm mass in the liver. MRI showed a lobulated-contoured lesion measuring 12,5 cm, with no evidence of a solid lesion infiltrating the vena cava. Elevated levels of alpha-fetoprotein (AFP) and CA 19-9 were noted.
Results: Histopathological examination of the liver core biopsy demonstrated tumour cells with chromophobic (clear) cytoplasm and abrupt, marked nuclear pleomorphism against a background of otherwise bland cytology. Scattered microscopic pseudocysts were also observed. Immunohistochemical analysis revealed positive staining for Glypican-3, HSP70, and polyclonal carcinoembryonic antigen (CEA), supporting the diagnosis of hepatocellular carcinoma.
Conclusion: We report a rare histological variant of hepatocellular carcinoma (HCC) characterized by neoplastic cells exhibiting chromophobic (clear) cytoplasm and focal areas of abrupt, severe nuclear atypia, set against a background of predominantly bland morphology. This case highlights the diagnostic challenges and histopathological uniqueness of this underrecognized HCC subtype.

E-PS-07-036
Delayed-onset hepatotoxicity after CFTR modulator therapy in a paediatric patient
J.P. Maldonado[1], J.L. Amaral[1], A. Alves[1], M.A. Cipriano[1]
[1]ULS Coimbra, Pathology, Coimbra, Portugal

Background & Objectives: Elexacaftor/tezacaftor/ivacaftor (ETI, Kaftrio) is a highly effective CFTR modulator that has significantly improved outcomes in cystic fibrosis (CF). While generally well tolerated, ETI is associated with mild and transient elevations in liver enzymes in approximately 10–15% of patients. However, rare cases of severe drug-induced liver injury (DILI) have been reported, including delayed acute liver failure even after discontinuation. This suggest a possible idiosyncratic or immune-mediated mechanism raising concern for serious hepatic events, particularly in paediatric populations.
Methods: We report the case of a 12-year-old girl with cystic fibrosis (CF) who developed severe liver injury despite the discontinuation of Kaftrio therapy, ultimately requiring liver transplantation. On day(D) 158 after starting therapy, she presented with elevated aminotransferases (AST/ALT: 150/297 U/L), which progressed to AST/ALT: 700/1354 U/L by day 178, prompting the suspension of ETI. On D192, she developed fever, anorexia, odynophagia, headache, abdominal pain and worsening of AST/ALT: 889/2015 U/L. On D206 a transjugular liver biopsy was performed and due to clinical and hepatic deterioation with evolution to acute liver failure she was prompt submitted to liver transplantation (D207).
Results: In both liver specimens a severe pattern of acute hepatitis with centro-central necro-inflamattory bridges leading to massive hepatocellular necrosis and parenchymal collapse was observed. There was mild to moderate portal and lobular mixed inflammatory infiltrate, predominantly neutrophilic, associated with marked periportal ductular reaction. No plasma cells, eosinophils or granulomas were identified and there were no signs of chronic liver disease. In the absence of other causes of severe acute liver damage the diagnosis of kaftrio induced severe acute hepatitis was considered.
Conclusion: This case underscores the potential severity of DILI in paediatric CF patients using CFTR modulators. Even short-term exposure can lead to progressive and life-threatening acute liver failure, reinforcing the need for close biochemical monitoring, early recognition of injury, and long-term hepatologic follow-up.

E-PS-07-037

Next-generation sequencing profile of pancreatic ductal adenocarcinoma after implementation of a dual grossing protocol in pancreatectomy specimens

J. González-López[1], L. Rubio-Martínez[2], O. Castells-Perona[3], C. Ballester-Ibáñez[4], C. López-Valdivia[1], R. Díaz-Beveridge[5], E. Montalvá-Orón[4], R. López-Andújar[4], J. Pérez-Rojas[1]

[1]Hospital Universitari i Politècnic La Fe, Pathology, València, Spain, [2]Hospital Universitari i Politècnic La Fe, Molecular biology, València, Spain, [3]Instituto de Investigación Sanitaria La Fe, València, Spain, [4]Hospital Universitari i Politècnic La Fe, Hepatobiliary Surgery, València, Spain, [5]Hospital Universitari i Politècnic La Fe, Oncology, València, Spain

Background & Objectives: Pancreatic ductal adenocarcinoma (PDAC) is characterized by its late-stage diagnosis and poor prognosis (only 10–20% of patients have resectable tumours). In light of new therapeutic targets in the field of precision medicine, the study of the molecular biology of PDAC has become essential. In this study, we evaluated the next-generation sequencing profile of PDAC cases and evaluated its correlation with recurrences and survival, considering the application of a dual-grossing protocol which combined the axial and bivalve grossing techniques.

Methods: This observational study includes all resected PDAC specimens diagnosed over the past five years in patients aged >18 at our institution. Next-generation sequencing (NGS) was performed on all samples. Statistical significance was assessed using a two-tailed Chi-square test, with a threshold of $p \leq 0.05$. If expected cell counts were <5, Fisher's exact test was employed. Long-Rank test was performed to analyse the survival differences with a significance level of $p \leq 0.05$. The dual grossing protocol has been developed by combining the axial and bivalve grossing techniques.

Results: 27 cases were analysed: 11 males (40.7%) and 16 females (59.3%), with a mean age of 68. R0 was achieved in 23 cases (85.2%), while R1 was observed in 4 cases (14.8%). *KRAS* mutations were identified in 25.9% of cases, accompanied by *TP53* (25.9%), *FGFR3* (3.7%), and *ATM* (3.7%). Loss of *SMAD4* was detected in 17 cases (53.1%), while *ARID1A* was detected in 1 case (3.7%). *POLE* mutations were not observed. Molecular alterations were associated with age (p=0.01), requirement for neoadjuvant therapy (p=0.046), and N stage (p=0.004), but showed no correlation with recurrences (p=0.47) or survival (p=0.205).

Conclusion: Our findings are comparable to those reported in the literature. Molecular alterations correlate with multiple pathological variables and are the basis for developing new targeted therapies.

E-PS-07-038

Neoplastic findings in cholecystectomy specimens: a 15-year retrospective study

G. Nogueira Fontinha[1,2], V. Almeida[1,2]

[1]ULS Coimbra, Pathology, Coimbra, Portugal, [2]University of Coimbra, Faculty of Medicine, Coimbra, Portugal

Background & Objectives: Cholecystectomy is one of the most common surgical procedures performed worldwide. The analysis of cholecystectomy specimens over a prolonged period can provide valuable insights into the prevalence and types of neoplasms encountered. This retrospective study aimed to evaluate the frequency and types of neoplasms found in cholecystectomy specimens over a 15-year period.

Methods: A retrospective review of cholecystectomy specimens diagnosis from the beginning of 2010 to the end of 2024 was conducted. A total of 11573 cholecystectomy specimen were reviewed. Age, gender and prevalence of primary neoplastic findings were recorded.

Results: Of the total cases 6797 (58,7%) were female and 4776 (41,3%) were male with age range 2-105 (mean: 59.1; median 60) and 78 cases (0.67%) exhibited neoplasms. The types of neoplasms identified included: 14 adenomas, 6 billiary intraepithelial neoplasia, 7 intracholecystic papillary neoplasm (IPN), 42 adenocarcinomas, 2 adenosquamous carcinomas, 1 squamous cell carcinoma, 3 undifferentiated carcinomas, 1 neuroendocrine carcinoma, 1 mixed neuroendocrine-non-endocrine neoplasm, and 1 inflammatory myofibroblastic tumour. 9 carcinomas were associated with IPN.

27/78 patients had non-invasive neoplasia and a mean age of 64.6 (39-81) while 51/78 had invasive neoplasia and a mean age of 72.3 (39-96). There was no gender or age diference between IPN (7/78) and IPN associated invasive carcinoma (9/78) patients. Between patients with adenocarcinoma (42/51) and patients with other invasive neoplasia (9/51) there was no age difference but while in the first group 57% of patients were female, in the second group females made up 78% of the total.

Conclusion: Neoplasms in cholecystectomy specimens are rare and varied, with adenocarcinomas being the most common. Non-invasive neoplasia presents in younger patients but no age difference was seen between IPN and IPN associated carcinoma. Non-adenocarcinoma invasive neoplasia are more common in females.

E-PS-07-040

Implication of Syndecan-1 during Extracellular Vesicles uptake in Pancreatic ductal adenocarcinoma cases

G. Kafiri[1], A. Kataki[2], E. Koniaris[1], A. Paraskeva[1], D. Riga[1], I. Angelioudaki[3], A.-G. Tzingounis[3], L. Stoupis[3], E. Mastoridou[4], A. Charchanti[4]

[1]Hippocration General Hospital, Pathology, Athens, Greece, [2]NKUA, Medical School, Hippocratio Hospital, 1st Department of Propaedeutic Surgery, Athens, Greece, [3]NKUA, Medical School, 'Aretaieio' Hospital, 2nd Department of Surgery, Athens, Greece, [4]University of Ioannina, Department of Anatomy, Faculty of Medicine, Ioannina, Greece

Background & Objectives: The field of Extracellular Vesicles (EVs) has been receiving increased attention, as they are considered important for cell communication. Tetraspanins including CD9, are among their major membrane constituents and therefore representing an often used surface markers. The mechanism underlying EVs uptake is not well defined although evidence suggest that it can be mediated by heparan sulfate proteoglycans such as Syndecan-1 (SDC1) that normally reside on the surface of recipient cells. Thus, the aim of the present study is to investigate the involvement of SDC1 during EVs uptake in cases of pancreatic cancer adenocarcinoma (PDAC).

Methods: Previously published data demonstrated that immunohistochemical identification of EVs using CD9 as a marker is feasible. Thus, the current study applies this methodology to sketch the presence of EVs either in normal adjacent (NA) or cancerous epithelium and stroma by analysing 75 patients with PDAC. Respectively, SDC1 expression was also inspected. Both percentage of positive cells and intensity were scored.

Results: NA epithelium was positive in 66.1% and 14.5% for SDC1 and CD9 while tumour's epithelium was positive in 42.7% and 23.7% of patients respectively. SDC1 intratumoral expression was not restricted on the cell membrane, as a translocation to the cytoplasm was observed in 25.3% of cases. A significant gain of expression compared to NA epithelium was apparent ($p \leq 0.001$) including both membranous and cytoplasmic expression ($p<0.001$ and p=0.009 respectively). Upon translocation of SDC1 to the cytoplasm in tumour's epithelium the supporting stroma was significantly enriched in CD9 expression (p=0.03). NA stroma was negative for both SDC1 and CD9 immunostaining.

Conclusion: The NA stroma profile as well as the accumulation of CD9 in PDAC supporting stroma upon SDC1 translocation to the cytoplasm in tumours epithelium favour the implication of SDC1 in the uptake of CD9 decorated EVs.

E-PS-07-041

Intracholecystic papillary neoplasm: histopathological, immunohistochemical, and molecular study of six cases

L. Ruiz Estigarribia[1], A. de Oliveira Gomes[1], A. González Zuñiga[1], V. Giménez Abadia[1], I. Fernández de los Reyes[1], R. Beloqui[1], M.R. Mercado[1], I. Amat Villegas[1]
[1]Hospital Universitario de Navarra, Pamplona, Spain

Background & Objectives: Intracholecystic papillary neoplasm (ICPN) is a non-invasive epithelial tumour of the gallbladder that was recently recognized as a distinct entity by the World Health Organization (WHO) and accounts for less than 1% of cholecystectomies. Four histological subtypes have been described: biliary, gastric, intestinal, and oncocytic, often with overlapping features. Its characterization remains limited compared to other hepatobiliary precursor lesions.
Methods: We retrospectively analysed six ICPN cases diagnosed at the University Hospital of Navarra between 2021 and 2024. Histological features (growth pattern, subtype, dysplasia grade, and presence of invasive carcinoma), immunohistochemical expression, and KRAS, NRAS, and BRAF mutation status were analysed.
Results: The mean patient age was 62.7 years, with a predominance of women (71%). Histological evaluation revealed high-grade dysplasia in four cases and invasive adenocarcinoma in one patient. The most frequent histological subtypes were biliary and gastric, followed by intestinal and mixed patterns. Immunohistochemically, CK7 was expressed in most cases and associated with MUC1 in the biliary pattern. CK20 and MUC2 were mostly negative except for the mixed gastric/intestinal subtype. CDX2 was expressed in both the mixed and biliary patterns. MUC5AC was positive in gastric-type lesions, and MUC6 was expressed in the biliary and gastric types. Ki-67 index ranged from 3% to 35%. Molecular analysis revealed that two patients harboured KRAS mutations: c.35G>T (p.Gly12Val) and c.35G>A (p.Gly12Asp).
Conclusion: In our series, most cases were associated with high-grade dysplasia, with only one case associated with invasive carcinoma. Unlike in previous reports, the mixed subtype was not predominant, and the immunohistochemical profiles did not correlate well with histological subtypes. The presence of activating KRAS mutations in two cases suggests a potential role of the RAS pathway in ICPN pathogenesis, consistent with findings in other papillary neoplasms of the pancreatobiliary tract.

E-PS-07-042

SMARCB1/INI1-deficient undifferentiated carcinoma of the ampulla of Vater with microsatellite instability: case report of a very rare and aggressive subtype of ampullary carcinoma

F.E. Costa[1,2], G. Carrola[1], B. Machado[1], N.J. Lamas[1,3], J.R. Vizcaíno[1,2]
[1]Unidade Local de Saúde de Santo António, Anatomic Pathology Service, Genetics and Pathology Clinic, Porto, Portugal, [2]University of Porto, Laboratory of Cell Biology, Department of Microscopy, ICBAS-School of Medicine and Biomedical Sciences; UMIB-Unit for Multidisciplinary Research in Biomedicine/ITR-Laboratory for Integrative and Translational Research in Population Health, Porto, Portugal, [3]University of Minho, School of Medicine, Life and Health Sciences Research Institute (ICVS), Braga, Portugal

Background & Objectives: Undifferentiated carcinomas of the gastrointestinal tract are rare, highly aggressive malignant neoplasms, even rarer in the ampullary region. Up to 50% are reported to be SMARCB1/INI1-deficient (SWI/SNF complex subunit), which may or may not have rhabdoid morphology, and these are also frequently associated with microsatellite instability.
Methods: We report the case of a 64-year-old male patient with a twenty-year history of kidney transplant for tubulointerstitial nephritis, with multiple comorbidities. He presented with a cholestatic analytical pattern along with pruritus, abdominal discomfort and nausea. During the diagnostic workup, he developed jaundice, choluria and acholia. Echoendoscopy revealed an ampullo-papillary lesion with dilation of the intrapancreatic common bile duct and the biopsy showed a poorly differentiated/undifferentiated carcinoma.
Results: The pancreatoduodenectomy specimen revealed a 2,5cm, firm, whitish ampullary neoplasm involving both the peri-ampullary and intra-ampullary regions. Histologically, there was a solid proliferation of highly atypical epithelioid cells, with varying amounts of eosinophilic cytoplasm and pleomorphic nuclei with prominent nucleoli. Rhabdoid-like cells were scarcely present. Immunohistochemistry showed reactivity for CAM5.2 and CK7 (multifocal), with absence of SMARCB1/INI1 and preserved expression of SMARCA4. Additionally, there was loss of MLH1 and PMS2 and intact expression of MLH6 and MSH2. This was confirmed by a microsatellite instability-high status by real-time PCR on the Idylla™ platform. Next-Generation Sequencing (NGS) using Oncomine Precision Assay (OPA) panel identified TP53 and GNAS pathogenic variants. The final diagnosis was SMARCB1/INI1-deficient undifferentiated carcinoma of the ampulla of Vater with microsatellite instability. The patient is currently under chemotherapy treatment, four months after initial presentation.
Conclusion: This case illustrates an extremely rare location of SMARCB1/INI1-deficient undifferentiated carcinoma in the gastrointestinal tract. Although it is postulated that loss of one of SWI/SNF complex subunits probably contributes to the arrest of cellular differentiation and consequent aggressive clinical behaviour, further research is needed in order to unravel effective therapeutic approaches.

E-PS-07-043

Clinicopathological perspectives of liver mass biopsies: single centre experience of 406 cases

Ö. Atmış[1], H.S. Mavili[1], F.S. Pehlivan[1], A.B. Ağaoğlu[2], A.P. Erdoğan[2], M. Faraşat[3], S. Ayhan[1]
[1]Manisa Celal Bayar University, Pathology, Manisa, Turkey, [2]Manisa Celal Bayar University, Medical Oncology, Manisa, Turkey, [3]Manisa Celal Bayar University, Radiology, Manisa, Turkey

Background & Objectives: The increasing use of imaging techniques has led to a rise in the detection of liver masses, making the accurate diagnosis of their nature crucial. While advances in radiology have reduced the need for liver biopsy in hepatocellular carcinoma (HCC), biopsy remains essential for diagnosing various liver lesions, including metastatic tumours. This study aims to evaluate diagnostic role of liver core needle biopsies, with a particular focus on identifying the primary tumour in cases of 9 liver metastases with an unknown primary.
Methods: A total of 406 liver core needle biopsies performed between 2017 and 2022 due to liver masses were reviewed. Clinical, radiological, histopathological and immunohistochemical data for primary and metastatic tumours were evaluated.
Results: Of the 406 liver biopsy cases, a significant portion were diagnosed as metastatic lesions, with common primary sites identified as gastrointestinal, lung, and breast cancers. Immunohistochemical markers showed varying positivity rates across different tumour types, with GATA-3, CDX2, and TTF1 proving particularly useful in distinguishing tumour origin. While some markers were highly specific, others exhibited variable expression, highlighting complexity of diagnosing metastatic tumours with unknown primaries.

Conclusion: Liver biopsy remains a crucial diagnostic tool in the identification of primary and metastatic liver tumours, especially when the primary site is unknown. Immunohistochemical analysis enhances the accuracy of diagnosis, though it should be used in conjunction with clinical and radiological data. This study underscores the importance of a multidisciplinary approach in managing liver masses, with further research needed to optimize diagnostic strategies and improve patient outcomes.

E-PS-07-044

Prognostic value of CD56 in extrahepatic biliary atresia: a retrospective analysis

J. Santos[1], M. Pinho Fialho[1,2], A. Gradil[1], L. Branquinho Ruivo[1,2], C. Ferreira[1], R. Moiteiro da Cruz[1,3,4]
[1]Unidade Local de Saúde de Santa Maria, Lisbon, Portugal, [2]ESTsEL, Lisbon, Portugal, [3]GIMM, Lisbon, Portugal, [4]Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal

Background & Objectives: Biliary atresia (BA) is a progressive fibrosing obstructive paediatric cholangiopathy that causes liver failure. Recent data suggests that CD56 expression may be associated with a worse prognosis in BA. We aimed to evaluate the clinicopathological features of our population, as well as the CD56 expression in ductular reaction of our specimens.
Methods: Our series included all patients with histological confirmation of BA in our department between 2003 and 2024. Clinical information was collected, and all histological findings were reviewed including biliary duct ratio, presence of ductular reaction, duct lesion type, amyloid deposits, presence of inflammation and immunohistochemical expression of CK7 and CD56.
Results: All patients had extrahepatic bile duct BA and 11 cases were included, with a mean diagnostic age of 68 days (σ =27.25), of which 73% were female (n=8) and 27% were male (n=3). Nine per cent (n=1) had died during gestation. Ninety-one percent (n=10) underwent Kasai portoenterostomy followed by liver transplantation. Approximately 36% (n=4) patients had histologically confirmed cirrhosis, 18% (n=2) had amyloid deposits, 91% (n=10) had mixed lobular and portal inflammatory infiltrate, 64% (n=7) had cholestasis and 91% (n=10) had ductular reaction. Fifty-four percent (n=6) of the cases were immunoreactive for CD56, all of them had fibrosis (grades 3-4) and ductal plate malformation. Forty-six percent (n=5) were CD56 negative, of which none had ductal plate malformation.
Conclusion: In our case series, CD56 immunoreactivity was associated with more severe histological features of BA, suggesting a potential role for CD56 as a marker for disease severity.

E-PS-07-045

Expression of some stem cell markers in hepatocellular carcinomas in correlation with clinco-pathological parameters and prognosis

A. Shalaby[1], H. Hany[2], M. Mohammed[2]
[1]SQU, Pathology, Muscat, Oman, [2]Mansoura University, Pathology, Mansoura, Egypt

Background & Objectives: Recently, cancer stem cells (CSCs) have been under focus as one of the determining factors which contribute to intra-tumour heterogeneity. *Cluster of differentiation* (CD) 133 and epithelial cell adhesive molecule (EpCAM) are frequently used markers for identification of CSCs in hepatocellular carcinoma (HCC). This study aimed to assess the relationship between the expression of these two markers in HCC and clinicopathological as well as histopathological parameters. Also, it aimed to evaluate the relation between the expression of these markers and the prognosis of the studied cases.
Methods: The study was conducted on 100 cases of HCC selected randomly from the surgical pathology laboratory at the Gastroenterology Centre, Mansoura University, Mansoura, Egypt, during the period from 2011 to 2014. Seven of these cases showed lost clinical follow-up. Immunohistochemical staining of CD133 and EpCAM for all studied cases was carried out.
Results: The relations between CD133 expression in HCC and the clinicopathological findings of patients revealed high CD133 expression in cases aged above 60 year (p=0.035) and in low grade HCC than high grade (p=0.031). There were no significant relations between EpCAM expression in HCC and the studied clinicopathological findings. Patients with positive CD133 and EpCAM expressions had better overall survival (OS) than those with negative expression (p=0.001 and p=*0.004,* respectively. There was no significant difference between CD133 expression in the disease survival rate (DSR) (p=0.350). Patients with positive EpCAM expression showed a better DSR than those with negative expression (p=0.001).
Conclusion: Immunohistochemical expression of CSC markers can be detected in cells that do not show stemness genes up regulation leading to false over expression of these markers.Also, variables in immunohistochemical staining technique and interpretation as the antibody used and the scoring system can cause wide variability in the obtained results.

Weakly supervised deep learning for worst pattern of infiltration assessment in oral squamous cell carcinoma

C. Dovin[1], V. Lacheretz-Szablewski[1], G. Galisot[2], A. Trinquet[1], V. Costes-Martineau[1], V. Racine[2]
[1]University Hospital of Montpellier, Montpellier, France, [2]Quantacell, Montpellier, France

Background & Objectives: The worst pattern of invasion (WPOI) is recognized as a prognostic factor in oral squamous cell carcinoma. Alongside other prognostic factors, its use could be valuable in guiding treatment decisions, particularly in low-stage cases. However, its assessment by pathologists sometimes shows moderate reproducibility. In this context, we developed an algorithm to determine WPOI based on histology slides.
Methods: A total of 173 anonymized digital slides of low-stage (T1, T2) oral squamous cell carcinoma were used to develop different classifiers for WPOI assessment through multiple approaches. The WPOI of these tumours was independently evaluated by two expert head and neck pathologists. The five WPOI classes were grouped into two categories: low-grade (combining grades 1, 2, and 3) and high-grade (combining grades 4 and 5). A deep-learning algorithm was trained to segment tumour areas and generate tumour masks reflecting the tumour shape. First, geometry-based features were extracted from the tumour masks and used to train a classifier with conventional machine learning methods (random forests, support vector machines). Secondly, a deep-learning pipeline incorporating the CLAM workflow was applied for feature extraction and classification. To optimize the results, analyses were conducted using various patch sizes, magnification levels, and different input configurations, including tumour masks, whole slides, or a combination of both.
Results: After testing various deep learning approaches using the CLAM workflow, the best method relied solely on tumour masks at a magnification of 2.5x. This approach achieved an accuracy of 80.2%. Without deep learning, we attained an accuracy of 75.6% using a linear support vector machine.
Conclusion: These results are promising, although the high proportion of low-grade cases (70%) in our dataset should be considered when interpreting them. This algorithm will enable us to improve WPOI assessment and could be further enhanced by incorporating additional prognostic factors.

E-PS-08-002

Algorithm-assisted evaluation improves consistency in mitotic counts, Ki-67 scoring, and grading in gastroenteropancreatic neuroendocrine neoplasms: a comparative study

M. Dogan Ayan[1], O. Yalcin[1], C. Comunoglu[1], R.S. Atamanalp[1], G. Solmaz Yılmaz[2], I. Sonmez[2], S. Cayir[2], B. Uzel[2]
[1]TC Saglik Bilimleri University Prof. Dr. Cemil Tascioglu City Hospital, Department of Pathology, Istanbul, Turkey, [2]Virasoft Corporation, New York, USA

Background & Objectives: Grading of gastroenteropancreatic neuroendocrine tumours (GEP-NETs) is based on mitotic count and Ki-67 scoring. Inter-observer variability between pathologists affects one third of cases. Therefore we evaluated whether integrating Virasoft's Ki-67 and mitotic count algorithms into the workflow of pathology residents improves diagnostic consistency and accuracy compared to manual assessment.
Methods: Ground truth (GT) mitotic, Ki-67 counts ang grade were established by 2 senior pathologists. Two pathology residents independently scored mitotic and Ki-67 counts, and grading on 42 WSIs of consecutive NET cases, both manually and with algorithm support. Manual and algorithm-assisted scores were compared with GT using paired t-tests, Pearson correlation coefficients, and Cohen's kappa values.
Results: Mean mitotic count by algorithm and GT were 0.83±1.83 and 0.54±1.41, respectively (p=0.063;Pearson r=0.847). Mean Ki-67 scores by algorithm and GT were 4.0 ± 6.8 and 3.7 ± 6.3, respectively (p=0.058; Pearson r=0.976). The mean manual mitotic counts of the residents were significantly lower than the GT: (Resident 1[R1]:0.29 ±0.81,p=0.023;Resident 2[R2]:0,29±0,93;p=0.04. Algorithm assistance eliminated these discrepancies (0.76±1.92,0.41±1.14,p>0.05). Mean Ki-67 scores of R1 were similar to GT, however R2's scores remained different from GT with some improvements (2.71±5.31,and 3.27± 6.15,p<0.05). NET grading accuracy improved with algorithm assistance, reducing errors for R1 (3 to 1) and R2 (5 to 3) (R1 manual κ=0.81, algorithm-assisted κ=0.86; R2 manual κ=0.75, algorithm-assisted κ=0.85).
Conclusion: The integration of algorithms improved the accuracy and consistency of mitotic count and GEP-NET grading among pathology residents. The role of algorithm support was limited in Ki-67 scoring in this study. Further studies with expanded cohorts and additional residents are needed.

E-PS-08-003

Enhancing diagnostic accuracy for cutaneous drug eruptions: a deep learning approach using whole-slide imaging

A. Türkmen Dedeoğlu[1], G. Fikir[1], H. Yanik[2], E. Değirmenci[3], Ü. Türsen[4], Y. Yuyucu Karabulut[1]
[1]Mersin University, Pathology, Mersin, Turkey, [2]Mersin University Erdemli School of Applied Technology and Business Administration, Department of Information Systems and Technologies, Mersin, Turkey, [3]Mersin University Faculty of Engineering, Electrical and Electronics Engineering, Mersin, Turkey, [4]Mersin University, Dermathology, Mersin, Turkey

Background & Objectives: Cutaneous drug eruptions represent 1-2% of outpatient dermatology consultations and 5-10% of inpatient dermatological cases worldwide. These reactions exhibit a broad spectrum of clinical and histopathological features, from mild maculopapular rashes to severe, life-threatening conditions like Stevens-Johnson syndrome and toxic epidermal necrolysis. This study aims to evaluate the performance of deep learning algorithms in improving diagnostic accuracy for drug eruptions across diverse patient populations.
Methods: A retrospective analysis was conducted using archived cases diagnosed as drug eruptions in a pathology department between 2014–2024. A control group comprised histologically normal skin tissues from reduction mammoplasty procedures. All slides were digitized using a slide scanner. The patient and control group images were analysed with Vision Transformers (ViTs), specifically the ViT-Large/16 architecture, which utilized pre-trained weights from IMAGENET1K_SWAG_E2E_V1. The model's diagnostic accuracy rates were systematically recorded and compared between the two groups.
Results: The Vision Transformer model achieved a training accuracy of 88.92% (loss: 0.407) and a test accuracy of 86.00% (loss: 0.4801), demonstrating robust performance in classifying biopsy images as normal or abnormal. The study highlights ViTs' effectiveness in analysing subtle histopathological patterns, supported by extensive experimental evaluations. Results indicate that transformer-based architectures may hold advantages over conventional deep learning models for medical image classification tasks, particularly in early detection scenarios requiring high precision.
Conclusion: Deep learning models like Vision Transformers offer a promising tool for improving the detection of cutaneous drug eruptions, which remain diagnostically challenging due to their variable presentations. By enhancing accuracy and enabling personalized risk stratification, these algorithms could support clinical decision-making. The study underscores the importance of standardized AI implementation frameworks that prioritize ethical considerations, algorithmic transparency, and equitable performance across diverse demographic groups to ensure reliability in real-world settings.

E-PS-08-004

Evaluating Large Language Models (LLMs) as a screening tool in breast biopsy diagnosis: a feasibility study

F. Soares Nogueira[1], L. Rodrigues[2], A. Félix[2,3], D. Gomes Pinto[1,2]
[1]ULS Almada-Seixal - Hospital Garcia de Orta, Almada, Portugal, [2]Faculdade de Ciências Médicas da Universidade Nova de Lisboa, Lisboa, Portugal, [3]Instituto Português de Oncologia Francisco Gentil de Lisboa, Lisboa, Portugal

Background & Objectives: Workloads in pathology have been increasing in volume and complexity. Advances in artificial intelligence (AI) promise increased productivity; adoption remains the exception, however. We investigated the performance of generative algorithms in breast biopsies, using different prompting strategies and retrieval augmented diagnosis (RAG), assessing their potential as screening tools for preliminary review, report pre-filling, and immunohistochemistry (IHC) recommendations.
Methods: Representative images of lesions were extracted from breast biopsies gathered from our archive and fed to GPT4o and o1 large language models (LLMs), alongside clinical information. Two different prompts were tested with each model: a short one, defining only the task – breast biopsy diagnosis – and a longer one detailing common differentials and a diagnostic approach. Each model and prompt were tested with and without RAG.
Results: Our series consisted of 65 cases, all female (ages 18-95). Twenty-three were benign and 42 malignant. Overall diagnostic accuracy varied between 35.38% and 53.85%. For the detection of malignancy, however, this value increased to 73.21-81.54%. Differences between runs did not show statistical significance. The best performing combination was GPT4o with the longer prompt, achieving a sensitivity of 83.33%, a specificity of 78.26%, a PPV of 87.50% and a NPV of 72.00% for the detection of malignancy. IHC studies for oestrogen, progesterone, HER2 and Ki67 were correctly ordered in between 67.69% and 83.07% of cases; when these were ordered, however, they were done so correctly in 92.68-95.07% of cases.

Conclusion: Our results highlight the potential of LLM use in breast biopsy screening and first look. Although the algorithms failed to identify lesions correctly in a significant proportion of cases, they showed good sensitivity and specificity in identifying malignancy and proved accurate in the ordering of additional IHC studies. Therefore, even with current limitations, productivity gains may be possible through screening prior to pathologist evaluation.

E-PS-08-005

Validation of a novel artificial intelligence-based tool for Ki-67 quantification in breast cancer: enhanced accuracy, reproducibility, and efficiency in resource-limited setting

A.P. Nellihela[1], R.M.N.D. Rathnayake[2], N.J. Asanthi[3], V.C. Bandaranayake[1], A. Ramanan[2], K. Thanikasalam[2], M. Senarathna[4]
[1]Teaching Hospital Anuradhapura, Department of Surgical Oncology, Anuradhapura, Sri Lanka, [2]University of Jaffna, Department of Computer Science, Jaffna, Sri Lanka, [3]Teaching Hospital Anuradhapura, Department of Histopathology, Anuradhapura, Sri Lanka, [4]University of Peradeniya, Postgraduate Institute of Science, Kandy, Sri Lanka

Background & Objectives: Ki-67 is an important proliferation marker in guiding breast cancer treatment. International Ki-67 Working Group (IKWG) recommends hot-spot, and the Global Scoring (GS) methods to quantify Ki-67 and levels are categorized as low (<5%), intermediate (6–29%), and high(>30%). These manual methods are time-consuming and prone to inter-observer variability and potential sampling bias based on selected microscopic fields.
This study aimed to validate a novel Artificial Intelligence (AI)-based tool, evaluating its accuracy and efficiency compared to manual scoring. The AI tool captures digital images of the entire Ki-67-immunohistochemistry-stained slide in the high-power microscopic field in real-time and automatically calculates the Ki-67 index.
Methods: An AI model was developed using EfficientNetV2 architecture, incorporating distance transformation and watershed algorithms for precise cell segmentation. The model was trained on 350 digital images annotated by pathologists and validated with an additional 350 images. Twenty Ki-67-stained slides from three distinct histopathology units in Sri Lanka were used to minimise variations in slide preparations. AI-derived Ki-67 indices were compared with blinded manual scores by three pathologists using Hot Spot and Global Scoring (GS) methods. Agreement was analysed using Intraclass Correlation Coefficient (ICC) and Bland-Altman plots. Assessment efficiency was compared by measuring evaluation time.
Results: The AI model showed 94.3% accuracy in cell-to-cell identification against pathologist annotations. ICC analysis indicated excellent reproducibility between AI and manual methods for Hot Spot (ICC=0.946, 95% CI:0.672–0.984) and Global Scoring (GS) method(ICC=0.963, 95% CI:0.879–0.987). Bland-Altman analysis confirmed strong agreement without significant systematic bias. The AI method significantly reduced evaluation time (seconds) compared to manual scoring by pathologists (Hot Spot: AI mean=25.5s, Pathologists mean=152.2s, $p<0.01$,t=-7.38; GS:AI mean=250.8s, Pathologist mean=455.1s, $p<0.01$, t=-6.96).
Conclusion: The AI-based tool offers accurate, reproducible, and significantly more efficient Ki-67 quantification, representing a reliable, standardised alternative to manual methods. The AI tool eases workload and reduces diagnostic turnaround times in resource-limited settings. Limitations include dependence on digital microscopy and high-quality slide preparation.

E-PS-08-006

Web application for the automatic segmentation and comprehensive morphometric analysis of arterial cross-sections

K. Spirgath[1], M. Kraftberger[1,2], T. Haase[3], R. Bandelin[3], N. Jaitner[3], T. Meyer[3], H. Tzschätzsch[1]
[1]Charité – Universitätsmedizin Berlin, Institute of Medical Informatics, Berlin, Germany, [2]Universität Potsdam, Institute of Biochemistry and Biology, Potsdam, Germany, [3]Charité – Universitätsmedizin Berlin, Department of Radiology, Berlin, Germany

Background & Objectives: Endovascular therapies using balloon catheters and stents are first line treatments of arterial occlusive diseases. In preclinical research, animal models are commonly used to study disease progression and therapeutic interventions. Morphometric analysis of histological cross-sections of stented arteries is an essential tool for these studies. However, manual measurements are subjective and time-consuming (10–15 minutes per cross-section). This study aimed to develop an automated, operator-independent system for comprehensive morphometric analysis to enhance efficiency and accuracy in large-scale data processing.
Methods: A deep learning-based segmentation system was developed to automatically identify arterial structures, including the lumen, internal elastic lamina, external elastic lamina, stent strut voids in histological cross-sections and further quantitative values to characterize the tissue. The neural network architecture nnU-Net v2 was trained and evaluated using a dataset of 820 images annotated by expert histologists. The model's performance was assessed using Dice coefficient, Hausdorff distance, and average surface distance metrics. Additionally, the program was integrated in a web application for free and easy usability for researchers worldwide.
Results: The model achieved a Dice coefficient between 0.892 and 0.996, a median Hausdorff distance between 35 and 104 µm, and a median average surface distance between 4.1 and 10.2 µm. Comparable values were observed for our inter-observer study and therefore demonstrate the excellent system's reliability. The integration of additional features, such as a fibrin quantification and inter-stent distance measurement, further improved the tool's applicability to specific medical research questions.
Conclusion: The developed automatic system enables accurate and efficient morphometric analysis of arterial cross-sections, reducing the processing time to approximately 20 seconds per section. This significantly improves the assessment of disease and therapy progression in preclinical models. The system's scalability allows for future adaptations to additional research applications, supporting further advancements in vascular pathology.

E-PS-08-008

Comparative analysis of ChatGPT models in describing the same histopathology slide

A. Alotaibi[1], Q. Salman[1]
[1]Jordan University of Science and Technology, Pathology, Irbid, Jordan

Background & Objectives: Accurate interpretation of histopathological images is essential in diagnostic pathology. With the rise of AI-based tools like ChatGPT, there is growing interest in evaluating their potential role in medical image description. This study aims to compare the descriptive capabilities of different ChatGPT models when presented with the same histological image of normal brain tissue.
Methods: Five versions of the ChatGPT model (GPT-4, GPT-4o, GPT-3 mini, GPT-3 mini-High, and GPT-4o mini) were presented with the same histopathology slide depicting the normal hippocampus, sourced from the University of Utah WebPath database (https://webpath.med.utah.edu/HISTHTML/NORMAL/NORM058.html). Each model was prompted with two questions:
1) "Describe what you see here" and
2) "From where was this biopsy taken?"
Their responses were analysed in terms of accuracy, anatomical specificity, descriptive detail, and consistency
Results: The models varied in the level of detail and specificity provided. GPT-4o consistently produced the most comprehensive

descriptions, accurately identifying neuronal structures and referencing the cerebral cortex or hippocampus as the likely biopsy site. Earlier or smaller models (such as GPT-3 mini and GPT-4o mini) provided more generalized descriptions, focusing on cellular morphology but with less precise anatomical localization. All models correctly identified the tissue as brain matter but differed in depth and terminology.
Conclusion: This comparative analysis demonstrates the variability in descriptive capabilities among different ChatGPT models when interpreting a standard histopathology image. While newer models like GPT-4o offer enhanced detail and specificity, standardization and further refinement are needed before widespread implementation in pathology practice. This study highlights the potential of AI tools as supplementary aids in histopathological education and diagnostics.

E-PS-08-009
Label- and compute-efficient learning for WSI segmentation: a comparative study of supervised, semi-supervised and self-supervised learning
H. Ji[1], M. Yook[2], J. Seo[2], S. Yoon[2], S. Hong[2], C.K. Jung[3], I. Choi[2]
[1]The Catholic University of Korea, Dept. of Precision Medicine and Big Data, College of Medicine, Seoul, Republic of Korea, [2]The Catholic University of Korea, Dept. of Medical Informatics, College of Medicine, Seoul, Republic of Korea, [3]The Catholic University of Korea, Dept. of Hospital Pathology, College of Medicine, Seoul, Republic of Korea

Background & Objectives: Whole Slide Images (WSIs) are essential in computational pathology, enabling detailed and high-resolution analysis of tissue structures. However, developing deep learning models for WSI segmentation typically requires extensive pixel-level annotations, which are labor-intensive and costly.
In addition, real-world applications often face challenges such as limited computational resources, long training times, and large-scale data, making scalable and efficient learning essential.
This study systematically compares supervised, semi-supervised, and self-supervised learning approaches for WSI segmentation. We aim to identify strategies balancing segmentation performance with annotation efficiency and computational cost, considering variations in backbone architecture and annotation ratio.
Methods: Tumour segmentation was performed on breast cancer WSIs from the CAMELYON dataset. To improve efficiency, we applied downsampling and ROI-based patch extraction to focus on informative regions.
We adopted widely used backbone models in computational pathology, including ResNet-18, ResNet-50, and Swin Transformer. Supervised models were trained using full annotations, while semi-supervised models used 5% to 50% of labeled data. Self-supervised models were pretrained with SimCLR and fine-tuned with limited annotations.
Segmentation performance was evaluated using Dice Score, mIoU, Precision, and Recall. A custom **Efficiency Index** was defined to jointly assess segmentation performance and computational cost:
Efficiency = Dice / (FLOPs × Training Time)
Results: Semi-supervised learning achieved segmentation performance comparable to fully supervised models with reduced annotations. Self-supervised learning also showed promising performance without annotations, albeit with higher computational costs.
Experiments demonstrated trade-offs between segmentation accuracy and computational efficiency depending on backbone and annotation ratio.
Conclusion: Our findings indicate that semi- and self-supervised learning can serve as practical and label-efficient alternatives to fully supervised learning for WSI-based cancer analysis in computational pathology. These approaches provide a promising direction for scalable and resource-aware AI systems in clinical settings.

Funding: This research was supported by a grant from the Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health & Welfare, Republic of Korea (grant number: RS-2021-KH113146)

E-PS-08-010
Diagnostic utility of image-based deep learning in the histopathological evaluation of prostatic lesions
A. Qureshi[1], A. Karuppasamy[2], A. Alsulaimani[3]
[1]Sultan Qaboos University, Pathology, Muscat, Oman, [2]Gulf College Oman, Department of Computing Sciences, Muscat, Oman, [3]Oman Medical Speciality Board, Pathology, Muscat, Oman

Background & Objectives: Prostate cancer remains a significant global health concern for men, including in Oman. In 2020, it was ranked among the top 10 most prevalent cancers affecting Omani men, accounting for 3.5% of all male cancer cases. The incidence rate of prostate cancer in Oman was estimated at approximately 8.3 per 100,000 individuals. With the growing advancements in artificial intelligence (AI), deep learning techniques have gained widespread attention in computer vision applications, particularly in medical imaging analysis. This study investigates various AI methodologies for the classification of prostate cancer histopathology images.
Methods: This research utilized a prostate cancer histopathological image dataset which comprised a total of 55 images, including 27 benign and 28 malignant tumour samples. The dataset contained cases of prostate adenocarcinoma as well as negative cancer cases. Each image was captured at a magnification of 40x with a resolution of 1360 x 1024 pixels. To facilitate deep learning model processing, all images were resized to 224 x 224 pixels. The dataset was divided into training and testing sets, with 70% (38 images) used for training and 30% (17 images) for testing. The models were evaluated based on key performance metrics, including accuracy, precision, recall, F1-score, and Area Under the Curve (AUC), which assesses the model's ability to distinguish between malignant and benign cases.
Results: Traditional machine learning techniques were applied to the SQUH dataset. Among them, the Support Vector Machine (SVM) demonstrated the highest performance, achieving an accuracy of 82.35%. Deep learning models, particularly those leveraging transfer learning, exhibited superior classification performance compared to traditional models such as SVM and Random Forest.
Conclusion: Our findings highlight the effectiveness of deep learning models in accurately identifying and classifying prostate cancer tumours. These models, once fully optimized, have the potential to assist pathologists in improving diagnostic precision and patient outcomes.

E-PS-08-011
Comparison of manual IHC and brightfield dual ISH HER-2 status results with automatic AI-based HER-2 membrane analysis and semi-automatic dual ISH detection application in gastric adenocarcinoma cases
N. Bakoglu Malinowski[1], S. Yilmaz Erozbek[1], A. Cakir[1], Y. Yagi[2]
[1]Istanbul Medipol University, Faculty of Medicine, Pathology, Istanbul, Turkey, [2]Memorial Sloan Kettering Cancer Centre, Pathology and Laboratory Medicine, New York, USA

Background & Objectives: HER-2 testing is recommended for patients with inoperable, locally advanced, recurrent, or metastatic gastric adenocarcinoma to determine eligibility for trastuzumab therapy. HER-2 status is evaluated based on a membranous stain scoring from 0 to 3+ for Immunohistochemistry (IHC) and counting HER-2 and CEP17 signals in at least 20 tumour cells for Brightfield Dual In-Situ Hybridisation (ISH). Reporting HER-2 status is time-consuming

and subject to interobserver variability. Artificial intelligence-based applications help pathologists achieve objectivity and rapid reporting. Our study aimed to introduce HER-2 automated assessment into our routine for adenocarcinoma cases.
Methods: Tweny six cases of gastric adenocarcinoma with HER-2 IHC and Dual ISH results were selected for this study. All glass slides were scanned with NanoZoomer S360 (Hamamatsu Photonics K.K Shizuoka, Japan) at ×40 magnification. Cases were visualized on Virasoft Image Viewer (Virasoft Corporation, USA). HER-2 IHC analysis was performed with the Virasight algorithm, and Dual ISH slides were analysed with AI-based application (Shimaris, in-house application, MSKCC, USA) previously evaluated for breast cancer specimens.[1],[2] Automated analyses were performed using specific Region of Interests (ROI) selected by pathologists based on hotspots.
[1] Journal of Medical Imaging 6.4 (2019): 047501-047501
[2] LABORATORY INVESTIGATION (Vol. 104, No. 3, pp. S115-S117)
Results: The results of automatic IHC, ISH and ASCO/CAP ISH Group classification were in agreement with the manual results in 88.4% (23/26), 82.6% (19/23) and 79% (17/23), respectively. Discordant cases were observed in heterogeneous and borderline tumours. We could not obtain automatic ISH results from 3 cases due to out-of-focus scans, faint ISH staining and small tumour areas.
Conclusion: To our knowledge, this is the first study to explore methods for providing an automated HER2 status based on both IHC and Dual ISH results simultaneously in gastric adenocarcinoma patients. Our next step is to work on other systems, such as gynecology, and to involve more pathologists.

E-PS-08-013
Incorporation of digital pathology in daily practice; Qualitative findings and perceptions from pathologists and technicians

Background & Objectives: Digital Pathology (DP) is revolutionizing diagnostics by enabling remote access, efficient slide storage, AI-driven image analysis, and enhanced collaboration and research. This study explores DP's qualitative impact on workflows, logistics, and the perspectives of pathologists and technicians in eight major European laboratories in EU4+UK, while addressing implementation challenges.
Methods: The study employed a targeted literature review, semi-structured interviews, and surveys to evaluate DP's impact on workflows and the perceptions of pathologists and technicians regarding changes in their current and future practices.
Results: A total of 45 pathologists and 47 technicians participated in the surveys. Respondents reported significant benefits of DP, including improved workflow, logistics, and laboratory organization. Among them, 34 pathologists and 29 technicians noted "an important positive impact" on workflows, while 36 pathologists expressed that DP had "an important positive impact" on patient case examination. Adaptation was smooth, with 35 pathologists and 28 technicians finding the DP learning curve "not difficult".
DP strengthened multidisciplinary collaboration, training, research, teaching, and remote work. DP-enabled labs were more attractive to pathologists, addressing staffing issues with temporary remote support and flexible work arrangements. Despite occasional challenges in visualizing details like depth perception, pathologists were generally satisfied, as these issues rarely affected diagnoses. Technicians observed shifts in responsibilities, with automation (e.g., data entry, slide triaging) improving efficiency.
Although Computational Pathology (CP) tools were not routinely used, there was strong interest among pathologists. Adoption was hindered by high costs, limited reimbursement, and the need for algorithm validation. In most CP-enabled labs, funding came through grants or vendor partnerships, raising concerns about long-term sustainability.
Conclusion: DP has a transformative impact on workflows and staff perceptions, with minimal adaptation challenges. However, to maximize its benefits, DP implementation must be supported by optimized laboratory processes. Financial constraints remain a major obstacle to its widespread and sustainable adoption.

Funding: This study was funded by AstraZeneca

E-PS-08-014
Stain normalization without information loss or delay
K. Moens[1,2], J. De Vylder[1], T. Tuytelaars[2], M. Blaschko[2]
[1]Barco NV, Kortrijk, Belgium, [2]KU Leuven, Electrical Engineering, PSI, Leuven, Belgium

Background & Objectives: Digital pathology is rapidly advancing, paving the way for AI-assisted diagnostics. Slide stain normalization, an AI-based preprocessing step, ensures consistent performance across institutions but can be confusing. However, given the large data size in pathology the processing speed of AI remains challenging, potentially disrupting workflow throughput.
AI operates by generalizing from training data. This generalization poses a risk, as the patterns learned from common data may not capture the nuances of rare cases, leading to information loss. When AI models attempt to fill these gaps, hallucinations can occur. In pathology, where precise details are crucial, such hallucinations can have serious consequences.
Methods: The proposed model is restricted to a colour mapping with only a few layers to prevent overwriting structures and to preserve all details in the normalized output. During training, an adversarial approach is utilized. A critic is trained in parallel and rates the realism of the normalized outputs. This critic, unlike the actual normalization model, is unrestricted and optimizes the normalized images to match the characteristics of a target set of images.
Results: The results of the method were compared using the public Mitos & Atypia 14 dataset with related deep learning methods, StainNet and StainGAN. The results demonstrated comparable resemblance

to the target set while surpassing the other methods in terms of structure preservation, showing minimal loss. Additionally, on average, StainGAN takes 129 seconds to preprocess a whole slide image (WSI) on an NVIDIA RTX 4090. In contrast, this method completes the same task in 3.8 seconds, allowing ample time for subsequent AI analysis.
Conclusion: The proposed method effectively balances the need for detailed structure preservation with the efficiency required for practical use in digital pathology. By significantly reducing preprocessing time without compromising on quality, it offers a viable solution for integrating into routine AI supported diagnostic workflows.

MammaPrint prediction from haematoxylin-eosin whole-slide images: preliminary interpretability analysis
I. Carretero-Barrio[1,2,3], J. Martínez-Aedo[4], A.D. Ramos-Guerra[4,5], J.E. Ortuño[4,5], C. Ariño-Palao[6,3], B. Pérez-Mies[1,2,3], M.J. Ledesma[4,5], J. Palacios[1,3,2]
[1]Hospital Universitario Ramón y Cajal, Servicio de Anatomía Patológica, Madrid, Spain, [2]Centre for Biomedical Research in Cancer Networks, Madrid, Spain, [3]Universidad de Alcalá, Facultad de Medicina, Madrid, Spain, [4]Universidad Politécnica de Madrid, Biomedical Image Technologies, ETSI Telecomunicación, Madrid, Spain, [5]CIBER-BBN, Madrid, Spain, [6]Hospital Universitario Severo Ochoa, Pathology, Madrid, Spain

Background & Objectives: Artificial intelligence (AI) models from H&E-stained whole-slide images (WSIs) often lack interpretability. We have implemented an attention-based AI algorithm that achieves strong performance (n=380 WSI, AUC=0.86), but its decision-making process remains unclear. This study evaluates attention heatmaps in a subset of correctly classified cases to identify histologic features influencing predictions.
Methods: Using an attention-based multiple instance-learning model (CLAM), we predicted MammaPrint risk (high vs. low risk) in early-stage breast cancer WSIs. Attention heatmaps were generated by colour-coding patches (red: high attention, blue: low attention). We assessed attention distribution across tumour epithelium, stroma, tumour-infiltrating lymphocytes (TILs), normal epithelium, and in situ carcinoma. Differences between MammaPrint risk groups were analysed using Chi-squared/Fisher's exact tests.
Results: We assessed 60 cases (20 high-risk, 40 low-risk) that were correctly classified by the model. Normal epithelium showed significantly higher attention in low-risk cases ($p<0.005$), while in situ carcinoma trended toward significance ($p=0.066$). Tumour epithelium and TILs consistently received high attention, irrespective of risk category. Stroma showed no differential attention.
Conclusion: The model's attention primarily focused on tumour epithelium and TILs in all cases, suggesting that these features drive predictions universally. Normal epithelium, however, was more attended to in low-risk cases, hinting at a potential discriminator. These preliminary findings reveal limited interpretability for MammaPrint prediction, warranting further analysis in additional cases to elucidate underlying patterns.

Funding: Supported by Instituto de Salud Carlos III (ISCIII) through the projects "PI22/01892" and "PMP22/00054", by CIBERONC (grant CB16/12/00316), by the European Development Regional Fund "A way to achieve Europe" (FEDER)

Automated nuclear grading of breast cancer based on the analysis of selected areas of histological slides (ROI) using AI
A. Semenova[1], V. Shatalov[1], V. Galkin[2], Y. Vishnevskaya[1], O. Isaeva[1], A. Artemyeva[3], V. Pirogova[4], D. Voronkina[5], N. Tyorov[6], L. Popyvanov[7], M. Goldin[8]
[1]State Budgetary Healthcare Institution "Moscow City Hospital named after S.S. Yudin, Moscow Healthcare Department", Pathology, Moscow, Russia, [2]State Budgetary Healthcare Institution "Moscow City Hospital named after S.S. Yudin, Moscow Healthcare Department", Oncology, Moscow, Russia, [3]OneCell, Medical Director, Saint Petersburg, Russia, [4]OneCell, Product Director, Saint Petersburg, Russia, [5]OneCell, Data Engineer, Saint Petersburg, Russia, [6]OneCell, AI Product Manager, Saint Petersburg, Russia, [7]OneCell, Senior ML Engineer, Bioinformatics Physician, Moscow, Russia, [8]OneCell, Lead ML Engineer, Moscow, Russia

Background & Objectives: Breast cancer is the leading oncological pathology among the female population worldwide and in Russia. A key factor in treatment strategy is the histological NGS grade, that includes tubular, nuclear, and mitotic grades. In routine analysis assessment is time-consuming, often subjective, leading to potential errors. The degree of nuclear atypia is scored (1, 2, 3) based on a combination of factors. As per WHO guidelines, the nuclear grade is determined by the highest score within the analysed tumour sections. Tumour heterogeneity may cause discrepancies in grading by pathologists.
The implementation of digital pathology into routine practice opens up the possibility of using AI in morphological diagnostics.
Methods: The research aimed to develop and validate machine learning algorithms to support medical decision-making in routine breast cancer diagnosis. The main task was to create methods for automated determination of nuclear grade based on AI analysis of extracted regions from histological slides (ROI).
The model is tested on regions annotated by two annotating doctors and a validating doctor, then sent for model inference. The results from the machine learning algorithm are compared with those of the doctors and analysed.
For the "Nuclear Grade" algorithm, the target metrics were: kappa score = 0.4 and mean accuracy = 0.6. Internal evaluation on the test dataset yielded kappa = 0.445 and mean accuracy = 0.67.
Results: The algorithm highlights tumour areas with different levels of nuclear atypia, showing the proportion of each class and calculating the weighted average score (with 1-2 decimal places). This helps the pathologist make more informed decisions and improves the reproducibility of grade assessments within and across studies.
Conclusion: The obtained metrics exceed the target values, that allows to make a preliminary conclusion about the successful implementation of the "Nuclear Grade" machine learning algorithm and the readiness of the ML model for clinical validation.

Deep learning-based diagnostic model for papillary thyroid cancer
A. Qureshi[1], M. Shafiq[2]
[1]Sultan Qaboos University, Pathology, Muscat, Oman, [2]Sultan Qaboos University, Electrical and Computer Engineering • College of Engineering, Muscat, Oman

Background & Objectives: Diagnosing PTC remains a significant clinical challenge, significantly when differentiating malignant lesions with borderline nuclear features. Manual histopathological examination, although a standard practice, is time-consuming and limited by subjective variability and the increasing volume of cases. The need for more accurate, efficient, and scalable diagnostic tools is growing, particularly in regions with a high incidence of PTC, such as Oman. Artificial intelligence (AI), intense learning, offers a promising avenue for improving diagnostic workflows in pathology. This study aims to develop and evaluate a novel deep learning-based neural network model to assist in the classification of malignant and benign thyroid pathology images. The goal is to support pathologists with an automated system that reduces workload, increases

diagnostic precision, and highlights suspicious regions for further review.
Methods: A team at Sultan Qaboos University is developing an automated, deep learning-based system to classify pathology images and assist pathologists in the diagnostic process. This article presents a compact, two-step neural network model trained on a limited dataset that enhances diagnostic efficiency and precision in PTC cases.
Results: The proposed solution is a lightweight (1.3 MB), two-step neural network model trained using a limited dataset from the Sultan Qaboos University pathology lab. In the first step, the model classifies the image as benign or malignant. If classified as benign with fewer than 2% false detections, it is forwarded to the pathologist with highlighted suspicious regions. Otherwise, it is processed by a second model that provides a detailed segmentation of malignancy.
Conclusion: This approach leverages deep learning to enhance diagnostic accuracy while maintaining model efficiency, offering a practical AI-based tool to support pathology workflows in thyroid cancer diagnosis

E-PS-08-019
Development of machine learning algorithms to improve the accuracy of diagnosis of HER2\ - status in breast cancer
A. Semenova[1], V. Galkin[2], Y. Vishnevskaya[1], V. Shatalov[1], Y. Andryukhina[1], A. Artemyeva[3], V. Pirogova[4], D. Voronkina[5], N. Tyorov[6], L. Popyvanov[7], M. Goldin[8], Y. Andreeva[9]
[1]State Budgetary Healthcare Institution "Moscow City Hospital named after S.S. Yudin, Moscow Healthcare Department", Pathology, Moscow, Russia, [2]State Budgetary Healthcare Institution "Moscow City Hospital named after S.S. Yudin, Moscow Healthcare Department", Oncology, Moscow, Russia, [3]OneCell, Medical Director, Saint Petersburg, Russia, [4]OneCell, Product Director, Saint Petersburg, Russia, [5]OneCell, Data Engineer, Data Analyst, Saint Petersburg, Russia, [6]OneCell, AI Product Manager, Saint Petersburg, Russia, [7]OneCell, Senior ML Engineer, Bioinformatics Physician, Moscow, Russia, [8]OneCell, Lead ML Engineer, Moscow, Russia, [9]Federal State Budgetary Educational Institution of Further Professional Education "Russian Medical Academy of Continuous Professional Education", Pathology department, Moscow, Russia

Background & Objectives: Breast cancer is the leading oncological pathology among female population and has the highest share in the 30-59 age group.
The HER2 status determines the possibility of prescribing targeted therapy (trastuzumab, etc.), which is indicated for HER2 protein overexpression (3+) and undefined expression (2+ with amplification confirmed by ISH testing) according to ASCO/CAP 2023 guidelines. However, with the introduction of medications of immunoconjugates type (trastuzumab deruxtecan), the approach to low levels of HER2 expression is changing, therapeutic effect may be achieved at any level of tumour cell membrane staining (except for an "absolute zero").
Methods: The research aimed to develop and validate ML algorithms for supporting breast cancer diagnosis and automating HER2 status determination using AI.
HER2 status analysis uses classification metrics like Precision, Recall, F1, and Accuracy, averaged across classes.
Despite achieving **0.9+ metrics** in studies, testing on real-world data typically results in significantly lower values. Therefore, it is proposed to adopt the following target metrics:
- Precision=0,8;
- Recall=0,8;
- F1=0,8;
- Accuracy=0,75 (Both for each class individually and for all classes as a whole).
The model is tested on regions annotated by two annotating doctors and a validating doctor, then sent for model inference. The results from the machine learning algorithm are compared with those of the doctors and analysed.
Results: During the **internal validation** of the model on a **test dataset of 516 polygons** from **184 whole slides**, the following metrics were obtained:
- Precision=0,9;
- Recall=0,9;
- F1=0,9;
- Accuracy=0,9
Conclusion: The achieved metric values during the testing of "**HER2-grade"** machine learning algorithm meet the target criteria, allowing for a preliminary conclusion on the successful implementation of the **"HER2-grade"** algorithm and the readiness of the ML model for clinical validation.

E-PS-08-020
Foundation model distillation to develop robust and efficient AI models for MSI testing in endometrial cancer
A. Filiot[1], M. Lubrano[1], E. Samuelsson[1], J. Klein[1], A. Lyon[1], C. Wiscart[1], A. Fouillet[1], L. van Praet[1], A. Vinçotte[1], C. Genestie[2], F. Deman[3], L. Cano Ayestas[1], K. Von Loga[1]
[1]Owkin, Paris, France, [2]Gustave Roussy, Department of Pathology, Paris, France, [3]Ziekenhuis aan de stroom (ZAS), Department of Pathology, Antwerp, Belgium

Background & Objectives: AI models for predicting microsatellite instability (MSI) from H&E slides require diverse, multi-centre datasets. This is challenging in cancers with lower MSI prevalence, such as endometrial cancer (EC). While recent foundation models (FM) address data scarcity, they often fail to overcome biases in digital pathology and contribute to high computational costs, limiting clinical applicability.
This study demonstrates that a distilled version of a large foundation model can offer an efficient, robust AI-assisted diagnostic tool for MSI testing in EC.
Methods: We developed AI models to predict MSI status in EC using multi-centre cohorts (2 proprietary, N=239 patients; TCGA, N=478). We compared the performance of a large foundation model ("H0") with a 13x smaller version ("H0-mini").
Results:
- **Performance**: The H0-mini model achieved an AUROC of 0.769 (0.738, 0.760, 0.810) and specificity of 0.497 (0.451, 0.393, 0.648) at 0.9 sensitivity across three left-out cohorts, outperforming H0 by 0.027 (p=0.03) and 0.291 (p<0.001), respectively.
- **Computational cost**: The H0-mini model is 9.1 times faster than H0 on a GPU machine. On standard pathology workstation, processing a WSI takes 15.2 minutes with H0-mini, compared to 120.4 minutes for H0, highlighting the intractability of large FMs without dedicated infrastructure.
- **Robustness**: H0-mini achieved an intra-class correlation of 0.725 (95% CI: 0.651-0.793) between paired resections and biopsies, compared to 0.665 (95% CI: 0.573-0.750) for H0 (p<0.01).

Conclusion: Advanced distillation techniques yield an enhanced, efficient AI model for MSI detection in EC, improving detection capabilities while lowering computational costs. These findings highlight the potential for broader implementation of robust MSI testing in routine clinical practice, aiding streamline diagnosis and targeted therapy in this under-researched cancer population.

E-PS-08-022
A shortcut for detecting collagenic fibres on H&E slides
Y. Chen[1], X. Qiu[1], Q. Lin[1], Y. Yang[1], L. Li[2]
[1]Fujian Medical University Union Hospital, Pathology Department, Fuzhou, China, [2]Fujian Normal University, Key Laboratory of

OptoElectronic Science and Technology for Medicine of Ministry of Education, Fuzhou, China

Background & Objectives: In present state,producing special stains can be rightly thought of as a tedious, labor-intensive, as well as time consuming task.Broad variability such as techniques and formulations has evolved from site to site,and practitioner to practitioner,until the same stain can appear markedly different from one institution to another. While the small nuances of a stain are often a matter of preference and familiarity,they can also be diagnostically significant differentiators.In this study, We tried to find the potential use of a new method in the detection of collagenic fibres which were visualized by special stains.
Methods: Samples were collected,including 20 liver tissues,20 heart tissues,20 lung tissues.Two serial sections (4μm)were cut from each sample by a cryostat microtome. We used multiphoton microscopy (MPM) to label-freely image on one section which was stained with haematoxylin and eosin (H&E). Images were then compared with the corresponding Masson-stained images (prepared from the adjacent section) to confirm experimental results by two experienced histopathologists.
Results: Data showed that multiphoton imaging allows label-free, rapid visualization of collagenic fibres.There were no differences in the detection of collagenic fibres between Masson-stained image and multiphoton image.
Conclusion: Multiphoton imaging would hold a promising future in rapid and label-free detection of collagenic fibres.

E-PS-08-023
Diagnostic accuracy of ChatGPT in thyroid FNA cytology
T. Laohawetwanit[1], S. Agarwal[2], S. Dixit[2], A. Yoshikawa[3], A. Bychkov[3]
[1]Chulabhorn International College of Medicine, Thammasat University, Division of Pathology, Pathum Thani, Thailand, [2]All India Institute of Medical Sciences, Pathology, New Delhi, India, [3]Kameda Medical Centre, Pathology, Chiba, Japan

Background & Objectives: Thyroid cytology is widely used to evaluate nodules, but interpreting fine needle aspiration (FNA) smears is challenging and requires expert input. Given the shortage of cytopathologists, supportive diagnostic tools are needed. ChatGPT, a large language model (LLM) developed by OpenAI (CA, USA), can analyse static images and has been studied in histopathology. However, its potential in interpreting thyroid cytology, particularly papillary thyroid carcinoma (PTC), the most common malignancy, remains unexplored. This study evaluates the diagnostic accuracy and consistency of ChatGPT 4.5 in interpreting thyroid FNA cytology images.
Methods: A total of 100 thyroid cytology samples were collected, including 50 PTC cases and 50 non-PTC cases, which consisted of 30 benign follicular nodules, 10 follicular neoplasms, 5 medullary thyroid carcinomas (MTCs), and 5 anaplastic thyroid carcinomas (ATCs). The representative images were selected by an expert cytopathologist and captured at 40x magnification with a resolution of 2448 by 1920 pixels. All diagnoses were independently confirmed by three pathologists. Each image was submitted to ChatGPT version 4.5 in five rounds to assess diagnostic accuracy and consistency.
Results: ChatGPT's average overall diagnostic accuracy was 26.2% when assessed by the Bethesda 2023 categories and 39.2% when assessed by specific diagnostic entities. For malignancy detection, the sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were 62.3%, 65.5%, 73.6%, and 53.6%, respectively. On average, ChatGPT made 51.2 malignant diagnoses (SD = 6.3), most classified as PTCs. MTCs and ATCs were rarely recognized, occurring in 1 and 2 instances. For PTC specifically, the sensitivity, specificity, PPV, and NPV were 64%, 62.8%, 63.6%, and 63.6%, respectively.
Conclusion: ChatGPT 4.5 demonstrated limited diagnostic accuracy and consistency in interpreting thyroid FNA cytology images. Despite moderate sensitivity and specificity for PTC screening, its performance reveals current limitations of LLMs for independent cytologic diagnosis. Further improvements are needed before reliable clinical use.

E-PS-08-024
Introductory framework for synthetic medical image assessment: Foundation Blueprint
W. Al-Zoughbi[1], R. Harb[1], M. Plass[1], H. Müller[1]
[1]Diagnostic and Research Institute of Pathology, Medical University of Graz, Graz, Austria

Background & Objectives: The adoption of medical image synthesis technology by both industrial and research communities hinges on the development of quality images. Because the accuracy and utility of synthetic images can vary significantly, rigorous validation against real-world data is indispensable. Unlike other fields, such as art and marketing, where creativity and maintaining a high level of visual appeal ensure a successful image-generation process, generating realistic-looking medical images with faulty architectures or features poses significant risks.
Methods: To date, no evaluation approach adequately addresses the aforementioned pressing difficulty in a manner warranted for grounding synthetic medical images with biological priors. To bridge this gap, we designed a purpose-driven dual-tier assessment method to evaluate the quality of synthetic medical images, whereby predefined assessment criteria are aligned with the specific applications for which the images are intended.
Results: In the course of presenting this study, we: a) detail the designed framework and provide recommendations for assessing the value of synthetic histopathology data, with a focus on images; b) introduce an evaluation matrix that examines two critical components: 1) accuracy, to ensure that synthetic images mirror real images, and 2) identifiability, to assess the risk of personal data leakage. Additionally, we aim to initiate the formation of a multinational consortium to standardize the quality assessment of synthetic histopathology images for both research and development and educational purposes. Adhering to this approach—in conjunction with complying with ethical requirements and regulatory processes being formulated—makes the responsible adoption of medical image synthesis technology viable.
Conclusion: As the emphasis on adopting private synthetic data becomes more pronounced compared to other technologies, the presented foundational method will support pathologists and other medical professionals in understanding this new technology and how it can be responsibly approached. This will result in cost savings and the faster emergence of meaningful synthetic image data sets.

E-PS-08-025
AI-powered mitotic rate assessment enhances diagnostic accuracy and prognostic prediction in liposarcoma
H. Park[1], S. Cho[2], G. Choe[1], K.S. Lee[1]
[1]Seoul National University Bundang Hospital, Pathology, Seongnam-si, Republic of Korea, [2]Lunit, Seoul, Republic of Korea

Background & Objectives: Distinguishing between well-differentiated (WD) and dedifferentiated (DD) liposarcoma can be challenging, especially when the low-grade (LG) spindle cell component does not meet the criteria for typical DD liposarcoma. Mitotic rate (MR) is a key prognostic factor, with ≥5 mitotic figures per 10 high-power fields (HPFs) suggested as a diagnostic criterion for DD liposarcoma. However, MR assessment by pathologists may not consistently reflect the

overall MR across the whole slide. Artificial intelligence (AI)-based MR detection models have emerged as supportive tools to enhance diagnostic accuracy. This study investigates whether AI-assisted MR assessment improves accuracy and consistency among pathologists of varying experience levels, reduces inter-rater discrepancies, and provides a more comprehensive MR evaluation across whole-slide images.
Methods: An AI-powered whole-slide image (WSI) analyser (Lunit SCOPE IO) was applied to 89 liposarcoma cases (74 DD, 15 WD) from Seoul National University Bundang Hospital. Three pathologists—a bone and soft tissue expert, a general pathologist, and a fellow—assessed MR without AI assistance, followed by AI-guided re-evaluation of discordant cases. The expert's reading served as the ground truth.
Results: The AI model achieved 89.9% concordance with the ground truth (80/89 cases). Initial agreement rates for the fellow and general pathologists were 85.4% and 84.3% (Cohen's $\kappa = 0.71$ and 0.68). After AI-assisted re-evaluation, agreement improved to 92.1% and 93.2% (Cohen's $\kappa = 0.84$ and 0.86). While the AI model effectively segmented tumour areas, it misclassified some mitotic cells due to incomplete segmentation or apoptotic body misidentification. Despite these limitations, AI-assisted review enhanced diagnostic accuracy.
Conclusion: AI-assisted MR assessment improved diagnostic agreement among pathologists and reduced interobserver variability. These findings highlight its potential to standardize MR evaluation in liposarcoma, enhancing diagnostic consistency and accuracy.

E-PS-08-026
Equivalency of digital Whole Slide Image (WSI) scoring to microscope glass slide scoring for evaluation of Programmed Death-Ligand 1 (PD-L1) expression in colorectal carcinoma
R. Marczak[1], S. Douglas[1], E. Nichols[1], S. Tabuena-Frolli[1], K. Kersch[1], F. Ponce[1], K. Martyniuk[1]
[1]Agilent Technologies, Inc., Research & Development, Carpinteria, USA

Background & Objectives: PD-L1 IHC 22C3 pharmDx (SK006) is a qualitative assay used to detect PD-L1 expression in formalin-fixed, paraffin-embedded (FFPE) tissues. This study aimed to demonstrate concordance between glass slide versus whole slide image (WSI) scoring on colorectal carcinoma (CRC) specimens using the combined positive score (CPS) algorithm at a CPS $\geq$ 10 cutoff.
Methods: Thirty unique CRC specimens were immunohistochemically stained with SK006 and scored using a light microscope; corresponding WSIs were generated using the Aperio AT2 Scanner and scored using ImageScope software. These specimens represented a dynamic range of PD-L1 expression.
Three observers scored blinded and randomized glass slides and WSIs with a minimum 14-day washout period between scoring the two modalities. Concordance in PD-L1 binary expression status between observer reads of each modality was assessed by estimating positive percent agreement (PPA), negative percent agreement (NPA), and overall agreement (OA).
Data for CRC specimens was combined with previously generated data from multiple tumour indications at the CPS $\geq$ 10 cutoff; prior to pooling data, the Fisher-Freeman-Halton test was performed to determine if significant heterogeneity in concordance across tumour types was present. Additional analysis was performed for CRC specimens alone. Acceptance criteria (AC) for the pooled analysis required the lower bound (LB) of the bootstrapped 95% confidence interval (CI) for PPA, NPA, and OA be $\geq$ 85%. Analysis conducted on CRC alone was not subject to AC.
Results: The pooled data had CI LB values $\geq$ 85% with point estimates > 92%. While not subjected to AC, all CI LB values for CRC alone were $\geq$ 84.4%, with point estimates > 91%.
Conclusion: These results support equivalency between glass slide and WSI scoring and support their interchangeable use by observers for PD-L1 expression of specimens from the multiple tumour indications stained with SK006, including CRC, that were analysed at the CPS $\geq$ 10 cutoff.

E-PS-08-027
Automated analysis of eosinophils in inflammatory nasal polyps: detection, classification, and quantification in haematoxylin-eosin-stained slides from patients treated with anti-IL5 immunotherapy
J.A. Hernandez Chinchilla[1], E. Giner Moreno[1], A. Garcia Pinero[2], C.A. Zac Romero[1], C.M. Lopez Valdivia[1]
[1]Hospital Universitario y Politecnico La Fe, Pathology, Valencia, Spain, [2]Hospital Universitario y Politecnico La Fe, ORL, Valencia, Spain

Background & Objectives: Chronic rhinosinusitis with nasal polyps (CRSwNP) is an inflammatory condition in which tissue eosinophilia plays a key role in both pathogenesis and treatment response. Accurate quantification of eosinophils in biopsies is essential for identifying candidates for targeted therapies such as mepolizumab, an anti-IL-5 monoclonal antibody. Manual identification in routine stains is a subjective process, typically involving the selection of three "hotspots" followed by the calculation of an average eosinophil count. This underscores the need for automated tools to improve objectivity and reproducibility in quantification.
Methods: Histological sections of nasal polyps from 18 patients with CRSwNP, stained exclusively with haematoxylin and eosin (H&E), were analysed. A total of 29 slides were collected. Images were digitized using a Leica Aperio CS2 scanner at 40x magnification and stored on a physical server. The dataset was subsequently divided into 15 images for training, 7 for testing, and 7 for validation.
A Random Forest model was used for automated classification. The model was configured with a maximum tree depth of 12 and a minimum of 5 samples per node to balance pattern capture and generalization. To assess model accuracy, a comparative analysis was conducted between manual and automated eosinophil quantification using the annotated H&E slides and corresponding pathology reports as reference standards.
Results: A total of 14 paired samples were analysed to compare manual eosinophil counts ("Manual") with digital quantification ("EOS-Q"). A strong and statistically significant correlation was observed ($r = 0.81$, $p = 0.0005$).
urthermore, the correlation between eosinophilic inflammation (EOS-Q) and symptom severity (SNOT scores) was assessed in 9 paired observations, yielding a weak and non-significant correlation ($r = 0.26$, $p = 0.49$).
Conclusion: This study demonstrates that automated analysis of eosinophils in H&E-stained inflammatory nasal polyps is a reliable and reproducible tool. Its application in clinical settings could optimize patient selection for targeted therapies.

E-PS-08-028
Automated quantification of CD34+ blasts in bone marrow biopsies using deep learning
J.A. Hernandez Chinchilla[1], F. Martí Pérez[2], P. González Rojo[3], C. Monserrat Aranda[2], L. Romano León[2], E. Mora Castera[4], M.D. Linares[4], A. Hernándiz Senent[1], P. Montesinos[1], N. Rausell-Fontestad[1], C. Ferri-Ramírez[2], E. Mayordomo-Aranda[1]
[1]Hospital Universitario y Politecnico La Fe, Pathology, Valencia, Spain, [2]Universidad Politecnica de Valencia, Inteligencia Artificial, Valencia, Spain, [3]Instituto de Investigación Sanitaria La Fe, Valencia, Spain, [4]Hospital Universitario y Politecnico La Fe, Haematology, Valencia, Spain

Background & Objectives: Quantifying CD34+ blasts in bone marrow is essential for diagnosing and classifying myelodysplastic syndromes (MDS) and acute leukemias. Currently performed manually, this process is prone to interobserver variability, affecting diagnostic accuracy. Digital pathology and deep learning offer a promising solution to improve objectivity and reproducibility.
Objective: To develop a deep learning model for automated quantification of CD34+ blasts in digitized bone marrow biopsies, improving diagnostic precision and efficiency.
Methods: A retrospective review was conducted on clinical cases with suspected MDS or leukaemia from a tertiary hospital between 2021 and 2024. A total of 110 bone marrow biopsy images stained with CD34 immunohistochemistry were collected and digitized. Expert pathologists manually segmented and annotated cellular components to create a training dataset.
A processing pipeline was developed to extract annotations and train multiple deep learning models. A UNet model was initially used as a baseline. Further evaluation included convolutional neural networks (CNNs) and Vision Transformers to identify the best-performing architecture. Data augmentation techniques, such as rotation and translation, were applied to improve generalization.
Results: Preliminary results indicate strong alignment between model predictions and expert assessments. For instance, in a case labeled as having <1% blasts by pathologists, the model predicted 1.6%. In another case assessed as >20%, the model estimated 17.6%. These outcomes demonstrate the model's potential to approximate human evaluation with clinically relevant accuracy.
Conclusion: Deep learning models can significantly enhance the quantification of CD34+ blasts in bone marrow biopsies. By reducing variability and improving consistency, such tools have the potential to support hematopathologists and improve diagnostic workflows in clinical practice.

E-PS-08-029
helloAmyloid: transforming amyloid screening with deep learning on smartphone-derived H&E images
B. Pamuk[1], S. Kiremitci[1], A. Ensari[1]
[1]Ankara University Medical School, Medical Pathology, Ankara, Turkey

Background & Objectives: Amyloid deposition in renal biopsies is confirmed by Congo Red staining under polarized light, though H&E remains routine. Over the past 6–7 years, we used Congo Red routinely, and using this data, we developed an almost no-cost, instant approach—helloAmyloid software—to predict amyloid accumulation directly from smartphone photographs of H&E sections as a screening (and eventually diagnostic) test. Images were captured through a microscope at 40× magnification using an iPhone 15, based on the hypothesis that a deep learning model could identify deposits prior to confirmatory staining.
Methods: We collected 1196 positive and 1224 negative H&E photographs (verified by Congo Red under polarized light on the same regions). Negative images were selected from areas morphologically mimicking amyloid in conditions such as diabetes, monoclonal gammopathy, hypertension, and FSGS. The central one-third of each image was cropped to yield 1900×1900 pixel patches, then resized to 950×950. A custom TensorFlow model (~4 million parameters) was trained on Google Colab using A100 and L4 GPUs. Performance metrics and the confusion matrix were determined at an ideal threshold (Youden index: 0.4157).
Results: The model achieved an AUC of 0.910 (DeLong test p=0.0184), with a sensitivity of 0.93 and specificity of 0.77 among 564 test images. These results indicate that our approach reliably distinguishes amyloid deposits from routine H&E preparations, achieving a high true positive rate with acceptable false positives.
Conclusion: HelloAmyloid v0.21 demonstrates high sensitivity and acceptable specificity in detecting amyloid deposits from H&E images. As the dataset expands and the model is refined, further improvements are expected. Moreover, we plan to extend the dataset to include images from other tissue types, exploring the model's potential as a universal screening tool. Ultimately, this approach may streamline early renal amyloid detection and reduce reliance on additional staining in resource and time-limited settings.

E-PS-08-030
The 3D fusion of complex medical image data in virtual reality
M. Vincze[1], M. Kozlovszky[2], B. Molnár[3]
[1]Óbuda University, AR/VR Laboratory, Budapest, Hungary, [2]Óbuda University, BioTech Research Centre, Budapest, Hungary, [3]3DHISTECH Ltd., Image Analysis Department, Budapest, Hungary

Background & Objectives: In our research, we focus on 3-dimensional (3D) fusion of data from different imaging modalities used in medicine. The main objective of our research was to design and develop a system in which CT/micro-CT images can be combined with their corresponding histological samples in 3D, allowing the user to examine any displayed tomogram from any sectional plane. In addition, in our research we aimed to be able to interactively display different measurement data in 3D to the user.
Methods: We implemented 3D data visualizations using a graphical engine. For our solution to produce the fused 3D image data, the CT image and the corresponding histological serial section are required as input parameters.
Results: We designed and developed a software solution that can simultaneously display 3D information from different imaging modalities to researchers in virtual reality (VR). With our solution, the user can see in 3D space exactly from where in the radiological tomogram the histological sample was taken. Our software is capable of multi-level 3D data visualization, i.e. the display of multiple tomograms embedded in each other. The software solution developed by us provides the user with the possibility to interactively display various diagnostic measurement data in 3D, in addition to the fused display of complex 3D image data structures. This allows us to provide the doctor with more data, reducing the time needed to make a diagnosis and increasing its accuracy.
Conclusion: In our research, we designed and developed a solution that can display complex, embedded 3D data structures to the user. Thanks to the embedded 3D data structures, the user can view different tomograms at the same time, allowing a quick overview along any virtual sectional plane. The VR solution we have developed provides a completely new perspective for doctors/researchers in terms of visualizing complex image data structures.

E-PS-08-031
A MedSAM-based interactive annotation tool for efficient and consistent pathology image segmentation
H. Ji[1], M. Yook[2], J. Seo[2], S. Yoon[2], S. Hong[2], C.K. Jung[3], I. Choi[2]
[1]The Catholic University of Korea, Dept. of Precision Medicine and Big Data, College of Medicine, Seoul, Republic of Korea, [2]The Catholic University of Korea, Dept. of Medical Informatics, College of Medicine, Seoul, Republic of Korea, [3]The Catholic University of Korea, Dept. of Hospital Pathology, College of Medicine, Seoul, Republic of Korea

Background & Objectives: Accurate and consistent annotation of pathology whole slide images (WSIs) is essential for developing AI models for cancer diagnosis and prognosis.
However, the annotation process is time-consuming and often suffers from inter-observer variability due to the ultra-high resolution and complex tissue structures present in pathology images.

Such variability directly impacts the reliability and generalization of AI models.
To address these challenges, we developed an annotation tool optimized for pathology image segmentation by integrating OpenSlide, PyQt5, and MedSAM, aiming to provide an efficient and consistent annotation workflow.
Methods: The proposed tool extracts region-specific tiles from WSIs using OpenSlide, enabling lightweight handling of large-scale pathology images without memory overload.
Through a PyQt5-based interactive interface, users can intuitively navigate WSIs using pan and zoom, and define regions of interest (ROIs) within each tile using point- or box-based prompts.
These prompts help MedSAM effectively segment ambiguous or complex tissue structures by incorporating expert guidance.
Users can interactively visualize, refine, and correct the generated segmentation masks in real-time.
The annotation results can be exported as binary mask images in either PNG or JPG format, along with annotation metadata in JSON or XML format, supporting practical usage for AI training and pathology analysis.
Results: The tool was evaluated on the Camelyon16 dataset for breast cancer metastasis detection.
The results demonstrated that the proposed tool significantly reduced annotation time while improving the accuracy and consistency of tumour region segmentation.
The combination of prompt-based input and automatic segmentation showed superior performance compared to automatic segmentation alone.
Conclusion: The proposed tool improves the efficiency, accuracy, and consistency of pathology image annotation.
It not only supports AI-based histopathological research but also serves as a practical assistant for pathologists by reducing annotation workload and facilitating consistent and efficient labelling in routine practice.

Funding: This research was supported by a grant from the Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health & Welfare, Republic of Korea (grant number: RS-2021-KH113146)

Evaluating the concordance between artificial intelligence and traditional histopathology in breast carcinoma grading

R. Bharadwaj[1], P. Doshi[1], P. Shelke[1]
[1]Bharati Vidyapeeth Deemed University Medical College, Maharasthra, Pathology, Pune, India

Background & Objectives: Breast carcinoma is the most prevalent malignancy among women, with global incidence rates increasing by 0.5-1% annually. Traditionally, diagnosis relies on histopathological examination of stained haematoxylin and eosin (H&E) slides providing insights into tumour morphology. Advancements in Artificial Intelligence (AI) offer potential to enhance diagnostic accuracy by efficiently analysing datasets, reducing human error, and improving objectivity. This study aims to compare the performance of an AI model in grading breast carcinoma with the conventional H&E-based grading method.
Methods: Conducted at the Department of Pathology, a tertiary care medical college. The study included pathology slides from patients who underwent radical surgeries such as wide local excision (WLE), breast-conserving surgery (BCS), and modified radical mastectomy (MRMS). Cases of invasive ductal carcinoma (IDC) were analysed using routine histopathological methods and an AI model. The AI's grading was compared to the Bloom-Richardson grading system by CAP reporting.
Results: A total of 48 cases were included, with patient ages ranging from 40 to 81 years; all were female. Tumour sizes ranged from 0.5 to 3.5 cm, with 36 left-sided and 12 right-sided tumours. The Bloom-Richardson grading revealed 16 Grade I (34%), 20 Grade II (41%), and 12 Grade III (25%) tumours. In comparison, the AI model classified 40 tumours as Grade I (83.4%), 8 as Grade II (16.6%), and none as Grade III.
Conclusion: The AI model demonstrated a tendency to under-grade tumours, particularly in identifying higher-grade cases. This suggests that the current AI model may not fully capture tumour heterogeneity discernible by pathologists. Therefore, AI alone may not suffice for accurate breast cancer grading. Integrating AI with human expertise is essential for reliable diagnoses. Further validation through larger, multicentric studies is needed to enhance the AI model's accuracy prior to its integration into clinical practice.

E-PS-08-034

LazySlide: efficient whole-slide imaging analysis framework across scales and modalities

Y. Zheng[1], E. Abila[1], A. Rendeiro[1]
[1]CeMM, Vienna, Austria

Background & Objectives: Computational pathology is advancing disease detection and classification, yet integrating histopathological images with other data modalities like clinical reports and genomics data remains challenging. Despite technological progress in whole-slide imaging (WSI) analysis, existing software solutions often operate in isolation, creating inefficiencies in data integration and limiting cross-scale analysis capabilities. This complexity presents substantial barriers for researchers seeking to conduct comprehensive multimodal studies. Thus, we propose a new interoperable, scalable framework that enables users of varied experience levels to analyse histopathological data across different scales and modalities.
Methods: We developed LazySlide (https://github.com/rendeirolab/LazySlide), an open-source Python package designed to enhance multimodal WSI analysis in clinical research. LazySlide enables efficient handling of WSIs across formats, providing efficient image processing capabilities across multiple spatial scales—from whole-slide overview, and regions of interest, to cellular features. The framework includes comprehensive functionalities such as quality control, automated segmentation of tissues, microanatomical structures and cells, morphological feature extraction using deep learning models, and integration with multiple data modalities such as clinical text reports and genomics data. Integration with workflow management systems ensures scalability to large cohorts while maintaining the reproducibility of analytical pipelines.
Results: LazySlide demonstrates superior efficiency in cross-scale analysis of gigapixel WSI data compared to existing solutions. The framework enables simultaneous investigation of mesoscopic tissue architecture and microscopic cellular morphology, with seamless integration of additional data modalities such as genomic profiles and clinical parameters. This multi-scale, multimodal approach has been applied in research across multiple pathologies, revealing clinicopathological associations that were previously difficult to detect using traditional single-modality analysis methods.
Conclusion: LazySlide streamlines multimodal, cross-scale analysis of histopathological data, facilitating the discovery of comprehensive insights into disease biology. It supports biomarker discovery and improved patient stratification, offering a practical tool for advancing translational pathology research.

AI-driven pathology and proteasome localization: advancing clinical prognosis in multiple myeloma

R. Ziv[1], I. Livneh[1,2], Y. Shimoni[3], M. Rosen-Zvi[3,4], M. Segev[1], A. Ciechanover[1]

[1]Technion - Israel Institute of Technology, Haifa, Israel, [2]Rambam Health Care Campus, Haifa, Israel, [3]IBM Research, Haifa, Israel, [4]The Hebrew University, Jerusalem, Israel

Background & Objectives: Multiple Myeloma (MM) is a plasma cell malignancy characterized by clonal synthesis of immunoglobulins. In accordance, proteasome inhibitors have been used in the treatment of MM, as they aggravate the stress experienced by MM cells, leading to their death. Recent evidence provides further mechanistic insights into the roles of the proteasome in MM, pointing out a link between the subcellular localization of the proteolytic complex and patients' response to treatment. However, extracting this localization information at the single-cell level across whole-slide biopsies remains labor-intensive, expensive, and impractical for clinical translation, motivating the development of automated computational approaches. Current computational pathology methods in MM are limited, typically focusing only on small tissue regions or cell analyses, requiring costly manual annotations with limited scalability. Here, we investigate whether advanced foundation model-based artificial intelligence (AI) approaches, leveraging large-scale pretraining, can accurately detect subcellular proteasome localization, towards prognosis in MM.
Methods: We developed a novel double-staining immunohistochemistry (IHC) protocol enabling simultaneous visualization of malignant cells and proteasome localization across entire biopsy slides from MM patients. Whole-slide biopsies were annotated at the tile level based on proteasome localization. We applied AI models to compare the predictive performance of a pretrained foundation model (GigaPath) with a conventional deep learning baseline for tile-level proteasome localization classification.
Results: The pretrained foundation model (GigaPath) achieved higher accuracy, F1-score, and AUC-ROC (7%,6%,4% improvement respectively) compared to the baseline deep learning model, without fine-tuning, demonstrating superior predictive performance for detecting proteasome subcellular localization, along with the ability to integrate whole slide information.
Conclusion: Our study highlights the feasibility and potential of leveraging pretrained foundation models to automate the detection of proteasome subcellular localization in MM biopsies, towards novel prognostic biomarkers. Ongoing work aims to integrate whole-slide proteasome localization data into a single predictive model for clinical outcomes such as patient survival and treatment response.

AI-assisted analysis of HER2-low and ultra-low breast cancer in correlation with low ER and PR expression

E. Colon[1,2]

[1]Sankt Görans Hospital- Unilabs-Karolinska Institut, Pathology, Stockholm, Sweden, [2]Unilabs, Pathology, Stockholm, Sweden

Background & Objectives: HER2-low and HER2-ultralow breast cancer classifications have emerged as distinct subgroups with potential therapeutic implications. Understanding their correlation with oestrogen receptor (ER) expression, particularly ER-low cases, is crucial for refining treatment strategies. This study utilizes AI-driven analysis to assess the relationship between HER2-low, HER2-ultralow, and PR and ER-low breast cancer cases.
Methods: A dataset of 105 comprising breast cancer biopsies analysed prospective via AI-assisted immunohistochemistry (IHC) was evaluated. HER2 expression was categorized as low (IHC 1+ or IHC 2+/non-amplified) and ultralow (IHC 0 with faint staining). ER expression levels were stratified, focusing on ER-low cases (defined as 1–10% ER positivity), and the same definition for PR. AI-assisted quantification Mindpeak provided an objective assessment of biomarker expression.
Results: Findings indicate a higher prevalence of HER2-low status in ER-low tumours compared to HER2-ultralow. The correlation suggests a potential biological link between ER-low expression and HER2-low tumours, which may influence responsiveness to targeted therapies. Additionally, HER2-ultralow cases exhibited a broader range of ER expression, with a subset showing ER-low characteristics.
Conclusion: AI analysis confirms a significant correlation between HER2-low and ER-low breast cancer cases, supporting the hypothesis that these tumours may represent a unique biological entity. Further research is warranted to explore the therapeutic implications, particularly in the context of novel antibody-drug conjugates targeting HER2-low disease.

Conclusion on HER2, ER, PR, and KI-67 Differences

1. **HER2:**
   HER2-Low (score 1+ or 2+ without amplification) represents **53%** of cases.
   HER2-Ultra-Low (score 0 but with detectable expression) accounts for **27%** of cases.
2. **Hormone Receptor Expression:**
   High Estrogen Receptor (ER) Expression is dominant, with no recorded cases of low ER expression in this dataset.
   High Progesterone Receptor (PR) Expression is also prevalent, with no cases of low PR expression reported.
3. **(KI-67):**
   High Proliferation (>20%) is observed in **30%** of cases.
   Low Proliferation (≤20%) is seen in **68%** of cases.

Using 3D histology to create training data for deep learning

N.K.N. Chow[1,2], B.T.Y. Wong[1,2], L. Zhang[1,2], C.N. Yau[1,2], E.P.L. Tsoi[1,2], H.M. Lai[1,2]

[1]The Chinese University of Hong Kong, Department of Chemical Pathology, Faculty of Medicine, Hong Kong, Hong Kong, SAR of China, [2]The Chinese University of Hong Kong, Li Ka Shing Institute of Health Sciences, Faculty of Medicine, Hong Kong, Hong Kong, SAR of China

Background & Objectives: Deep learning has numerous applications in histopathology, including cell segmentation, cancer diagnosis, cancer grading, metastasis detection and prognosis prediction. While model architectures are well researched by computer scientists, insufficient data is often the bottleneck of deep learning in histopathology. Since traditional 2D histology requires labour-intensive sectioning and staining steps, we aim to use 3D histology to produce data for training a tissue classification model.
Methods: We obtained 6 tissue blocks of different tissue types (ileum, lung, pancreas, spleen, tongue epithelium, tongue muscle). Each tissue block underwent the 3D histology protocol. We performed oblique 3D slicing to increase the amount and variety of training images, as this was the key advantage of 3D histology over 2D histology. After that, we used this dataset to train a model to classify the 6 tissue types. We used the EfficientNetB0 model architecture pretrained on ImageNet.

We evaluated the model using a testing dataset of real-world H&E images unseen by the model.
Results: The model achieved 99.4% accuracy on the training dataset and 91.0% accuracy on the testing dataset. On the testing dataset, the model performed well on ileum, lung, spleen and tongue epithelium. Notably, the model could classify ileum images correctly despite variations in longitudinal, transverse and tangential images. However, the model performed less well on pancreas and tongue muscle. We found that discrepancies between training and testing images led to poorer classification performance of pancreas and tongue muscle.
Conclusion: Although we have only used 1 tissue block for each tissue type, we could already train a model which achieves 91.0% classification accuracy on real-world images. This shows the remarkable ability of 3D histology to use limited tissue blocks to generate training data for deep learning.

E-PS-08-041
Does size and colour matter in computational pathology? First results
D. Hieber[1,2,3], D. Müller[4,5], E. Spieß[1], F. Holl[1,6], F. Liesche-Starnecker[2], R. Pryss[3], J. Schobel[1]
[1]DigiHealth Institute, Neu-Ulm University of Applied Sciences, Neu-Ulm, Germany, [2]Medical Faculty, University of Augsburg, Neuropathology, Augsburg, Germany, [3]Institute of Medical Data Science, University Hospital of Würzburg, Würzburg, Germany, [4]Faculty of Applied Computer Science, University of Augsburg, Augsburg, Germany, [5]Institute for Digital Medicine, University Hospital Augsburg, Augsburg, Germany, [6]Leibniz Science Campus Digital Public Health Bremen, Bremen, Germany

Background & Objectives: Computational pathology is gaining increasing popularity, expanding both its clinical applications and computational demands. Unlike radiology, digital pathology relies on extremely high-resolution, colour-rich images, resulting in substantial storage and processing requirements. This raises a critical question: are high magnifications and colour information truly essential for computational pathology models?
Methods: We analysed three open-access datasets: RINGS (prostate cancer, tile-based, binary segmentation), CoCaHis (colon cancer, tile-based, binary segmentation), and PANDA (prostate cancer, whole-slide images, multi-class segmentation). Each dataset was used to train a U-Net model implemented in PyTorch Lightning with MONAI, utilizing both colour and grayscale inputs. For PANDA, models were trained at 5x (colour + grayscale) and 10x (only colour) magnifications. An approximate 80/20 train-test split was applied. To ensure consistency in colour models, H&E staining was normalized using the modified Reinhard method.
Results: On validation data, the PANDA model trained at 5x outperformed the 10x model (Dice: 68.74% vs. 64.49%), but this trend reversed on the test set (47.10% vs. 63.94%). For CoCaHis, colour-based models consistently outperformed grayscale models (validation Dice: 80.07% vs. 50.87%; test Dice: 51.38% vs. 39.80%). The same pattern was observed for the RINGS dataset (validation Dice: 59.13% vs. 52.36%, test Dice: 61.42% vs 50.96%). For PANDA at 5x magnification, the colour model performed better during validation (68.74% vs. 63.81%) but worse during testing (47.10% vs. 61.95%).
Conclusion: Color input generally improved performance, though not universally. Similarly, higher resolution enhanced test performance in the PANDA dataset. These findings align with current best practices but suggest that the benefits from high resolution and colour may not always be consistent. As these are preliminary results, further investigation is needed to determine when such enhancements are truly justified. Limitations such as inprecise labels, the use of only three datasets (with only one whole-slide image dataset) should be addressed in following work.

E-PS-08-042
Virtual H&E staining and computer assisted assessment of lymph node metastases in colorectal carcinoma and neck dissections
A. Eissing-Al-Mukahal[1], G. Wilkens[2], V.Q. Tran[1], V. Kern[1], M. Rust[1], N. Farkouh[1], C. Mogler[2], L. Wilkens[1]
[1]University of Magdeburg, Pathology, Magdeburg, Germany, [2]Technical University Munich, Pathology, Munich, Germany

Background & Objectives: A chemical produced H&E- stain (Haematoxylin and Eosin) is high in resources and needed chemicals. To find a more sustainable and faster alternative an algorithm to virtually stain tissue was developed and applied to tissue specimens processed in daily routine. A computer assisted detection method for automated detection of metastasis in lymph nodes was also applied. Comparison of the results with standard processing and histological evaluation enabled a proof of concept of this attempt.
Methods: Slides of unstained tissue were scanned using a commercially available scanner and virtually stained using a research software optimized to the features of the scanner. Evaluation of virtual stainings was done by a team of pathologists. Then standard H&E stainings were done and microscopic evaluation followed. Results of virtually stained and H&E stained slides were compared added by the results of the computer assisted assessment of lymph node metastases.
Results: Lymph nodes in 43 cases of colorectal carcinoma and 20 cases of neck dissections were analysed. In both groups of tissue no significant difference was found between virtual and H&E-stained slides (Fig. 1). Moreover, the computer assistance was able to detect metastasis in lymph nodes of colorectal carcinoma with computer assistance with a sensitivity of 100% and a specificity of 93%.
Conclusion: These data demonstrate, that it is possible to apply virtual staining in a sufficient and reliable way. This possibly will help to improve diagnostic processes by avoiding time consuming staining processes. Moreover, it is possible to save tissue sections useable for other additional stainings and/or molecular analysis. Overall, these algorithms could change the way of staining and evaluating tissue in the long. At the time there has to be spent further efforts to integrate these algorithms in daily routine work. Nevertheless, we assume these efforts as worth it.

E-PS-08-043
Stepping into digital transformation of a pathologist's work in Greece
D.S. Gkanetsou[1], A. Pomoni[1], O. Kouroukli[2], E. Lampri[3], S. Lakis[4], M. Nifora[5,6], V. Tzelepi[7]
[1]University Hospital of Patras, Department of Pathology, Patras, Greece, [2]Evaggelismos General Hospital of Athens, Department of Pathology, Athens, Greece, [3]University Hospital of Ioannina, Department of Pathology, Ioannina, Greece, [4]Foundation Medicine GmbH, Pathology Department, Penzberg, Germany, [5]Istomedica S.A., Histopathology Lab, Athens, Greece, [6]University of West Attica, Department of Biomedical Sciences, Athens, Greece, [7]University of Patras School of Medicine, Department of Pathology, Patras, Greece

Background & Objectives: Digital Pathology (DP) transforms the everyday workflow of Pathologists. Although Greek hospitals have not integrated DP yet, there is growing interest towards upgrading the healthcare system. A group of Pathologists decided to capture the willingness for that advancement by making a thorough questionnaire.
Methods: After a thorough literature review, seven pathologists created a questionnaire consisting of 46 questions—categorized into different sections—on the current use of and views on digital pathology. This questionnaire was distributed electronically among members of the Hellenic Society of Pathology. The response format included

yes/no questions, multiple-choice dropdowns, and one open-ended question.
Results: A total of 118 responses were obtained, from pathologists of various age groups and professional experience levels. Despite 78% having read relevant literature, only 33% reported DP usage, mainly for education and research. Most respondents (82.5%) considered DP necessary, >70% would use DP for primary diagnosis and IHC evaluation, and 47.9% support full implementation within the next five years. DP was considered useful mainly for remote diagnosis (90.7%) and access to expert opinions (85.6%), while technical problems (57.8%) and cyber security (49.5%) were major risks. The lack of a national strategic plan (95,1%), relevant infrastructure (93,5%), and DP value recognition by Hospital Administrations (80,7%) and high costs (84,5%) were identified as major barriers in DP integration.
Conclusion: Overall, the findings highlight a strong interest in Digital Pathology (DP). However, concerns about technical infrastructure, training requirements, and regulatory frameworks remain significant. Addressing these challenges requires a coordinated effort from healthcare institutions, professional societies, and policy makers. As awareness builds around the experience of pathology laboratories around the world that have already moved towards the digital way, more and more surveys conclude into the advantages of the new work environment of Pathologists.
Acknowledgements: We would like to thank the Hellenic Society of Pathology for its support.

E-PS-08-044
Application of digital pathology foundation models for disease scoring in MASH
C. Hendra[1], C.Z.L. Ong[1], C.-L. Chin[2], R. Baumgartner[3], A.A.B. Ali[1], D. Abdurrachim[1]
[1]MSD, Quantitative Biosciences, Singapore, Singapore, [2]Merck & Co., Inc., Cardiometabolic Diseases, South San Francisco, USA, [3]Merck & Co., Inc., Biostatistics and Research Decision Sciences, Rahway, USA

Background & Objectives: Liver biopsy remains the gold standard for assessing metabolic dysfunction-associated steatohepatitis (MASH) due to its direct examination of hepatic histological abnormalities. However, the complex pathological features in MASH and inconsistent disease definition may lead to inter-/intra-pathologist score variability. Artificial Intelligence (AI) may offer a solution by providing more consistent and granular continuous scoring, which enhances the evaluation of disease progression or treatment response. Foundation models maximize AI's potential through self-supervised learning, allowing an increasingly larger model to be trained on a wealth of unannotated datasets. Here, we evaluated the application of several recently developed foundation models in computational pathology for MASH scoring.
Methods: We utilized 120 H&E-stained & Masson's Trichrome (MT)-stained whole slide images (WSIs), with the associated NASH-CRN scores evaluated by four expert hepatopathologists. We employed three foundation models (UNI, Prov-Gigapath, H-optimus-0) on the H&E WSIs, divided into 256x256 non-overlapping patches at 20x, to extract feature representations of each patch and fit a linear regression model on the max-pooled features. Model performance was evaluated using Pearson's correlation between the predicted score and the median pathologists' grading on a 5-fold cross validation run.
Results: The foundation models overall achieved high correlation on most NASH-CRN categories, with H-optimus-0 outperforming all other foundation models in the benchmark (fibrosis: 0.83, steatosis: 0.8, ballooning: 0.67, lobular inflammation: 0.38). Most interestingly, all foundation models achieved a correlation greater than 0.7 on H&E WSIs against pathologists' fibrosis stage graded on MT slides, indicating that the models can capture subtle fibrotic features on H&E-stained slides that may not be as apparent to pathologists.
Conclusion: Our results highlight the potential of foundation model for future deployment in MASH scoring. Future work needs to include a more rigorous testing and benchmarking across a wider patient cohort as well as model explainability to foster greater trust between AI and pathologists.

E-PS-08-045
Unhuddle: a heuristic method for deconvolution of shared border signal in image-based spatial proteomics
T. Noordenbos[1,2,3], J. Shi[2,4], T. Sugio[1,2], C.L. Liu[1,2], M. Diehn[4], N. de Miranda[3], J. Vermaat[5], M. Esfahani[4], A. Alizadeh[1,2]
[1]Stanford University, Medicine, Divisions of Oncology and Haematology, Palo Alto, USA, [2]Stanford University, Stanford Cancer Institute, Palo Alto, USA, [3]Leiden University Medical Centre, Pathology, Leiden, The Netherlands, [4]Stanford University, Radiation Oncology, Palo Alto, USA, [5]Leiden University Medical Centre, Haematology, Leiden, The Netherlands

Background & Objectives: Histopathology and immunohistochemistry (IHC) are foundational for cancer diagnosis and classification. Recently, understanding the local immune environment has gained prominence due to advances in immunotherapy. Highly multiplexed IHC methods (>20 markers) enable simultaneous analysis of numerous immune markers within tissue sections but pose substantial interpretative challenges, requiring robust computational pipelines. A common step in spatial analysis is cell segmentation, which attributes signal intensities to individual cells. However, most existing approaches rely on absolute segmentation, which fails to account for shared signal at the cell-cell borders, originating from insufficient resolution, lateral bleed of signal, and z-level overlap. Without correction, this "neighbor noise" leads to systematic misclassification of cell types. This issue is particularly pronounced in dense tissues, where typically >50% of informative pixels for a cell's membrane marker are located in the outer border (benchmark: 1um resolution).
Methods: We developed a computational workflow to correct shared intensity at cell-cell borders via deconvolution, following absolute segmentation in image-based spatial proteomics. We validated the method on *in silico* tissues reconstructed from individually curated cells, serving as ground truth. And we benchmarked performance on real-world human lymphoma data, by measuring the fraction of ambiguous phenotype calls using a pre-trained random forest classifier.
Results: Unhuddle reduced error to ground truth in reconstructed tissues and in 68 real-world lymph node and lymphoma samples, Unhuddle assigned definitive phenotypes in 63% of prior ambiguous cells.
Conclusion: The "Unhuddle" algorithm effectively resolves a significant part of segmentation-related noise in multiplexed IHC images, enhancing accuracy in high-density tissues such as lymphoid tissues or infiltrates. We envision that integration of this method into high-plex IHC workflows will improve phenotypic accuracy, allowing identification of subtle variations in the immune microenvironment. Consequently, Unhuddle has the potential to drive novel spatial biomarker discovery and enhance the selection of personalized immunotherapeutic strategies in oncology and diagnostic pathology.

Artificial Intelligence-based detection of Tumour-Infiltrating Lymphocytes (TILs) in breast carcinomas: an approach
N. Katsoulas[1], E. Lakiotaki[1], P. Korkolopoulou[1], A. Nonni[1], E. Gavves[2,3], E. Kanoulas[2,3]
[1]School of Medicine, National & Kapodistrian University of Athens, 1st Department of Pathology, Athens, Greece, [2]Ellogon.AI,

Amsterdam, The Netherlands, [3]Informatics Institute, University of Amsterdam, Amsterdam, The Netherlands

Background & Objectives: Tumour-Infiltrating Lymphocytes (TILs) constitute an important biomarker, with an increasingly developing importance in the prognostic assessment and therapeutic interventions of triple-negative breast carcinomas (TNBCs). High TILs scores have been linked with better overall prognosis of TNBCs, while they indicate them as potential candidates for immunotherapy. Artificial Intelligence (AI) algorithms have been recently developed to assist and facilitate the time-consuming process of biomarkers assessment in H/E slides. The aim of this study is to evaluate a novel system of TILs detection in breast carcinomas, and to discuss its advantages and disadvantages.
Methods: 86 cases of breast carcinomas, either NST or lobular type, have been selected for the study. The H/E slides were scanned, and digital slides were uploaded in V7 annotation platform. The annotation process included, for each slide, 4 tissue segmentation Regions Of Interest (ROIs) and 4 cellular detection ROIs, in order to train the EidosAI™ Technology algorithm to estimate TILs scores. Two pathologists assessed the slides and excluded the TILs scores for each slide. The TILs scores of the pathologists and the pertinent scores of the algorithm were analysed.
Results: The provisional results showed an overall good concordance between the pathologists and the AI algorithm, regarding the compared TILs scores. There was a slightly increased estimation according to AI algorithm (mean TILs percentage 5.6%), while the remaining 64% of cases were underestimated by the algorithm (mean TILs percentage 13%). Interestingly, lobular carcinomas, mimicking lymphoplasmacytic infiltrates, showed a severe discordance. Additional technical interventions, as well as better case selection, are needed to optimize the observed results.
Conclusion: AI technology may be of great assistance in the detection of TILs scores in breast carcinomas, aiding the pathologists in their routine. Thorough training of the AI-based algorithms is of paramount importance, in order to surpass possible discrepancies between pathologists and algorithms.

E-PS-08-049
Determining the significance of tumour-stroma ratio in high-grade serous ovarian carcinomas using multi-prototype few shot learning
C. Matek[1,2,3], D. Firmbach[1], P. Kuritcyn[4], V. Bruns[4], M. Eckstein[1,2,3], A. Hartmann[1,2,3], M. Benz[4]
[1]Institute of Pathology, University Hospital Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany, [2]Comprehensive Cancer Centre EMN, University Hospital Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany, [3]Bavarian Centre for Cancer Research, Erlangen, Germany, [4]Fraunhofer Institute for Integrated Circuits IIS, Erlangen, Germany

Background & Objectives: Tumour-Stroma ratio (TSR) has been shown to be as a marker of clinical outcome in various solid tumour entities (Wu et al., 2016). However, in the case of ovarian carcinomas, its overall significance is still unclear, due to limited cohort sizes and lack of standardization in determination of TSR (Lou et al., 2024). In this work, we develop a segmentation algorithm allowing us to quantitatively determine TSR in high-grade serous ovarian carcinomas.
Methods: A cohort of 150 cases of high-grade serous ovarian carcinomas was compiled, comprising clinical information on overall survival and progression-free survival. Histologic slides were digitized on a Hamamatsu S210 digital slide scanner at a resolution of 0.22µm/pixel. Using a multi-prototype few-shot learning approach (Benz et al., 2024), an existing segmentation algorithm for colorectal carcinomas was adapted to be applied for segmenting tumour and stroma components, among other histologically relevant compartments (fat, blood vessels, corpus albicans, necrosis) in the Ovarian Carcinoma Cohort. Segmentation quality was supervised by two pathologists. Overall, prototypes were drawn from a sub-cohort of 10 slides.
Results: The network adapted by multi-prototype few-shot learning provided good segmentation quality that captured relevant histologic compartments well across the cohort. Our results show a consistent tendency of low-TSR cases to be associated with reduced overall survival and progression-free survival in our cohort.
Conclusion: Multi-prototype few-shot learning allows developing a consistent and precise segmentation algorithm for high-grade serous ovarian carcinomas. Building on segmentation results, we find that in a cohort of 150 high-grade serous ovarian carcinomas, lower TSR tends to be associated with worse outcome.

E-PS-08-050
Out-of-hospital Digital Pathology environment for increased security, full remote access and important cost reduction
L. Alfaro[1]
[1]Hospitales Vithas Valencia-Castellón, Pathology, Valencia, Spain

Background & Objectives: Digital Pathology has demonstrated its importance in the progress of our discipline and the capacity to improve efficiency and to implement continuous advances led by artificial intelligence. The main obstacle to its implementation remains in its high cost.
We have designed a system to achieve significant cost reductions, while improving telecommunications security issues, and facilitating remote out-of-hospital access.
Methods: We operate in three independent private hospitals 80 km apart, with a staff of 10 pathologists, and three scanners of different vendors (Leica GT450, Hamamatsu S210 and 3D-Histech Panoramic-Midi) running on the same Hamamatsu NzConnect server with full compatibility. To meet our objectives, the digital diagnostic server is external and the usual reporting infrastructure has been separated and remains within the hospital intranet with its HIS and LIS. Pathologists use dual monitors to connect to the digital slides server and the LIS. The diagnostic server does not include any patient information or metadata to minimise security risks.
Results: The connection to the hospital LIS is made in the remote accesses through a VPN configured by the hospital IT team and to the diagnostic server with a double access system: web-based and with an independent VPN based on Tailscale. Pathologists have simultaneous access to both servers to perform their work, which can be carried out from any location without the need to be present in the hospital.
Conclusion: The use of the LIS already implemented and separated from the diagnostic server avoids the need for complex integration processes, of a network organisation and the provision of security measures. This reduces the costs of the digital pathology system to hardware (scanners) and minimal server software costs, while maintaining the full efficiency of the digital transition.

E-PS-08-051
IHC staining intensity normalization to account for IHC variability in quantitative computational pathology analysis
N. Harder[1], M. Azqueta Gavaldon[1], A. Hidalgo Sastre[1], L. Kausch[1], N. Brieu[1], M. Gustavson[1], G. Schmidt[1]
[1]Computational Pathology, Oncology R&D, AstraZeneca, Munich, Germany

Background & Objectives: Immunohistochemical (IHC) staining is commonly employed to assess target expression, which is essential for patient stratification and drug development. Computational methods like Quantitative Continuous Scoring (QCS) can be utilized for highly accurate and reproducible measurement of staining intensities in IHC. IHC staining can vary based on sample preparation, assays,

and scanners, leading to slight fluctuations in the measured raw staining intensities. To enhance the comparability and consistency of measurements across different batches, we have developed a normalization approach for staining intensities.
Methods: To develop and test our approach we used cell line pellets (N=10) embedded into cell micro arrays (CMAs), providing a highly controlled environment. Replicates (N=12) of consecutive slides were prepared on different days. The cell lines exhibited expression levels from negative to high when stained with an established membrane marker, and staining intensities were quantified using QCS. We calculated the *minimum*, *medium*, and *maximum* staining intensities per slide based on three selected cell lines with established negative, medium, and maximum expression levels. To account for the observed IHC variability we developed a step-wise linear minimum-medium-maximum normalization approach that transforms the raw staining intensity distribution per slide such that its *minimum* is shifted to 0, its *maximum* to a fixed constant SI_{max} and its *medium* to $SI_{max}/2$.
Results: By applying our normalization scheme, we achieved a significant decrease in variability of IHC staining intensity. This reduction was observed in all CMA cores and was quantified using the Normalized Root Mean Square Deviation (NRMSD) per core across all slides (average NRMSD-baseline: 0.046, average NRMSD-normalized: 0.020, Wilcoxon $p<0.001$).
Conclusion: This proof-of-concept study demonstrates that normalization significantly enhances the consistency of IHC staining intensity measurements. By utilizing on-slide or batch controls to determine *minimum*, *medium*, and *maximum* staining intensities of the analysed data, our approach can be readily applied to reduce inter-slide or inter-batch variability.

E-PS-08-052
Pathology image generation with flow matching diffusion models
A. Vigdorovits[1], R.-A. Barna[2], G.-E. Olteanu[3], A.-C. Pop[1], S.-A. Vese[1], A. Orosz[1], N. Orosz-Bogya[1], M.-M. Muresan[1], A. Camarasan[1], A.-V. Pascalau[1], O. Pop[1]
[1]Bihor County Clinical Emergency Hospital, Department of Pathology, Oradea, Romania, [2]Victor Babes University of Medicine and Pharmacy, Anapatmol Research Centre, Timisoara, Romania, [3]BC Cancer, Department of Pathology, Vancouver, Canada

Background & Objectives: Generative models offer an alternative data source that overcomes issues such as scarcity, manual labelling, and privacy concerns. Early generative architectures such as Generative Adversarial Models (GANs) have been widely used across medical applications. Despite the high quality image generation, GANs lack diversity, are unstable, and suffer from mode collapse. Denoising Diffusion Probabilistic Models (DDPMs) offer a more stable alternative that can outperform the image quality of GANs. However, these models work by iterative denoising through numerical ordinal differential equation solvers, leading to slow inference. Here, we employ optimal transport flow matching diffusion to accelerate training and inference time.
Methods: We extracted 5000 images patches from 112 WSI of squamous cell carcinoma in situ biopsies. An optimal transport flow matching diffusion model based on a UNet backbone with flash attention was trained for 100 epochs using the images on a single NVIDIA RTX 3060Ti graphics card, using an Adam optimiser, a batch size of 4 and a learning rate of 0.0001. Synthetic images were subsequently generated using the trained model.
Results: Model training concluded after 6 hours. A total of 1000 images were generated in under 3 minutes of inference (0.163 seconds/patch). Pathologists were not able to reliably distinguish between the real and synthetic images. Pathologists (4 specialists, 6 residents) were given a Turing test with 20 images in which they were required to discriminate between real and synthetic images (10 images in each category). Specialists had a higher average accuracy than residents (51.66% vs. 44%).
Conclusion: Our study highlights how optimal transport flow matching diffusion models offer a lightweight, compute-efficient alternative to GANs and classical diffusion models. The model can be trained on several thousands of images in the span of a few hours on an affordable, consumer-grade GPU, while also providing practical inference times, all while generating reliable synthetic images.

E-PS-08-055
Artificial intelligence in the detection of homologous recombination deficiency in ovarian cancer
P. Regitnig[1], M. Kargl[1], R. Harb[1], G. Fiala[1], E. Jungwirth[1], H. Müller[1], D. Kumar[2], M. Plass[1]
[1]Medical University of Graz, Diagnostic and Research Institute of Pathology, Graz, Austria, [2]Aifora, Helsinki, Finland

Background & Objectives: In ovarian carcinoma, the primary molecular pathogenetic mechanism is homologous recombination deficiency (HRD), a repair dysfunction that leads to genomic instability (GI). Patients with HRD are eligible for therapy with PARP inhibitors. Currently, advanced molecular diagnostics are the only means of accurately assessing HRD deficiencies and GI.
Methods: Our study investigated the impact of GI on the microscopic morphology of ovarian cancer and explored the potential for its detection using artificial intelligence. Cancer slides were digitized using the Pannoramic P1000 digital slide scanner (3DHistech). Our dataset included 293 haematoxylin and eosin (H&E) stained whole-slide images (WSIs) scanned at high magnification with a resolution of 0.1219 µm/pixel and 388 WSIs scanned at standard magnification with a resolution of 0.2438 µm/pixel. Each WSI represents a representative slide from a different case.
All WSIs underwent automated quality control, feature extraction, and analysis using multi-instance learning (MIL) detection algorithms. The methodologies included fine-tuned ResNet-18 CNN models, which were analysed using either MIL VarAttention or a combination of CLAM/VarAttention with different feature sets. As the next step, we will use CNNs provided by Aiforia Create, part of the Aiforia Platform, to validate these results and to find complementary outcome of the study.
Results: For the high-resolution WSI dataset, the classifier achieved a mean area under the curve (AUC) of 0.8 and a mean F1 score of 0.71. For the lower-resolution dataset, both the mean AUC and F1 score were 0.71 and 0.64, respectively.
Conclusion: This suggests that microscopic morphology possesses distinct characteristics that could serve as criteria for genomic instability score (GIS) and HRD detection. Notably, in some cases, GIS/HRD positivity could be identified solely using H&E-stained WSIs. Our findings indicate that scanning at higher resolutions enhances detection accuracy, as most probably cell nuclear morphological features might play a significant role in the analysis.

E-PS-08-056
AI-assisted TPS and CPS scoring of PD-L1 expression in kidney cancer
C. Liu[1], C. Simmat[1], R. Peyret[1], S. Sockeel[1], M. Sockeel[1], L. Albiges[2], S.F. Kammerer-Jacquet[3], N. Rioux-Leclercq[3]
[1]Primaa, Paris, France, [2]Gustave Roussy, Oncology, Villejuif, France, [3]Rennes University Hospital, Cytology and Pathological Anatomy, Rennes, France

Background & Objectives: As part of the European Care1 project on metastatic kidney cancer, Programmed death-ligand 1 (PD-L1) expression is studied as a predictive biomarker for immune checkpoint

inhibitors (ICI) treatment. Quantified with eyeballing methods on immuno-histochemistry stains, their evaluation is laborious and suffers from moderate inter-observer variability. Pathologists could therefore benefit from Artificial Intelligence (AI) assistance in clinical diagnosis scenarios.
Methods: Using annotated whole slide images (WSIs) from CARE1 european project, we developed computer vision algorithms to select and segment tumour regions as well as the surrounding inflammatory regions. In those identified regions, Deep learning-based cell detection and classification are applied, including cell type and PD-L1 expression. Based on this data, tumour proliferative score (TPS) and combined positive score (CPS) are computed and compared to a threshold for positive or negative PD-L1 expression assessment.
Results: The proposed method enables consistent and precise localization of the diagnostic area in WSIs. We also demonstrate promising robust Deep learning algorithms in PD-L1 expression evaluation with accuracy metrics at slide-level on a multi-centric dataset.
Conclusion: In this study, we propose an end-to-end automatic pipeline able to both identify tissue regions on IHC WSIs and achieve accurate and efficient PD-L1 scoring.

E-PS-08-058
Enhancing security and traceability in clinical and forensic histopathology: a pilot study on digital pathology and secure data transmission
M. Brunelli[1], N. Pigaiani[1], F. Ausania[1], F. Bortolotti[1], A. Scarpa[1], S. Gobbo[1]
[1]University of Verona, Department of Diagnostic and Public Health, Verona, Italy

Background & Objectives: The application of whole slide imaging (WSI) in forensic and clinical histopathology requires improvements to ensure the security and traceability of histopathological documentation in legal and medico-legal procedures. This study aims to enhance and ensure the security and privacy of the transmission of these image-based documents for judicial purposes.
Methods: A network and cloud infrastructure were set up for sharing these WSI with secure access controlled by user credentials. Following the updated recommendations from the College of American Pathologists Pathology and Laboratory Quality Centre, this pilot study assessed the reliability of a digital approach for forensic and clinical histopathological secure data transmission. The slides were digitized using the Aperio GT 450 DX Digital Slide Scanner (Leica Biosystems, Nussloch, Germany).
Results: A total of 160 representative slides of organic lesions related to deceased individuals, included in judicial records—both forensic and clinical autopsies—were digitized and transmitted via the local network to a cloud-based repository securely. In detail, the secure access to the repository was ensured through a four-step process: 1) multi-factor authentication, 2) role-based access control, 3) audit logging, and 4) secure network protocols. Only the coexistence of all four factors met the required security criteria.
Conclusion: This pilot study highlights the potential of digital pathology to improve the security, traceability, and efficiency of forensic histopathological documentation, while ensuring data integrity and confidentiality in legal contexts.

E-PS-08-059
Comparison of plasma cell quantification using digital pathology software in bone marrow trephines associated with multiple myeloma
S. Khan[1,2,3], N. Nandi[1], M. Rodriguez-Justo[1,2]
[1]University College London, Research Department of Pathology, London, United Kingdom, [2]University College London Hospital, Department of Histopathology, London, United Kingdom, [3]University College London Hospital, Department of Nuclear Medicine, London, United Kingdom

Background & Objectives: Diagnosis and prediction of treatment response in multiple myeloma is achieved by accessing plasma cell infiltrates in bone marrow trephines. Current methods involve manual interpretation of histologically stained bone marrow trephines by pathologists. However, current limitations include inter and intra observer variability, lack of reproducibility and is very time consuming. Advancements in digital pathology has allowed for faster and potentially more accurate method of plasma cell counts. Thus, we aimed to compare two digital pathology software's, Visiopharm® and Qupath, and analyse their accuracy against the current gold standard scoring method undertaken by pathologists.
Methods: Ten sections stained for plasma cell marker CD138 were analysed using both digital pathology software's and positive cell classification counts were compared to pathologist scoring. Analysis was undertaken using SPSS to calculate Pearson correlation for manual scoring vs Visiopharm® (Ma-Vi) and manual scoring vs Qupath (Ma-QU).
Results: Overall correlation for Ma-Vi and Ma-Qu were $r=0.96$ $p<0.001$ and $r=0.69$ $p<0.05$ respectively. For cases with diffuse plasma cell infiltrates, there was significant correlation associated with Ma-Vi ($r=0.99$ $p<0.001$) however Ma-Qu showed no significant correlation ($r=0.43$ $p>0.05$). Similarly, for cases with patchy infiltrates and aggregates, significant correlation was associated with Ma-Vi $r=0.95$ $P<0.05$ however Ma-Qu showed no significant correlation $r=0.41$ $p>0.05$.
Conclusion: These results suggest that digital pathology does offer a potentially viable alternative to accurately quantify plasma cell infiltrate. Visiopharm® demonstrated greater significant correlation with the pathologist compared to Qupath overall and in specific sub cases. Qupath struggled to identify both positive and negative cells in background/artefact regions. As Visiopharm® contains far more adjustable parameters and functions, it allowed for better characterisation of positive cell counts.

E-PS-08-060
The utility of AI-associated algorithm in determining the PD-L1 status in non-small cell lung cancer
J. Borowczak[1], J. Durślewicz[2,3], M. Maniewski[3,4,5], M. Zdrenka[3], Ł. Szylberg[3,5]
[1]Prof. Franciszek Łukaszczyk Oncology Centre, Clinical Department of Oncology, Bydgoszcz, Poland, [2]Bydgoszcz University of Science and Technology, Department of Animal Biotechnology and Genetics, Faculty of Animal Breeding and Biology, Bydgoszcz, Poland, [3]Prof. Franciszek Łukaszczyk Oncology Centre, Department of Tumour Pathology and Pathomorphology, Bydgoszcz, Poland, [4]Ludwik Rydygier Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University in Toruń, Doctoral School of Medical and Health Sciences, Bydgoszcz, Poland, [5]Ludwik Rydygier Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University in Toruń, Department of Obstetrics, Gynaecology and Oncology, Bydgoszcz, Poland

Background & Objectives: AI algorithms are increasingly being integrated into immune marker assessment, enhancing routine pathology workflows and reducing workload. However, their comparability with human pathologists remains uncertain, as potential inaccuracies could impact future treatment decisions. This study examined the compatibility of PD-L1 expression assessment in non-small cell lung cancer (NSCLC) between an expert pathologist and an AI algorithm.
Methods: The study cohort included 333 NSCLC cases evaluated by an expert pathologist and uPath, a VENTANA PD-L1 (SP263) Assay Algorithm. All slides were digitally scanned for whole-slide analysis. Samples were stained with the SP263 clone antibody, and PD-L1 expression was assessed using the TPS formula. Expression was

categorized as negative (TPS <1%), low (TPS 1–49%), or high (TPS ≥50%). Samples were considered PD-L1-positive if TPS was ≥1%.
Results: We observed a high level of concordance between uPath and pathologist assessments. In 317 cases (95.2%), the samples received the same PD-L1 status (κ = 0.945 [0.932–0.956]), and in 313 cases (94%), they were assigned the same PD-L1 category (κw = 0.92 [0.89–0.96]). There were no significant differences between the results provided by uPath and those given by the pathologist (p = 0.33). On average, PD-L1 expression assessed by uPath was 3 percentage points (pp) higher than that determined by the pathologist, with a 0.5 pp difference in the <1% TPS group, 6.7 pp in the 1–49% TPS group, and 4.3 pp in the ≥50% TPS group. Compared to the pathologist, uPath downstaged 13 cancers and upstaged 7. In our cohort, if clinical decisions had been based solely on uPath assessment, up to 6% of patients might have been affected.
Conclusion: AI-based algorithms show high concordance with expert pathologists in assessing PD-L1 status; however, relying solely on them may impact clinical decision-making. Until more high-quality data become available, verification by a pathologist is recommended.

E-PS-08-061
Digitisation of the London Neurodegenerative Diseases Brain Bank histology archive
T. Mistry[1], D. Oukrif[1], A. Vamanu[2], F. Rocca[2], S. Li[2], S. Downes[2], S. Ometto[3], M. Rodriguez-Justo[1,4], C. Troakes[2], C.A. Glastonbury[3], A.P. Levine[1,4]
[1]University College London, Research Department of Pathology, London, United Kingdom, [2]King's College London, London Neurodegenerative Diseases Brain Bank, London, United Kingdom, [3]Human Technopole, Milan, Italy, [4]University College London Hospitals NHS Foundation Trust, Department of Cellular Pathology, London, United Kingdom

Background & Objectives: The London Neurodegenerative Diseases Brain Bank (LNDBB) is one of the largest brain banks in the United Kingdom with access to central nervous system (CNS) tissue from over 3,000 donors. Formalin-fixed, paraffin-embedded (FFPE) sections from multiple CNS regions stained with H&E, immunohistochemical markers and tinctorial stains are available. We set about digitising slides from over 640 patients, mainly with Alzheimer's disease (AD), with a view to creating a rich digital atlas of the histomorphological features of the CNS and its perturbation in AD.
Methods: Archived slides were retrieved, catalogued, and scanned using Hamamatsu NanoZoomer scanners (S360 and S60), with a custom mount for irregular format slides (2.0-RS). Scanning involved semi-automated focus point setting and quality checks, with rescanning as needed. Whole-slide images (WSI) were de-identified using a Python script/NZMask and uploaded to an OMERO server for management and visualisation.
Results: To date, 11,129 WSI from 271 cases (~40%) have been generated: 10,336 standard/mega and 793 irregular slides. Each case includes an average of 41 slides (range: 12–113), covering 47 CNS regions, seven of which are comprehensively covered (with data from at least 75% of the cases). H&E comprise 29% of the WSI; other common stains include Tau (20%), α-synuclein (15%), amyloid-β (12%), Bielschowsky (8%), TDP-43 (7%), and p62 (6%). The total data size is 30TB.
Conclusion: Despite format variability and data volume challenges, digitising the LNDBB archive is producing a high-value resource for neuropathology research. The WSI dataset will enable computational quantification of histological features and support the development of machine learning models for disease classification and staging. Integration with structured clinical data, whole genome sequencing, and spatial transcriptomics (being generated in parallel) will offer new opportunities for multi-modal analysis and deeper insight into disease mechanisms. The WSI database will be made available to the research community in due course.

Funding: The Jean Shanks Foundation/The Pathological Society of Great Britain & Ireland

E-PS-08-062
Computational pathology improves concordance of Her2-Low diagnosis in breast cancer between experts and routine pathologists from 64 countries using a dataset from CADQAS Her2 IHC digital interpretive proficiency testing (DIPT)
C. D'Arrigo[1], A. Baltan[1], S. Costache[1], A. Chefani[1,2,3], K. Billingham[4], A. Waydelich[5], E. Andersson[5], S. Wedden[3]
[1]Poundbury Cancer Institute, Dorchester, United Kingdom, [2]University Hospital Dorset NHS FT, Histopathology, Poole, United Kingdom, [3]CADQAScic, Dorchester, United Kingdom, [4]Great Western Hospital NHS FT, Histopathology, Swindon, United Kingdom, [5]Roche Diagnostics International Ltd, Rotkreuz, Switzerland

Background & Objectives: CADQAS digital interpretive proficiency testing (DIPT) demonstrated high concordance in Her2 IHC diagnosis amongst participants using the two-tier system (Her2-Positive/Her2-Negative). With the three-tier system (Her2-Positive/Her2-Low/Her2-Negative), there were more clinical errors (20.58% for 3-tier versus 1.89% for 2-tier). We analysed the DIPT responses to identify cases that contributed to the most clinical errors and re-evaluated them using computational pathology to determine if it would improve concordance.
Methods: A total of 724 participants from 64 countries scored 61 cases (7783 scores) in CADQAS Her2 IHC PT from 2021 to date. We identified eight cases (12.5%) that had high discordance amongst DIPT participants. These cases were digitised using a Roche DP600 and assessed with the Roche Her2 algorithm. In parallel, a consensus diagnosis was provided by four experts. The eight cases were assessed independently and any discordance resolved through conference microscopy. Computer-aided diagnoses were compared with expert consensus to assess degree of concordance. We simulated the impact on diagnostic errors if computer-aided diagnoses were used by participants in these challenging cases.
Results: In the simulation, changing participants' diagnoses for computer-aided diagnoses for the eight challenging cases increased concordance with the expert consensus across the whole spectrum of 61 cases and reduced clinical errors. We describe these 8 challenging cases to define parameters identifying cases that should be referred prospectively for computational pathology.
Conclusion: The use of computational pathology for challenging cases improves concordance amongst pathologists. Greater improvement could be obtained by referring challenging cases for expert second opinion but this would impact turnaround times and is limited by capacity of expert pathologists. Implementing computer-aided assistance could be an effective tool to support pathologists in routine practice.

E-PS-08-063
Prediction of pulmonary adenocarcinoma driver mutations using whole slide images through a home made deep learning model
B. Pamuk[1], S. Dizbay Sak[1]
[1]Ankara University Medical School, Medical Pathology, Ankara, Turkey

Background & Objectives: Although driver mutations do not affect the test algorithm for lung adenocarcinomas (LACs), it is known that there are some relationships between morphology and driver mutations. Using artificial intelligence (AI), it may be possible to predict driver mutations based on morphological features. In this study, we aimed to

investigate the extent to which some common driver mutations in LAC can be predicted using AI on H&E (Haematoxylin and Eosin) sections.
Methods: We built a deep learning model (Lung Adenocarcinoma Mutation Prediction Software-LAMPS) to classify LAC mutation based on morphology utilizing 212,592 patches (1024x1024 resolution) from 162 NGS-confirmed cases across five mutation groups (1.KRAS-n:46, 2.EGFR-n:36, 3.BRAF-n:5, 4.Other-n:23, 5.Negative-N:47). We implemented a ResNet50 architecture using TensorFlow, fine-tuning the last 50 layers while preserving nuclear details at 512x512 resolution compatible with WSIs at x20 magnification. Training occurred on Google Colab's A100 GPU using case-based data splitting (70/15/15%) without augmentation to maintain morphological integrity. We employed adaptive learning rates (initial: 4e-5) with automatic reduction upon validation plateau. Classification decisions integrate patch-level predictions to determine case-level results.
Results: Preliminary results at epoch 2 demonstrate 36% case-level accuracy across five mutation groups, significantly exceeding random classification (20%). The model currently shows equivalent patch-level (36.26%) and case-level (36%) accuracy, suggesting consistent feature identification across magnification levels. The classifier performs better on groups with larger sample sizes (G1, G2, G5). We anticipate substantial improvement as training progresses through the remaining epochs with adaptive learning rate adjustments. Based on learning curve trajectories, we project final case-level accuracy above 70%.
Conclusion: LAMPS demonstrates promising potential for predicting LAC mutations from histomorphology providing cost-effective and rapid diagnostic approaches, and act as a screening tool particularly in regions with limited access to genetic testing. Future work will focus on continued training, incorporating additional patient data, and exploring specific histomorphological features associated with each mutation.

E-PS-08-064
Modeling the impact of recall bias on digital pathology and AI performance evaluation and validation
M. Zarella[1], S. Adam[2]
[1]Mayo Clinic, Division of Computational Pathology and Informatics, Department of Laboratory Medicine and Pathology, Rochester, MN, USA, [2]Drexel University, Department of Psychology, Philadelphia, PA, USA

Background & Objectives: Intra-pathologist concordance is a fundamental measure to examine the impact of an intervention on the diagnostic outcome. For example, when AI is clinically validated, a pathologist may be asked to review the same case with and without AI and the results may suggest improvement in accuracy, speed, or reproducibility. However, the influence of study design must also be considered, as viewing the same slide twice can introduce recall bias. Common approaches to reduce recall bias include:

- **Introducing a washout period.** However, as previously shown, even after doubling washout from 2 to 4 weeks ~30% of slides may still be recalled.
- **Randomizing presentation order.** Interleaving AI trials with the control can destroy the correlation between presentation order and the intervention, but for concordance studies the influence of recall persists.
- **Introducing a third trial.** Presenting the slide a third time can enable direct measure of the impact of recall by repeating a previous presentation.
- **Relying on inter-pathologist review.** Each pathologist's performance can be measured against their population results to estimate the effect of the intervention.

Methods: We developed a computational model to simulate the influence of recall bias in a validation study. We then simulated each of the above designs to model the impact of each approach on recall bias.

Results: We found that as recall magnitude and likelihood grows, concordance becomes overestimated. Introducing washout was insufficient to eliminate the impact of recall bias and was only effective when recall approached zero. We found that factors such as strategic and cognitive biases, expectation bias, and difficulty of the task differentially amplified these effects. Inter-pathologist review was the most effective method, but only when inter-pathologist variability was known or measured.
Conclusion: These results emphasize the importance of study design in any validation and provide a reference frame from which to better interpret studies in AI.

Collagen deposition of small bowel neuroendocrine tumour and associated mesenteric deposits under digital investigation
A. Gambella[1], M. Ali[1], F. Checchin[2], D. Malerba[3], V. Sambuceti[4,5], E. D'Este[6], C. Bortolotto[7,8], A. Vanoli[6,9], F. Grillo[1,10]
[1]Department of Surgical Sciences and Integrated Diagnostics, University of Genoa, Genoa, Italy, [2]University of Pavia, Diagnostic Imaging and Radiotherapy Unit, Department of Clinical, Surgical, Diagnostic, and Paediatric Sciences,, Pavia, Italy, [3]University of Pavia, Department of Clinical, Surgical, Diagnostic, and Paediatric Sciences, Pavia, Italy, [4]University of Genoa, Department of Internal Medicine, Genoa, Italy, [5]IRCCS San Martino Hospital, Radiology Unit, Genoa, Italy, [6]University of Pavia, Department of Molecular Medicine, Pavia, Italy, [7]University of Pavia, Diagnostic Imaging and Radiotherapy Unit, Department of Clinical, Surgical, Diagnostic, and Paediatric Sciences, Pavia, Italy, [8]Fondazione IRCCS Policlinico San Matteo, Radiology Institute, Pavia, Italy, [9]Fondazione IRCCS San Matteo Hospital, Anatomic Pathology Unit, Pavia, Italy, [10]IRCCS San Martino Hospital, Pathology Unit, Genoa, Italy

Background & Objectives: Small bowel neuroendocrine tumours (sb-NETs) and related mesenteric tumour deposits (MTDs) can frequently present dense collagen and fibrosis. Remarkably, the relationship between collagen deposition in SB-NETs and MTDs has been poorly evaluated so far, despite their crucial clinical consequences for affected patients in terms of bowel obstruction and ischemia. In this setting, this study explored the relationship between sb-NETs and MTDs fibrosis via tissue-tethered collagen quantitation (CQ).
Methods: Sirius-Red-stained histology sections of sb-NETs and MTDs were retrospectively collected for whole slide image (WSI) development with Leica Aperio AT2 scanner. WSIs were analysed for CQ (i.e., percentage of tissue area occupied by collagen over the whole tissue area of interest) via an automated image analysis algorithm (ImageScope, software version 12.4). CQ was performed on sb-NETS and MTDs as a whole and in sb-NETS mucosa/submucosa and serosa/subserosa compartments.
Results: Seventy sb-NET patients (median age: 70.5 years; 48/70 males) and related MTDs (n=52) were analysed for CQ. Focusing on sb-NETs, we observed significantly higher ($p<0.001$) collagen deposition in the serosa/subserosa (mean CQ: 20.0%) compared to the mucosa/submucosa (mean CQ: 11.4%). The CQ of the sb-NETs as a whole (mean CQ: 14.6%) and of MTDs (mean CQ: 14.5%) did not differ significantly ($p=0.9$). Still, we observed a mild yet significant ($p=0.008$) positive correlation ($r=0.3$) between sb-NETs serosa/subserosa and MTDs CQ.
Conclusion: Our pilot study documented that the overall collagen deposition in sb-NETs and related MTDs did not differ significantly. However, MTD CQ was directly related to the CQ of the sb-NET serosa/subserosa compartment. These preliminary findings indicate that compartment collagen deposition rather than absolute quantitation may be relevant for sb-NET MTD patients. Therefore, we endeavor to further

enrich our tissue-tethered CQ analysis with spatial metabolomic and molecular granularity to evaluate and identify clinically meaningful predictive biomarkers.

Ultrastructure of transformed smooth muscle cells in the myometrium of patients with placenta accreta spectrum

N. Nizyaeva[1], T. Sukhacheva[1], E. Milyutina[2], N. Gabitova[2], T. Patsaev[3], R. Deev[4], L. Mikhaleva[4]

[1]Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Reproduction Pathology, Moscow, Russia, [2]Vidnovskiy Perinatal Centre, Vidnoe, Russia, [3]National Research Centre "Kurchatov Institute", Moscow, Russia, [4]Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Moscow, Russia

Background & Objectives: The myometrium of patients with placenta accreta spectum disorder (PAS) in late gestation undergoes significant changes, especially in the area adjacent to the scar.
The aim of the study: To investigate the ultrastructure of smooth muscle cells (SMCs) in the periscar area.
Methods: The myometrium of 19 patients (28-42 years old) with a gestation of 32-38 weeks diagnosed with placenta increta, excised from the area adjacent to the scar, was examined. Tissue fragments were fixed with glutaraldehyde, embedded in araldite, samples were studied using a transmission electron microscope. Semi-thin sections were stained with PAS reaction.
Results: In the myometrium adjacent to the scar, a peculiar transformation of some SMCs was found (tSMCs), determined only at the ultrastructural level. tSMCs, with an average diameter of 5,2±1,1 μm, were located among SMCs of normal structure and size (average diameter 6,9±2,1 μm). The cytoplasm of tSMCs was almost completely devoid of myofibrils, contained ribosomes, small clusters of cisterns of granular endoplasmic reticulum, rare mitochondria, nuclei contained dispersed chromatin, fragments of dense bodies were visualized under the plasma membrane. An unusual feature of tSMCs were numerous protrusions of the plasmalemma, with the formation of bubbles, with a diameter of 1,55±0,64 μm, in which microvesicles were preserved. On semi-thin sections clusters of such bubbles were visible in the intercellular space near the SMCs. This resembles a peculiar variant of programmed cell death, but without the change in chromatin condensation characteristic of apoptosis. Such changes were recorded in 31,5% of cases.
Conclusion: In the myometrium of patients with PAS at 32-38 weeks of gestation, tSMCs with unusual ultrastructural signs of cytoplasm budding with the formation of "bubbles" were detected in the area adjacent to the scar. Perhaps, these signs may indicate the initiation of a previously unknown mechanism of peculiar cell death, which requires further study.

Analysis of the effects of aggressive subtypes of papillary thyroid carcinoma. Histological subtype as a good predictor of clinical outcome

R. Onieva[1], M.R. Escoda[1], R.S. Gómez[1], F. Alberto[1], C. Padilla[1], J.C. Ferreres[1], M.R. Bella[1]

[1]Parc Taulí Hospital Universitari, Institut d'Investigació i Innovació Parc Taulí (I3PT-CERCA), Universitat Autònoma de Barcelona, Pathology, Sabadell, Spain

Background & Objectives: Papillary thyroid carcinoma (PTC) is the most common malignant endocrine neoplasm. Currently, there are no reliable indicators to predict which cases will recur. For this reason, identifying aggressive histological subtypes (AS) is crucial, as it may indicate cases with a higher risk of recurrence. In this study, we aim to reclassify PTC according to the current criteria (WHO, 5th edition) to assess the impact of identifying AS on defining patients at higher risk of recurrence.
Methods: Retrospective cohort study. All PTC cases of AS diagnosed at our centre between 2000 and 2017 were selected as cases, and all non-aggressive subtype PTCs were selected as controls. Each case was histologically reviewed, excluding non-invasive follicular thyroid neoplasms with papillary carcinoma-like nuclear features (NIFTP) and incidental diagnoses. The PTC subtype was re-diagnosed and correlated with 5-year follow-up.
Results: A total of 313 cases were selected. 107 cases were excluded (15 NIFTP, 81 incidental diagnoses, and 11 incidental NIFTPs). Of the 206 included cases, 10 were AS (mean age 55 years, 60% women, 60% with affected lymph nodes at diagnosis; 8 tall cell subtype, 2 hobnail subtype) and 196 were non-aggressive subtypes (mean age 44 years, 75% women, 50% with affected lymph nodes at diagnosis; 72% classic subtype). AS, compared to non-aggressive subtypes, showed a higher frequency of recurrence (50% vs 6.6%, $p<0.05$), angiolymphatic and/or perineural invasion (70% vs 26%, $p<0.05$), and the only case of disease-related death within the 5-year follow-up.
Conclusion: Identifying AS in PTC is essential for identifying cases with a higher likelihood of recurrence. In our cases, aggressive subtypes represent 4.9% of cases but account for 27.8% of recurrent cases. Therefore, it is of utmost importance to identify them, as it seems useful to define a subgroup of patients at higher risk of recurrence.

Unraveling neoplastic progression in NETs: comprehensive genomic profiling of two composite G1-G3 cases

V. Guastafierro[1,2], A. Destro[2], N. Rudini[2], S. Fraticelli[1,2], U. Silvia[1,2]

[1]Humanitas University, Department of Biomedical Sciences, Milano, Italy, [2]IRCCS Humanitas Research Hospital, Department of Pathology, Milan, Italy

Background & Objectives: The molecular landscape of NETs is heterogeneous, varying by grade and anatomical site. Due to their rarity and diversity, comprehensive molecular profiling has been limited. G3 NETs have been shown to share a molecular profile with G1-G2 NETs, but little is known about neoplastic progression from G1 to G3. Here, we present two cases of composite NETs, one pancreatic and one rectal, with G1 and G3 components. Separate histopathological and deep genomic profiling on both components were performed, with the aim to investigate neoplastic progression.
Methods: Histological examination, immunohistochemical studies and molecular genetics testing were performed on FFPE material. Genomic profiling was performed with the Ion Torrent Oncomine™ Comprehensive Assay Plus (OCA-Plus), a NGS approach analysing more than 500 genes simultaneously in terms of single-gene variants, copy number variations (CNV) as well as other genetic parameters (e.g., MSI, LOH, GIM).
Results: **Pancreatic NET:** G1 component revealed a KMT2A missense mutation (VAF 64.2%) with no LOH, CNVs, or chromosomal structural aberrations. In contrast, G3 component harboured a VHL frameshift mutation (VAF 34.4%), multiple CNV losses (e.g. PTEN, ARID5B, PBRM1, RASA1), and chromosome arm loss (3q, 10q), with LOH increasing to 12.5%.
Rectal NET: G1 component exhibited a ST6GAL2 missense mutation and CNV losses of X-linked genes, while G3 showed an RBM10 indel (VAF 69.7%), widespread CNV losses (including but not limited to SETD2, ARID5B, PTEN, KMT2A, SMAD4), and a TSC2 gene gain.

The higher CNVs and LOH in rectal G3 NETs support a progressive accumulation of genomic alterations during tumour evolution.
Conclusion: This is the first report of two composite G1-G3 GEP NETs with deep molecular characterization, providing novel insights into neoplastic progression, particularly in rectal NETs, with potential implications for precision oncology.

E-PS-10-003
An almost impossible case - testicular adrenal rest tumour in a patient without congenital adrenal hyperplasia
M.A. Publik[1], A.V. Dumitru[2], O. Bratu[3], C. Alius[4], M.C. Ceausu[1]
[1]"C.I. Parhon" National Institute of Endocrinology, Pathology, Bucharest, Romania, [2]University Emergency Hospital, Pathology, Bucharest, Romania, [3]University Emergency Hospital, Urology, Bucharest, Romania, [4]University Emergency Hospital, General Surgery, Bucharest, Romania

Background & Objectives: Testicular adrenal rest tumours (TARTs) are adrenal tumours that develop within the testicle. They are most commonly associated with congenital adrenal hyperplasia (CAH), where their prevalence ranges from 6% to 54%, depending on the subtype. However, in non-CAH populations, TARTs are exceedingly rare, with no documented cases in otherwise healthy individuals.
Methods: We present the case of a 43-year-old male who presented to the emergency room with left testicular pain. A local examination revealed a testicular mass of unclear origin, confirmed by ultrasound. The patient had undergone a left inferior polar nephrectomy two months earlier for clear cell renal cell carcinoma (CC-RCC). Given the potential for metastasis, an orchidectomy was performed. Blood tests ruled out CAH.
Results: Macroscopic examination revealed a 6mm, yellow, nodular mass within the testicular parenchyma, finely encapsulated. Microscopic analysis showed a nodular mass composed of medium- and large-sized cells with abundant multivacuolated cytoplasm, mitotically inactive. The cells were organized in nests separated by fine fibrous septa, with no areas of necrosis and a peripheral pseudocapsule. Immunohistochemistry showed positivity for SF1, MART-1, and AR, while S100, CAIX, PAX8, SALL4, and CD68 were negative. These findings support a diagnosis of TART with a cortical component and exclude the possibility of a metastatic nodule.

Conclusion: Although the clinical context and macroscopic appearance initially suggested a secondary tumour from CC-RCC, this case represents an extremely rare occurrence, likely the only documented instance in the literature. Immunohistochemistry was the sole reliable diagnostic tool in this case.

E-PS-10-004
Thyroid incidentalomas. The experience of a regional university hospital
S. Haro Yuste[1], J. Osuna Soto[1], I. Sánchez Ramírez[1], M.J. Gálvez Medina[1], F. Leiva-Cepas[1]
[1]Hospital Universitario Reina Sofía de Córdoba, Anathomical Pathology, Córdoba, Spain

Background & Objectives: Papillary carcinoma (PTC) is the most common primary thyroid malignancy. It is clinically suspected after cervical examination and ultrasound examination of the lesion. Incidental pathological diagnosis in some autopsy series rises to 30%.
Methods: A retrospective review of thyroidectomy specimens received at our centre over the past 5 years was conducted, and the clinical characteristics of the patients and the pathological characteristics of the tumours were compiled for those specimens in which a malignant tumour was incidentally diagnosed. Thus, those procedures in which there was prior clinical, radiological, or cytological suspicion of a malignant thyroid tumour were excluded.
Results: Between 2020 and 2024, a total of 377 thyroidectomies were performed at our centre without prior suspicion of malignancy. Of these, 23 PTC(6%) were incidentally diagnosed. In these cases, the tumours had a median size of 5 mm (range, 1–50 mm); the most frequent histological subtype was the classic pattern (16, 69%). The remaining subtypes consisted of 3 cases of encapsulated PTC, 2 cases of encapsulated and invasive follicular papillary carcinoma, 1 case of tall cell variant, and 1 case with a solid-trabecular pattern. The tumour was multifocal in 3 cases; no bilateral tumours were detected. Lymphovascular invasion was identified in 2 cases. Six cases presented involvement of the thyroid capsule.
Conclusion: The incidental finding of papillary thyroid carcinoma in thyroidectomy specimens indicated for benign pathology is not uncommon and should be taken into account when performing the pathological study of these specimens. Although in most cases these are small, early-stage tumours, in which surgical resection is considered curative, their diagnosis is always important for subsequent patient follow-up. Therefore, it is always advisable to perform a comprehensive sampling of the specimen and actively search for them so that they do not go unnoticed.

E-PS-10-005
Atypical parathyroid adenomas - case report series
L. Ilic[1], A. Lazarević[1], A. Milićević[1], N. Medić-Milijić[1], O. Živković[1], N. Santrač[2]
[1]Institute for Oncology and Radiology of Serbia, Department of Pathology and Other Diagnostics, Belgrade, Serbia, [2]Institute for Oncology and Radiology of Serbia, Clinic for Oncological Surgery, Belgrade, Serbia

Background & Objectives: Atypical parathyroid adenoma (APA) is a rare entity within the spectrum of parathyroid neoplasms, exhibiting histological features suggestive of malignancy but lacking the definitive criteria for parathyroid carcinoma. APA is defined as an intermediate lesion, requiring careful evaluation due to its uncertain malignant potential. Given its atypical histopathological features and potential for recurrence, an accurate diagnosis is critical for optimizing clinical management. This case series presents three patients diagnosed with APA, highlighting the diagnostic challenges and surgical outcomes.
Methods: The study included three patients: two males (66 and 76 years old) and one 46-year-old female, all presenting with elevated serum calcium (Ca) and parathyroid hormone (PTH) levels, consistent with primary hyperparathyroidism. Radiographic evaluation using neck ultrasound and scintigraphy localized enlarged and hyperfunctioning parathyroid lesions. Each patient underwent parathyroidectomy, and the resected specimens were subjected to intraoperative frozen section analysis, which was inconclusive, necessitating further histopathological examination.
Results: Macroscopic examination revealed well-circumscribed tumours without definitive invasion into surrounding tissues. Histopathological analysis demonstrated trabecular and solid growth patterns, increased cellularity, fibrous bands with hemosiderin deposition, and focal nuclear atypia with prominent nucleoli. Immunohistochemical analysis confirmed GATA3, synaptophysin, and chromogranin expression, with low Ki-67 proliferation indices.
Conclusion: APA presents a diagnostic and management challenge due to its histological overlap with parathyroid carcinoma. Unlike benign adenomas, APAs exhibit atypical cytological features and require long-term follow-up due to their potential for recurrence. Surgical resection remains the primary treatment, and accurate classification using WHO diagnostic criteria is essential for appropriate patient management. This case series underscores the importance of comprehensive histopathological evaluation in differentiating APA from other parathyroid neoplasms.

E-PS-10-006

SDHB expression in pheochromocytomas: immunohistochemical correlation and genetic findings

A.M. Montaña Ramirez[1], R. Rendon Garcia[1], A. Alvarez Muñoz[1], C. Alfonso Rosa[1], J. Machuca Aguado[1], J. Rubio Garrido[1]
[1]Hospital Universitario Virgen Macarena, Pathology, Seville, Spain

Background & Objectives: Pheochromocytoma is a rare neuroendocrine tumour originating from the sympathetic or parasympathetic ganglia, primarily in adrenal medulla chromaffin cells. It generally presents with a low incidence and favourable prognosis following surgical resection. Approximately 40% of cases have genetic origins, notably associated with mutations in the SDH, VHL, RET, and NF1 genes.

Methods: A cohort of 30 patients diagnosed with pheochromocytoma at our centre between 2001 and 2024 was analysed. Immunohistochemical (IHC) staining for SDHB expression was performed and evaluated by three pathologists.

Results: The cohort comprised 16 women (53.3%) and 14 men (46.7%), with a mean age of 52.1 years at diagnosis. The right adrenal gland was the most common site of involvement (17 cases, 56.6%). Bilateral involvement was observed in 2 cases (6.6%), both linked to MEN2a syndrome. Only one patient presented with metastatic disease, showing vertebral involvement at D5.

IHC for SDHB was negative in 6 of the 30 cases (20%), indicating a clear loss of expression with proper internal positive controls. Germline genetic testing was conducted in 14 patients, two of whom exhibited SDHB loss without corresponding germline mutations.

Other germline alterations identified in these 14 patients included:

- 4 cases linked to MEN2a, all with medullary thyroid carcinoma.
- 1 case associated with VHL, resulting in clear cell renal carcinoma.
- 1 case with NF1.

Conclusion: Various genetic mutations causing pheochromocytoma have been reported, with SDH complex mutations being the most common, present in over 10% of cases. In our cohort, 20% exhibited SDHB loss, the predominant alteration. Notably, two of the 6 patients with SDHB loss (33.3%) did not have germline SDH mutations, suggesting additional molecular alterations contribute to SDHB loss, underscoring the importance of further molecular analysis in clinically suspicious cases.

E-PS-10-007

Oncocytic adrenal cortical carcinoma in a one-year-old male infant, a rare finding

S. Al Khatib[1], R. Darayseh[1], S. Al Bashir[1], S. Al-Sweedan[2]
[1]Jordan University of Science and Technology, Pathology and Laboratory Medicine, Irbid, Jordan, [2]Jordan University of Science and Technology, Paediatrics, Irbid, Jordan

Background & Objectives:

- A one-year-old male infant who presented to the Endocrinology out-patient clinic after his mother had noticed increasing hair growth on lower limbs, upper lip and genital area for the past two months. The patient's voice getting deeper, acne starting to form on his forehead, with increasing irritability and aggression. P/E revealed enlarged testicles and a large penile shaft.
- The 24-hour suppression test yielded a cortisol level of 324.24 mcg/dl, i.e. not suppressed. CT-adrenal protocol showed a large left suprarenal mass with foci of calcification and heterogeneous enhancement measuring 6.3 x 4.2 cm.
- DHEAS level was very high of 1000 mcg/dl. 24-hour urine collection for VMA and HVA was within normal range.

Methods:

- The specimen was fixed in 10% buffered neutral formalin. PEFF sections were stained with routine (H&E).

Results:

- M/E shows an encapsulated tumour composed of sheets of oncocytic polygonal cells with granular eosinophilic cytoplasm amongst scattered foci of necrosis associated with dystrophic calcifications. The cells exhibit marked pleomorphism with variably bizarre nuclear forms, including binucleated and multinucleated giant cells, and enlarged "cherry-red" nucleoli.
- Grading done according *to the Weiss criteria:* nuclear Fuhrman grade III or IV, diffuse architecture (more than 33% of tumour volume), patchy necrotic areas with associated dystrophic calcifications, subcapsular sinusoidal invasion, and focal capsular infiltration. Mitotic rate is > 5 /50 HPF, no atypical mitotic figures. Clear cells are < 25% of tumour volume. Tumour achieved a score of 7, rendering the diagnosis, adrenal cortical carcinoma.
- *Pertaining to the Lin-Weiss-Bisceglia (LWB) system:* Tumour exhibits a major criterion: >5 mf/50 high power fields, rendering the diagnosis malignant adrenal cortical tumour.

Conclusion: The annual incidence of adrenal cortical carcinoma (ACC) is extremely low, with only 0.2 to 0.3 cases per million children. Oncocytic ACC in children is an even rarer diagnosis, with around only 20 cases reported in the literature.

E-PS-10-008

Tall cell papillary thyroid carcinoma with desmoid fibromatosis-type stroma: a case report and molecular study

K. Christofidis[1], J. Tantot[1], F. Descotes[2,3], J. Lopez[2,3], L. Maillard[4], M. Decaussin-Petrucci[1,5]
[1]Lyon Sud Hospital, Hospices Civils de Lyon, Department of Pathology, Pierre Benite, France, [2]Lyon Sud Hospital, Hospices Civils de Lyon, Biochemistry and Molecular Biology Department, Pierre Benite, France, [3]Claude Bernard Lyon 1 University, Lyon, France, [4]Lyon Sud Hospital, Hospices Civils de Lyon, Endocrine Surgery Department, Pierre Benite, France, [5]Cancer Research Centre of Lyon, Lyon 1 University, INSERM1052 CNRS5286, Lyon, France

Background & Objectives: Papillary thyroid carcinoma (PTC) is a common cancer with several histological subtypes. Less than 60 cases of PTC with fibromatosis/fasciitis-like/desmoid-type stroma have been reported, with only a few published molecular data. This subtype has two distinct components: a classic PTC and a stromal component resembling fibromatosis, nodular fasciitis, or desmoid tumours. The latter component complicates both the diagnosis and the treatment.

Methods: We report a case of a 47-year-old woman who came to our hospital for a total thyroidectomy following the incidental discovery of a 26 mm, EU-TIRADS 4 and Bethesda V (suspicious for papillary carcinoma) thyroid nodule. Upon histological examination we discovered a biphasic tumour. The epithelial component was a tall cell papillary thyroid carcinoma, BRAF-V600E positive by immunohistochemistry. The mesenchymal component had a desmoid fibromatosis morphology with long, sweeping fascicles of bland fibroblasts and myofibroblasts. These cells were negative for cytokeratins, BRAF-V600E, TTF1 and PAX8 and positive for SOX11 and SMA, with focal nuclear expression of β-catenin. The tumour invaded focally the strap muscles. No vascular invasion and lymph node metastasis were found. The surgical margins were negative. A large NGS panel was performed by dissecting each component: BRAF-V600E and CTNNB1 mutations were found in the epithelial and the mesenchymal component, respectively. The patient received radioactive iodine therapy and is free of recurrence 12 months after surgery.

Results: This case adds to the current knowledge of the very rare PTC with fibromatosis/fasciitis-like/desmoid-type stroma and highlights the importance of its accurate diagnosis, since it may be easily misdiagnosed, especially as anaplastic carcinoma. The prognosis will be influenced by both components. While distant metastases have not yet been documented in the literature, extrathyroidal extension and lymph node metastases are frequent. Recurrence rates vary between studies.
Conclusion: Greater understanding of this tumour will help pathologists avoid diagnostic errors and clinicians formulate better treatment strategies.

E-PS-10-009
Diagnostic utility of Cadherin 17 in well differentiated neuroendocrine tumours and paragangliomas
Š. Lopatová[1], F. Gabalec[2], M. Kosák[3], J. Soukup[1,4,5]
[1]Military University Hospital Prague, Department of Pathology, Prague, Czech Republic, [2]Charles University, Faculty of Medicine in Hradec Králové and University Hospital Hradec Králové, 4th Department of Internal Medicine, Hradec Králové, Czech Republic, [3]First Faculty of Medicine, Charles University and Military University Hospital, Department of Internal Medicine, Prague, Czech Republic, [4]Charles University, First Faculty of Medicine and General University Hospital in Prague, Prague, Czech Republic, [5]Charles University, Faculty of Medicine in Hradec Králové and University Hospital Hradec Králové, Hradec Králové, Czech Republic

Background & Objectives: Cadherin-17 (CDH17) is a membranous protein expressed primarily in intestinal epithelial cells and tumours of gastrointestinal origin. However, the data on CDH17 in neuroendocrine neoplasms are limited. This study aimed to evaluate CDH17 expression across various subsets of neuroendocrine tumours and to correlate differences with tumour type and primary site of origin.
Methods: Tissue microarrays (TMAs) were created using representative samples from 96 neuroendocrine tumours, including paragangliomas (n = 32), well-differentiated neuroendocrine tumours (WDNETs, n = 59) of different sites, and medullary thyroid carcinomas (MTC, n=5). TMAs were analysed with CDH17 antibody, and the staining intensity was assessed using the immunoreactive score (IRS). The associations between CDH17, tumour subtype and its origin were assessed.
Results: WDNETs exhibited significantly higher expression of CDH17 ($P < 0.00001$) compared to paragangliomas. CDH17 immunoreactivity was observed in 57.6% (34/59) WDNETs, while all the paragangliomas were negative. In the WDNET group, CDH17 expression varied by primary site and it could be detected in 95% (19/20) of gastrointestinal tumours, 57.1% (8/14) pancreatic tumours, 23.5% (4/17) lung tumours. All parathyroid adenomas (n=4) and MTCs (n=5) were negative. The IRS in gastrointestinal tumours was significantly higher (median 8), compared to pancreatic (median 1), lung (median 0), and parathyroid tumours ($p<0.00001$). CDH17 immunoreactivity showed 100% specificity but only 57.63% sensitivity for distinguishing between WDNETs and paragangliomas. Any CDH17 positivity was 95% sensitive and 65.71% specific for WDNETs of gastrointestinal origin.

Conclusion: CDH17 seems to be a highly specific marker of WDNETs and a sensitive marker of a subset of gastrointestinal WDNETs.

Improving sensitivity in the study of TERT C228T mutation in thyroid adenoma and carcinoma: use of digital PCR and the challenge of low allele frequencies
R. Onieva[1], A. Asensi[1], L. Escudero[1], B. Bella[1,2], A. Casas[3], R. Gómez[1], N. Papaleo[1], R. Carrera[1], M.R. Escoda[1], J.C. Ferreres[1], M.R. Bella[1]
[1]Parc Taulí Hospital Universitari, Institut d'Investigació i Innovació Parc Taulí (I3PT-CERCA), Universitat Autònoma de Barcelona, Pathology, Sabadell, Spain, [2]Hospital Universitari Dr. Josep Trueta, Pathology, Girona, Spain, [3]Universitat Autònoma de Barcelona, Bellaterra, Spain

Background & Objectives: The differential diagnosis between follicular or oncocytic thyroid adenoma and carcinoma requires the assessment of invasion, which is only possible in surgical specimens. In this context, the study of the C228T TERT mutation becomes relevant due to its association with carcinoma. At our centre, we replaced pyrosequencing (PS) with digital PCR (dPCR), a more sensitive and precise technique. Using dPCR, we studied thyroid lesions that were considered indeterminate for the TERT mutation by PS.
Methods: All thyroid lesions from our centre with indeterminate results for the TERT mutation over the past 10 years were selected. Additionally, 4 follicular carcinomas and 1 oncocytic adenoma with C228T TERT mutation and 4 without it by PS were included. dPCR for TERT C228T was performed on all samples, with a positive result considered when the allele frequency of the mutation was >1%.
Results: 12 cases indeterminate for the C228T TERT mutation were included (6 follicular carcinomas, 5 oncocytic adenomas, 1 follicular adenoma). dPCR showed concordant results with PS in the 5 positive cases (including the oncocytic adenoma) and the 4 negative ones. Of the indeterminate cases, 4 follicular carcinomas, one oncocytic adenoma, and one follicular adenoma were positive for the TERT mutation. 2 follicular carcinoma and 4 oncocytic adenomas were negative. Adenomas with the TERT mutation showed allele frequencies lower than 8%, but 3 follicular carcinomas that were indeterminate by PS and positive by dPCR showed similar allele frequencies.
Conclusion: dPCR allows determinations of the presence or absence of the C228T TERT mutation in PS-indeterminate cases, with concordance in both positive and negative results. However, C228T TERT mutation should be interpreted with caution as a malignancy criterion, as it may occur in adenomas, especially at low allele frequencies.

Altered expression of autophagy-related molecules and β-catenin in different subtypes of thyroid cancer: colocalization with intranuclear cytoplasmic inclusion
Y. Sailaubekova[1], K. Matsuda[1], Y. Akazawa[2], H. Kurohama[1], Y. Matsuoka[1], K. Suzuki[3], A. Kerimbayeva[1], V.P.T. Nguyen[1], T.N.A. Nguyen[1], T.N. Nhung[1], S. Satoh[4], H. Shindo[4], H. Yamashita[4], M. Nakashima[1]
[1]Atomic Bomb Disease Institute, Nagasaki University Graduate School of Biomedical Sciences, Department of Tumour and Diagnostic Pathology, Nagasaki, Japan, [2]Nagasaki University Graduate School of Biomedical Sciences, Department of Histology and Cell Biology, Nagasaki, Japan, [3]Atomic Bomb Disease Institute, Nagasaki University Graduate School of Biomedical Sciences, Department of Radiation Medical Sciences, Nagasaki, Japan, [4]Yamashita Thyroid Hospital, Fukuoka, Japan

Background & Objectives: Different histological subtypes of thyroid carcinomas (TCs) are strongly associated with tumour aggressiveness. Autophagy is a crucial cellular process that plays an important role in

maintaining cellular homeostasis. Intranuclear cytoplasmic inclusions (INIs), which represent an important diagnostic pathological feature of papillary (TC), may be involved in autophagy and proteolysis, owing to the presence of the autophagy-associated proteins p62 and LC3 within them. This study aimed to clarify the expression levels of autophagy-related molecules, such as, LC3B, p62, and β-catenin, in cases of TC of different histological subtypes and clinicopathological characteristics.
Methods: A total of 70 surgically resected thyroid nodules, including five follicular adenoma (FA), five hyalinizing trabecular tumour (HTT), five follicular TC (FTC), 43 PTC, six poorly differentiated TC (PDTC), and six anaplastic TC (ATC), were analysed by dual-colour immunofluorescence for β-catenin, LC3B, and p62. Statistical analyses were used to determine the associations of autophagy-related molecules with *BRAF*^{V600E}*/TERT* promoter mutations, Ki-67 labelling index, and clinicopathological characteristics.
Results: p62 immunoreactivity was most frequently seen in PTC, particularly in the papillary and tall cell types. This protein appeared to colocalize with LC3B and β-catenin in PTC INIs. Conversely, p62 expression was only rarely seen in both FTC and PDTC. The expression levels of p62 and its colocalizations with β-catenin and LC3B correlated significantly with the presence of the *BRAF*^{V600E} mutation. Frequent colocalization of dot-shape perinuclear β-catenin signals with a component of the trans-Golgi apparatus in tall cell PTC was also observed.
Conclusion: This study revealed differences in the expression patterns of LC3B, p62, and β-catenin among different TC subtypes. Abnormal β-catenin expression may be linked to autophagy dysfunction that triggers genomic instability and promotes tumour aggressiveness. These autophagy-related molecules may be cooperatively associated with formation of INIs during PTC carcinogenesis.

NGS analysis for non-invasive thyroid nodules showing nodule-in-nodule appearance with poorly differentiated component with homemade thyroid cancer gene panel

K. Matsuda[1], M. Ueda[1], H. Kurohama[1], T. Cohen[1], H. Mishima[2], H. Shindo[3], S. Sato[3], H. Yamashita[3], K.-I. Yoshiura[2], N. Mitsutake[4], N. Masahiro[1]
[1]Atomic Bomb Disease Institute, Nagasaki University, Department of Tumour and Diagnostic Pathology, Nagasaki, Japan, [2]Atomic Bomb Disease Institute, Nagasaki University, Department of Human Genetics, Nagasaki, Japan, [3]Yamashita Thyroid Hospital, Fukuoka, Japan, [4]Atomic Bomb Disease Institute, Nagasaki University, Department of Radiation Medical Sciences, Nagasaki, Japan

Background & Objectives: Poorly differentiated thyroid carcinoma (PDTC) is aggressive and is reportedly evoked by well-differentiated thyroid follicular-patterned tumours (TFTs). TFTs showing nodule-in-nodule (NN) appearance with PD component (PDc) but neither invasion nor metastasis are regarded as benign nodules despite their high-grade histological features. Our recent study demonstrated the prevalence of *NRAS* and *TERT* promoter (*TERT*-p) mutations in PDc was comparable to that of carcinomas, presuming that PDc in NN is potentially a precursor lesion associated with PDTC (*Cancers 2022:14,3577*). Therefore, this study analysed NN with PDc by NGS on our homemade thyroid cancer panel (HTCP) to furtherly characterized its genetic profiles.
Methods: Total 87 cases of TFTs, such as NN with PDc (n=13), adenomatous goiters (AGs, n=27), Follicular adenoma (FAs, n=24), and follicular TCs (FTCs, n=23), were available in this study. All subjects were FFPE samples and analysed using a HTCP containing 29 oncogenes by HiSeqX Ten (Microgen, Tokyo, Japan).
Results: Frequencies of *RAS* mutations were significantly higher in NN with PDc [76.9% in both PDc and Outer nodule (OutN)] than AG (7.4%) or FA (25.0%) but not significantly different from FTC (39.1%). *TERT*-p mutations were more frequent in PDc (23.1%) than OutN (7.7%), AG (3.7%), and FA (4.2%) but comparable to FTC (21.7%). Double mutation in *RAS* and *TERT*-p were found in 15.4% of PDc and 21.7% of FTC, but not in OutN. Furthermore, our analysis with our HTCP could detect any mutations (MAF>10%) in 92.3% of NN with PDc, 48.1% of AG, 45.8% of FA, and 65.2% of FTC.
Conclusion: This study demonstrated a higher incidence of detectable mutations in NN with PDc than FTC. *TERT*-p mutations in PDc were comparable to FTC. *TERT*-p mutations are most common in PDTC but rare in TFTs, supporting our hypothesis that PDc in NN is potentially a precursor lesion associated with PDTC.

Prognostic markers in paragangliomas: the role of histopathology, SDHB, MAML3 and MCM6 expression

E. Yaldır[1], B.B. Cengiz[2], O.F. Mülkem[1], M.F. Açikalin[1]
[1]Eskisehir Osmangazi University, Faculty of Medicine, Pathology, Eskişehir, Turkey, [2]Kütahya Health Sciences University Evliya Çelebi Education and Research Hospital, Pathology, Kütahya, Turkey

Background & Objectives: There are currently no definitive prognostic markers that accurately predict malignant behaviour in paragangliomas. While metastasis develops in only 10-15% of adrenal-origin tumours, this rate can rise up to 50% in those with extra-adrenal localization. This study aims to investigate the potential predictive effect of known histopathological features in paragangliomas, alongside SDHB, S100, Ki-67 proliferation index, and the expression of MAML3 and MCM6 in predicting metastatic disease.
Methods: The specimens of 71 patients who were diagnosed with pheochromocytoma and paraganglioma and underwent total excision between 2010 and 2021 were re-examined. Demographic, clinical, and histopathological data, as well as immunohistochemical results for Ki-67, S100, SDHB, MCM6, and MAML3, were recorded.
Results: While distant organ metastasis was observed in 3.4% (n=1/29) of pheochromocytomas and 21.2% (n=7/33) of head and neck paragangliomas, this rate was found to be significantly higher at 66.7% (n=6/9) in abdominal paragangliomas ($p<0.001$). No MAML3 overexpression was observed in any of the cases. Distant organ metastasis was more frequently detected in cases with MCM6 overexpression.
Conclusion: Although there is still no definitive feature that predicts metastasis, in line with the literature, extra-adrenal localization, vascular invasion, capsular invasion, nuclear pleomorphism, hyperchromasia, and confluent necrosis were found to be associated with distant organ metastasis in our study. Additionally, in the multivariate analysis, larger tumour size (>5.1 cm), the presence of >3/10 HPF mitosis, and SDHB loss were associated with lower metastasis-free survival. While no conclusions could be drawn regarding MAML3, the prognostic value of MCM6 appears promising.

E-PS-10-014

Metastatic mesenchymal chondrosarcoma with unusual thyroid involvement

S. Yilmaz Erozbek[1], T.C. Savli[1], A. Cakir[1], Y. Ozdenkaya[2]
[1]Istanbul Medipol University, Pathology, Istanbul, Turkey, [2]Istanbul Medipol University, General Surgery, Istanbul, Turkey

Background & Objectives: Mesenchymal chondrosarcoma is a rare, high-grade malignant chondrogenic tumour, characterized by a biphasic pattern consisting of a primitive mesenchymal component and a well-differentiated cartilaginous matrix. It typically arises in soft tissue or bone. Distant metastasis can be observed even many years later. Visceral involvement/presentation is rare, only a few cases of metastasis to the thyroid have been reported.
Methods: A 32-year-old male patient presented with a thyroid mass. A 4 cm nodule was detected in the right thyroid lobe. Due to an inadequate fine-needle aspiration, total thyroidectomy was performed for definitive diagnosis.
Results: Gross examination revealed two separate firm, cream-white nodular lesions (4.5×3.4×2.5 cm and 1×0.8×0.8 cm) in the right lobe. Histologically, tumour showed small to medium-sized, poorly differentiated high cellular round cells, along with well-differentiated hyaline cartilage tissue. The round cell component was accompanied by staghorn vascular structures and had high mitotic activity (24/10 HPF, 12/mm²). Immunohistochemically, the tumour was diffusely SOX-10 positive. CD99 was positive in the round cell component, and S100 in the chondroid component. TLE-1 was patchy, while TTF-1, PAX-8, SS18-SSX were negative.
Further investigation revealed a prior diagnosis (2 years earlier) of a 'mitotically active spindle cell tumour' in the lung. NGS analysis of this tumour identified a HEY1-NCOA2 fusion.
Based on these findings, we established the diagnosis of metastatic mesenchymal chondrosarcoma.
Conclusion: Mesenchymal chondrosarcoma is a rare tumour, primarily affecting young adults. Pulmonary and thyroid involvement are uncommon, making diagnosis challenging, especially in small biopsies without a cartilaginous component, in such situation tumour can be misdiagnosed as other small round cell neoplasms, such as Ewing sarcoma, lymphoma, synovial sarcoma, rhabdomyosarcoma without immunohistochemical evaluation. The HEY1-NCOA2 gene rearrangement is a key molecular marker. Given its aggressive nature, complete surgical resection followed by adjuvant chemotherapy remains the preferred treatment.

E-PS-10-015

Shared and pattern-specific molecular signatures in anaplastic thyroid carcinoma identified by spatial transcriptomics and immunohistochemical profiling

C.K. Jung[1,2], F. Haq[1,2,3], S. Jeon[2], A. Bychkov[4], O. Mete[5]
[1]College of Medicine, The Catholic University of Korea, Department of Hospital Pathology, Seoul, Republic of Korea, [2]Cancer Research Institute, The Catholic University of Korea, Seoul, Republic of Korea, [3]The Catholic University of Korea, Department of Biomedicine and Health Sciences, Seoul, Republic of Korea, [4]Kameda Medical Centre, Department of Pathology, Kamogawa, Japan, [5]University Health Network, University of Toronto, Department of Pathology, Toronto, Canada

Background & Objectives: Anaplastic thyroid carcinoma (ATC) is a rare and highly aggressive malignancy characterized by marked histological heterogeneity. However, the extent to which this morphological variation reflects underlying molecular programs remains poorly understood. This study aimed to identify both shared and histologic pattern-specific molecular features by integrating spatial transcriptomics with immunohistochemical analysis.
Methods: Spatial transcriptomic analysis was performed on a tumour specimen containing ATC coexisting with papillary thyroid carcinoma. Five histologic patterns—epithelioid, squamoid, spindle, inflammatory, and mixed—were analysed. Differential gene expression and pathway enrichment analyses were conducted to identify common and pattern-specific molecular alterations. Selected transcriptomic findings were validated by immunohistochemistry using tissue microarrays comprising various types of thyroid tumours.
Results: A consistent set of differentially expressed genes was identified across all histologic patterns, independent of morphological subtype or *BRAF* mutation status. These genes were associated with extracellular matrix remodelling, tumour invasion, and the downregulation of tumour-suppressive functions. Immunohistochemical analysis confirmed differential protein expression between ATC and other thyroid tumour types, consistent with transcriptomic findings. Pathway enrichment analysis revealed distinct histology-specific profiles: the spindle pattern demonstrated upregulation of oxidative phosphorylation, tricarboxylic acid cycle, and glutathione metabolism pathways; the mixed subtype was enriched for ECM-receptor interaction and focal adhesion; and the squamoid pattern showed selective enrichment in PI3K-Akt signalling. The inflammatory pattern exhibited marked activation of innate immune and immunoregulatory pathways, including neutrophil extracellular trap formation, NF-κB signalling, IL-17 signalling, and leukocyte transendothelial migration.
Conclusion: ATC demonstrates both shared and histologic pattern-associated molecular alterations. Uniformly dysregulated markers may serve as robust diagnostic indicators, while pattern-specific pathways provide insight into the biological mechanisms underlying morphological heterogeneity. These findings underscore the utility of spatial transcriptomics in the molecular characterization of aggressive thyroid tumours.

Primary Pulmonary Paraganglioma Presenting as a Solitary Lung Nodule: Case Report

S.K. Dursun[1], A. Atasoy[1], Z. Tosuner Koçyiğit[1]
[1]Basaksehir Cam ve Sakura City Hospital, Department of Pathology, Istanbul, Turkey

Background & Objectives: Primary pulmonary paraganglioma (PPP) is an extremely rare neuroendocrine tumour arising from extra-adrenal paraganglia in the lung. It is typically asymptomatic and incidentally detected, though symptoms such as cough, haemoptysis, or chest pain may occur. Due to its rarity and morphological overlap with carcinoid tumours, distinguishing PPP requires detailed histopathological and immunohistochemical evaluation.
Methods: A 24-year-old male with no known medical conditions or smoking history presented with haemoptysis. A similar episode 25 days earlier was attributed to mucosal irritation. Chest CT revealed a 2.5 cm nodular mass in the right upper lobe, without lymphadenopathy or pleural effusion. A right upper lobectomy was performed.
Results: Macroscopically, the tumour was well-circumscribed, bronchi-associated, and solid without necrosis or haemorrhage. Microscopically, it exhibited Zellballen architecture, cytoplasmic eosinophilia, intracytoplasmic vacuoles, and well-formed nests of neoplastic cells. Immunohistochemically, the tumour was diffusely positive for synaptophysin, chromogranin, CD56, GATA-3, and tyrosine hydroxylase, while pan-cytokeratin and p40 were negative. Sustentacular cells were highlighted by S-100. SDHB loss raised suspicion of an SDH-related

syndrome. The Ki-67 index was 3-5%. No lymph node metastasis was detected.
Based on histomorphological features and immunoprofile, a diagnosis of PPP was made. Genetic counselling and further systemic evaluation were recommended.
DOTA-PET imaging demonstrated no additional lesions, confirming primary pulmonary origin rather than metastatic disease.
Conclusion: PPP should be considered in the differential diagnosis of lung masses, particularly in young patients. Given histological similarities, PPP must be distinguished from carcinoid tumours through comprehensive immunohistochemical evaluation. SDHB loss raises suspicion for an SDH-related syndrome; however, genetic analysis is necessary for definitive diagnosis. The presence of sustentacular cells is crucial for confirming the primary pulmonary origin. Additionally, thorough clinical and radiological evaluation should be performed. Early recognition, complete surgical resection, and genetic assessment are essential for optimal management and surveillance.

E-PS-10-017
A novel approach to the follicular neoplasm category in thyroid fine-needle aspiration: assessing the applicability of Nikiforov's nuclear scoring scheme
K. Katipoğlu[1], A. Kılıçarslan[2], T.D. Kökenek Ünal[2], A. Aksoy Altınboğa[2]
[1]Ankara Bilkent City Hospital, Patoloji, Ankara, Turkey, [2]Ankara Bilkent City Hospital and Ankara Yildirim Beyazıt University, Pathology, Ankara, Turkey

Background & Objectives: Although the follicular neoplasm (FN) category is well-defined within the Bethesda System for Reporting Thyroid Cytopathology, FN cases range from benign to malignant lesions. This study evaluates the utility of Nikiforov's nuclear scoring system in subclassifying FN nodules and its correlation with histopathological outcomes to improve risk stratification and clinical decision-making.
Methods: This retrospective study included 38 patients diagnosed with FN at Ankara City Hospital between 2019 and 2024. Patients who underwent thyroidectomy and had slides for reassessment were selected. Cases were confirmed and subclassified based on nuclear atypia presence. Histopathological diagnoses followed the WHO classification of endocrine tumours. Statistical analyses included chi-square testing, sensitivity, specificity, and likelihood ratio calculations.
Results: Among 38 thyroidectomy cases, final histopathological diagnoses included 9 benign cases (follicular nodular disease: 3, follicular adenoma: 6), 10 low-risk neoplasms (Non-invasive follicular thyroid neoplasm with papillary-like nuclear features: 7, well-differentiated tumour of uncertain malignant potential: 2, follicular tumour of uncertain malignant potential: 1), and 19 malignant tumours (classic papillary thyroid carcinoma PTC: 7, follicular variant PTC: 8, oncocytic carcinoma: 2, follicular carcinoma: 1, poorly differentiated thyroid carcinoma: 1). Nuclear scoring distribution showed 7 cases with low scores (0-1) and 24 with high scores (2-3). The presence of nuclear atypia in FNAs was significantly associated with malignancy risk ($p = 0.047$). The nuclear scoring system demonstrated high sensitivity (81.48%) despite relatively low specificity (54.55%), indicating its potential role in risk assessment.
Conclusion: Nikiforov's nuclear scoring system effectively predicts malignancy in follicular neoplasm thyroid nodules but remains an imperfect tool in cytological evaluation. Further refinement is needed to enhance its clinical applicability. Our findings emphasize subclassification's role in refining risk assessment, potentially improving surgical decision-making by reducing unnecessary procedures while ensuring appropriate management of high-risk cases.

E-PS-10-018
Immunophenotypical expression variability in aggressive poorly differentiated and anaplastic thyroid carcinoma – case series
M. Ceausu[1], D. Ioachim[1], D. Terzea[1], C. Cristea[1], D.O. Alexandrescu[2], D. Manda[3], S. Schipor[3], S. Dutulescu[4]
[1]"C.I. Parhon" National Institute of Endocrinology, Department of Pathology, Bucharest, Romania, [2]"C.I. Parhon" National Institute of Endocrinology, Department of Surgery, Bucharest, Romania, [3]"C.I. Parhon" National Institute of Endocrinology, Department of Research, Bucharest, Romania, [4]"Matei Bals" National Institute of Infectious Diseases, Department of Pathology, Bucharest, Romania

Background & Objectives: Poorly differentiated thyroid carcinoma (PDTC) and anaplastic thyroid carcinoma (ATC) represent rare but aggressive thyroid malignancies, accounting for 2 – 5% of all thyroid cancers for PDTC and less than 2% for ATC. They have a worse prognosis and a low capability of up-taking I^{131}.
Methods: We analysed a series of 12 cases with aggressive thyroid tumours (9 with PDTC and 3 with ATC) subjected to total thyroidectomy and immunotherapy / chemotherapy combination treatment. The surgical specimens were investigated by means of histopathology and immunohistochemistry. The immunophenotype expression was investigated using B-RAF, K-RAS, TERT and PAX-8 on FFPE tissues. Univariate biostatistical method was performed.
Results: Histopathology investigation showed a diffuse proliferation of small to medium size tumour cells arranged in cords and nests in PDTC (G2) and a diffuse proliferation of a mixture of spindle-shape cells, pleomorphic and multinucleated giant cells in ATC (G3), accompanied by various degrees of necrosis. The mitotic rate was high (> 5 mitoses / HPF). The pattern of IHC expression was heterogenic with variable intensity in the tumour cells. B-RAF was positive in half of cases with a high cytoplasmic variability. K-RAS had a high diffuse cytoplasmic expression level in 8 cases. TERT expression was between 15 – 50% in all cases, with strong perinuclear reaction. Significant statistical correlations were found between B-RAF and K-RAS ($r = 0.56$, $p = 0.04$) and B-RAF and TERT ($r = 0.49$, $p = 0.0003$) respectively. A slightly positive correlation was also found between TERT and PAX-8 ($r = 0.35$, $p = 008$).
Conclusion: Besides the histological criteria, the immunophenotype expression of the aforementioned markers have their own significance. Despite their variability, B-RAF and K-RAS remain mutually exclusive main drivers in aggressive thyroid carcinoma, while TERT mutation represent the most common alteration in PDTC and ATC in conjuncture with PAX-8 and B-RAF abnormal status.

E-PS-10-019
Papillary thyroid cancer: the role of oxidative stress and positive mast cells
K. Ivanova[1], A. Zdraveski[2], E. Georgieva[3], Y. Karamalakova[3], M. Hadzhi[1]
[1]Trakia University, Medical Faculty, General and Clinical Pathology, Stara Zagora, Bulgaria, [2]Trakia University, Medical Faculty, Surgery, Stara Zagora, Bulgaria, [3]Trakia University, Medical Faculty, Medical Chemistry and Biochemistry, Stara Zagora, Bulgaria

Background & Objectives: Papillary thyroid carcinoma (PTC) is the most common type of thyroid cancer. The rate of development and growth of tumours is regulated by a delicate balance between pro-and anti-tumorigenic effects, stimulated by the tumour cells themselves, as well as the surrounding microenvironment. On the other hand the oxidative stress (OS) plays a major role in thyroid carcinogenesis. Patients

PTC have a worse oxidative profile and increased lipid peroxidation compared to healthy individuals and patients with autoimmune thyroid disease.
Methods: We investigated immunohistochemically tryptase- and chymase-positive mast cells (MCT and MCC). The study group consists of 69 patients, males (n=9) and females (n=60), (median 54.17±14.48years). MC counts have been reported to correlate with tumour stage, prognosis, and invasiveness. For OS we use EPR spectroscopy in group from 51 patients and 23 controls.
Results: In our study we demonstrated that mast cell, MCT and MCC numbers were significantly more in PTC as compared to the surrounding normal thyroid structure ($p<0.001$).) Patients with lower numbers of MCT in tumour stroma ($p=0.043$) tended to have worse survival. With EPR spectroscopy we observed inverse correlation between nitroxide radical TEMPOL (in PTC 5.856 ±0.598 v.s TEMPOL/ controls 11.27) compare with confirmatory method ROS (in PTC 5.411±0.789 v.s ROS/controls 0.467±0.390).
Conclusion: MCs in the process of angiogenesis release proangiogenic factors, such as VEGF, thymidine phosphorylase, tryptase and chymase, stored in their secretory granules. It is well demonstrated that MCT is one of the most powerful angiogenic mediators released by human MCs, is involved in tissue remodelling, and it may also act indirectly on tissue neovascularization by releasing latent angiogenic factors bind to the extracellular matrix. ROS accumulation confirmed the presence of oxidative stress in patients with PTC.

Funding: This research was funded by the Bulgarian Ministry of Education and Science (MES) in the frames of the Bulgarian National Recovery and Resilience Plan, Component "Innovative Bulgaria", Project No. BG-RRP-2.004-0006-C02, "Development of research and innovation at Trakia University in service of health and sustainable well-being" and NIP 9/2022

Parathyroid carcinoma in haemorrhagic thyroid cyst – case report
M. Ćuk[1], S. Kulić[2], M. Vasić Milanović[3], R. Marić[4], N. Lalović[4], R. Gajanin[5], D. Batinić Škipina[6], J. Vladičić Mašić[7], N. Dukić[7]
[1]University Hospital Foča, University of East Sarajevo, Faculty of Medicine Foča, Pathology, Foča, Bosnia and Herzegovina, [2]University of East Sarajevo, Faculty of Medicine, Pathology, Foča, Bosnia and Herzegovina, [3]General Hospital Zvornik, University of East Sapajevo, Faculty of Medicine Foča, Pathology, Zvornik, Bosnia and Herzegovina, [4]University Hospital Foča, University of East Sarajevo, Faculty of Medicine, Surgery, Foča, Bosnia and Herzegovina, [5]University of Banja Luka, Pathology, Banja Luka, Bosnia and Herzegovina, [6]University Hospital Foča, Pathology, Foča, Bosnia and Herzegovina, [7]University Hospital Foča, University of East Sarajevo, Faculty of Medicine Foča, Oncology, Foča, Bosnia and Herzegovina

Background & Objectives: Parathyroid carcinoma is rarest endocrine malignancy, with prevalence of 0.005% of all cancers and incidence of 11 in 10 million adults. It occurs in less than 1% of all cases of hyperparathyroidism.
Methods: We present a 46-year-old male with an unusual clinical-radiological and pathomorphological presentation of parathyroid cancer.
Results: Clinically, on front right side of neck, there was palpable, painless, mobile tumour mass without local reactions on the skin. Radiological methods, US and CT, it was described that right lobe of thyroid gland was occupied by heterodense, expansive, clearly limited, probably haemorrhagic cyst, measuring 49 x 39 x 68 mm. Reactive submandibular and parajugular lymph nodes were evident. Operative treatment is indicated. Intraoperatively, right lobe of thyroid gland was enlarged due to cyst filled with haemorrhagic contents. Pathohistological analysis of frozen sections revealed a cystic formation filled with coagulated blood and necrotic debris. A thyroidectomy is performed. On definitive pathohistological sections, invasive tumour tissue with infiltration of the thyroid gland parenchyma was found only in 10% of the tissue sections from the cystic lesion. The tumour was composed of small bands and rare medium-large folliculoid formations, which are made up of mild atypical tumour cells with pale eosinophilic cytoplasm and eccentrically placed hyperchromatic nuclei. Definitive diagnosis was confirmed by immunocytochemical profile: Thyreoglobulin-, TTF 1-, Calcitonin-, GATA3+, Chromogranin +, Ki 67 shows proliferative activity in 10% of tumour cells. Multiple endocrine neoplasia is ruled out. Three years after the operation, the patient has no recurrence of the disease.
Conclusion: Our case shows an extremely unusual presentation of parathyroid carcinoma, and also indicates the importance of proper and complete lesion sampling for pathohistological analysis, as viable tumour cells were present in only 10% of cyst wall sections. Once again, the importance of immunohistochemical analysis in the diagnosis of malignant tumours was confirmed.

E-PS-10-021
Breast carcinoma metastasis discovered during thyroidectomy for worsening thyroiditis more than a decade after the primary diagnosis: a case report
N. Valtiene[1,2], I. Paškevičiūtė[2], L. Poškienė[1,2], M. Masevičienė[1]
[1]Hospital of Lithuanian University of Health Sciences Kauno klinikos, Pathological anatomy department, Kaunas, Lithuania, [2]Lithuanian University of Health Sciences, Kaunas, Lithuania

Background & Objectives: Metastasis to thyroid gland is highly unusual and represents only about 1.4% to 3% of all thyroid cancer despite high vascularization and rapid blood flow. Thyroid metastases are difficult to diagnose as it typically presents as nodules with minimal symptoms. While primary breast cancer usually spreads to bones and visceral organs, metastasis to the thyroid is rare and is associated with poor prognosis.
Methods: A 70-year-old female patient with non-toxic multinodular goiter, medically managed hypothyroidism caused by autoimmune thyroiditis presented with symptoms of dysphagia and worsening lethargy. X-ray showed compression of the trachea and narrowing of the oesophagus. Notably, the patient underwent partial mastectomy for invasive ductal carcinoma 13 years ago. Due to worsening symptoms, thyroidectomy was decided to be performed.
Results: Histopathological examination, in addition to findings of advanced thyroiditis, revealed diffuse multiple microfocal neoplastic infiltration in both lobes. Infiltration was composed of medium-sized cells with mild-moderate polymorphism features and pronounced spreading to the vessels. Tumour cells reacted positively with the GATA3, oestrogen and progesterone receptor immunomarkers (significantly less pronounced than primary tumour), and the same as primary- were negative for HER2 immunomarker.
Conclusion: A metastasis from a primary cancer diagnosed 13 years ago, now affecting the thyroid gland was identified. This finding highlights that primary thyroid pathology can sometimes mask the presence of metastatic disease in the thyroid gland. A thorough review of a patient's medical history is essential to ensure that potential metastases are not overlooked and managed properly. Although primary thyroid conditions, such as thyroiditis, are far more common than metastases to the thyroid gland, it is crucial to maintain suspicion for metastasis, even many years after the successful treatment of the primary cancer, and even in the absence of obvious metastatic signs.

E-PS-10-022

Immunophenotype of parathyroid adenoma, multiglandular parathyroid disease and parathyroid carcinoma: diagnostic implications

R. Uljanovs[1], M. Sperga[1], L. Vidusa[1], B. Strumfs[1], K. Merkurjeva[1], I. Strumfa[1]
[1]Riga Stradins University, Department of Pathology, Riga, Latvia

Background & Objectives: Reflecting the dominant role of surgery for treatment of primary hyperparathyroidism, significant changes were implemented in WHO classification of parathyroid lesions (2022). In particular, the entity of multiglandular parathyroid disease (MPD) was defined, a term that is more in line with surgeon's needs than the former primary parathyroid hyperplasia. Diagnostics of hyperparathyroidism is based on laboratory and radiological investigations. However, pathological assessment of surgically removed glands can help to verify the diagnosis or to reach it in difficult and/or recurrent cases. The **aim** of our study was to evaluate immunophenotype of parathyroid adenoma, MPD and parathyroid carcinoma.
Methods: Expression of Ki-67, parafibromin, p53, p21, p27, cyclin D1, intermediate filaments (IFs), CD56, CD44, E-cadherin and Bcl-2 was detected and quantified by immunohistochemistry/ digital morphometry in adenomas (102), MPD (27) and parathyroid carcinomas (5); normal glands (45) formed the control group. Descriptive statistics, Kruskal-Wallis and Mann-Whitney tests were performed.
Results: The expression of parafibromin, Ki-67, p21 (all: $p<0.001$), p27 ($p=0.01$) and cyclin D1 ($p=0.002$) showed statistically significant differences. The mean fraction of Ki-67 [95% confidence interval] was 1.6%[1.3-1.8] in adenoma, 1.0%[0.7-1.3] in MPD and 5.8%[0.2-11.4] in carcinoma; of p21: 12.8%[11.4-14.2] in adenoma, 15.7%[13.4-18.0] in MPD and 7.6%[0.0-18.8] in carcinoma; of cyclin D1: 12.0%[10.5-13.6] in adenoma, 24.8%[14.6-35.0] in MPD and 31.5%[0.0-80.1] in carcinoma. Only carcinomas showed loss of p27(59.0%[13.3-100.0]), contrasting with adenomas (92.8%[89.7-96.0]) and MPD 94.3%[90.9-97.8]. Similarly, loss of BCL2 was notable in carcinoma (28.2%[0.0-76.4]), compared to adenoma (66.7%[59.7-73.7]) and MPD (61.3%[44.3-78.2]). Loss of parafibromin was invariable in all carcinomas, contrasting with adenomas (0%). CD56, CD44, E-cadherin, IFs and p53 have no role in differential diagnostics of parathyroid lesions.
Conclusion: Loss of parafibromin is the hallmark of parathyroid carcinoma. However, carcinomas feature also loss of p27 and Bcl-2, contrasting with benign lesions. Adenoma show higher proliferation, but lower p21 and cyclin D1 expression than MPD.

E-PS-10-023

Clear cell parathyroid adenoma: a rare diagnostic challenge in endocrine head and neck pathology

M.A. Forero Rivera[1], A.L. Rozo Cruz[1], M.A. Palau Lazaro[1]
[1]Fundación Santa Fe de Bogotá, Universidad de los Andes, Bogotá, Colombia

Background & Objectives: Uniglandular parathyroid adenoma is a benign neoplasm responsible for over 85% of primary hyperparathyroidism (PHPT), with a female-to-male ratio of 2-3:1. These adenomas comprise oncocytic, clear, or transitional cells, lipoadenomas and clear cell adenomas. Clear cell subtype constitutes 1.5 per 1000 cases. Up to 10% have a hereditary component, and neck radiation exposure is a risk factor. Clinically, they present with hypercalcemia, weakness or anxiety. Genetic alterations include 11q13 loss of heterozygosity and MEN1 inactivation. Preoperative localization employs ultrasound, scintigraphy, or PET/CT, though clear cell adenomas are frequently asymptomatic and undetectable by scintigraphy. Differentials include renal cell carcinoma. Most cases are effectively treated surgically. This case report provides a comprehensive description of the diagnosis, treatment, and clinical outcomes, contributing to the limited literature on clear cell parathyroid adenomas and offering valuable insights for pathologists and clinicians.
Methods: We present the case of a 56-year-old female with a history of chemical PHPT. A thyroid scan using 5mCi Technetium revealed a nodule in the posterior aspect of the right thyroid lobe's lower pole, with no thyroid uptake. She underwent right parathyroidectomy. Postoperatively, her PTH levels normalized (15.9 pmol/L preop to 1.6 pmol/L post-op). Macroscopically, a dark brown nodular fragment (1.7 x 1.0 x 0.9 cm, 0.7 g) with a thin pseudocapsule was observed.
Results: Histopathology revealed a hypercellular parathyroid gland predominantly composed of clear cells with vacuolated cytoplasm and mild nuclear atypia, surrounded by a fibrous capsule with atrophic peripheral parathyroid tissue. Immunohistochemistry showed strong GATA-3 and weak PAX-8 reactivity, with negative TTF1 and thyroglobulin. These findings, along with intraoperative PTH reduction, confirmed a uniglandular clear cell parathyroid adenoma.
Conclusion: This case underscores the importance of accurate diagnosis and effective treatment, highlighting parathyroidectomy as the definitive intervention for PHPT. Further molecular studies may elucidate genetic factors associated with this rare and morphologically distinct subtype.

E-PS-10-024

A rare tumour: signet-ring cell adenoma of the thyroid

S.Y. Çelik[1], Ö. Ilhan Çelik[1], Y. Dere[1], Ö. Dere[2]
[1]Mugla Sitki Kocman University, Faculty of Medicine, Department of Pathology, Mugla, Turkey, [2]Mugla Sitki Kocman University, Faculty of Medicine, Department of General Surgery, Mugla, Turkey

Background & Objectives: Folicular adenoma is a benign, encapsulated tumour that exhibits thyroid follicular cell differentiation. Signet-ring cell adenoma of the thyroid is a rare variant of it. The important thing in this entity is the correct differential diagnosis of it from metastasis of malignant tumours showing signet-ring cell differentiation.
Methods: A soliter and solid nodule was found by ultrasonography incidentally in the thyroid left lobe of a 74-year-old man during the hospital check-up because of palpitation. In the fine needle aspiration cytology smears thyrocytes with microfolicular organisation and some cells with clear cytoplasms were seen. However immunohistochemical or histochemical staining was not posssible in order to understand the nature of these clear cells as only two slides were sent after fine needle aspiration process. He was hematologically euthyroid. Then bilateral total thyroidectomy process was applied by the General surgeons.
Results: In the macroscopic sections of the material, a solid encapsulated nodule with a diameter of 2,2cm was found. Total of the nodule was evaluated microscopically and an encapsulated tumour composed of clear cells with a folicular organisation was seen. In the immunohistochemical evaluation; clear cells expressed TTF-1, Thyroglobulin, Pankeratin, CD56; however they were not stained with RCC, s100, GATA3, HBME-1, Galectin3, Calcitonin, Synaptophysin. The cytoplasmic vacuoles contained Pas with and without diastase positive mucin. The whole capsule of the nodule was examined and capsular or vascular invasion were not present. The lesion was diagnosed as Signet-ring cell adenoma of the thyroid.
Conclusion: Signet-ring-cell adenoma of the thyroid is a rare variant of Folicular adenoma. It is a benign tumour; however pathologists should keep this rare primary tumour of the thyroid in mind when examining thyroid lesions and not confuse it with metastatic signet-ring cell carcinomas of other organs or the thyroid.

E-PS-10-025

Identification of predictive variables of clinical outcomes in benign parathyroid tumours and parathyroid carcinomas: a multicentre study

J. Machuca-Aguado[1], P. Rodríguez de Vera[2], Á. Gutiérrez-Domingo[1], B. Rodríguez-Jiménez[2], E. Montijano-Pozas[3], R.C. Romo-Remigio[4], C. Sánchez-Malo[4], M.D. Salvago-Martín[5], T. Martin-Hernández[2], M.Á. Idoate-Gastearena[6]

[1]Virgen Macarena University Hospital, Pathology, Seville, Spain, [2]Virgen Macarena University Hospital, Endocrinology and Nutrition, Seville, Spain, [3]Virgen del Rocío University Hospital, Pathology, Seville, Spain, [4]Jaén University Hospital, Endocrinology and Nutrition, Seville, Spain, [5]Jaén University Hospital, Pathology, Seville, Spain, [6]Gregorio Marañón University Hospital, Pathology, Madrid, Spain

Background & Objectives: Primary hyperparathyroidism is mainly caused by benign parathyroid adenomas, but atypical adenomas and carcinomas show greater aggressiveness. Identifying clinical, biochemical, and histopathological factors, along with immunohistochemical markers like parafibromin, is crucial for improving prognostic stratification and optimizing postoperative management.

Methods: A multicentre, retrospective cohort study in three Spanish hospitals, including referred cases. Patients with non-metastatic parathyroid carcinoma or atypical adenoma (WHO 2022) were compared to typical adenomas. Clinical, biochemical, histopathological, and immunohistochemical variables were analysed, including the expression of parafibromin, Galectin 3, PGP9.5 and ki67.

Results: A total of 139 patients were included (90 typical adenomas, 21 atypical adenomas, and 28 carcinomas). Preoperative hypercalcemia was higher in atypical adenomas (12.92±2.11mg/dL) and carcinomas (13.14±2.37mg/dL) compared to typical adenomas (11.54±1.44mg/dL,$p<0.001$). Postoperative hypocalcemia was more frequent in atypical adenomas (27.8%) and carcinomas (24%) than in typical adenomas (3.3%,$p<0.001$). Capsular invasion was observed in 76.2% of atypical adenomas and 100% of carcinomas ($p<0.001$). Loss of parafibromin expression was more frequently identified in carcinomas and atypical adenomas ($p<0.001$) linked to aggressive histological features, such as higher cellular proliferation and an infiltrative growth pattern. Additionally, its absence correlated with a higher recurrence risk and a shorter disease-free survival in survival analysis ($p<0.05$).

Conclusion: Preoperative hypercalcemia, postoperative hypocalcemia, and capsular invasion are associated with the aggressiveness of parathyroid tumours. Loss of parafibromin expression is linked to a more aggressive phenotype, a higher recurrence risk, and worse prognosis, highlighting its relevance as a key biomarker for risk stratification and postoperative management.

E-PS-10-026

Exploring histologic patterns in anaplastic thyroid carcinoma: a case series with molecular correlation

S. Çolak[1], E. Özoğul[1], C. Sökmensüer[1]

[1]Hacettepe University Faculty of Medicine, Department of Pathology, Ankara, Turkey

Background & Objectives: Anaplastic thyroid carcinoma (ATC) is a highly aggressive thyroid malignancy composed of undifferentiated cells that may exhibit areas of follicular differentiation or remnants of well-differentiated thyroid carcinoma. Despite advances in treatment modalities, overall survival remains below two years in most cases. Therefore, the integration of histopathological features with prognostically and therapeutically relevant molecular findings is essential for clinical decision-making.

Methods: We present a case series of four patients diagnosed with ATC between 2015 and 2025 at Hacettepe University Faculty of Medicine, all of whom underwent molecular analysis. Histological evaluation included haematoxylin and eosin staining and immunohistochemistry. Next-generation sequencing (NGS) was performed in two cases, while the remaining two were tested for the BRAF V600E mutation.

Results: **Case 1:** A 63-year-old female patient presented with foci of papillary thyroid carcinoma exhibiting tall cell features and anaplastic carcinoma with squamoid differentiation. NGS identified *TP53* p.V272M and *HRAS* p.Q61K missense variants.

Case 2: A 50-year-old male patient showed sarcomatoid-type ATC arising in the background of follicular carcinoma. NGS revealed two *TERT* promoter mutations (c.-124C>T and c.-245T>C), with c.-124C>T representing a well-characterized gain-of-function variant associated with increased *TERT* expression. Additionally, an *FGFR1–FGFR3* fusion was detected.

Case 3: A 60-year-old male patient demonstrated anaplastic carcinoma with squamoid morphology adjacent to papillary thyroid carcinoma. A *BRAF* V600E (c.1799T>A) mutation was detected.

Case 4: A 70-year-old female patient exhibited classical and follicular variant papillary thyroid carcinoma with transition into squamoid areas of anaplastic carcinoma. A *BRAF* V600E (c.1799T>A) mutation was confirmed.

Conclusion: ATC displays a wide morphological spectrum. Adequate and extensive sampling is key to identifying transition zones between differentiated and anaplastic areas. Molecular profiling supports diagnosis and therapeutic planning and should be interpreted alongside histopathologic findings.

E-PS-10-027

Metastatic medullary thyroid carcinoma to the gallbladder and prostate gland in a patient with MEN2B syndrome (*RET* p.M918T mutation)

D. Efthymiou[1], S. Avgousti[1], A. Mpairamis[1], K. Koniari[1], G. Kyriakopoulos[1]

[1]Evaggelismos Hospital, Athens, Greece

Background & Objectives: Medullary thyroid carcinoma (MTC) is a rare neuroendocrine tumour, accounting for only 5% of thyroid cancers, with up to 25% of cases being hereditary. It has a high metastatic potential, most commonly to the lymph nodes, lung, liver and bones with distant metastases frequently present at time of initial diagnosis. This study presents the case of a male patient with MEN2B syndrome (*RET* p.M918T mutation), who underwent a total thyroidectomy at age seven, leading to an MTC diagnosis. Twenty-two years later, he developed MTC in the gallbladder and prostate gland with increasing calcitonin levels starting at 560 pg/ml.

Methods: Imaging revealed a gallbladder mass, and despite surgical removal of the organ, calcitonin levels continued rising. Four months later, a prostate lesion was identified and the gland was excised. Gross sectioning of both specimens showed a yellow-toned, solid and elastic tumour. Histopathology and immunohistochemistry were performed.

Results: Microscopic examination demonstrated neoplastic infiltration in both organs of similar morphology by a well-differentiated neuroendocrine neoplasm exhibiting a nested pattern within an amyloid-like stroma and no necrosis. Immunohistochemistry confirmed neuroendocrine differentiation with chromogranin A and synaptophysin positivity. Cytokeratins and calcitonin were expressed. The proliferation rate was up to 1.4 mitoses in 2mm2 and Ki67 up to 8% in both. Immunohistochemical and morphological similarities between the thyroid, gallbladder and prostate suggested the metastatic nature of the later lesions.

Conclusion: MEN2B syndrome with *RET* p.M918T mutation has an aggressive biological behaviour, characterised by the early onset of MTC and necessitating prophylactic thyroidectomy within the first year of life. Without timely intervention, these patients face an increased risk of developing metastatic MTC, with an average life expectancy of under 30 years. We note the low incidence in the literature of metastatic

MTC in the gallbladder and prostate, as well as the diagnosis of secondary tumours in these organs.

E-PS-10-028

MGMT protein expression by immunohistochemistry and promoter methylation status in metastatic endocrine tumours

S. Barbe[1], E. Rouleau[2], S. Moog[3], R. Tang[2], L. Lamartina[3], N. Ben-Othman[1], D. Hartl[4], L. Lacroix[2], M. Faron[4], M. Degaud[2], E. Baudin[3], J. Hadoux[3], M.-A. Bani[1]

[1]Gustave Roussy Cancer Campus, Medical Biology and Pathology Department, Pathology Laboratory, Villejuif, France, [2]Gustave Roussy Cancer Campus, Medical Biology and Pathology Department, Tumour Genetics Laboratory, Villejuif, France, [3]Gustave Roussy Cancer Campus, Endocrine Oncology, Villejuif, France, [4]Gustave Roussy Cancer Campus, Oncological Surgery, Villejuif, France

Background & Objectives: O6-methylguanine-DNA methyltransferase (MGMT) is a DNA repair enzyme characterized by its dealkylating effect. Low MGMT levels may sensitize tumours to alkylating agent. Thus, MGMT is emerging as a biomarker in metastatic endocrine neoplasm (m-EN), assessed by immunohistochemistry (IHC). However, there are no recommendations on the contribution of molecular biology in this context. This study aims to explore the relationship between MGMT protein expression and methylation status.

Methods: Over a one-year period, we prospectively analysed MGMT expression by IHC and promoter methylation using ddPCR in 42 FFPE tumour samples from consecutive m-EN. MGMT expression was assessed by two pathologists using the IHC H-score [0–300], with a threshold ≤ 100 to consider expression loss and ddPCR value >6% to consider methylated status.

Results: MGMT loss of expression by IHC (median H-score 7.5[0–100]) and promoter methylation were, respectively, found in: 8/23 & 2/23 digestive neuroendocrine neoplasms, 1/5 & 0/5 adrenocortical carcinomas, 3/6 & 0/6 atypical carcinoids, 0/5 & 1/5 medullary thyroid carcinomas, and 2/3 & 0/3 pheochromocytomas. IHC and ddPCR concordance was 29/42, mainly for IHC expression retention and unmethylated promoter (27/28). 12/34 don't expression MGMT and had no methylation, and 1/3 had a methylation with high expression. Discordant samples had higher tumour cellularity and were frequently surgery specimens. Follow-up under treatment is yet to be assessed to confirm the predictivity of the two markers.

Conclusion: IHC can predict absence of expression of MGMT and potentially the absence of full promoter methylation status in m-EN. But may be more sensitive to detect MGMT loss in the tumour. Indeed, H-scores >100 may indicate a non-methylated profile. It may also be more sensitive to detect MGMT loss in the tumour. These findings could support the use of IHC as a cost-effective screening tool in m-EN and the need to better understand the methylation profile in this tumour.

E-PS-10-029

Study of immunohistochemical profile in pituitary neuroendocrine tumours: correlation trends of Ki67, p53, and CK18 immunomarkers

J. Makstiene[1], R. Ramonas[2], B.R. Žaliūnas[2], M. Kuprytė[1], L. Poškienė[1], L. Treine[3]

[1]Hospital of Lithuanian University of Health Sciences Kauno Klinikos, Pathological Anatomy, Kaunas, Lithuania, [2]Lithuanian University of Health Sciences, Kaunas, Lithuania, [3]Hospital of Lithuanian University of Health Sciences Kauno Klinikos, pathological anatomy, Kaunas, Lithuania

Background & Objectives: Currently, Ki-67, p53, and CK18 immunohistochemical markers are being studied across various tumour types. However, their role and co-interactions in pituitary neuroendocrine tumours (PitNETs) are still not fully characterized. The aim of this study is to investigate the possible relationship between these markers in PitNETs.

Methods: Immunohistochemical assessment of Ki-67, p53, and CK18 protein expression was conducted using monoclonal antibodies SP6 (Vitro S.A., Spain), DO-7 (Roche Diagnostics, Switzerland) and DC-10 (Vitro S.A., Spain), respectively. CK18 immunohistochemical reactions were classified as "Positive" or "Negative". Ki-67 and p53 were evaluated in hotspot areas by manually assessing 300 tumour cell nuclei, and positivity was expressed as a percentage (%). Ki-67 immunohistochemical reaction results were categorized into "<3%" and "3%+" groups. P53 intensity expression (p53H) was assessed by calculating the Histoscore (H-score): 1 × percentage of weakly + 2 × percentage of moderately + 3 × percentage of strongly staining nuclei. The inter-observer and intra-observer variability was evaluated by Kappa statistics (Cohen's kappa coefficient>0.9). Spearman's correlation, Chi-Square test, and Mann-Whitney U test were applied ($p<0.05$).

Results: A total of 99 PitNET samples were evaluated for CK18, Ki-67 and p53 protein expression in neoplastic cells. A weak positive correlation ($\rho=0.261$, $p=0.011$) was detected between Ki-67% and p53%, and likewise between Ki-67% and p53H ($\rho=0.223$, $p=0.031$). No statistically significant differences were found between Ki-67 groups and CK18 results ($p=0.774$), nor between p53H and CK18 results ($p=0.140$).

Conclusion: Immunohistochemical profile of pituitary neuroendocrine tumours with correlative trends of Ki67, p53, and CK18 protein expression within neoplastic cells are characterized. Proliferation-demonstrating markers (Ki67, p53) demonstrated significant correlative trends, whereas there were no significant correlative trends between Ki-67 groups and CK18, as well as p53H and CK18, suggesting differences in diagnostic potential of these markers while implementing them in pituitary neuroendocrine tumour diagnostics in clinical pathology setting.

E-PS-10-030

Complex case of synchronous medullary and papillary thyroid carcinoma with oncocytic adenoma and central compartment lymph node metastasis

A. Uncu[1], A.O. Fărcaș[2], I. Vicsi[3], R. Neagoe[3], T. Mezei[1]

[1]University of Medicine, Pharmacy, Science and Technology George Emil Palade of Târgu Mureș, Pathology, Târgu Mureș, Romania, [2]University of Medicine, Pharmacy, Science and Technology George Emil Palade of Târgu Mureș, Cell Biology, Târgu Mureș, Romania, [3]University of Medicine, Pharmacy, Science and Technology George Emil Palade of Târgu Mureș, Târgu Mureș, Romania

Background & Objectives: We describe the clinical and pathological features of a patient diagnosed with unilateral medullary thyroid carcinoma (MTC), stage pT1aN1a, associated with multifocal bilateral papillary thyroid carcinoma (PTC), stage pT1a (m), and oncocytic adenoma.

Methods: A 66-year-old patient was followed up clinically with variable, albeit progressively increasing, calcitonin levels. She had a benign/Bethesda 2 fine needle aspiration (FNA) cytology report in 2019. Due to progressive serum calcitonin elevation and the presence of a hypoechoic nodule in the left thyroid lobe, FNA was repeated in 2024, with a suspicious for MTC/Bethesda 5 diagnosis. A total thyroidectomy with central compartment dissection was performed.

Results: Histopathology revealed two ill-defined foci in the right thyroid lobe, one with papillary architecture and the other with follicular architecture. Tumour cells showed enlarged, irregular, and clear nuclei, while adjacent thyroid parenchyma appeared normal. In the left lobe, an ill-defined tumour with medium-sized cell nests in a collagenous stroma was found. The left-sided lesion was positive for calcitonin and CEA and negative for thyroglobulin. A well-defined oncocytic adenoma was also found adjacent to this tumour. PTC foci were present

in the middle and lower thirds of the left lobe as well. Two of the six central compartment lymph nodes harboured MTC metastases.
Conclusion: This study exemplifies the scenario when histological divergent tumours (MTC, PTC, and oncocytic adenoma) are present within the same thyroid. The immunohistochemical profile supports the diagnosis of MTC. Lymph node metastasis underscores the progression of the disease. These findings emphasize the need for thorough diagnostic evaluation and suggest that early detection and appropriate treatment strategies are critical for managing patients with mixed thyroid malignancies.

E-PS-10-031
A large parathyroid gland adenoma clinically misinterpreted as an atypical thyroid nodule in a patient with tertiary hyperparathyroidism and persistent parathyroid hyperplasia
S. Neves[1], M. Mexia Leitão[1], J.P. Cabral[1], J.R. Brandão[1]
[1]Unidade Local de Saúde de Santo António, Serviço de Anatomia Patológica, Clínica de Genética e de Patologia, Porto, Portugal

Background & Objectives: Secondary hyperparathyroidism (SHPT) causes parathyroid hyperplasia, which is a non-neoplastic process of multiple parathyroid glands. After long-standing SHPT, one of the glands, through a "hyperplasia-to-neoplasia progression sequence", may autonomously gain function, developing tertiary hyperparathyroidism (THPT). We report a case demonstrating both an adenoma and parathyroid hyperplasia simultaneously.
Methods: The patient was a 58-year-old male with chronic kidney disease (CKD) of unknown aetiology, who had received a kidney transplant 30 years ago and progressively developed loss of function. Cervical imaging exams were obtained during follow-up, partly due to complaints of cervical pain. Ultrasound revealed a large nodule in the right thyroid lobe ("TI-RADS" 3), while scintigraphy favoured a large hyperfunctioning right-sided parathyroid gland. A fine needle aspiration cytology of the nodule was performed.
Results: Cytology revealed rare three-dimensional groups composed of small epithelial cells. The report conclusion was atypia of undetermined significance - other. The patient underwent total thyroidectomy and subtotal parathyroidectomy. Macroscopically, the nodule measured 85 mm in its longest axis and was connected by a thick stalk to the right lobe. The remaining specimen was unremarkable. Microscopically, the nodule corresponded to a parathyroid gland with an organoid chief cell proliferation without malignant features. Additionally, both thyroid lobes had multiple foci of papillary thyroid carcinoma measuring between 1 and 4 mm. Contrary to expectations, only one other parathyroid gland was isolated, which also displayed chief cell proliferation. Thus, the final diagnosis was of an adenoma superimposed on parathyroid hyperplasia, consistent with THPT.
Conclusion: Postoperatively, due to the persistence of CKD, PTH levels and other analytical parameters remained abnormal, indicating persistent parathyroid hyperplasia. The patient died 4 months after surgery due to myocardial infarction. This case highlights the challenge of making certain diagnoses (especially when organs are closely related) and underscores the importance of correlating clinical, analytical, imaging and pathological findings.

E-PS-10-032
Prognostic profiling of papillary thyroid carcinoma: unraveling the impact of PD-L1 expression and genetic alterations on tumour behaviour and clinical outcomes
C. Rana[1], P. Ramakant[2], K. Singh[2], A. Mishra[2], P. Mishra[3], I. Makkar[1]
[1]King George's Medical University, Department of Pathology, Lucknow, India, [2]King George's Medical University, Department of Endocrine Surgery, Lucknow, India, [3]SGPGIMS, Biostatistics, Lucknow, India

Background & Objectives: While papillary thyroid carcinoma (PTC) generally has an excellent prognosis, a subset of cases exhibits aggressive behaviour, leading to recurrence and metastasis. Identifying robust prognostic biomarkers is crucial for refining risk stratification. This study explores the prognostic relevance of PD-L1 expression, assessed using the Tumour Proportion Score (TPS), in relation to key molecular alterations (BRAF, TERT, RAS) and clinicopathological features in PTC.
Methods: A retrospective cohort of 84 PTC patients diagnosed between 2016 and 2024 at King George's Medical University, India, was analysed. PD-L1 expression was evaluated by immunohistochemistry on formalin-fixed paraffin-embedded tissues, with TPS categorized as high or low based on the median value. Genetic testing identified BRAF, TERT, and RAS mutations. Clinicopathological data, including tumour stage, lymph node involvement, extrathyroidal extension, and recurrence, were examined. The relationship between PD-L1 expression, molecular alterations, and clinical outcomes was assessed statistically.
Results: PD-L1 expression was observed in 60.7% of cases, with 38.1% classified as TPS high. High PD-L1 expression correlated significantly with older age, advanced stage, lymph node metastasis, and aggressive histological subtypes ($p < 0.05$). BRAF and TERT mutations were more frequently detected in PD-L1 high tumours ($p = 0.032$ and $p = 0.038$, respectively). High PD-L1 expression was associated with an increased risk of recurrence ($p = 0.043$) and distant metastasis ($p = 0.002$). Multivariate analysis identified multiple mutations as independent predictors of poor survival (AOR = 15.8, $p = 0.021$) and recurrence (AOR = 11.22, $p < 0.001$).
Conclusion: High PD-L1 expression, particularly in tumours harbouring BRAF and TERT mutations, is indicative of aggressive disease in PTC. These findings support the potential role of PD-L1 as a prognostic biomarker and highlight its relevance for risk stratification and personalized therapeutic approaches. Further prospective studies are required to validate these results and investigate the clinical utility of immune checkpoint inhibitors in PTC

Funding: Indian council of medical research

E-PS-10-033
Mixed corticomedullary tumour of the adrenal gland: a rare entity
O. Pedro[1], M. Honavar[1], T. Amaro[1]
[1]ULS Matosinhos, Matosinhos, Portugal

Background & Objectives: This work aimst o present a rare case of a Mixed corticomedullary tumour of the adrenal gland, along with a brief overview of its histopathological and clinical features.
Methods: A 62-year-old woman with a history of hypertension, type 2 diabetes, breast cancer, and total thyroidectomy for multinodular goiter was referred to the Endocrine Surgery clinic due to an incidental finding of a 25 mm right adrenal mass. Functionally, there was an elevation of both plasma and urinary metanephrines. Due to suspicion of pheochromocytoma, she started medical treatment and was scheduled for laparoscopic right adrenalectomy. Surgical specimen was submited for histopathological analysis.
Results: Gross description: Adrenal gland weighing 10.5 grams and measuring 40 x 25 x 14 mm. At the transition between the cortical and medullary regions, a brownish nodule measuring 27 x 23 x 14 mm was identified.
Microscopy: mixed tumour with elements of pheochromocytoma and adrenal cortical adenoma was observed. Architecture in Zellballen pattern, trabeculae, and large nests and pseudorosettes (<1%) were seen. No marked nuclear pleomorphism, capsular, lymphovascular, or perineural invasion. No necrosis was observed. <1 mitosis/mm2 with a Ki-67 of <2%. Immunohistochemical study revealed positivity for synaptophysin and chromogranin in the pheochromocytoma component and positivity for alpha-inhibin, melan A, and calretinin in the adrenal

cortical component. The tumour was limited to the adrenal gland without extending beyond the capsule.
Conclusion: Mixed corticomedullary tumour of the adrenal gland is an extremely rare condition, characterized by the coexistence of cells of both cortical and medullary origin within a single tumour mass. These tumours have the potential to simultaneously secrete catecholamines and adrenocortical steroid hormones, leading to a complex clinical presentation. To date, fewer than 40 cases have been described.

E-PS-10-034
Anaplastic thyroid carcinoma: clinicopathological, immunohistochemical and molecular study of 10 cases
V. Cristóbal Redondo[1], V. Pedrero Castillo[2], A. Francia García-Calvo[3], C. Huerta Belmar[4], D. Parra Trujillo[5], R.E. Casco Zuniga[1], G. Peiró Cabrera[1], F. Peiró Marqués[1]
[1]Dr. Balmis General Universitary Hospital of Alicante, Institute for Health and Biomedical Research of Alicante, Pathology, Alicante, Spain, [2]General Hospital of San Juan, Pathology, Alicante, Spain, [3]Santa Cristina University Hospital, Pathology, Madrid, Spain, [4]Gregorio Marañón University Hospital, Pathology, Madrid, Spain, [5]Dr. Balmis General Universitary Hospital of Alicante, Oncology, Alicante, Spain

Background & Objectives: Anaplastic thyroid carcinoma (ATC) is one of the most aggressive solid tumours, often presenting as a rapidly enlarging cervical mass with invasion of adjacent structures, causing dyspnea, dysphagia, and hoarseness. Although it accounts for only 1–2% of thyroid carcinomas, it causes over 50% of thyroid cancer-related deaths. We aimed to describe the clinical, histopathological, immunohistochemical, and molecular features of a series of ATC cases diagnosed at our institution.
Methods: All ATC cases diagnosed between January 2010 and January 2025 were retrospectively reviewed. Clinical data, histological features (H&E and immunohistochemistry), and molecular results from Next Generation Sequencing (Oncomine Comprehensive Assay, Thermo Fisher) were analysed.
Results: Ten patients were included, 80% women (8/10), with a mean age of 73.2 years (range, 55–88). Half presented with stage IVC at diagnosis, with the lungs as the most common metastatic site (4/5). A surgical specimen was available in all but one case. The mean tumour size was 9.5 cm (range, 4–20). Histologically, 8/10 tumours exhibited a sarcomatoid pattern with undifferentiated follicular cell proliferation, showing spindle-shaped atypical cells, frequent mitoses, and fascicular or storiform architecture. Two cases displayed a pleomorphic pattern with giant tumour cells and marked pleomorphism. Necrosis was present in 9/10 cases, lymphovascular invasion in 5/10, and a differentiated component in 7 tumours (4 with Hürthle cell carcinoma and 3 with papillary carcinoma). Immunohistochemically, 80% were negative for TTF-1, PAX8, and thyroglobulin, while the rest showed weak, focal TTF-1 positivity. P53 mutations were identified in 6 cases; BRAF and NRAS mutations in 3 and 1 cases, respectively. Overall survival was 8.2 months (range, 1–22), with 8 patients deceased.
Conclusion: ATC is a highly aggressive neoplasm with predominant sarcomatoid morphology, extensive necrosis, high mitotic activity and loss of thyroid-specific markers. Due to its rarity and poor prognosis, further studies are needed.

E-PS-10-038
Study of clinical and histopathological features of pheochromocytomas diagnosed at 2007-2024: morphological trends of rare clinical entity
N. Valtienė[1,2], I. Paškevičiūtė[2], D. Pranys[1], L. Poškienė[1,2], M. Masevičienė[1], M. Kuprytė[1,2]
[1]Hospital of Lithuanian University of Health Sciences Kauno Klinikos, Pathological anatomy department, Kaunas, Lithuania, [2]Lithuanian University of Health Sciences, Kaunas, Lithuania

Background & Objectives: Pheochromocytoma is a neuroendocrine neoplasm that originates from chromaffin cells of the adrenal medulla. The incidence of pheochromocytomas ranges from 0.4 to 9.5 cases per 1 million person-years with national and regional differences. The aim is to overview clinical and histopathological features of pheochromocytomas cases in local pathology department.
Methods: Pheochromocytoma cases processed and analysed morphologically in pathology laboratory from 2007 to 2024 were selected for the study. The patient's age, sex and pathology report data were collected, and cases were re-examined based on TNM classification, GAPP grading system (histological patterns, cellularity). Statistical analysis was performed ($p \leq 0,05$).
Results: Among 114 cases, 43% were male (n=49; median age: 53 years, IQR: 23) and 57% female (n=65; median age: 58 years, IQR: 23; U=1476, p=0.51). The number of cases increases linearly, peaking at 45-60 years for males (40.8%, n=20) and 55-75 for females (49.2%, n=32). Number of cases increased from 0.9% (n=1) in 2010 to 13.2% (n=15) in 2023. Right-sided tumours were subtly more common (51.8%), with 1.8% (n=2) bilateral cases. Most tumours (65.5%, n=74) were <5 cm. The zellballen pattern was most frequent (49.1%, n=56) mostly in females (60.7%, n=34), followed by large and irregular cell nests (47.2%, n=51, p=0.374). Moderate cellularity was most common amongst different patterns (43.5%, n=47, χ^2=2.741, p=0.602). Metastasis was found in 7% (n=8) of the cases and in 75% (n=6) females. Metastasis occurred mainly 10-12 years after the primary tumour diagnosis with tumour size <5cm (87.5%, n=7).
Conclusion: The incidence of diagnosed pheochromocytomas has been increasing annually. Pheochromocytomas were more prevalent in older age groups predominantly in females. No significant distribution difference was observed between left- and right-side tumours. Most metastases were detected 10–12 years after the initial tumour diagnosis, mostly in females, suggesting that follow-up should be prioritized beyond a decade after the primary diagnosis.

E-PS-10-039
Expression of neuroendocrine markers in digestive neuroendocrine neoplasms - an immunohistochemical study of 104 cases
A. Zammouchi[1], W. Ouahioune[1], N. Moulai[1], R. Bennoui[1], G. Ifaidi[1], S. Ahmed allal[1], M. Guermi[1]
[1]Faculty of Medicine, University Blida 1, Medecine Department, Laboratory of Cancer Research, Blida, Algeria

Background & Objectives: Immunohistochemistry is essential for the diagnosis of digestive neuroendocrine neoplasms (NENs), even when the morphology is obvious. The European Neuroendocrine Tumour Society (ENETS) requires that at least two neuroendocrine markers be positive for the diagnosis of digestive NENs. These markers include Chromogranin A (CgA), Synaptophysin (SYN), and Insulinoma-associated protein (INSM1), which was recently introduced into the WHO 2022 classification of NENs.
The aim of this study was to examine the expression of neuroendocrine markers in digestive NENs and to compare INSM1 with traditional neuroendocrine markers (CgA and SYN).
Methods: A retrospective comparative study of the three neuroendocrine markers (CgA, SYN, and INSM1) on a series of 104 cases of digestive neuroendocrine neoplasms diagnosed at the Department of Pathology and Cytology at Blida University Hospital over a period of 5 years (2017 - 2021).
Results: CgA was positive in 98.9% of well-differentiated neuroendocrine tumours (NETs) and 88.2% of neuroendocrine carcinomas (NECs). SYN was positive in 98.9% of NETs and 94.1% of NECs. INSM1 was positive in 95.4% of NETs and 94.1% of NECs.
Conclusion: We conclude that INSM1 is a useful marker of neuroendocrine differentiation in Gastroenteropancreatic neuroendocrine

neoplasms. Compared with traditional neuroendocrine markers, INSM1 is less sensitive but more specific.

E-PS-11 E-Posters Gynaecological Pathology

E-PS-11-001

Evaluation of clinical and pathological prognostic findings in granulosa cell tumour cases: a retrospective study

B. Timur[1], Z. Bayramoglu[1], S. Kurt[2], H.T. Timur[2], B. Saatli[2]
[1]Dokuz Eylul University School of Medicine, Pathology, Izmir, Turkey, [2]Dokuz Eylul University School of Medicine, Obstetrics and Gynaecology, Izmir, Turkey

Background & Objectives: Adult granulosa cell tumours are the most common type of ovarian sex cord-stromal tumours, yet they remain rare. These tumours typically present in perimenopausal women, often with estrogenic effects. Due to their rarity, studies on these tumours are limited.
Methods: 55 patients diagnosed with granulosa cell tumours at Dokuz Eylül University Hospital between 2004 and 2023 were identified. The clinical and pathological characteristics of these patients were analysed.
Results: The mean age was 53.2 ± 12.98 years,with an average tumour size of 8cm(range: 0.5- 25cm). Vascular invasion was detected in 2 patients(12 patients were not evaluable). Unilateral tumours were observed in 40 patients,and a bilateral tumour in 1 patient. The tumour was located on the right side in 24 patients and on the left side in 21 patients.Tumour rupture was present in 10 patients and absent in 32. 25 tumours were cystic, while 12 were solid.Metastasis was detected in 8 patients, and 10 patients had died. The distribution of tumour stages was as follows:31 patients in stage 1a, 1 patient in stage 1b, 8 patients in stage 1c, and 1 patient in stage 2a. Among 38 patients, 23 had endometrial hyperplasia, 3 had endometrial tumours, and 12 had a normal endometrium.The average time to metastasis was 5.43 ± 5.68 years.No significant association was found between rupture and metastasis($p = 1$).A significant relationship was observed between stage and metastasis($p = 0.003$). No association was found between tumour rupture and mortality($p = 1.0$), while a borderline relationship was observed between stage and mortality($p = 0.057$) and a significant association was found between metastasis and mortality($p < 0.001$).
Conclusion: Granulosa cell tumours are generally low-grade, with a better prognosis compared to other ovarian tumours.These hormone-secreting tumours, as demonstrated in our study(in 69.42% of cases), are often associated with endometrial pathologies. Given the potential for late-onset metastasis, long-term follow-up is essential.

E-PS-11-002

Ovarian fibrothecomas, fibromas, and thecomas: a clinicopathological and imaging analysis of 73 cases

N. Selak[1], I. Cerkez[1], E. Latifagic Iljazovic[1], A. Sadikovic[1], M. Konrad Custovic[1]
[1]University Clinical Centre Tuzla, Department of Pathology, Tuzla, Bosnia and Herzegovina

Background & Objectives: Ovarian fibrothecomas, fibromas, and thecomas are rare sex cord-stromal tumours with overlapping clinical and pathological features. This study aims to analyse their incidence, clinical characteristics, imaging findings, and histopathological features to better characterize their presentation and management.
Methods: This retrospective study analysed 73 cases diagnosed at our institution from January 2011 to December 2024. Clinical parameters, imaging findings, tumour markers, and histopathological features were assessed.
Results: The cohort included 49 fibromas, 14 fibrothecomas, and 10 thecomas. The mean patient age was 59 years (±12). The median tumour size was 85 mm (IQR: 60–120 mm). Three cases (4.1%) were bilateral, and two were extraovarian. Half of the cases were incidental, while symptomatic patients presented with chronic or acute abdominal pain (18 cases, 24.7%), ascites (4 cases, 5.5%), or vaginal bleeding (1 case, 1.4%). Most patients (46/73, 63%) underwent total hysterectomy with bilateral adnexectomy, while most of the remaining patients primarily had unilateral adnexectomy. Imaging findings varied, with lesions appearing solid, cystic, or mixed on ultrasound. CT and MRI typically confirmed an adnexal origin, with most lesions showing mild, heterogeneous post-contrast enhancement. CA-125 was elevated in 10/29 patients and CEA in 3/12. Histopathological analysis revealed tumours with generally low mitotic activity, with only three classified as cellular and mitotically active. Sudan staining, performed in 22 cases, was positive in 2 thecomas and 10 fibrothecomas, supporting lipid-rich stromal differentiation. Reticulin staining, when performed, confirmed a pericellular pattern. No recurrences were observed during follow-up.
Conclusion: Ovarian fibrothecomas, fibromas, and thecomas are uncommon neoplasms predominantly affecting postmenopausal patients. While imaging and tumour markers aid preoperative assessment, diagnosis is histological. Fertility-sparing tumour resection is preferred in younger patients when feasible, while radical surgery is generally indicated for perimenopausal and postmenopausal patients.

E-PS-11-003

Extraovarian fibrothecomas: a report of two rare cases, including one associated with Meigs syndrome

I. Čerkez[1], N. Selak[1], E. Latifagic Iljazovic[1], A. Sadikovic[1], M. Konrad Custovic[1]
[1]University Clinical Centre Tuzla, Department of Pathology, Tuzla, Bosnia and Herzegovina

Background & Objectives: Fibrothecomas are rare ovarian tumours, accounting for approximately 4% of all ovarian neoplasms. Extraovarian fibrothecomas are exceptionally rare, with only 15 cases reported in the literature. These tumours have been identified in the broad ligament, retroperitoneum, and mesocolon. Accurate diagnosis requires thorough histopathological and immunohistochemical evaluation.
Methods: We present two cases of extraovarian fibrothecomas with distinct clinical, radiological, and histological features.
Results: The first case involved a 56-year-old woman with a mass adherent to the omentum and intestines. Ultrasound revealed a solid, well-defined 15 cm lesion with free fluid in the Douglas space. Tumour resection, along with a 22 cm segment of the small intestine, was performed. Histopathological analysis confirmed a fibrothecoma with low mitotic activity, positive for vimentin, SMA, WT1, focal inhibin, and calretinin. There was no recurrence observed. The second case was a 75-year-old patient with a 25 cm abdominal mass, ascites, and pleural effusion, consistent with Meigs syndrome. Imaging suggested a cystic-solid ovarian tumour with significant free peritoneal fluid, and CA-125 was markedly elevated. The patient underwent tumour resection along with a total hysterectomy and bilateral salpingo-oophorectomy. Surgery revealed intact ovaries and an extraovarian tumour, likely originating from the broad ligament. Histopathological examination showed typical features, including a characteristic reticulin framework and Sudan-positive lipid droplets, with low mitotic activity. Immunohistochemistry confirmed positivity for FOXL2, CD56, and focal inhibin and calretinin. Postoperatively, the patient's preexisting pleural effusion worsened, requiring drainage, but she recovered well with supportive treatment. There was no tumour recurrence, and follow-up remained uneventful.
Conclusion: Extraovarian fibrothecomas are rare and can clinically mimic ovarian malignancies. Awareness of their clinicopathological and radiological characteristics is essential for accurate diagnosis and optimal management.

E-PS-11-004

Malıgnant transformatıon in mature cystıc teratoma: a serıes of 6 cases

E. Cingi Doğan[1], İ. Özöver Çelik[1], C. Comunoglu[1], O. Yalcin[1], T. Işgörücü[1]
[1]TC Saglik Bilimleri University Prof. Dr. Cemil Tascioglu City Hospital, Pathology, Istanbul, Turkey

Background & Objectives: Mature cystic teratoma is the most common ovarian germ cell neoplasm. Malignant transformation is rarely observed, usually in older patients and typically in patients with unilateral tumours. The most common somatic malignancy in ovarian teratoma is squamous cell carcinoma. Sarcomas occur more often in younger patients than carcinomas. Tumour marker concentration levels (CEA), age, and the tumour maximum diameter are predictive indicators for malignant transformation. The prognosis of patients with malignant transformation is unfavourable, only 15-30% of patients survive 5 years.
Methods: In this study, between 2017 and 2024, at İstanbul Prof. Dr. Cemil Taşcıoğlu City Hospital, malignant transformation was observed in 6 out of 247 patients diagnosed with mature cystic teratoma.
Results: In one of these six cases, neuroendocrine tumours were observed, while three cases had papillary thyroid carcinoma, one case had squamous cell carcinoma and one case presented with thyroid oncocytic adenoma. In half of these six cases, the tumours originated from the left ovary. Median age was found to be 48,3 (31-74 years) and the average tumour size is 8,4 cm (5,5-17). However, elevated CEA levels were not observed in any of our patients. The prognosis of patients with mature cystic teratoma with malign transformation in unfavourable. Better prognosis has been reported when the malignant element is a squamous cell carcinoma confined to the ovary. In such cases, the reported 5- year survival is 63%. All of our patients are still alive today.
Conclusion: In conclusion, although mature cystic teratoma is the most common benign germ cell neoplasm of the ovary, malignant transformation can occur. Malignant transformation should remain in consideration, especially with increased patient age, tumour size, or tumour marker levels. Macroscopically, careful examination should be performed, and multiple samples should be taken from different areas.

E-PS-11-005

Unveiling mesonephric-like adenocarcinoma: a case series highlighting variability in immunohistochemical expression

D.-G. Nicolcea[1], D. Anderco[1], S. Costi[1], S. Tăban[1,2], A. Dema[1,2]
[1]"Pius Brînzeu" County Clinical Emergency Hospital, Department of Pathology, Timișoara, Romania, [2]"Victor Babeș" University of Medicine and Pharmacy, Department of Microscopic Morphology – Anatomic Pathology, ANAPATMOL Research Centre, Timișoara, Romania

Background & Objectives: Mesonephric-like adenocarcinoma is a rare and recently recognized subtype of gynaecologic malignancy. It was first introduced in the 5th edition of the World Health Organization Classification of Female Genital Tumours and is still frequently misdiagnosed. This case series describes the only two cases of mesonephric-like adenocarcinoma in our Pathology Department, emphasizing the diagnostic challenges of this rare tumour.
Methods: We present two cases of mesonephric-like adenocarcinoma involving the uterus and ovaries. The first case is that of a 64-year-old female who underwent a routine CT scan during her neurological check-up, uncovering bilateral adnexal tumours with uterine involvement. She had a total hysterectomy, adnexectomy, peritoneal biopsy, and peritoneal liquid cytology. The second case is a 49-year-old female with recurring pelvic pain, who underwent a CT scan, uncovering a left adnexal cyst. She had a left adnexectomy.
Results: In the first case, histopathology revealed synchronous primary mesonephric-like adenocarcinoma of the uterus and both ovaries, with direct extension to the left fallopian tube and pelvic soft tissues and distant peritoneal metastases. Immunohistochemistry showed PAX8 and TTF1 positive, GATA3 and WT1 negative, thus supporting the diagnosis of mesonephric-like adenocarcinoma. In the second case, histology demonstrated a mesonephric-like adenocarcinoma involving the left ovary, and immunohistochemistry supported the diagnosis with PAX8 and GATA3 positivity, while TTF1 and WT1 were negative.
Conclusion: Mesonephric-like adenocarcinoma is a rare and challenging diagnosis that requires a high level of suspicion and detailed immunohistochemical profiling. The cases described highlight the variability in the immunohistochemical expression of GATA3 and TTF1, which can present in an inverse pattern in different cases. Fewer than 100 cases have been reported in the literature, therefore further research is essential to define diagnostic criteria and guide clinical management of these rare tumours.

E-PS-11-007

Precancerous lesions and squamocellular carcinoma of the vulva

J. Baljak[1,2], M. Panjković[1,2], T. Lakić[1,2], A. Ilić[1,2], Z. Milinković[1,2], N. Gardić[3,2]
[1]University Clinical Centre of Vojvodina, Department of Pathology, Novi Sad, Serbia, [2]Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia, [3]Institute for Pulmonary Diseases of Vojvodina, Department of Pathology, Sremska Kamenica, Novi Sad, Serbia

Background & Objectives: The spectrum of vulvar lesions includes a variety of conditions, from infectious and benign dermatological changes to precancerous lesions and invasive carcinoma. Studies have shown that HPV-associated invasive vulvar carcinomas have better overall survival and lower recurrence rates compared to HPV-negative tumours. The aim of this retrospective study was to analyse the histopathological and immunohistochemical features of squamous precancerous lesions and invasive squamous cell carcinomas of the vulva, as well as the demographic characteristics of affected patients.
Methods: Data were collected from the archives of the Centre for Pathology and Histology at University Clinical Centre of Vojvodina. Tissue samples were obtained through biopsy or excision between January 2021 and December 2024 at the Clinic for Gynaecology and Obstetrics. Analyses included immunohistochemical staining with p16 and p53 antibodies.
Results: The average age of patients was 55 years (range 19–90). Condylomas were the most frequent lesions (35%), while differentiated VIN (dVIN) was least common (3%). Most samples (57%) were obtained via biopsy. Of all lesions, 36.6% underwent immunohistochemical analysis. Among these, HPV-associated carcinomas were the most frequent (32%; average age 57.4), followed by usual VIN (uVIN) uVIN3 (23%; 59.4), HPV-independent carcinomas (18%; 74.5), uVIN1 (14%; 62), dVIN (9%; 56), and uVIN2 (4%; 52). The majority of invasive carcinomas exhibited moderate differentiation (57%), whereas HPV-independent carcinomas showed a higher degree of differentiation (which can complicate diagnosis).
Conclusion: The study concluded that HPV-associated lesions occur in younger patients, while HPV-independent lesions are more common in older individuals and tend to show higher differentiation. This distinction is clinically significant and presents a diagnostic challenge.

E-PS-11-008

Small cell carcinoma of the ovary, hypercalcaemic type

A. Mayer[1], S. Tomić[1], M. Vuletić[1], I. Čović[1]
[1]University Hospital Split, Pathology and Cytology, Split, Croatia

Background & Objectives: 31-year-old female patient presented with pelvic pain, abdominal swelling and general weakness.

Ultrasound and CT showed bilateral ovarian tumours. Laboratory results showed elevated serum calcium levels and CA-125. Anamnesis showed that the patient's sister died with same diagnosis, aged 32.
Methods: Intraoperative analysis, histology, immunohistochemistry and FoundationOne test were used.
Results: Intraoperative analysis showed bilateral, solid, large ovarian tumours sized 28 and 20 cm, with areas of haemorrhage, necrosis and cystic degeneration.
Histology showed diffuse tumour growth, minimal intervening stroma and follicle-like spaces with eosinophilic secretion. Tumour cells had monomorphic, small, round to ovoid nuclei with small nucleoli, scant cytoplasm and brisk mitotic activity. Immunohistochemically, tumour cells were WT1, EMA, CK8/18, NSE and vimentin positive, synaptophysin focally positive. p53 immunohistochemistry revealed mutated immunophenotype. Inhibin, calretinin, CD10, OCT4, PLAP, C-kit, TTF-1 and melan A stains were negative. Using FoundationOne test, genomic alterations were identified – SMARCA4 E650 loss exons 9-13.
Conclusion: Patient received platinum-based chemotherapy and died ten months after diagnosis.
Small cell carcinoma of the ovary accounts for <1% of ovarian tumours. Somatic or germline mutations on SMARCA4 (gene involved in chromatin remodelling) are detected in almost all tumours. The mutation leads to loss of function and it is highly specific and sensitive for making the final diagnosis.
Differential diagnosis include: juvenile granulosa cell tumour, undifferentiated carcinoma, poorly differentiated Sertoli-Leydig cell tumour, metastatic melanoma and lymphoma.
One third of patients have a germline mutation, even those without a positive family history (35%). Every patient with this diagnosis needs to be referred to a genetic counselling centre.
Stage is the most important prognostic factor, with less than 30% of patients with stage IA being alive without disease after surgery. International prospective multicentre protocols with collection of data are urgently needed to be considered for both first-line and relapsed disease in this particularly rare condition.

E-PS-11-009
Borderline ovarian tumours – frozen section versus final diagnosis
S. Ivić[1,2], M. Panjković[1,2], T. Lakić[1,2], N. Gardić[1], V. Trivunović[2], D. Miljković[3]
[1]Faculty of Medicine, Department of Pathology, Novi Sad, Serbia, [2]University Clinical Centre of Vojvodina, Centre for Pathology and Histology, Novi Sad, Serbia, [3]Faculty of Medicine, Department of Histology and Embryology, Novi Sad, Serbia

Background & Objectives: Borderline ovarian tumours are considered low malignant potential tumours, with some characteristics of malignancy but lacking destructive stromal invasion. The most common types are serous and mucinous borderline tumours, while other histological types are rarely encountered. Our study examined the difference between the diagnosis made after the frozen sections and after the surgery.
Methods: A retrospective study conducted at the University Clinical Centre of Vojvodina, Novi Sad, Serbia, evaluated a total of 71 patients diagnosed with borderline ovarian tumours following a frozen section examination during the five years (2019-2023). Archival medical documentation from the Centre of Pathology and histology were analysed.
Results: Borderline ovarian tumours usually occur in the working-age population (median age 49). From a total of 71 patients who were diagnosed with borderline tumours following frozen section examination, after the additional sampling and pathohistological examination of the surgical material, we found that in 51 (71.8%) of cases, the pathologist confirmed the initial diagnosis of borderline tumour. The initial diagnosis was downgraded from borderline tumour to benign tumour in 4 (5.6%) of cases or to benign tumour with focal proliferation of less than 10% in 6 (8.5%) of cases. Upgrade from initial diagnosis of borderline tumour to malignant tumour in surgical material was present in 10 (14.1%) of cases. Almost all tumours were diagnosed in the pT1 stage (94,4%), while the most common histological types encountered were serous borderline tumour (54,9%), mucinous borderline tumour (12,7%), and serous carcinoma (9,9%).
Conclusion: Borderline ovarian tumours are a real diagnostic challenge, with a significant influence on the decision in further treatment of patients. Detailed gross examination and proper sampling during frozen section analysis can significantly reduce errors in making this challenging diagnosis.

E-PS-11-010
The impact of the 2023 FIGO staging system on endometrial carcinoma: a five-year case series analysis
V. Hincapié Baena[1], V. Macarrón[1], I. Ochoa Grille[2], S. Quinones[1], A. Berjón[1], L. Yébenes[1], D. Hardisson[1]
[1]Hospital Universitario La Paz, Pathology, Madrid, Spain, [2]Universidad Autónoma de Madrid, Madrid, Spain

Background & Objectives: Risk categorization in endometrial cancer (EC) rely on integrating clinical-pathological and molecular features. The 2023 FIGO staging system (FSS) incorporates molecular profiling for prognostic accuracy and personalized therapy. The objective of this study was to compare the 2009/18 and 2023 FSS in a large series of EC.
Methods: A study of EC cases (2020–2024) was performed at a tertiary-level hospital. Clinical and histopathological reports were reviewed for staging using the 2009/2018 and 2023 FSS.
Results: A total of 261 EC cases were diagnosed. Based on the 2009/2018 FSS, 61.7% (n=161) were classified as stage IA, with 44 cases (27.3%) upstaged according to the 2023 FSS: IC (4 cases, 9.1%), IIB (12 cases, 27.3%), IIC (7 cases, 15.9%), and IICm (p53abn) (21 cases, 47.7%). In the 28 cases (14.6%) classified as stage IB, 16 (42.1%) were upstaged: IIB (7 cases, 43.7%), IIC (6 cases, 37.5%), and IICm (p53abn) (3 cases, 18.7%). Conversely, four cases (1.5%) previously classified as stage II were reclassified as stage IIA (three cases, 75%) and IICm (p53abn) (one case, 25%). Stages IIIA, IIIB, IIIC1, IIIC2, and IVA remained unchanged. Of the 18 cases (6.9%) classified as IVB, 6 (33.3%) remained IVB, while 12 (66.7%) were reclassified as IVC.
Conclusion: The 2023 FSS incorporated pathological and molecular features into EC staging. In this study, 25% of stage IA cases were upstaged, and more than 40% of stage IB cases were upgraded to stage II. Stage II remained largely unchanged as no POLEmut cases were downgraded. Stage III cases exhibited no significant changes except for newly added subclassifications. Stage IVA remained unmodified, while stage IVB was subdivided, with one-third of cases being upstaged to IVC. In summary, the 2023 FSS significantly impacts stages I and II, enhancing staging accuracy and optimizing therapeutic management based on clinicopathological prognostic factors.

E-PS-11-011
Uterine carcinosarcoma: a rare biphasic tumour with aggressive features
A.M. Fifiita[1], A. Ilieșiu[1], A.V. Tudorache[1]
[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background & Objectives: Uterine carcinosarcomas are rare, aggressive biphasic tumours composed of high-grade carcinomatous and sarcomatous components. They typically occur in postmenopausal women, and are often associated with tamoxifen use or prior pelvic radiotherapy. Thought to arrise from carcinoma through

transdifferentiation, they frequently harbour TP53 mutations, resembling serous endometrial carcinoma.
Methods: This report presents the case of a 69-year-old patient presenting with vaginal bleeding. She had no history of external oestrogen exposure. Pelvic CT showed a thickened endometrium and a distended uterine cavity. The patient underwent curettage biopsy and histopathological examination that was suggestive of carcinosarcoma or undifferentiated adenocarcinoma, requiring further investigation. Surgical treatment involved total hysterectomy, bilateral salpingo-oophorectomy and Wertheim lymphadenectomy.
Results: Gross examination revealed a 6 cm endometrial tumour with necrotic areas, infiltrating the outer layer of the myometrium, with focal serosal involvement. Microscopically, a biphasic malignant proliferation was detected, composed of high-grade endometrioid carcinoma and a poorly differentiated mesenchymal component, confirming the diagnosis of carcinosarcoma. Extensive necrosis (60%) and lymphovascular invasion were present.
Immunohistochemistry showed p53 mutant-type positivity (95% of cells), MMR proficiency, and focal positivity for ER, AE1/AE3 and PAX8 in the epithelial component. The sarcomatous component was negative for desmin, CD34, and strong positive for INI1. HER2neu expression was not detected.
Conclusion: Uterine carcinosarcomas are rare tumours, accounting for about 5% of uterine malignancies. These tumours are usually at an advanced stage at the time of diagnosis. While not required for diagnosis, immunohistochemistry is useful in confirming the biphasic nature.
Co-expression of epithelial and mesenchymal markers by itself is insufficient for diagnosis and heterologous elements in endometrioid carcinoma do not confirm carcinosarcoma. Considering its rarity, recognizing this tumour is important for the accurate management of patients.

E-PS-11-012
Histopathological changes in placentas of substance-using individuals: a retrospective study
Y. Aksoy[1], H.S. Toru[1]
[1]Akdeniz University, Department of Pathology, Antalya, Turkey

Background & Objectives: In today's society, substance addiction poses significant economic, social, and physiological challenges. Substance abuse can lead to various adverse effects on the human body, including arterial thrombosis in the lungs, acute vasculitis, drug-related liver disease, and arterial thrombosis in the central nervous system. Additionally, substance abuse during pregnancy can result in detrimental effects on the placenta, the enigmatic organ connecting the foetus and the mother, leading to various anomalies and intrauterine growth retardation. In this retrospective study, we examine five placental specimens from pregnancies between 2017 and 2025 at our institution.
Methods: We will examine seven placental specimens collected at our hospital between 2017 and 2025. Six of these specimens are from preterm pregnancies, and one is from a term pregnancy. The specimens, fixed in 10% formalin, embedded in paraffin, and sectioned at 4-5 micrometers thickness, will be stained with haematoxylin-eosin for examination. Macroscopic and microscopic analyses will be conducted using the Placental Work Group Consensus Statement as a guide.
Results: Upon examination of the seven placental specimens, we observed findings consistent with Maternal Vascular Malperfusion (MVM) and Foetal Vascular Malperfusion (FVM). Deciduitis was identified in two of the specimens. Dystrophic calcification was observed in six of the seven specimens, while chorangiosis was observed in three specimens. Sclerosis of some villi was noted, and delayed villous maturation was observed in one placenta. Maternal Inflammatory Response was observed in two placental specimens, while Foetal Inflammatory Response was observed in one.
Conclusion: Our study reveals a significant increase in Maternal Vascular Malperfusion in placentas of individuals with substance addiction compared to those of normal pregnancies. However, we found similar rates of Foetal Vascular Malperfusion, Maternal Inflammatory Response, and Foetal Inflammatory Response compared to normal pregnancies.

E-PS-11-013
Correlation of TP53 mutation types with immunohistochemical p53 staining patterns in high-grade serous ovarian carcinomas
G. Sivrikaya[1], G. Serin[1], O. Zekioğlu[1]
[1]Ege University Faculty of Medicine, Medical Pathology, Izmir, Turkey

Background & Objectives: High-grade serous ovarian carcinoma is characterized by a high frequency of mutations in the TP53 tumour suppressor gene. The majority of TP53 mutations are missense mutations, typically clustered around specific hotspot amino acid residues. This retrospective study aimed to analyse the frequency, types, and distribution of TP53 mutations in high-grade serous ovarian carcinoma.
Methods: Data from 75 cases were collected, including p53 immunohistochemical (IHC) staining patterns and TP53 mutations identified through next-generation sequencing (NGS).
Results: According to the next-generation sequencing (NGS) results, the majority of cases exhibited missense mutations (65.3%). Missense mutations were followed by stop-gained variants (13.3%), splice-site mutations (6.7%), and frameshift mutations (5.3%). IHC analysis of p53 staining patterns revealed overexpression in 73.3% of cases and a null staining pattern in 26.7% of cases. When comparing IHC staining patterns with mutation results, it was observed that 93.9% of cases with missense mutations exhibited overexpression staining. Conversely, the majority (81%) of cases with mutations causing significant alterations in protein structure demonstrated a null staining pattern ($p<0.001$). In 5 cases, overexpression staining was observed despite the absence of detectable mutations in the NGS analysis.
Conclusion: In conclusion, the IHC staining patterns of p53 significantly correlated with mutation types. The majority of mutations (88.6%) were located within the DNA-binding domain (DBD) of the TP53 gene (amino acids 102-292).

E-PS-11-014
Hydatidiform moles: the contribution of ancillary techniques in refining the histopathological diagnosis
T.A. Balan[1], I.D. Căruntu[1], C. Amalinei[1], S.E. Giușcă[1], R.A. Balan[1]
[1]University of Medicine and Pharmacy "Grigore T. Popa" Iasi, Department of Morphofunctional Sciences I, Iasi, Romania

Background & Objectives: The hydatidiform mole (HM) is the most common type of gestational trophoblastic disease. Differentiating HM from non-molar pregnancies, and distinguishing complete HM (CHM) from partial HM (PHM), is difficult due to overlapping morphological features. As studies showed a high rate of misclassification, we aimed to assess reliable markers for distinguishing and classifying HM, addressing the limitations of current molecular techniques.
Methods: Our retrospective study included 64 cases of HM and hydropic abortions (HA), diagnosed in women between 17-36 years old, during 2010-2024, within the Pathology Department of "Elena Doamna" Clinical Hospital of Obstetrics and Gynaecology, Iasi, Romania. The surgical specimens were histopathologically assessed by routine histological methods, supplemented with additional immunohistochemical techniques, using a panel of specific markers, together with semiquantitative immunoscores.
Results: The histopathological examination revealed 38 (59.37%) cases of PHM, 16 (23.88%) cases of CHM and 10 (15.62%) cases of HA.

In order to differentiate HM from HA and CHM from PHM, all cases underwent immunohistochemical assessment of p57, Ki-67, β-hCG and E-cadherin. The assessment of p57 showed 18% positivity for CHM and 100% positivity for PHM and HA, the immunoexpression of Ki-67 was weak in 12.5%, moderate in 50% and strong in 37.5% of CHM, while weak in 57.8%, moderate in 23.68% and strong in 10.52% of PHM, and weak in 100% cases of HA. As for β-hCG, the highest immunoscore was assessed in CHM, followed by PHM and HA, while for E-cadherin, the highest immunoscore was expressed in HA, followed by PHM and CHM.
Conclusion: Morphology offers relative information in the diagnosis of molar pregnancies, requiring the corroboration with clinical, paraclinical and imagistic data, as well as a series of ancillary techniques. The histopathological diagnosis of HM continues to be negatively influenced by interobserver variability, an algorithmic histopathology-immunohistochemistry approach, completed by genotyping, refining the accuracy of the histopathological examination.

E-PS-11-015
Exploring TTF-1 expression in endometrial carcinomas: implications for pulmonary metastasis diagnosis and the role of PAX8
C.M. Alfonso Rosa[1], A.M. Montaña Ramirez[1], R. Rendon Garcia[1], A. Lopez Prieto[1], R. Mora Diaz[1], J. Machuca Aguado[1]
[1]Hospital Universitario Virgen Macarena, Pathology, Seville, Spain

Background & Objectives: The expression of TTF-1 in endometrial carcinomas is rare, found in 8% of cases, and only in 2% of low-grade endometrioid tumours. This necessitates careful management when studying a pulmonary lesion in patients with a history of endometrial carcinoma. PAX8 is a characteristic marker of the gynaecological tract that could assist in differential diagnosis.
Methods: Based on a case of pulmonary metastasis from a TTF-1+ endometrial carcinoma, a search was conducted in the archive of our department over the last 15 years, identifying 26 other cases. The expression of TTF-1 was studied in all of them.
Results: The index case is that of a 79-year-old woman with low-grade endometrioid adenocarcinoma at stage III, treated 5 years ago. Three years later, a pulmonary lesion suggestive of primary neoplasia was identified, and it was diagnosed as primary pulmonary adenocarcinoma with a compatible immunohistochemical profile (TTF1+/NapsinA+/CK7+/CK20-). Following radiological monitoring, two months ago, bone, lymph node, and pulmonary lesions were detected. The pulmonary biopsy showed a morphology compatible with the endometrial lesion, with positivity for TTF1, NapsinA, PAX8, and oestrogen receptors, suggesting metastasis from endometrioid adenocarcinoma. Molecular analysis revealed mutations in KRAS, PI3KCA, and ARID1A. KRAS mutations have been associated with mucinous changes in low-grade endometrioid adenocarcinoma, as well as the rare expression of TTF-1 in these neoplasms. In 19 additional cases, TTF1 expression was negative.
Conclusion: Although advancements in immunohistochemistry and molecular techniques have been crucial in improving diagnosis, the value of morphology should not be overlooked. Immunohistochemical patterns, such as TTF-1+/CK7+/CK20-, are suggestive of primary pulmonary neoplasia, but they should be interpreted alongside clinical history and a detailed morphological evaluation. The expression of TTF1 in other neoplasms, such as endometrial carcinoma, should be considered, and in patients with gynaecological histories, the use of PAX8 for differential diagnosis would be recommended.

E-PS-11-016
Primary ovarian malignant melanoma arising in a mature teratoma with synchronous endometrial carcinoma: a rare case report
S. Hacıoğlu Erşahan[1], S. Kevser Dursun[1], S. Altinay[1], N.R. Ökten[1]
[1]Basaksehir Cam and Sakura City Hospital, Department of Pathology, Istanbul, Turkey

Background & Objectives: Malignant transformation in ovarian mature cystic teratomas is a rare phenomenon, occurring in approximately 1.5–2% of cases. The most common malignant component is squamous cell carcinoma. Malignant melanoma arising within a mature teratoma is exceedingly rare, with only a few cases reported in the literature. Here, we present a unique case of primary ovarian malignant melanoma arising in a mature teratoma, coexisting with synchronous endometrioid endometrial carcinoma—one of the rarest combinations of dual primary gynaecologic malignancies.
Methods: A 59-year-old postmenopausal woman presented with vaginal bleeding. Imaging revealed a complex left adnexal mass and endometrial thickening. She underwent total abdominal hysterectomy, bilateral salpingo-oophorectomy, splenectomy, omentectomy, and pelvic-paraaortic lymph node dissection.
Results: Histopathological examination revealed malignant melanoma arising within a mature cystic teratoma of the left ovary, adjacent to teratomatous elements such as squamous epithelium, hair shafts, bone, respiratory epithelium, and sweat glands. The tumour had metastasized to the spleen and 13 pelvic-paraaortic lymph nodes. Immunohistochemical analysis showed positivity for HMB45, Melan-A, SOX10, and PRAME. Additionally, synchronous grade 2 endometrioid carcinoma was identified in the endometrium and tumour cells positive for PAX8, CK7, ER, and PR. p53 exhibited wild-type expression, and MMR protein expression was retained (MS-Stable). A comprehensive systemic evaluation, including dermatological assessment, was performed to exclude primary cutaneous melanoma. No primary cutaneous or ocular lesion was identified, leading to the diagnosis of primary ovarian malignant melanoma. At the 10-month follow-up, the patient remains asymptomatic and is undergoing anti-PD-1 immunotherapy (nivolumab).
Conclusion: Melanoma arising in an ovarian teratoma is extremely rare, and its coexistence with synchronous endometrial carcinoma presents additional diagnostic and therapeutic challenges. Differentiating primary ovarian melanoma from metastatic melanoma is crucial, as management strategies differ significantly. This case underscores the importance of thorough histopathological evaluation and integration of clinical and radiological findings for accurate diagnosis and optimal patient management.

E-PS-11-017
Intravenous leiomyomatosis: a double-sided tumour
M. Alaya[1], G. Sahraoui[1], E. Khemir[1], N. Boujelbene[1], I. Abbes[1], L. Charfi[1], H. Arbi[1], R. Doghri[1], K. Mrad[1]
[1]Salah Azaiez Institute, Pathology Department A, Tunis, Tunisia

Background & Objectives: Intravenous leiomyomatosis is a rare type of benign smooth muscle tumour that is defined by the presence of vascular extension and invasion of smooth muscle lesions in pelvic or systemic vasculature system. Its incidence low and the pathogenesis is still unclearnowadays. However, most studies prove that the primary tumour is usually located in the uterus then spreads along the intra- and extrauterine veins and can extend to the inferior vena cava, right atrium, right ventricle, and pulmonary artery. Clinical symptoms in aregenerally non-specific and it is easy to be misdiagnosed. It is however an aggressive diseaseand can prevent fatal consequences.
Methods: Our study is descriptive and retrospective about 7 cases. All data were collected from the PCR Laboratory of the ISA between 2010 and 2024. These samples underwent anatomopathological study followed by an immunohistochemical study.
Results: Our patients were aged between 38 and 72 years old. The average age was 46.7. All patients consulted for pelvic pain or metrorrhagia.

CT scan was performed, revealing cavitary fibrous nodules and a similar image in superior veina cava in one case. The patients underwent hysterectomy. Macroscopic examination revealed whitish fasciculated intracavitary nodules. These were associated with intravascular masses in the form of finger-like strips dissociating the muscle with retraction clefts.
On histological examination, the nodules responded to a regular proliferation of smooth muscle cells arranged in long intersecting bundles without cytonuclear atypia, mitotic figures or foci of necrosis. The digitiform masses also had a superposable histological appearance. The tumour cells were Desmine (+), lined with cells CD31 (+) thus confirming diagnosis of intravascular leiomyomatosis.
Conclusion: Despite its rarity, intravascular leiomyomatosis may be associated with high morbidity. Moreover, it presents with non-specific symptoms which could easily be misunderstood. Therefore, early recognition is important and should be considered in patients with a history of uterine fibroids or surgery

E-PS-11-018
Pelvic-genital hydatid cyst: a case report series
D. Aloui[1], W. Ajouli[1], L. Belhadj kacem[1], M. Ksontini[1], A. Blel[1], R. Aloui[1], S. Rammeh[1]
[1]Charles Nicolle Hospital, Department of Pathology, Tunis, Tunisia

Background & Objectives: Hydatid cyst is a public health problem in endemic areas. It often affects the liver and the lung. Pelvic-genital location in women is rare. We present 4 cases of pelvic-genital hydatid cysts which were diagnosed by anatomopathological diagnosis.
Methods: We collected four cases of pelvic hydatid cysts in our department between January 2016 and January 2023. The epidemiological and clinical data were obtained from patients' medical records, while anatomopathological information was retrieved from anatomopathological reports.
Results: Mean age was 55 years. The hydatid cyst was found in all 4 cases as a pelvic mass during imaging for abdominal pain. In 2 cases, it was located in the pelvic area, in 1 case, it was adjacent to the uterine wall and ovary, and in 1 case, it was located in the left broad ligament. It was multilocular in one case and unilocular in the remaining 3 cases, and there was no extra-pelvic location. Macroscopic examination showed a white cystic wall containing fragments of translucent proligere membrane. Histologically, it was a typical hydatid cyst, with a pericyst, an anhist cuticle, and a germinative proligere membrane.
Conclusion: Echinococcosis can affect individuals of any age, although it is more commonly seen in young adults. Pelvic-genital hydatid cysts are rare, with a frequency ranging from 0.3 to 4.27%. The genital location is the most common site of pelvic hydatidosis. It should be considered in the differential diagnosis of any pelvic-genital cystic lesion, such as ovarian cyst, hydrosalpinx and ovarian tumours especially in endemic areas.

E-PS-11-019
Epithelioid trophoblastic tumour: case report of a rare entity
A.I. Pestana Lopes[1], R. Lyrio[1], A. Catarino[1]
[1]Hospital da Luz Lisboa, Pathology, Lisbon, Portugal

Background & Objectives: Epithelioid trophoblastic tumour (ETT) is a rare neoplasm arising from chorionic intermediate trophoblast cells. It typically affects women of reproductive age following a gestational event and presents a diagnostic challenge due to its rarity and histological similarities to other pathologies. We report a case of ETT to highlight its clinical and histopathological features.
Methods: A 45-year-old woman presented with a submucosal lobulated mass in the lower uterine segment, incidentally identified via ultrasonography and later evaluated by magnetic resonance imaging (MRI). The tumour, measuring 3.4 cm on MRI, was initially considered a leiomyoma/adenomyoma with no suspicious features. The patient, who had an intrauterine device (IUD) inserted one year prior, had no symptoms or recent pregnancy history. She underwent a total hysterectomy.
Results: Gross examination revealed a 6.5 cm submucosal mass in the lower uterine segment, with a white-yellowish, fleshy appearance on sectioning. Histological analysis showed a well-circumscribed lesion with nodular perivascular growth forming cords and nests of cells, along with extensive areas of geographic necrosis. The neoplastic cells exhibited vesicular nuclei and abundant eosinophilic cytoplasm. Hyaline eosinophilic material was also observed within the tumour. Immunohistochemical staining revealed positivity for p63, Inhibin, GATA3, CD10 and focal expression of PLAP. The Ki67 proliferation index was 25%. The tumour cells were negative for hCG, oestrogen receptors, and progesterone receptors, supporting the diagnosis of ETT.
Conclusion: Most ETT develop after a gestational event, with a latency period ranging from months to up to 10 years. Accurate diagnosis is crucial for effective management. ETT has a reported mortality rate of 10–24%, with stage IV being an independent prognostic factor. While ETT can sometimes occur as part of a mixed trophoblastic tumour, no other forms of gestational trophoblastic neoplasia were identified in our case. The patient is currently doing well with no signs of metastatic disease.

E-PS-11-020
Adenosarcoma arising in an endometrial polyp - a case report
M. Moreira[1], C. Padrão[1], J. Tinoco[1], R. Theias Manso[1], M. Ferreira[1]
[1]Hospital Prof. Doutor Fernando Fonseca, Anatomia Patológica, Lisboa, Portugal

Background & Objectives: Uterine adenosarcoma is a rare malignant biphasic tumour composed of a benign epithelial component and a malignant stromal component. It commonly presents with abnormal uterine bleeding. Diagnosis is based on morphological and immunohistochemical features. The occurrence of adenosarcoma within endometrial polyps is rare, with only isolated case reports in the literature. Herein, we report an adenosarcoma arising in a uterine polyp, focusing on its clinical presentation, gross examination, and histopathological findings.
Methods: An 80-year-old woman presented with abnormal uterine bleeding. MRI revealed a 9 cm, heterogeneous lesion with multiple cystic and haemorrhagic nodular areas, filling the uterine cavity and extending to the cervix. CA 125 and CA 19-9 were elevated. Biopsies were performed, with no evidence of malignancy. Due to the suspicious aspects of the intrauterine lesion, total hysterectomy with bilateral salpingo-oophorectomy was performed.
Results: Gross examination revealed a 12 cm polyp filling the uterine cavity. Histologically, it was a conventional endometrial polyp. Focally, in a 2 cm area, a biphasic tumour with stromal growth and a leaf-like pattern, with dilated glandular spaces lined by benign endometrial epithelium was identified. The stroma had areas with moderate cellularity, composed of oval-shaped cells with moderate to severe atypia and a mitotic index of up to 4 mitoses per 10 high-power fields. There was no myometrial infiltration, necrosis, heterologous elements, or vascular invasion. Immunohistochemical analysis showed CD10 positivity, focal expression of oestrogen and progesterone receptors, Ki-67 proliferation index of 15%, and wild-type p53 expression in the mesenchymal component.
Conclusion: The final diagnosis was adenosarcoma in an endometrial polyp (with focal areas of high-grade sarcoma) (pT1a; FIGO: IA). This occurrence is rare and presents diagnostic challenges. It underscores the importance of a thorough gross examination, careful sectioning, the number of sections submitted, meticulous histopathological evaluation, and differential diagnosis with other uterine biphasic and mesenchymal tumours.

E-PS-11-021

Analysis of reticulin, trichrome staining and Ki67 proliferative activity in pregnancy-associated leiomyomas

J. Mirkovic[1,2], M. Aldhuhoori[1,2], E. Olkhov-Mitsel[1], C. Parra-Herran[3]
[1]Sunnybrook Health Sciences Centre, Division of Anatomic Pathology, Department of Laboratory Medicine and Molecular Diagnostics, Precision Diagnostics and Therapeutics Program, Toronto, Canada, [2]University of Toronto, Laboratory Medicineand Pathobiology, Toronto, Canada, [3]Brigham and Women's Hospital, Harvard Medical School, Department of Pathology, Boston, USA

Background & Objectives: Pregnancy-associated leiomyomas (PALMs) often pose diagnostic challenges due to histologic similarities to leiomyosarcoma (LMS). A prior study documented differences in reticulin/collagen (trichrome) networks, and differential ki67 labelling at the viable-non-viable interface between leiomyoma (LM) and LMS (PMID 25698060). However, the distribution of reticulin, trichrome and Ki67 staining in PALMs has not been assessed.
Methods: Reticulin, trichrome and ki67 were assessed on whole-tissue sections of 30 PALM with necrosis. Reticulin distribution in nonviable areas was categorized as honeycomb, linear or absent, while trichrome was noted as present or absent. Ki-67 labelling at the viable–nonviable interface was estimated as even, decreased or increased compared to areas away from necrosis.
Results: Complete loss of reticulin, reported in 61% of LMs, was seen in only 11% of PALMs. Trichrome staining was similar to that reported in LMs, being present in non-viable areas of all cases. Ki67 proliferative activity was present evenly in the viable-non-viable interface of 84% PALMs, while 12% showed an increasing gradient; only 4% showed a decreasing gradient toward the interface. This was similar to the reported predominant absent, even or increasing labelling seen in most (77%) LMs, but contrasting with LMS, where 44% show decreased Ki-67 labelling at the viable-non-viable interface.
Conclusion: This study shows differences in reticulin/collagen networks and proliferative patterns in PALM versus LM and LMS.
Similarly to LMS, most PALMs retain honeycomb/linear reticulin patterns in non-viable areas. However, similar to LM and unlike LMS, there was collagen accumulation in the non-viable areas of all PALMs, as well as similar ki67 labelling at the viable-non-viable interface. While ischemia in PALM is a rather recent event given the absence of reticulin remodelling, collagen deposition and shifts in proliferation occur, in keeping with a benign process. A panel of trichrome, reticulin and ki-67 may aid in differentiating PALMs from LMS.

E-PS-11-022

Prognostic significance of tumour budding and stromal tumour-infiltrating lymphocytes in endometrial carcinoma

S. Ahuja[1], M. Singh[1], S. Zaheer[1]
[1]Vardhman Mahavir Medical College and Safdarjung Hospital, Pathology, New Delhi, India

Background & Objectives: Endometrial cancer (EC) is a common gynaecological malignancy with increasing global incidence. The tumour microenvironment, particularly stromal tumour-infiltrating lymphocytes (TILs) and tumour budding, has been studied in various malignancies for prognostic significance. The present study aimed to evaluate the association of tumour budding and stromal TILs with clinicopathological parameters in endometrial carcinoma.
Methods: A retrospective study was conducted on 30 cases of histologically confirmed endometrial carcinoma. Tumour budding was assessed in haematoxylin and eosin (H&E)-stained sections and categorized as low, intermediate, or high. Stromal TILs were quantified using the standardized method recommended by the International Immuno-Oncology Biomarkers Working Group and categorized as low (<20%) or high (≥20%). Immunohistochemistry for CD3 and CD20 was performed to assess the immune cell composition. Associations between tumour budding, TILs, and clinicopathological parameters were analysed using Fisher's exact test, chi-square test, and multivariate logistic regression, with a significance threshold of $p < 0.05$.
Results: High stromal TIL levels were significantly associated with lower tumour grade ($p = 0.01$), early stage ($p = 0.04$), lower myometrial invasion ($p = 0.03$), and absence of nodal involvement ($p = 0.01$). Multivariate analysis confirmed an independent association between high TILs and lower grade ($p = 0.04$), early stage ($p = 0.03$), and low tumour budding ($p = 0.02$). Tumour budding was significantly associated with advanced tumour stage ($p = 0.02$), nodal involvement ($p = 0.007$), and higher tumour grade ($p = 0.03$). Immunohistochemistry revealed no significant differences in CD3 and CD20 positivity across cases.

Conclusion: Stromal TILs and tumour budding are significantly associated with key prognostic factors in endometrial carcinoma. High TIL infiltration correlates with favourable tumour characteristics, whereas increased tumour budding is linked to aggressive features. These findings support the potential role of TILs and tumour budding as prognostic markers in EC and highlight their relevance in histopathological assessment.

E-PS-11-023

Expanding the morphological spectrum of Mixed Mullerian Adenosarcoma and adenocarcinoma of the uterus and ovary: report of 3 cases

Z. Zhao[1], C.H.R. Goh[1]
[1]Singapore General Hospital, Pathology, Singapore, Singapore

Background & Objectives: Mixed Müllerian adenosarcoma and adenocarcinoma (MAA) is a rare gynaecological biphasic malignancy, distinct from carcinosarcoma in morphology and clinical behaviour. Both components are often low grade (LG) and low stage, with prognosis likely driven by the sarcoma. Its pathogenesis remains unclear.
Methods: We report 3 cases of MAA.
Results: Case 1 was a 63-year-old patient with 22cm ovarian mass, featuring predominantly high grade (HG) adenosarcoma with sarcomatous overgrowth and focal heterologous differentiation (chondrosarcomatous, liposarcomatous and rhabomyosarcomatous). There was admixed clear cell carcinoma with focal somatically derived yolk sac tumour (YST) and associated endometriosis. Both components showed wild-type p53 expression. Additionally, a separate mucinous borderline tumour (MBT) with intraepithelial carcinoma was identified in the same tumour. The tumour involved the myometrium (pT2a).
Case 2 was a 67-year-old patient with 5.4cm polypoid endometrial mass, exhibiting predominantly LG adenosarcoma involving adenomyosis without myometrial invasion (pT1a), and focal HG adenocarcinoma with ambiguous morphology confined to the polyp (pT1a). Adenocarcinoma showed normal expression of DNA mismatch repair proteins (MMR) and p53 overexpression, while adenosarcoma showed p53 wild-type expression.
Case 3 was a 64-year-old patient with 4.8cm polypoid endometrial tumour, showing mixed LG endometrioid carcinoma and HG adenosarcoma. The sarcoma exhibited multifocal HG cytological atypia and frequent mitoses, without sarcomatous overgrowth or malignant heterologous differentiation. Adenocarcinoma showed MMR normal expression and subclonal p53 overexpression, while adenosarcoma showed p53 overexpression in HG areas and wild-type expression in LG areas. Both carcinoma and sarcoma involved outer half of the myometrium, with the carcinoma metastatic to both ovaries and pelvic lymph nodes as well (FIGO 2023 Stage IIIC1ii). Adenosarcoma was confined within the uterus (pT1b).
Conclusion: This series broadens the morphological spectrum of MAA, highlighting the occurrence of HG carcinoma, as well as rare somatic YST differentiation and co-existing MBT. Recognizing this entity facilitates proper clinical management.

E-PS-11-024

Pelvic Adenosarcoma arising 10 years after an extrauterine adenomyoma

W. Mokni[1], N. Abdessayed[1], A. Mahmoudi[1,1], I. Hadhri[1], Z. Nfikha[1], B. Sriha[1], M. Mokni[1]
[1]Farhat Hached University Hospital, Pathology, Sousse, Tunisia

Background & Objectives: Pelvic adenomyomas (PA) are rare, benign lesions characterized by the presence of endometrial tissue surrounded by smooth muscle tissue outside the uterus, typically in the pelvic cavity. Adenosarcoma is an aggressive malignant tumour that can arise from such lesions, usually years after initial diagnosis.
Our aim is to shed light on the potential for some benign tumours to undergo malignant transformation through a case of pelvic adenosarcoma arising 10 years after the excision of an extrauterine adenomyoma (EA).
Methods: It is a case of pelvic adenosarcoma arising 10 years after the excision of an adenomyoma (EA), diagnosed at our laboratory.
Results: A 50-year-old woman, who has presented, 10 years ago, with a rapidly growing abdominal mass. Ultrasound and imaging studies had initially revealed a solid-cystic mass independent of the uterus and adnexa, which was diagnosed as an EA. Recently, the patient reported abdominal distention and imaging showed a 16 cm abdominopelvic mass with mild ascites. Surgical resection revealed a myxoid mass with cystic foci and areas of necrosis. Histopathological examination identified two components: a benign epithelial component resembling endometrial glands with areas of squamous metaplasia and a second component of atypical spindle cells within a myxoid matrix. The latter exhibited focal rhabdoid differentiation, expressing desmin and myogenin, indicative of a heterologous rhabdomyosarcomatous component. The diagnosis was pelvic adenosarcoma with rhabdomyosarcoma-like differentiation. The patient underwent successful surgical resection with no immediate complications or recurrence.
Conclusion: Adenosarcomas are rare malignancies that usually arise in the endometrium. Extraendometrial adenosarcomas that originatine from adenomyosis or adenomyomas are rare. The rhabdomyosarcomatous differentiation seen in our case is also rare and can make the diagnosis more challenging. It also highlights the aggressive potential of such tumours
Regular follow-up is crucial in managing patients with these rare lesions to ensure an early detection of potential malignant transformation.

E-PS-11-025

Microinvasive endocervical mucinous adenocarcinoma arising from pseudomyxoma peritonei associated with low grade appendiceal mucinous neoplasm

S.-J. Lee[1], Y.S. Choi[2], K.-R. Kim[3], W.-J. Sung[1], J.I. Lee[1], H.-K. Oh[1]
[1]Daegu Catholic University School of Medicine, Pathology, Daegu, Republic of Korea, [2]Daegu Catholic University School of Medicine, Obstetrics and Gynaecology, Daegu, Republic of Korea, [3]Ewha Womans University School of Medicine, Pathology, Seoul, Republic of Korea

Background & Objectives: Pseudomyxoma peritonei (PMP) is a clinical condition characterized by the presence of mucous deposits within the peritoneal cavity, generally arising from the rupture of mucinous tumours of the appendix. Low-grade appendiceal mucinous neoplasms (LAMNs) are commonly associated with deposition of mucin, with or without admixed low-grade epithelium, on peritoneal surfaces, including intraabdominal and pelvic organs. Here, we report a very unusual presentation of PMP presumed to occur in LAMN with an endocervical invasion.
Methods: A 59-year-old female presented with weight loss with no significant past medical history and showed diffuse irregular peritoneal thickening in images. US-guided omental biopsy was diagnosed as PMP and the patient underwent debulking operation with total hysterectomy and bilateral salpingo-oophorectomy.
Results: Intraoperatively, dense adhesion of greater omentum, bowel, bladder, uterus and both adnexa was identified. Appendix was not identified, even though there was no history of appendectomy. On histological examination, grade 1 PMP was diagnosed in omentum, mesentery, and peritoneal surface of both ovaries and fallopian tubes, etc. Separately, a microinvasive low grade mucinous adenocarcinoma was found in the uterine endocervix. A small amount of intraluminal acellular mucin in fallopian tubes and diffuse endometrial reepithelialization by low-grade mucinous neoplasm was also identified. There was no invasion of endometrial stroma. Immunohistochemical stains demonstrated that the neoplastic cells of both peritoneum and endocervix were positive for CK20 and CDX-2 and negative for CK7, indicating intestinal differentiation. According to morphologic and immunohistochemical examination, the endocervial invasive lesion was interpreted as microinvasive low grade mucinous carcinoma originating from ruptured LAMN resulting PMP. The patient continues to do well without evidence of recurrence 3 years after surgery.
Conclusion: Even with low-grade disease, PMP could be make invasive implantations in distant organs, such as ovary and endometrium. In our knowledge, this is the first case which report the endocervical invasion of LAMN with PMP.

E-PS-11-026

Cervical cellular myofibroma/myopericytoma with SRF::RELA fusion, mimicking adenosarcoma, an extremely rare case report and review of literature

F. Kubba[1]
[1]Ealing Hospital, London North West University Healthcare NHS Trust, Histopathology, London, United Kingdom

Background & Objectives: We present a 45 year old Phillipino female who presented with a large cervical polyp measuring 35x20x15mm which was excised by hysteroscopy.
Methods: Microscopically sections showed an ulcerated neoplasm with a leaf-like architecture lined by Mullerian-type epithelium composed of uniform ovoid to small spindle cells with subepithelial cellular condensation. Scattered mitoses are noted in the stroma. The epithelial element was cytologically bland. There was no necrosis. Immunohistochemistry showed diffuse and strong stromal staining for SMA, ER and PR. CD10 was positive in the subepithelial areas (cambium layer). On RNA-based Next Generation Sequencing (NGS) testing, an in-frame SRF::RELA fusion was detected.
Results: The lesion was initially thought to be a low grade adenosarcoma but was reviewed later as cellular myofibroma/myopericytoma with SRF::RELA fusion. This is an extremely rare entity which has been described only in three uterine tumours (age range 20-39 years), two intrauterine and one in intracervical canal. Follow up to 15 months was uneventful. Longer follow up is needed to confirm the true biological behaviour (PMID: 35852178). Similar gene fusions have been reported in perivascular myoid tumours. Other locations of these tumours are head and neck, including parotid gland, small bowel wall, extremities and trunk. SRF regulates the activity of immediate-early and muscle-specific genes and participates in cell cycle regulation, apoptosis, cell growth and cell differentiation, especially muscle differentiation.
Conclusion: We presented an extremely rare case of cervical cellular myofibroma/myopericytoma with SRF::RELA fusion in a middle-aged female initially diagnosed as a low grade adenosarcoma. It expresses characteristic histological features of a cellular spindle cell stroma with subepithelial condensation and follows a benign clinical course. It is

important in similar cases to request NGS testing as the diagnosis, based on immunohistochemical stains alone, may be mistaken for a more sinister adenosarcoma, which requires total hysterectomy and neo/adjuvant chemotherapy for treatment.

E-PS-11-027

Evaluation of clinical, pathological, and prognostic data in cervical adenocarcinomas: a retrospective study

B. Timur[1], Z. Bayramoglu[1], S. Kurt[2], H.T. Timur[2], B. Saatli[2]
[1]Dokuz Eylul University School of Medicine, Pathology, Izmir, Turkey, [2]Dokuz Eylul University School of Medicine, Obstetrics and Gynaecology, Izmir, Turkey

Background & Objectives: Cervical cancer is a significant cause of cancer-related mortality among women. The most common type is squamous cell carcinoma, followed by adenocarcinoma. In recent years, with the increased frequency of screening, the incidence of squamous cell carcinoma has decreased while the rate of adenocarcinoma has risen. The Silva invasion pattern is used in HPV-positive endocervical adenocarcinomas.
Methods: 18 patients diagnosed with cervical adenocarcinoma or adenocarcinoma in situ between 2014 and 2025 at Dokuz Eylül University Hospital were identified. The slides of these patients were retrieved from the archives and evaluated for prognostic parameters.
Results: The mean age was 48 years(range: 25-76).The average tumour size was 2.6 cm(range: 0.7-5.5 cm).Three patients were diagnosed with adenocarcinoma in situ. When classified according to the Silva invasion pattern, 7 cases showed Silva pattern A, 3 cases showed Silva pattern B and 2 cases showed Silva pattern C.Six cases could not be classified: 2 due to biopsy status, 3 due to the presence of only adenocarcinoma in situ, and 1 due to being HPV-negative. Lymphovascular invasion(LVI) was observed in 3 cases. Among patients with Silva pattern C, one had paraservical tissue invasion and LVI, and was alive 4 years post-diagnosis; the other had bladder and rectum serosal invasion and LVI and died within the same year. The last patient with LVI had bilateral pelvic lymph node metastasis and exhibited Silva pattern B. Additionally, 5 patients had HSIL, 4 had LSIL, and 1 had squamous cell carcinoma.
Conclusion: The incidence of cervical adenocarcinomas has increased over the years. Due to their association with HPV, accompanying lesions(such as HSIL) are frequently observed. Patients with Silva pattern B and C may experience variable survival and/or metastasis, with prognoses differing from other patients. Prognostic parameters such as the Silva pattern, presence of LVI, metastasis, and tumour size play critical roles in staging, survival, and disease management.

E-PS-11-029

The role of intraoperative consultation in lymph node dissection for endometrioid carcinoma: a four-year experience

G. Arslan[1], F.E. Gökalp Satici[1], M. Ay[1], E. Polat Yapici[1], M. Yaldiz[1]
[1]Mersin University, Pathology, Mersin, Turkey

Background & Objectives: Endometrioid carcinoma is the sixth most common cancer in women, with increasing incidence in some regions. Cases with low-grade histology, less than 50% myometrial invasion, no lymphovascular invasion, and no extrauterine spread typically have a favourable prognosis. Hysterectomy alone is usually sufficient, and frozen section during surgery helps guide decisions on lymph node dissection. This study reviews our institutional experience with intraoperative frozen section evaluation of endometrioid carcinoma cases.
Methods: We retrospectively reviewed 157 endometrioid carcinoma cases subjected to frozen section evaluation between 2019 and 2022. Data on histologic grade, myometrial invasion, cervical/adnexal involvement, tumour size, and lymph node dissection were compared between frozen section and final pathology reports. Statistical analyses were performed to assess correlations between frozen section findings and final diagnoses, particularly regarding lymph node dissection.
Results: The mean age of the cases was 60.8 years, and the mean tumour size was 3.61 cm. Lymph node dissection was performed in 67 cases (42.7%), while it was not performed in 90 cases (57.3%). When comparing the intraoperative consultation reports with the final reports in terms of concordance, the concordance rates were found to be 85.2%, 82.1%, and 92% for histological grade, myometrial invasion, and cervical invasion, respectively. Among the cases where discrepancies were detected, it was found that lymph node dissection was necessary according to the parameters reported in the final report in nine cases, but it could not be performed due to the parameters reported during intraoperative consultation. In two cases, unnecessary dissection was performed.
Conclusion: In endometrioid carcinomas, frozen section examination performed under appropriate conditions and in collaboration with clinical teams plays a crucial role in reducing morbidity and mortality. Evaluating the concordance between frozen section findings and final pathology reports is essential for identifying and addressing potential discrepancies in future cases.

E-PS-11-030

What is the importance of invasion in vulvar Paget's disease?

Z. Bayramoglu[1,2], B. Timur[1], Y. Cakır[1,2], S. Kurt[3], H.T. Timur[3], B. Saatli[3]
[1]Dokuz Eylul University Faculty of Medicine, Pathology, Izmir, Turkey, [2]The Instıtutte of Health Sciences, Department of Molecular Pathology, Izmir, Turkey, [3]Dokuz Eylul University Faculty of Medicine, Department of Gynaecological Oncology, Izmir, Turkey

Background & Objectives: Vulvar Paget's disease (VPD) is an extremely rare malignancy of the vulva with a high local recurrence rate and low mortality. Due to its non-specific symptoms and lack of clinical knowledge, VPD is often misdiagnosed with eczematous skin lesions and the definitive diagnosis is often delayed. Since there is currently no global consensus on the optimal management of VPD, we aimed to evaluate the clinico-pathological features and survival outcomes among intraepithelial VPD, microinvasive VPD and invasive VPD.
Methods: The cases of VPD operated in the Gynaecological Oncology Department of Dokuz Eylül University Faculty of Medicine Hospital and diagnosed in the Department of Pathology between 2000 and 2021 were retrospectively reviewed. Clinicopathological features of VPD cases were analysed.
Results: A total of 60 patients were identified. 44 patients were diagnosed with intraepithelial VPD, 12 with microinvasive (<=1 mm) VPD and 4 with invasive VPD. Most of the patients 48/60 (80%) were treated with surgery. Local recurrence was observed in 45/60 (75%) patients with no significant difference between the 3 groups ($p = 0.33$). At 120 months, cancer-specific survival was 100% for intraepithelial and microinvasive VPD and 31% for invasive VPD (log-rank $p = <0.0001$).
Conclusion: We found that microinvasive VPD and intraepithelial VPD have the same prognosis. We wanted to emphasise that the biggest risk for VPD patients is tumour invasion.

E-PS-11-031

Fibroblast Activation Protein (FAP) expression in Deep Endometriosis (DE): a feasibility study of using Ga68 Fibroblast Activation Protein Inhibitor (FAPI) PET imaging in DE

M. Shahi[1], A. Packard[2], W. VanBuren[2], T. Burnett[3], D. Bartlett[2], H. Takahashi[2]
[1]Mayo Clinic, Pathology and Laboratory Medicine, Rochester, USA, [2]Mayo Clinic, Radiology, Rochester, USA, [3]Mayo Clinic, Obstetric and Gynaecology, Rochester, USA

Background & Objectives: Endometriosis affects approximately 10% of reproductive-age women, with deep endometriosis (DE) accounting for up to 20% of cases. DE causes chronic pelvic pain, fibrosis, and adhesions, and increasing the risk of gynaecologic malignancies. Conventional imaging techniques such as ultrasound often fail to detect deep or extra-pelvic lesions. Fibroblast activation protein (FAP), a type II cell surface glycoprotein overexpressed in activated fibroblasts during tissue remodelling and fibrosis, represents a promising molecular imaging target. 68Ga-FAPI-46, a quinoline-based PET tracer that binds to FAP, enables non-invasive visualization of fibrotic activity. In this study, we assessed FAP expression in bowel-involved DE surgical specimens using immunohistochemistry (IHC) to evaluate the potential utility of 68Ga-FAPI PET imaging in this context.
Methods: We retrospectively assessed FAP expression via IHC in 13 rectosigmoid DE surgical specimens resected by segmentectomy or full thickness discoid resection. All lesions had muscularis propria involvement. Five rectosigmoid colorectal adenocarcinomas from male patients served as positive controls, and benign colonic mucosa served as negative controls. FAP expression was evaluated in three compartments: endometrial glands, endometrial-type stroma, and the altered stroma surrounding the lesions. Expression was scored based on extent (focal, patchy, diffuse: 1–3) and intensity (none to strong: 0–3), with H-scores calculated accordingly. H-scores were compared with using unpaired t-test. $P<0.05$ was considered statistically significant.
Results: Endometrial glands in DE showed no FAP expression (H-score = 0). In contrast, the endometrial-type stroma and altered surrounding stroma had mean H-scores of 5.0 (1-9) and 4.4 (2-7.5), respectively ($p < 0.001$ vs. glands). Stromal reaction in colorectal adenocarcinoma exhibited a mean H-score of 7.2 (range: 6-7.5; $p < 0.0001$ vs. endometriosis stroma). No expression was detected in colorectal glands or muscularis propria.
Conclusion: Our findings demonstrate significant FAP expression in the stromal components of DE, supporting the potential use of Ga68-FAPI PET imaging in patients with DE.

E-PS-11-032
A "typic" lesion of the uterine endometrium
B. Işik[1], F. Demir[1]
[1]Düzce University, Department of Pathology, Düzce, Turkey

Background & Objectives: Atypical polypoid adenomyoma (APA) is a rare benign uterine lesion composed of endometrial-type glands and a myomatous stroma. It primarily affects premenopausal women and is often associated with abnormal uterine bleeding. APA is commonly located in the lower uterine segment but can also be found in the fundus, corpus, or endocervix.
Methods: A 44-year-old woman presented with abnormal uterine bleeding for one month. An endometrial biopsy revealed endometrial hyperplasia with focal atypia. She underwent a hysterectomy with bilateral salpingo-oophorectomy.
Results: Macroscopic examination showed a $2.7 \times 1.7 \times 1.5$ cm polypoid lesion in the posterior uterine wall without myometrial invasion. Histologically, the lesion had focal complex endometrial glands with mild nuclear atypia and squamous morules within a myomatous stroma. Immunohistochemistry revealed CDX2 and CD10 positivity in squamous morules, while ER and p63 were negative. The myomatous stroma was positive for Desmin, and SATB2, confirming APA.
Conclusion: The differential diagnosis of APA includes several entities that share overlapping histological features. Endometrial carcinoma must be excluded, as it lacks myomatous stroma, exhibits higher nuclear atypia, and has a higher Ki-67 proliferation index. APA can also resemble adenosarcoma, but the latter is distinguished by periglandular stromal cuffs and a higher mitotic index. Malignant mixed Müllerian tumour (MMMT) is another important differential, characterized by highly malignant glandular and stromal components, unlike APA. Additionally, APA can be mistaken for an endometrial polyp, but polyps lack myomatous stroma and nuclear atypia. Given its potential for recurrence and its histological overlap with malignant lesions, APA should always be considered in the differential diagnosis of polypoid uterine lesions. Proper pathological evaluation and adequate sampling are essential to avoid misdiagnosis and unnecessary aggressive treatment.

E-PS-11-034
Mixed trophoblastic tumour of the uterus: a clinicopathological challenge in diagnosis
M. Karakuş[1], G. Turan[1], G.G. Gurel[1], B. Yaprak Bayrak[1]
[1]Kocaeli University School of Medicine, Department of Pathology, Kocaeli, Turkey

Background & Objectives: Gestational trophoblastic tumours are rare neoplasms derived from placental tissue. Among them, epithelioid trophoblastic tumour (ETT) and placental site trophoblastic tumour (PSTT) are even less common than choriocarcinoma. The coexistence of these three components in a single endometrial tumour is extremely rare. We present a challenging case of a mixed trophoblastic tumour involving ETT, PSTT, and choriocarcinoma in the uterus of a middle-aged woman.
Methods: A 47-year-old woman presented with heavy vaginal bleeding. Endometrial sampling revealed decidualized tissue with atypical trophoblastic differentiation. Total abdominal hysterectomy with bilateral salpingo-oophorectomy was performed. Macroscopic and microscopic evaluation, along with a comprehensive immunohistochemical panel, was applied.
Results: A 10 cm tumour was detected in the endometrium, infiltrating more than half of the myometrium. No tumour was observed in the ovaries, tubes, omentum, or sampled lymph nodes. Histopathological examination revealed three distinct trophoblastic components: ETT, PSTT, and choriocarcinoma. The tumour showed lymphovascular invasion and a mitotic count of 18 per 10 high-power fields. Immunohistochemically, tumour cells were diffusely positive for pancytokeratin and showed focal expression of β-HCG, inhibin, p63, p16, EMA, and GATA3. The Ki-67 proliferation index was approximately 50%.
Conclusion: Mixed trophoblastic tumours of the uterus with coexisting ETT, PSTT, and choriocarcinoma are extremely rare and can be diagnostically challenging, especially when presenting with subtle or overlapping histologic features. Accurate diagnosis requires careful morphological assessment supported by immunohistochemistry. Recognizing this entity is essential due to differences in prognosis and therapeutic approaches for each component. This case underscores the importance of considering mixed trophoblastic tumours in the differential diagnosis of endometrial masses, even when β-HCG levels are not markedly elevated.

E-PS-11-035
Molecular characteristics and survival in cervical adenocarcinomas: an in-silico analysis
Y. Cakir[1], Z. Bayramoglu[1]
[1]Dokuz Eylül University Medical School, Pathology, Izmir, Turkey

Background & Objectives: The objective of this study was to identify the molecular characteristics that influence survival outcomes in cases of cervical adenocarcinoma, utilising data from the TCGA (The Cancer Genome Atlas) database.
Methods: The 'TCGA Firehose Legacy' dataset was accessed through the Cbioportal website (www.cbioportal.org). Cases were divided into two groups according to overall survival status (living or deceased). Subsequent analysis involved the comparison of mutation presence, mRNA expression status, protein expression and DNA methylation data

between these two groups. A pathway analysis for significant genes was performed on the G:Profiler website (https://biit.cs.ut.ee/gprofiler/gost). P and q < 0.05 were considered statistically significant.
Results: The study identified 27 cases of endocervical adenocarcinoma. Of these, 22 (81.5%) were alive, while 5 (18.5%) were ex. A comparison of the two groups in terms of protein expression revealed that PREX1 expression was higher in the living cases (*q=8.700e-3*). While *WDR89* exhibited a higher methylation rate in living cases, *MCEMP1, RNNASE2, RINL, CCL17, THBD, SFXN5, PRR19* genes demonstrated higher methylation frequency in deceased cases (*p and q <0.05*). A subsequent pathway analysis of these genes revealed an association with KLF9, a transcription factor (*p=3.011x10-3*). However, no significant differences were observed in the presence of mutations, mRNA expression and copy number changes (p>0.05).
Conclusion: Cervical adenocarcinoma is a challenging diagnosis in routine practice due to its relatively rare occurrence. The identification of its diagnostic molecular features may facilitate more precise diagnosis and prognosis.

E-PS-11-036
MGMT and p16 immunohistochemistry evaluation in melanomas of the gynaecological system
D. Arik[1], O.F. Mülkem[1], E. Telli[2], T. Öge[2], Ö.T. Yalçin[2]
[1]Eskişehir Osmangazi University, Pathology, Eskişehir, Turkey, [2]Eskişehir Osmangazi University, Gynaecologic Oncology, Eskişehir, Turkey

Background & Objectives: Primary gynaecological melanomas are rare. Between 3-7% of melanomas in the whole body have been detected in the genital tract. O6-methylguanine-methyltransferase (MGMT), a DNA repair protein that removes methyl groups from the O6-position of guanine. P16 functions as a negative regulator of the pRb/E2F pathway, which is mainly involved in cell cycle control.
Methods: In this study, we re-evaluated a cohort of 13 patients diagnosed with melanoma in our centre between 2010 and 2024. EP337 clone of MGMT immunohistochemistry was applied. MGMT expression was assessed and scored in tumour cells using a 3-tier scale (complete loss=negative or <10% positive tumour staining, partial loss=10% to 50% staining, retained= >50% staining). p16 immunohistochemistry was assessed as lost or retained.
Results: The mean age of the patients was 76.9±10 years. Tumour localisations were recorded in vulva, vagina, cervix and uterine corpus. Diagnoses were usually made from biopsy specimens (n=9 69.2%). The most common tumour localisation was vagina and vulva equally (n=4 30.8%). All cases were positive for at least one melanocytic marker. Loss of p16 immunohistochemistry was present in 7 cases (53.8%). MGMT immunohistochemistry usually showed loss (n=7 53.8%) and these losses were usually accompanied by p16 loss (n=5 38.5%). Complete loss of MGMT was observed in all cases of melanoma of the cervix, whereas complete loss was observed in 25% of cases of melanoma of the vulva. In vulvar melanomas, MGMT was found to be retained in 2 cases (50%). The majority of patients died after a minimum of 3 maximum 69 months (n=11 84.6%).
Conclusion: Most gynaecological melanomas are mucosal melanomas, distant metastasis is common and overall survival is limited. We believe that MGMT and p16 immunohistochemistry together with demographic data in larger case series studies may provide insight in terms of prognosis and recurrence.

E-PS-11-037
Atypical Leiomyomas: the Importance of suspecting Fumarate Hydratase gene mutation
D. Baptista[1,2], H.C. Dias[3], A.R. Costa[3,4], R. Portugal[1,2]
[1]ULS São João, Pathology, Porto, Portugal, [2]Faculdade de Medicina da Universidade do Porto (FMUP), Pathology, Porto, Portugal, [3]ULS São João, Gynaecology, Porto, Portugal, [4]Faculdade de Medicina da Universidade do Porto (FMUP), Gynaecology, Porto, Portugal

Background & Objectives: The Fumarate Hydratase (FH) gene mutation is associated with Hereditary Leiomyomatosis and Renal Cell Carcinoma (HLRCC) syndrome, an autosomal dominant disorder. This syndrome presents with multiple and atypical uterine leiomyomas, cutaneous leiomyomas, and renal cell carcinoma (RCC). Early recognition enables targeted oncologic surveillance and genetic counselling.
Methods: We present three cases of FH mutation, focusing on the clinical and histological findings that supported the suspicion.
Results: Case 1: A 32-year-old with a family history of RCC, history of myomectomy, and a polymyomatous uterus with leiomyomas up to 150 mm. Histology showed smooth muscle tumours with eosinophilic inclusions, hemangiopericytoma-like vasculature, alveolar-pattern myxoid degeneration, haemorrhage, and ischemic-type necrosis. FH loss of expression was confirmed by immunochemistry.
Case 2: A 25-year-old with abnormal uterine bleeding and prior multiple myomectomies (52 leiomyomas removed) with rapid recurrence, requiring hysterectomy. Histology demonstrated spindle cells with nuclear atypia and expansive growth.
In the immunohistochemical study performed on the uterine wall neoplasm, the neoplastic cells show expression of actin, desmin, and progesterone-receptors (PR), with an absence of oestrogen-receptors (ER) expression. And "fumarate hydratase" serum demonstrates a loss of expression in the neoplastic cells.
Case 3: A 39-year-old with abnormal uterine bleeding and a 73 mm leiomyoma. Histology revealed spindle cell neoplasms with branched vessels, oedema, and eosinophilic inclusions. The neoplastic cells show expression of actin, desmin, PR, ER; with an absence of STAT-6 and CD10 expression. And "fumarate hydratase" serum demonstrates a loss of expression in the neoplastic cells.
Conclusion: In young women, the presence of rapidly-growing/extensive, or histologically atypical leiomyomas should raise suspicion for an FH mutation. Pathologists and gynecologists are essential in early identification, facilitating genetic referral and renal surveillance. Timely clinical suspicion can significantly impact both individual and familial prognosis by enabling early detection of renal carcinoma and providing guidance on Assisted Reproductive Technologies for preimplantation genetic testing.

E-PS-11-038
Search for morphological criteria of the early and late stages of scleroatrophic lichen of the vulva
A. Drobintseva[1], A. Agafonnikova[2], R. Nasyrov[2]
[1]Saint Petersburg State Paediatric Medical University, Histology and Embryology named after A.G. Knorre, Saint Petersburg, Russia, [2]Saint Petersburg State Paediatric Medical University, The Prof. D.D. Lohov Department of Pathological Anatomy with Course of Forensic Medicine, Saint Petersburg, Russia

Background & Objectives: Scleroatrophic lichen (LS) is a degenerative skin disease primarily affecting the anogenital region. Vulvar lesions of both benign and precancerous nature pose an interdisciplinary challenge for dermatovenerologists, gynecologists, and oncologists. The aim of the study was to compare early and late stages of LS using histology and immunohistochemistry to identify key disease changes.
Methods: Biopsy specimens from 20 women with LS were analysed. Two groups were defined: 1- patients with clinical manifestations lasting ≤1 year; 2- Patients with clinical manifestations lasting >1 year. Histological staining included haematoxylin-eosin and Van Gieson's picrofuchsin. IHC staining targeted CD31 (angiogenesis marker), CD95 (apoptosis marker), and VEGF (vascular endothelial growth factor).

Results: Histological observation revealed in group 1: parakeratosis in the epidermis, pronounced acanthosis, lymphocytic infiltration in the dermis, swelling of the endothelium in the capillaries. In group 2: atrophy foci in the epidermis, lymphocytic infiltration in the dermis, endotheliocyte apoptosis in the capillaries, thrombotic masses. VEGF expression showed an inverse correlation with disease duration (80% vs 15%). CD31 expression patterns shifted from focal strong to predominantly weak staining. CD95 expression intensity increased dramatically with disease progression (20% to 85%).
Conclusion: Key histological and IHC features diagnostic of early and late LS stages were identified. Microvascular wall damage, confirmed by IHC, suggests that LS-related skin changes result from impaired blood supply due to vascular dysfunction. These findings may inform the use of anti-apoptotic and angiogenic therapies in LS management.

E-PS-11-039
Malign Brenner Tumour with immunohistochemical positivity of MDM2: a case report and literature review
V. Elibol[1], P. Aşkin[1], D. Yavuzer[1], M. Aban[2]
[1]Sancaktepe Sehit Prof. Dr. Ilhan Varank Training and Research Hospital, Department of Pathology, Istanbul, Turkey, [2]Sancaktepe Sehit Prof. Dr. Ilhan Varank Training and Research Hospital, Department of Obstetrics and Gynaecology, Istanbul, Turkey

Background & Objectives: Malignant Brenner tumours (MBTs) are rare ovarian neoplasms, accounting for less than 5% of Brenner tumours. They are characterized by aggressive behaviour and poor prognosis. The molecular and immunohistochemical profiles of MBTs are not well understood, with limited data available in the literature. MDM2, an oncogene known for its role in tumour progression, has been identified in various malignancies but is rarely reported in MBTs. This case report aims to present a rare case of MBT with immunohistochemical positivity for MDM2 and review relevant literature to explore its potential diagnostic and prognostic significance.
Methods: A 52-year-old postmenopausal woman presented with abdominal distension and pelvic discomfort. Imaging studies revealed a cystic right ovarian mass with a fokal solid component and surgical intervention was performed. The histopathological evaluation confirmed the diagnosis of MBT, and immunohistochemical analysis included markers such as MDM2, p53, p63,CK7, WT1, and GATA3. A literature search was conducted using databases to review previously reported cases of MBT and their molecular profiles.
Results: Histological examination revealed cystic areas within the tumour lined by multilayered epithelium, which resembles urothelial epitel and malignant transitional-type epithelial cells with nuclear atypia, prominent nucleoli, and invasion areas in the densely fibromatous background. Immunohistochemistry showed diffuse positivity for GATA3 and CK7 while p53 is wild type and WT1,p63 is negative. Benign Brenner tumour nests support the diagnosis. Strong nuclear immunohistochemical expression of MDM2 is identified in the malignant component. A literature review identified a few cases of MBTs with molecular characterization, with one reporting of MDM2 amplification that evaluated by fluorescence in-situ hybridization (FISH) correlates with immunostaining of MDM2
Conclusion: This case highlights a rare MBT with MDM2 positivity, suggesting a potential role for MDM2 in the tumorigenesis of MBTs. Given its rarity, further studies are needed to establish the clinical and prognostic implications of MDM2 expression in MBTs.

E-PS-11-040
Comparative analysis of the role of endometrial and ovarian factors in the genesis of female reproductive dysfunction
V. Pechnikova[1], D. Masalimova[1], Z. Gioeva[1], R. Mitrelis[1], O. Parfyonova[1], S. Mikhalev[2], A. Ilyichev[1], L. Mikhaleva[1]
[1]Avtsyn Research Institute of Human Morphology of Federal State Budgetary Scientific Institution, Petrovsky National Research Centre of Surgery, Moscow, Russia, [2]Pirogov Russian National Research Medical University, Moscow, Russia

Background & Objectives: The issue of infertility remains relevant in modern medicine. Endometrial and ovarian factors play a key role in the genesis of reproductive dysfunction. A comparative analysis of the influence of these factors on the receptivity of the endometrium allows a deeper understanding of the mechanisms of infertility and the development of more effective methods of pregravid preparation of patients.
Methods: We have studied pipelle biopsy specimens of endometrium in the secretion phase from 135 patients: 50 patients with endometrial pathology (group 1), 50 with ovarian pathology (group 2), 35 patients - comparison group (healthy women before surrogacy). Chronic endometritis was diagnosed in 50% of group 1 patients, endometrial polyp in 10% of patients, and a combination of the two pathologies in 40% of patients. Group 2 consisted of patients with endometrial ovarian cysts. Sections were stained with haematoxylin and eosin, Mallory staining, IHC analysis was performed with monoclonal antibodies to oestrogen and progesterone receptors.
Results: The study revealed delayed secretory transformation of the endometrium in patients of both groups. Endometrial stromal fibrosis was noted in 45 patients (90%) of group 1 and in 19 (38%) patients of group 2, which was combined with chronic endometrial inflammation. Both groups showed delayed maturation of pinopodes, reduced 2.5 times in group 1, 1.6 times in group 2 in contrast to the comparison group. Disruption of receptivity to oestrogen and progesterone receptors was noted both in the glandular and stromal compartments of the endometrium in patients of group 1, in the glandular compartment - in group 2, in relation to the comparison group ($p<0.05$).
Conclusion: The study demonstrated more significant morphofunctional changes in the endometrium (chronic endometritis, fibrosis of endometrial stroma, delayed maturation of pinopodes, impaired secretory transformation of the endometrium and a more significant decrease in receptivity to hormones) in study group 1 with endometrial pathology.

E-PS-11-041
Primary malignant melanoma of the uterine cervix
K. Cruz[1], J.D. Serrano Arias[1], B. Wills Sanin[2], J. Castro Gonzalez[3], D.E. Sanabria Serrano[4], A. Rueda Herrera[1]
[1]Fundación Santa Fé de Bogotá, Pathology, Bogotá, Colombia, [2]Fundación Santa Fé de Bogotá, Oncology, Bogotá, Colombia, [3]Fundación Santa Fé de Bogotá, Internal Medicine, Bogotá, Colombia, [4]Fundación Santa Fé de Bogotá, Gynaecology, Bogotá, Colombia

Background & Objectives: Primary malignant melanoma of the cervix (PMMC) is an exceptionally rare and aggressive malignancy, accounting for less than 1% of cervical cancers. Its diagnosis relies on histopathological and immunohistochemical evaluation due to its rarity and similarity to other cervical malignancies. PMMC has a poor prognosis, with no standardized treatment protocol. Management typically follows regimens used for cutaneous melanoma, including radical surgery and emerging immunotherapies. The objective is to describe a case of a women with a primary malignant melanoma of the uterine cervix.
Methods: Clinical data from a patients with primary malignant melanoma of the cervix.
Results: A 60-year-old female, presented with foul vaginal odor and intermittent pelvic pain. Gynaecological examination revealed hyperpigmented macules on the ectocervix. Histopathological analysis confirmed invasive melanoma of the cervix. Histopathological findings included a Breslow thickness of 22 mm, ulceration present, and a mitotic rate of 1/mm². Tumour-infiltrating lymphocytes were present

but not prominent, while lymphovascular invasion, neurotropism, and tumoral regression were not identified. Additionally, with immunohistochemical positivity for SOX10, Melan A, and HMB-45. PET-CT revealed mild hypermetabolism localized to the cervix without evidence of metastasis. The patient remains under surveillance with ongoing molecular analysis and imaging follow-ups.
Conclusion: PMMC remains a diagnostic and therapeutic challenge due to its rarity, nonspecific clinical presentation, and aggressive behaviour. Early detection through biopsy and immunohistochemistry is crucial. Surgical intervention is the mainstay of treatment, with adjuvant radiotherapy and emerging immunotherapies playing an increasing role in management. Further research into targeted therapies and immunomodulatory approaches may improve outcomes for this rare malignancy.

E-PS-11-042
De novo myeloid sarcoma in the uterine cervix: a literature review of its rare topographical manifestation as a myeloid neoplasm
T. Guchashvili[1], N. Chelidze[1], T. Dzindzibadze[2], M. Sarishvili[1]
[1]MEGALAB, Pathology, Tbilisi, Georgia, [2]Tbilisi State Medical University, Pathology, Tbilisi, Georgia

Background & Objectives: Primarily diagnosed myeloid sarcoma within the gynaecological system is a rare entity. A literature review spanning the past five decades identified 54 reported cases, with the majority 30 (55.6%) localized to the uterine cervix.
Methods: We present the clinical case of a 46-year-old woman who underwent curettage of a hyperplastic endometrial layer and conization of ectocervical tissue, following a clinical and radiological diagnosis of endometrial hyperplasia and cervical squamous carcinoma in situ. Macroscopical examination of the specimen revealed a $4.5 \times 2 \times 0.5$ cm grayish lesion with firm consistency on the cutting surface of the cervix. To determine tumour's nature and origin, beside thorough gross and histological assessment a broad panel of antibodies was analysed using immunohistochemical diagnostic methods.
Results: Macroscopically described tumorous lesion histologically was composed of a diffuse, unconfined proliferation of epithelioid and spindle-shaped atypical cells, with nuclear hypochromasia and multiple mitotic figures. The diffuse positivity of CD45 and CD43 confirmed the hematolymphoid origin of the lesion. Further studies showed extensive expression of CD33, Muramidase, MPO, and scattered positivity of CD68 and CD163, indicating the presence of a dominant myeloid population in the tumour. The immature profile of the tumour was excluded by the negativity of CD34 and CD117.Involvement of cervical tissue by circulating immature myeloid cells in the case of coexisting systemic myeloid leukaemia was ruled out through clinical correlation and the absence of any morphological and phenotypical signs of bone marrow and peripheral blood damage. Based on aforementioned diagnostic procedure and the exclusion of other possible entities, a final diagnosis of myeloid (granulocytic) sarcoma was established.
Conclusion: The rarity of tumour locations, particularly in the absence of preexisting acute or chronic myeloid disorders, can contribute to diagnostic challenges and subsequent delays in initiating appropriate therapy.

E-PS-11-043
Changing glycodelin A level in serum patients with ovarian neoplasms
A. Mglinets[1], N. Gabitova[1], A. Kedrova[1], E. Goufman[2], T. Belousova[3], N. Sovaev[4], M. Ermoshchenkova[5], M. Mglinets[6], I. Stepanova[2], N. Nizyaeva[2]
[1]Academy of Postgraduate Education of The FSCC FMBA of Russia, Department of Obstetrics and Gynaecology, Moscow, Russia, [2]Avtsyn Research Institute of Human Morphology of FSBSI "Petrovsky National Research Centre of Surgery", Moscow, Russia, Laboratory of the Reproduction Pathology, Moscow, Russia, [3]Vidnovskiy Perinatal Centre, Director, Vidnoe, Russia, [4]Vidnovskiy Perinatal Centre, Head of the Gynaecology Department, Vidnoe, Russia, [5]The fist Oncology Hospital named after S. Yudin, Head of the Oncology Department, Moscow, Russia, [6]I.M. Sechenov First Moscow State Medical University, Resident, Moscow, Russia

Background & Objectives: Ovary cancer is the one of the most common gynaecological neoplasms, which annually takes away more than lives. Mortality from ovarian cancer reaches 152 000 lives per year. Therefore, the search for new markers of early diagnosis of ovarian cancer is relevant. Glycodelin A is a glycoprotein associated with progesterone production, secreted by endometrial glands. According to literature data, the possibility of using the marker in the diagnosis of oncological diseases is being discussed.
The aim was detect the level of Glycodelin A in the serum of women with ovarian tumours.
Methods: We analysed the concentration of Glycodelin A in serum 100 patients 18–78 years old with ovarian neoplasms. The level of Glycodelin A of serum was determined by ELISA. The differences in criteria were considered statistically significant at $p<0.05$.
Results: Benign ovary formations detected in 21 (21%) patients, border tumours in 10 (10%), malignant formations 69 (69%). There were histologically distributed as follows: serous adenocarcinoma amounted to 68% (n=47), mucinous was 11% (n=8), endometrioid was 18.8% (n=13). The level of serum Glycodelin A is associated with the histological type of ovary neoplasms: benign was 2.9 ng/mL (1.95-6.05). In cases of serous adenocarcinoma were in 24.5 ng/ml (7.95-66.90), mucinous was 9.15 ng/ml (3.38-13.53), endometrioid adenocarcinoma was 9.60 ng/ml (5,40-19.10). The level of Glycodelin A correlates with the size of the tumour If the tumour size is more than 5 cm, its average level was 4.10 ng/ml (3.10-6.60); >10 cm (38 patients (55%) were 13.10 ng/ml (5.43-43.48). Depending on the stage Glycodelin A level was increased. Glycodelin A concentration were the highest at III stage in the group with ovarian neoplasms. The average level of Glycodelin A was 22.70 ng/ml(9.50-63.80) which shows its prognostic adverse significance.
Conclusion: Determining the level of Glycodelin A in patients with ovarian neoplasms may be predictive value.

Funding: 123030700104-3

E-PS-11-044
Intravascular endometrial glands and stroma in a patient without endometriosis
S. Bagbudar[1], A.C. Güner[1], A. Bayram[1], C. Yasa[2], S. Onder[1]
[1]Istanbul Faculty of Medicine, Istanbul University, Department of Pathology, Istanbul, Turkey, [2]Istanbul Faculty of Medicine, Istanbul University, Department of Gynaecology and Obstetrics, Istanbul, Turkey

Background & Objectives: Endometrial gland and stroma in the myometrium vessels were initially described as an uncommon finding related to the menstrual period, but later it was reported that it could be related to adenomyosis, not to menstruation. We reported a case of IEM in a hysterectomy and bilateral salpengectomy specimen removed from a 47-year-old premenopausal patient with myoma uteri.
Methods: A 47-year-old female patient with a history of breast carcinoma in her mother and father, and negative for *BRCA1* and *BRCA2* mutations, underwent hysterectomy and bilateral salpingectomy due to myoma uteri.
Results: In the hysterectomy specimen, a total of nine myomas, the largest of which was 7 cm. Strikingly there were endometrial glands and stromal structures in the intravascular spaces of the

myometrium. Endometriosis was not observed in the myometrium or myomas in any of the numerous samples taken. Immunohistochemical stains were performed to identify the intravascular endometrial glands and stroma. Vascular structures were evaluated with CD31, CD34, D2-40, and CD61. Glandular structures in the intravascular space were visualized with Estrogen receptor, and stromal structures with CD10.
Conclusion: Although the identification of this entity is facilitated in the presence of adenomyosis, mimicking vascular invasion poses a diagnostic challenge, particularly in the absence of adenomyosis and even in the presence of malignancy. Therefore, we presented this case to emphasize the importance of awareness of this rare entity.

E-PS-11-045
High–grade endometrial stromal sarcoma with *BCOR-MAML3* fusion presenting as polypoid cervical mass: a case report
N. Ibisevic[1], S. Murtezic[2], N. Bilalovic[1], S. Vranic[3]
[1]Clinical Centre University of Sarajevo, Pathology Department, Sarajevo, Bosnia and Herzegovina, [2]Clinical Centre University of Sarajevo, Gynaecology Department, Sarajevo, Bosnia and Herzegovina, [3]College of Medicine, QU Health, Qatar University, Pathology Department, Doha, Qatar

Background & Objectives: High-grade endometrial stromal sarcoma (HGESS) is a rare and aggressive uterine neoplasm originating from the endometrial stroma. Several different molecular alterations have been identified in HGESS, such as *YWHAE: NUTM2A/B* fusions, *BCOR* fusions, and *BCOR* internal tandem duplication (ITD).
Methods: Given the limited number of reported cases, we present a case of a *BCOR-MAML3* fused HGESS, with clinical, pathologic, immunohistochemical, and molecular correlations.
Results: A 40-year-old woman presented with irregular vaginal bleeding for several months. Clinical examination revealed a 45x40 mm, polypoid mass, protruding from the cervical canal. The tumour was surgically removed. Microscopic examination showed a malignant neoplasm with fibromyxoid stroma having spindle and round cells with scant to moderate eosinophilic cytoplasm, with mild to moderate nuclear atypia with mitotic activity of 7-10/10 HPF. Necrosis and lymphovascular invasion were not seen. Immunohistochemically, the tumour cells were positive for CD10, pan-TRK, and cyclin D1, whereas other biomarkers were negative (ER, SMA, desmin, h-caldesmon, CD34, CD117). p53 showed a wild-type expression pattern. Subsequent molecular analysis revealed a *BCOR-MAML3* fusion. *NTRK1-3* fusions were not detected. Consequently, the patient underwent a total hysterectomy with bilateral salpingo-oophorectomy, with no residual disease.
Conclusion: We confirm that HGESS with a *BCOR-MAML3* fusion often shows diffuse immunohistochemical positivity for pan-TRK, not associated with the presence of *NTRK1-3* fusions. Our case study also highlights the importance of molecular profiling in the proper classification of soft tissue neoplasms, such as HGESS.

E-PS-11-046
Serum markers of pathological placental attachment in pregnant women
A. Mglinets[1], N. Niziaeva[2], K. Artemyeva[2], I. Kulikov[3], I. Stepanova[2], N. Tikhonova[4]
[1]Academy of Postgraduate Education of The FSCC FMBA of Russia, Moscow, Russia, [2]Avtsyn Research Institute of Human Morphology of FSBSI "Petrovsky National Research Centre of Surgery", Moscow, Russia, Laboratory of the Reproduction Pathology, Moscow, Russia, [3]Vidnovskiy Perinatal Centre, Vidnoe, Russia, [4]Avtsyn Research Institute of Human Morphology of FSBSI "Petrovsky National Research Centre of Surgery", Moscow, Russia, Moscow, Russia

Background & Objectives: Currently, there is no clinically reliable biomarker of placenta accreta PAS. Objective: to evaluate changes in serum concentrations of glycodelin A (GdA), placental alpha-microglobulin-1 (PAMG-1) and adiponectin in pregnant women and to determine the possibility of their use in predicting PAS.
Methods: In pregnant women with PAS (n=18) and uncomplicated pregnancy (n=20) at 30-35 weeks of pregnancy, the levels of GdA, PAMG-1, adiponectin in the serum were determined by ELISA and assessed in points: GdA (ng/ml): 0-40 - 3 points, 41-80 - 2 points, 81-130 - 1 point; PAMG (ng/ml): 1-30 - 3 points, 31-60 - 2 points, 61-120 - 1 point; adiponectin (μg/ml): 0-5 - 3 points, 5.1-8 - 2 points, 8.1 to 20 - 1 point; N - the number of caesarean sections in the anamnesis in whole numbers as points, then the points and the "N" are summed up.
Results: Women with PAS had significantly lower serum levels of all studied proteins relative to the comparison group. GdA level was 32.3 (14.1;71.6) vs 65.05 ng/ml (45.95;74.4), PAMG 19.6 (12.1;29.2) vs 33.45 (25.75;58.2) ng/ml, adiponectin 3.96 (3.49;4.69) vs 10.39 (6.52;16.21) μg/ml. The number of CS in the anamnesis was 2 (1;2) vs 0 (0;1). The risk of PAS in points was 10 (8;10) versus 5.5 (5;8). With a total score of 8 or more, PAS is predicted in a given pregnancy with 100% sensitivity and 90% specificity.
Conclusion: A formula for predicting PAS has been established that, with high sensitivity and specificity, a patient's score of 8 or more points indicates the presence of PAS.

Invasive stratified mucin-producing carcinoma of uterine cervix: clinicopathological features of 5 cases
A. Oruç[1], A.E. Akın[1], D. Ateş[1], A. Usubütün[1]
[1]Hacettepe University, Pathology, Ankara, Turkey

Background & Objectives: Invasive stratified mucin-producing carcinoma (ISMC), defined as a subtype of HPV-associated endocervical adenocarcinoma, is a rare neoplasm characterized by morphologic variability and an aggressive clinical course. We aimed to provide more data on the clinicopathologic features of ISMC.
Methods: Hysterectomy specimens from five patients were analysed. Four cases were consecutively diagnosed as ISMC, while one was identified retrospectively during reclassification of 48 adenosquamous carcinomas. Initial biopsy specimens were obtained at an outside centre after evaluation of the patients' symptoms. Clinicopathologic data and initial diagnoses were reviewed.
Results: The median age at diagnosis was 42.2 (22-50) years. Initial diagnoses included adenosquamous carcinoma (2 cases), squamous cell carcinoma (1 case), poorly differentiated endometrioid adenocarcinoma (1 case), and adenocarcinoma, NOS (1 case). Microscopic examination revealed solid nests of stratified cells resembling squamous cell carcinoma but morphologically similar to adenocarcinoma. Tumour cells showed variable intracellular mucin production as confirmed by mucin staining. Immunohistochemistry showed diffuse block positivity for p16 and peripheral staining for p63. Deep stromal involvement was observed in four cases, with extensive lymphovascular invasion (LVSI) in three cases and focal LVSI in one case. Paraaortic lymph node metastases were found in three cases. According to FIGO staging, two patients were in stage 1 and three in stage 3. The mean postoperative follow-up was 8.4 (3-14) months. Two patients died of the disease in the 3rd and 9th months of follow-up, while three patients are alive.
Conclusion: This study presents five cases of ISMC, highlighting the rarity and aggressiveness of the tumour. ISMC may be misdiagnosed

as adenosquamous carcinoma, conventional squamous cell carcinoma, or cervical involvement of poorly differentiated endometrial adenocarcinoma. Due to its biologically aggressive nature, careful differential diagnosis is essential.

E-PS-11-048

Mesonephric-like carcinosarcoma of the uterus with a BRAF p.G466V mutation: a case report and review of diagnostic and molecular features

M.C. Rovira Aguilo[1], A.M. Quintero Duarte[1], A.T. Flores[1], D. Laguna Macarrilla[1], D.S. Romano[1], I. Sureda Albertí[1], E. Prados Pérez[1], G. Matheu Capó[1]
[1]Hospital Universitari Son Espases, Anatomical Pathology, Palma, Spain

Background & Objectives: Mesonephric-like carcinosarcoma (MLCS) of the uterus is an extremely rare and aggressive neoplasm characterized by the coexistence of a mesonephric-like adenocarcinoma (MLA) and a sarcomatous component. While the mesonephric-like adenocarcinoma component has been increasingly recognized, the biphasic carcinosarcomatous variant remains poorly understood. Molecular alterations involving the MAPK/ERK pathway, mainly KRAS mutations, have been proposed in its pathogenesis. We present a new case harbouring an uncommon BRAF mutation, contributing to the expanding knowledge of this entity.
Methods: A 62-year-old woman presented with postmenopausal bleeding. A diagnostic endometrial biopsy was performed, followed by total hysterectomy with bilateral salpingo-oophorectomy. The surgical specimen was thoroughly examined, including macroscopic assessment, histopathological evaluation, immunohistochemical (IHC) profiling, and targeted next-generation sequencing (NGS) for molecular characterization.
Results: Grossly, a 5.5 cm endometrial mass was identified, infiltrating more than 50% of the myometrial thickness. Microscopically, the tumour showed a biphasic morphology, composed of a predominant epithelial component (70%) with tubular, papillary, and retiform architectural patterns, and a sarcomatous component (30%) of undifferentiated spindle cells, mainly located in the luminal area. The epithelial component expressed PAX8 and GATA3, and was negative for oestrogen and progesterone receptors, with wild-type p53 expression. The sarcomatous component showed positivity for vimentin, caldesmon, and focal CD10 expression, without evidence of aberrant p53 staining. NGS revealed no gene fusions or TP53 mutations but identified a rare BRAF p.G466V mutation, suggesting MAPK/ERK pathway activation. The final diagnosis was mesonephric-like carcinosarcoma, FIGO stage IB.
Conclusion: This case contributes to the limited series of uterine MLCS, underlining the importance of its recognition. The identification of a rare BRAF mutation supports the role of the MAPK/ERK pathway in its pathogenesis and may provide relevant insights for future targeted therapies.

E-PS-11-049

Prevalence of microsatellite instability in cervical adenocarcinoma

E. Porubayeva[1], A. Zakharkina[1], S. Kovalenko[2], D. Berdyugina[2], N. Danilova[1]
[1]Lomonosov Moscow State University, Moscow, Russia, [2]LLC "Biolink", Novosibirsk, Russia

Background & Objectives: Despite widespread use of cytologic screening, the incidence of cervical adenocarcinoma has been increasing in recent years. This histologic subtype is characterized by a poor prognosis and immunotherapy is the promising therapeutic strategy. Microsatellite instability (MSI) is one of the key biomarkers to predict response to immune checkpoint inhibitors, but some data have been accumulated on the frequency of MSI among cervical adenocarcinomas. The aim of this work is to investigate the incidence of MSI in cervical adenocarcinoma as it may reveal new therapeutic strategies to improve patient prognosis.
Methods: Surgical specimens were collected from 38 patients with cervical adenocarcinoma. Immunohistochemistry for MSH2 (FE-11), MSH6 (EP-49), PMS2 (EP-51) and MLH1(ES05) (Dako, Agilent Technologies, USA) was performed on 3-mm thick sections of a representative formalin-fixed, paraffin-embedded (FFPE) tumour tissue using PrimeVision detection system (PrimeBioMed LLC, Russia) in Autostainer 480S immunostainer (ThermoFisherScientific, USA). DNA was isolated from FFPE tumour tissue by phenol-chloroform extraction using a DNA extraction kit (BioLink LLC, Russia). PCR followed by fragment analysis of PCR products by capillary electrophoresis was used as a reference method with application of the reagent kit "COrDIS MSI" (BioLink LLC, Russia) according to the manufacturer's instructions. PCR was performed on the amplifier "BIS" M111-02-96 (NovosibBioPribor LLC, Russia). Fragment analysis was performed according to the GeneMapper manual for Applied Biosystems 3500 genetic analyser (ThermoFisherScientific, USA).
Results: The incidence of MSI in cervical adenocarcinoma was 10,5% (4/38) when analysed by immunohistochemistry and 13,1% (5/38) when analysed by molecular technique (the concordance of the two methods was 98,2%).
Conclusion: MSI in cervical adenocarcinoma is not a common event. The introduction of MSI assay into clinical practice may help to identify a limited group of patients who will benefit from immunotherapy. Both immunohistochemical and molecular technique may be considered depending on the capabilities of the particular laboratory.

E-PS-11-050

Frequency of KRAS gene mutations and their association with histologic variants in cervical adenocarcinoma

E. Porubayeva[1], A. Zakharkina[1], S. Kovalenko[2], D. Berdyugina[2], N. Danilova[1]
[1]Lomonosov Moscow State University, Moscow, Russia, [2]LLC "Biolink", Novosibirsk, Russia

Background & Objectives: Adenocarcinomas account for at least 20% of all cervical cancers. This histological subtype represents a heterogeneous group of tumours that differ in the profile of molecular abnormalities and response to treatment. The targeted drug has been approved in a number of cancers as it has been shown to improve outcomes in patients with activating somatic mutations of KRAS gene. The aim of the present work is to investigate the frequency of these mutations among different histological variants of cervical adenocarcinoma, which may help in the search for personalized treatment strategies.
Methods: Surgical specimens were collected from 24 patients with cervical adenocarcinoma. Distribution by histologic types was as follows: usual 50% (12/24), endometrioid 25% (6/24), mucinous, intestinal subtype 4,1% (1/24), mesonephral 8,3% (2/24), villoglandular 4,1% (1/24), serous-like 8,3% (2/24). DNA was isolated from a representative formalin-fixed, paraffin-embedded (FFPE) tumour tissue block by phenol-chloroform extraction using a DNA isolation kit (BioLink LLC, Russia). DNA samples were tested for mutations in codons G12X, G13X, Q61X and A146X of KRAS gene by real-time PCR using Real-time-PCR-KRAS-4R kit (BioLink LLC, Russia) according to the manufacturer's instructions. Reactions were performed on the CFX96 amplifier (Bio-Rad Laboratories, USA) according to the following protocol: 1 cycle - 95°C 3 min; 48 cycles - 95°C 15 sec, 55°C 40 sec. PCR products of KRAS gene with mutations were detected in 5'-exonuclease reaction using TaqMan probe labeled with fluorophore.
Results: The frequency of KRAS gene mutations in cervical adenocarcinoma was 16,67% (4/24). All specimens with the identified mutation had endometrioid histologic variant and no mutations were found

among other histologic variants. According to the results, KRAS gene mutations were more frequent in endometrioid histologic variant of cervical adenocarcinoma (p=0,0004).
Conclusion: KRAS gene mutation may be considered as a potential therapeutic target in the endometrioid histologic variant of cervical adenocarcinoma.

E-PS-11-051
Keratinising HPV-negative squamous cell carcinoma of the uterine cervix in uterine prolapse
A.K. Höhn[1], B. Aktas[2], A. Dannenmann[3], J. Einenkel[3], M. Höckel[2], I. Krücken[4], M. Stiller[4], U. Obeck[4], L.-C. Horn[1]
[1]Institute of Pathology, Division of Breast Gynaecologic & Perinatal Pathology, Leipzig, Germany, [2]Department of Obstetrics & Gynaecology, University Hospital of Leipzig, Leipzig, Germany, [3]Department of Obstetrics & Gynaecology, Sana Country Hospital, Borna, Germany, [4]Institute of Pathology, Leipzig, Germany

Background & Objectives: In contrast to the relatively high frequency of uterine prolapse, the coexistence with cervical carcinoma is extremely rare, and the knowledge about its morphologic and molecular characteristics is very scarce. Furthermore, morphologic features of HPV-independent squamous precursor lesions are very limited.
Methods: Detailed histopathological and immunohistochemical analyses of p16, p53 and CK 17 were performed, as was a molecular evaluation for HPV-DNA and p53-mutation of four consecutive cervical squamous cell carcinomas associated with uterine prolapse with the definition of a hitherto not well-described precursor lesion and molecular tumorigenetic pathway.
Results: The cases were diagnosed during a period of seven years with a mean age of 75 (range 69-83) years and a mean tumour size of 7.3 cm (range 5.2-9.4cm). All patients presented with locally advanced disease, and one woman died within four, another within 14 months of follow-up. Histopathologically, all keratinizing squamous cell carcinomas (SCC) with infiltrative growth and were negative for p16, showed an aberrant p53-expression and diffuse and strong staining for CK 17 on immunohistochemistry. On the molecular level, the SCCs were negative for HPV-DNA but harboured a TP53-mutation. An HPV-independent pathogenetic pathway with a p53-alteration was identified for these cases.
Conclusion: The coexistence of cervical SCC with uterine prolapse is extremely rare. These specific SCCs represent highly keratinized, HPV-independent tumours harbouring a TP53-mutation.

E-PS-11-052
***POLE/POLD1* mutations in uterus endometrial carcinoma: study of trends in morphologic / molecular classification and lymphovascular progress of oncogynecologic disease**
M. Masevičienė[1,2], U. Košelienė[2], M. Kuprytė[1], A. Čižauskas[1], N. Valtienė[1], L. Poškienė[1,2]
[1]Hospital of Lithuanian University of Health Sciences Kauno Klinikos, Pathological Anatomy Department, Kaunas, Lithuania, [2]Lithuanian University of Health Sciences, Kaunas, Lithuania

Background & Objectives: Genomic classification of uterus endometrial carcinoma (*POLE/POLD1, TP53* mutations, and microsatellite instability (MSI) markers) was integrated into clinical pathology practice in last decade, carrying a more significant prognostic effect for the progress of this disease. Objective is to detect specific morphologic / molecular features of progressing endometrial carcinoma tested for *POLE/POLD1* mutations.
Methods: 45 cases of endometrial carcinoma verified by morphology analysis of surgical material and tested for *POLE/POLD1* mutations in local clinical pathology laboratory were selected. Morphologic parameters (histologic type, pT, pN stages, differentiation grade (G), lymphovascular invasion (LVI)) were analysed and molecular profile (presence of *POLE/POLD1* mutations, *MSI*, p53, receptors of oestrogens and progesteron (ER, PR)) was determined by immunohistochemic and rtPCR methods. Statistical analysis was performed ($p<0.05$).
Results: Median age of patients was 61 and mostly (n=24, 53.3%) in age group >60 years. Majority of carcinomas were endometrioid type (n=39, 86.7%), pT1b (n=19, 42.2%), pN0 (n=26, 57.8%) and G1-2 (n=34, 75.6%). Lymphovascular invasion (LVI1) was detected in 35.6% (n=16) cases. A small group of carcinomas was *POLE/POLD1*-mutated (n=4, 8.9%). Majority of cases were MSS (n=18, 78.3%), and *TP53* mutations were absent in 71.4% (n=25) cases. Expression of ER and PR was positive in 57.8% (n=26) and 53.3% (n=18) cases, correspondingly. *POLE/POLD1*-mutated cases were more likely to be diagnosed for 40-49 years old patients (p=0.003). LVI1 status was less likely to manifest in endometrioid carcinoma (p=0.01), pT1a / pT1b ($p<0.001$), G1-2 (p=0.003), ER-positive (p=0.037), and non-heterogenic p53 expression (p=0.05) cases. No significant trends were detected between LVI and *POLE/POLD* mutations, *MSI*, and PR expression status ($p>0.05$).
Conclusion: *POLE/POLD1* mutations were more likely to manifest for 40-49 years old patients, and LV progression of uterus endometrial carcinoma was more likely to be detected in ER-negative and heterogenic p53 expression cases, without any significant associations to *POLE/POLD1* mutations, *MSI*, and PR expression status.

E-PS-11-053
A rare clinical presentation – somatically-derived Yolk Sac Tumour of the ovary with chondrosarcomatous differentiation
C. Stacey[1], M. Nur[1]
[1]University Hospital Waterford, Department of Histopathology, Waterford, Ireland

Background & Objectives: Yolk sac tumours (YSTs) are malignant tumours derived from germ cells that morphologically mimics the foetal yolk sac.[1] YSTs usually present in children and younger women, they are rare over age 40.[2] Somatically-derived YSTs were first described in 1987, and described as a YST deriving from an epithelial neoplasm through a process of neometaplasia or retrodifferentiation.[3]
Methods: Here, we describe a case of a somatically derived YST with chrondrosarcomatoid differentiation. We present the case of a 59-year-old woman who presented with abdominal pain and nausea in April 2022
Results: A CT scan showed a 15.5cm left ovarian mass as well as extensive metastatic disease involving peritoneal deposits, encasing the bowel. The patient underwent a hysterectomy, bilateral salpingo-oophorectomy and resection of bladder peritoneum. Tumour was present in the left ovary and within the bladder peritoneum, FIGO Stage 3C. Histologically, a tumour with a distinct biphasic appearance was seen. This component was positive with villin, CDX2, Glypican 3, SALL4 & AFP and represented a yolk sac tumour. The second malignant component comprised of solid diffuse arrangements of epithelioid cells, some with rhabdoid morphology within a chondromyxoid stroma. A wide range of immunohistochemistry was performed on this element with no definitive answer, and expert consultation was sought. The final diagnosis was given as a somatically derived sarcomatoid yolk sac tumour with a chondrosarcomatous component.
Conclusion: The patient had a good treatment response to chemotherapy, both 1st and 2nd line, however unfortunately, in September 2024, a large RIF metastatic deposit causing a bowel obstruction was surgically removed. Histologically, this showed a recurrence of the chondrosarcomatous component of the YST. This case is a rare presentation of a somatically derived YST. Less than 50 cases of somatically derived YSTs have been described in the literature and none with a sarcomatoid component.

E-PS-11-054

Advancements in cervical cancer screening in the bulgarian population: improving HPV testing and triage strategies

M. Koleva[1], A. Mollova-Kysebekirova[1], Y. Merdzhanova-Gargova[2], A. Mihaylova[3], N. Parahuleva-Rogacheva[2], E. Uchikova[2]
[1]Medical University, Department of General and Clinical Pathology, Faculty of Medicine, Plovdiv, Bulgaria, [2]Medical University, Department of Obstetrics and Gynaecology, Faculty of Medicine, Plovdiv, Bulgaria, [3]Medical University, Department of Healthcare Management, Faculty of Public Health, Plovdiv, Bulgaria

Background & Objectives: Cervical cancer is a common gynaecological malignancy, with screening mainly based on Pap smears. Since persistent HPV infection is a key factor, HPV genotyping is considered for primary screening but has low specificity in young women due to transient infections. Patients with low-grade squamous intraepithelial lesion (L-SIL) or atypical squamous cells of undetermined significance (ASC-US) undergo further tests like colposcopy and biopsy to rule out high-grade H-SIL, though 70–90% of L-SIL cases, especially in women under 30, regress spontaneously, leading to unnecessary procedures. To improve risk assessment, immunohistochemical markers like p16/Ki-67 offer reliable alternative, aiding early oncogenesis detection in liquid based cytology (LBC), HPV genotyping, and biopsies.
Methods: Fifty women under 30 undergoing routine screening were enrolled, with liquid-based cytology and HPV testing performed. Based on risk levels, groups were formed, and p16/Ki-67 dual staining was applied to high-risk cases. Results were analysed, identifying high-risk patients needing biopsy in the Bulgarian population.
Results: It was established that LBC is generally preferred due to better sample quality, higher sensitivity, and the ability to perform additional test such as HPV genotyping and dual-stain p16/ki-67. From the investigated cases 12 (24%) were ASC-US, 7 (58%) of them HPV positive and 3 (6%) cases with L-SIL, 2 (67%) of them HPV positive. Dual-stain were performed on 9 cases.

Conclusion: Our study is the first attempt in comparing conventional versus liquid based cytology smears and assess the accuracy of dual-staining p16/Ki-67 combined with HPV genotyping and colposcopy on Bulgarian population. Our results show thatthe p16/Ki-67 test could be useful in the triage of young patients with ASC-US or L-SIL and should be taken into consideration for the diagnostic algorithm and obtain a new management protocol for patients under the age of 30 years positive for HPV and with cytological abnormalities on the LBC.

E-PS-11-055

Solitary pulmonary nodule: an unexpected diagnosis

E. Mateo Álvarez[1], Y. Rey Fanjul[1], J.A. Costas Fernandez[1], G. Mejide Santos[1], D. Rodriguez Villar[1], M. Poch Arenas[1], H.E. Torres Rivas[2], R. Rodriguez Aguilar[1]
[1]Hospital Universitario de Cabueñes, Servicio de Anatomía Patológica, Gijón, Spain, [2]Hospital Universitario Central de Asturias, Servicio de Anatomía Patológica, Oviedo, Spain

Background & Objectives: Low-grade endometrial stromal sarcoma is a malignant stromal tumour composed of cells resembling the endometrial stroma in the proliferative phase and showing infiltrative growth with or without lymphovascular invasion. Patients present with abnormal uterine bleeding, pelvic pain, uterine mass, and / or pulmonary, adnexal or lymph node metastases.
Methods: A 52 year old woman with persistent cough underwent a scanner, which identified a 2 cm solitary pulmonary nodule in the left upper lobe, without others visible lesions. A biopsy of the nodule was perfomed.
Results: The histopathological examination of the pulmonary biopsy showed the presence of small, uniform cells with scant cytoplasm and an oval nucleus, with a delicate arteriolar network surrounding these cells. With the initial suspected diagnosis of lymphoproliferative pulmonary lesion, a complete immunohistochemistry study was performed, which showed negativity for CD45, CD20, CD79a, CD3, CD43, CD23, Cyclin D1, and CD56. The immunohistochemistry study was extended to include oestrogen receptors, progesterone receptors, and CD10, all of which were positive. The patient was evaluated by a multidisciplinary team that decided to perform a lobectomy. A specimen measuring 21 x 10 cm was received, in which a well-defined, reddish lesion of 2.3 cm in size was observed. Microscopic examination confirmed the result of the pulmonary biopsy, reporting it as a metastasis of endometrial stromal sarcoma. A hysterectomy with bilateral salpingo-oophorectomy was performed, the macroscopic appearance showed no abnormalities. However, microscopic examination revealed a focus of low-grade endometrial stromal sarcoma measuring 9 x 13 mm with three lymphovascular invasions.
Conclusion: Pulmonary metastasis from low-grade endometrial stromal sarcoma can be its first clinical manifestation, highlighting the importance of considering this entity in female patients. This case underscores the significance of correlating the clinical context, histopathology and immunohistochemical studies in reaching an unusual diagnosis.

E-PS-11-056

Prognostic significance of Wnt5A expression in cervical carcinoma

R. Gajanin[1], V. Gajanin[2], T. Gajanin[3], Ž. Gajanin[4]
[1]University of Banja Luka, Faculty of Medicine, University Clinical Centre Republic of Srpska, Republic of Srpska, Banja Luka, Bosnia and Herzegovina, [2]University of Banja Luka, Faculty of Medicine, Republic of Srpska, Banja Luka, Bosnia and Herzegovina, [3]University of Vienna, Bachelor Student in Field of Molecular Biology, Vienna, Austria, [4]General Hospital, Kotor Varos, Republic of Srpska, Bosnia and Herzegovina, Republic of Srpska, Kotor Varos, Bosnia and Herzegovina

Background & Objectives: Cervical cancer (CC) is the second most common cancer of the female reproductive organs and the fourth leading cause of cancer-related death in women. The Wnt signalling pathway involves numerous proteins essential for initiating cell proliferation and differentiation processes in various organs. There is evidence that the Wnt signalling pathway plays a crucial role in carcinogenesis and tumour progression. Our study aims to determine the expression of the Wnt5A protein in samples of invasive cervical cancer and its impact on survival.
Methods: In the study, a total of 98 patients with cervical cancer were included. Patients were selected randomly, regardless of age and histological tumour type. Patient follow-up: The course and outcome of treatment, survival duration, and cause of death were determined based on medical documentation and data obtained through interviews with the patient or her family. Immunohistochemical detection of antigens was performed using the peroxidase reaction, applying commercial antibodies in appropriate dilutions. Survival probability and the impact of Wnt5A expression on patient survival were calculated using the Kaplan-Meier algorithm. Fisher's exact test and the Log-Rank test were used to determine statistical significance.
Results: Ekspresija Wnt5A (umjerena i visoka) u tumorskim ćelijama CC bila prisutna u 72,4% slučajeva. Ekspresija Wnt5A je odsutna kod 27,6% slučajeva. Utvrđeno je da je procentualno veće preživljavanje pacijentica čiji tumori su bili negativni na Wnt5A (81%), u odnosu na pacijentice čiji su tumori pokazivali ekspresiju Wnt5A (69,2%). Primjenom Fisher-ovog testa nije dobijena statistički značajna razlika ($p = 0.405$) s obzirom na prisustvo i stepen ekspresije Wnt5A u tumorskim ćelijama i preživljavanja.
Conclusion: Wnt5A expression was identified in 72.4% of invasive cervical cancer cases in our study. No statistically significant difference in

survival was confirmed among patients with cervical cancer concerning the presence and degree of Wnt5A expression.

E-PS-11-057

Expression patterns of molecular chaperones Hsp27 and Hsp90 in serous ovarian cancer

S. Vtorushin[1,2], E. Kaigorodova[1,3], O. Kovalev[2]
[1]Cancer Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Department of General and Molecular Pathology, Tomsk, Russia, [2]Siberian State Medical University of the Ministry of Health of Russia, Pathology Department, Tomsk, Russia, [3]Siberian State Medical University of the Ministry of Health of Russia, Department of Biochemistry and Molecular Biology with the Course of Clinical Laboratory Diagnostic, Tomsk, Russia

Background & Objectives: Serous ovarian cancer (SOC) is the most aggressive histological subtype of ovarian tumours and a major cause of gynaecological cancer mortality. Heat shock proteins (Hsp27 and Hsp90) are molecular chaperones involved in protein folding, cell survival, and resistance to therapy. This study aimed to evaluate the expression and intracellular localization of Hsp27 and Hsp90 in SOC compared to borderline ovarian tumours (BOT), to assess their potential diagnostic and prognostic significance.
Methods: Tissue samples from 23 patients with newly diagnosed SOC and 6 patients with BOT were analysed using immunohistochemistry (IHC). Paraffin-embedded tumour blocks obtained during diagnostic laparoscopy were stained with antibodies against Hsp27 and Hsp90. The percentage of positive tumour and stromal cells was assessed using optical microscopy and QuPath 0.5.0 software. Statistical analysis was performed using non-parametric tests (Mann–Whitney, Wilcoxon) with significance set at $p<0.05$.
Results: he proportion of Hsp27-positive tumour cells significantly exceeded that of Hsp90 ($p=0.0006$), and both markers showed significantly higher expression in tumour cells than in the stroma. Hsp27 expression in SOC exceeded that in the stroma by 10.8 times (cytoplasmic) and 7.41 times (nuclear); Hsp90 exceeded stromal levels by 40.4 and 86.7 times, respectively. Compared to BOTs, SOC tissues showed a 7.1-fold increase in Hsp27 and a 4.3-fold increase in Hsp90 expression ($p<0.005$). Hsp27 expression was consistently higher than Hsp90 in all intracellular compartments.
Conclusion: Hsp27 and Hsp90 are overexpressed in serous ovarian cancer compared to borderline tumours and stromal tissue, suggesting their potential as differential diagnostic and prognostic IHC markers. Hsp27, due to its ATP-independent function, may serve as a more reliable biomarker and therapeutic target in the hypoxic and metabolically stressed tumour microenvironment of ovarian cancer. Their differential expression patterns also highlight the role of stress-induced chaperone networks in tumour progression, chemoresistance, and metastatic potential, warranting further investigation.

E-PS-11-058

Sclerosing Stromal Tumour. A report of three cases presenting as huge pelvic masses

K. Adoke[1], U. Mohammed[2], S. Mohammad Haruna[2], A. Adamu[3], U. Ibrahim Augie[3], U. Muktar[4]
[1]Federal Teaching Hospital, Pathology, Birnin Kebbi, Nigeria, [2]Usmanu Danfodio University Teaching Hospital, Morbid and Forensic Pathology, Sokoto, Nigeria, [3]Federal Teaching Hospital, Obstetrics and Gynaecology, Birnin Kebbi, Nigeria, [4]Usmanu Danfodio University Teaching Hospital, Surgery, Sokoto, Nigeria

Background & Objectives: Sclerosing stromal tumour (SST) is a rare benign ovarian neoplasm classified under sex cord-stromal tumours. It account for 2-6% of ovarian tumours with patients presenting in the second and third decades of life. Patients usually presents with pelvic pain, irregular menses and abdominal mass. We report three cases presenting as huge pelvic masses.
Methods: This is a retrospective study of all cases diagnosed as SST over a ten year period. Electronic records of patients diagnosed as SST was retrieved and data was extracted.
Five immunohistochemical markers were used in this study (vimentin, smooth muscle actin, S-100, cytokeratin and ER).
Results: Three cases were seen during the study period. Their ages are 45, 43, 42 respectively with a mean age of 43.3. All three cases presented with huge pelvic mass measuring up to 60cm, 48cm and 40 cm respectively. Histopathological examination shows spindle areas with pseudo-lobular formation, collagen deposition and cystic changes. Immunohistochemistry shows vimentin, smooth muscle actin and ER positive staining. The rest showed negative staining.
Conclusion: Sclerosing stromal tumour in our setting presents in the fourth and Fifth decade as huge pelvic masses.

E-PS-11-060

A 74-year-old patient with endometrial carcinoma: a case report of a VUS-POLE-mutation with poor prognosis

M.I. Aysul[1], G. Kir[1]
[1]Istanbul Medeniyet University, Pathology, Istanbul, Turkey

Background & Objectives: Recent studies on endometrial carcinoma (EC) emphasize patient survival and prognosis, as mortality rates have increased by 1.5% annually from 2013 to 2022. A diagnostic algorithm based on The Cancer Genome Atlas (TCGA) highlights four prognostic subgroups, with patients exhibiting POLE mutations typically demonstrating more favourable outcomes. However, we present a case of a 74-year-old woman diagnosed with advanced stage EC and demonstrated VUS-POLE mutation for EC, who died 4 months after her diagnosis.
Methods: We searched for the specific POLE mutation in the complete TCGA (Genome Data Commons) catalogs and COSMIC (https://cancer.sanger.ac.uk/cosmic, accessed 16 March 2025).
Results: A 74-year-old woman presented to our clinic with a history of vaginal bleeding lasting one week. Curettage specimen revealed high-grade endometrial carcinoma (MMR intact, p53 wild-type), prompting POLE mutation testing. She underwent debulking surgery and was classified as FIGO Grade IIC, with noted cervical stromal invasion. After three weeks, a lesion at distal vagina was observed and biopsied, revealing infiltration by undifferentiated carcinoma. CT scan indicated multiple lung lesions suspected to be metastatic. The patient passed away after a month of hospitalization, before the genetic analysis was completed, which identified VUS-POLE EDM variant (c.1264C>T p.H422Y, rs745356467) for endometrial carcinoma.
Conclusion: Research in the TCGA and COSMIC databases revealed only three cases of this POLE variant (c.1264C>T p.H422Y, rs745356467), all linked to colorectal cancer, highlighting its rarity in endometrial carcinoma.

E-PS-11-061

Wolffian tumour of the broad ligament: a rare case with diagnostic challenges

I. Teixeira[1], J. Pardal[1], M. Teixeira[1]
[1]Unidade Local de Saúde de Braga, Pathology, Braga, Portugal

Background & Objectives: Female adnexal tumours of probable Wolffian origin (FATWO) rank among the rarest gynaecologic neoplasms, with fewer than 200 cases documented worldwide. This underrecognized entity frequently mimics malignant adnexal tumours, risking overtreatment. We present an unusual case that presents diagnostic challenges.

Methods: A 57-year-old postmenopausal woman presented with an incidental left adnexal mass. Left salpingectomy and excision of the left broad ligament, along with complete removal of the mass, revealed a well-demarcated nodular lesion measuring 5 cm in diameter adjacent to the fallopian tube.
Results: Histologically, the tumour demonstrated striking morphologic diversity: dominant tubular architecture with focal solid/retiform patterns, moderate cytologic atypia in a sclerohyaline stroma with frequent calcifications.
The mitotic index was 2 mitoses/10 HPF.
The immunohistochemical study revealed diffuse positivity for cytokeratins AE1/AE3, calretinin and WT1, focal expression of alpha-inhibin and CD-10 and negativity for EMA, CK7, CD99, Chromogranine, Synaptophysin, GATA3 and PAX8.
Postoperative surveillance showed no residual disease after total hysterectomy, right salpingectomy and bilateral oophorectomy, confirming the tumour's origin as primary to the broad ligament.
Conclusion: This case provides important insights into the broad ligament as a primary site for Wolffian tumours, a diagnosis that can be challenging in frozen section. It highlights the importance of precise clinical correlation to exclude involvement from an ovarian tumour.

E-PS-11-062
Gynaecologic PEComas: predominantly malignant case series with pathologic and clinical findings
A. Mladenovic[1], A.M. Cheriyan[1], B.B. Griffin[1], K. Hanley[1], M. Dibbern[1]
[1]Emory University, Pathology and Laboratory Medicine, Atlanta, USA

Background & Objectives: Gynaecologic perivascular epithelioid cell tumours (PEComas) are rare mesenchymal neoplasms with both melanocytic and smooth muscle differentiation. Correct diagnosis is challenging due to morphological and immunohistochemical overlap with more common smooth muscle tumours.
Methods: Institutional archive search identified 13 gynaecologic PEComa cases (2015-2025). Clinical-pathologic data were reviewed.
Results: Patient age ranged 35-83 years (median 50). Specimens included 9 hysterectomies, 3 endometrial curettage and/or myomectomy, and 1 salpingo-oophorectomy. The most common clinical presentation was abdominal pain (5/11;38.5%), followed by postmenopausal/abnormal uterine bleeding (4/11;30.8%). Tumour locations were most frequently uterine (10/13;76.9%), and otherwise 1 case each cervical, ovarian, and pelvic wall (3/13;23.1%). Tumour size ranged 2.3-27.1 cm (median 17.6). Nine tumours (69.2%) were classified as malignant and 4 (30.8%) as uncertain malignant potential by 2020 WHO gynaecologic criteria. Necrosis and lymphovascular space invasion were each present in 4 malignant cases (30.7%). Mitotic count ranged 1-36 per 10 high-power fields (median 15.5). Immunohistochemistry performed on all cases showed widely variable expression of both smooth muscle (SMA, desmin, and/or caldesmon) and melanocytic markers (Melan A, HMB45, and/or MITF). Most tumours showed expression of cathepsin K (10/12;83.3%) and ER (6/7;85.7%). Cases showed variable expression of CD10 (3/6;50%), and none showed expression of SOX10 or S100. All tested cases showed retained fumarate hydratase expression (3/3;100%). Amongst malignant cases, over half demonstrated aberrant p53 expression (4/7;57.1%). Of 10 cases with clinical follow-up, 7 (70%) showed no evidence of disease, 1 (10%) was alive with disease, and 2 (20%) died of disease; all patients with disease on follow-up were originally diagnosed with malignant PEComa.
Conclusion: Pathologic awareness of morphologic features, immunoprofile, and malignancy criteria in gynaecologic PEComas is essential for accurate diagnosis, clinical prognostication, and patient management.

E-PS-11-063
HPV E6/E7 oncogene expression determination in the detection of squamous intraepithelial lesions in women with atypical squamous cell cytology
I. Benedetti[1], A. Diaz[2], G. Di Filippo[2]
[1]University of Cartagena, Histopathology Research Group, School of Medicine, Cartagena, Colombia, [2]University of San Buenaventura, Microbiology, Cartagena, Colombia

Background & Objectives: The overexpression of human papillomavirus (HPV) oncogenes E6/E7 is an indicator of viral integration. Determination of these markers may be important in the diagnosis and clinical monitoring of patients with cervical intraepithelial neoplasia. This study evaluated the determination of E6/E7-mRNA in the detection of cervical intraepithelial neoplasia, in women with abnormal atypical squamous cell (ASC) cytology.
Methods: One hundred twenty-one patients between 18 and 82 years of age with ASC cytology results were included. A cervical swab was taken and embedded in nucleic acid preservation medium, the samples were subjected to RNA extraction. Ninety-eight samples underwent PCR amplification to determine E6/E7-mRNA of HPV 16, 18, and 31. The results of HPV E6/E7-mRNA in the cervical swab samples were compared with the results of the histopathological study as gold standard.
Results: Were positive for E6/E7-mRNA 14.3% (14/98) of the samples. Of these, 71.4% (10/14) were positive for HPV-16 E6/E7, 21.4% (3/14) for HPV-31 E6/E7, and 7.14% (1/14) for HPV-18 E6/E7. The estimated percentages of agreement between these results and colposcopy findings or histopathology ranged from 27.5% to 84.7%. When comparing molecular detection of viral mRNA with the detection of high- and low-grade squamous intraepithelial lesions (HSIL and LSIL), by colposcopy, the following were found: sensitivity of 11.1% (6/54; 95% CI, 5.2% to 22.2%), specificity of 81.8% (36/44; 95% CI, 68.0% to 90.5%), positive predictive value of 42.9% (6/14; 95% CI, 21.4% to 67.4%), and negative predictive value of 42.9% (36/84; 95% CI, 32.8% to 53.5%).
Conclusion: The determination of mRNA of the E6/E7 oncogenes of genotypes 16, 18 and 31 of the human papillomavirus, proved to be a moderately useful test to confirm the presence of HPV E6/E7 mRNA in low and high grade squamous intraepithelial lesions of the cervix, which are the target of early detection programs for cervical cancer.

E-PS-11-064
Endometrial polyps in breast cancer patients: a comparative analysis from King Hussein cancer centre
M. Al-Hussaini[1], H. Sultan[2], S. Al Sharie[2]
[1]King Hussein Cancer Centre, Department of Cell Therapy and Applied Genomics, Amman, Jordan, [2]King Hussein Cancer Centre, Office of Scientific Affairs and Research, Amman, Jordan

Background & Objectives: Endometrial polyps (EPs) are common findings in women, but their association with breast cancer, particularly with hyperplasia or malignancy, remains under-researched in certain regions. This study aims to compare the clinical and pathological features of endometrial polyps in breast cancer patients, managed at King Hussein Cancer Centre, focusing on those with and without hyperplasia or malignancy.
Methods: A total of 196 breast cancer patients were included in the study over 10 years (2014-2023). They were divided into two groups: Group 1 (n=173, 88.3%) consisting of patients with polyps without hyperplasia or malignancy, and Group 2 (n=23, 11.7%) consisting of patients with polyps with hyperplasia or malignancy.
Results: The median age at diagnosis for all patients was 50 years, with no significant difference between the two groups ($p = 0.7479$). The majority had invasive breast cancer (92.3%). Hormonal

treatment, particularly tamoxifen, was administered in 98.8% of the cases, with no significant difference between both groups (p = 1.000).
In Group 1, functional polyps predominates (92.5%), whereas Group 2 shows polyps with hyperplasia 16 (69.6%), and carcinoma (n=7, 30.4%) including serous carcinoma (n=4, 17.4%), endometrioid carcinoma (n=1, 4.3%) and metastatic breast carcinoma (n=2, 8.7%). The overall incidence of malignant changes in endometrial polyps from the overall cohort was 3.6%.
Conclusion: Endometrial polyps in breast cancer patients treated with tamoxifen should be removed and examined to rule out malignancy. The incidence of malignancy in this cohort is 3.6%, which is similar to international figures.

E-PS-11-065
Tumour immune microenvironment of tubo-ovarian high-grade serous carcinoma: unveiling the role of HLA Class I and II
R. Ciudino[1,2], A. De Leo[3,4,5], M. Grillini[6], C. Ravaioli[3,4], T. Maloberti[4], A. De Gaetano[4], D. de Biase[4,7], G. Tallini[4,5]
[1]University of Bologna, Department of Biomedical and Neuromotor Sciences, Bologna, Italy, [2]Santa Maria delle Croci Hospital, Pathology Unit, Ravenna, Italy, [3]University of Bologna, Anatomic Pathology - Department of Medical and Surgical Sciences (DIMEC), Bologna, Italy, [4]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Solid Tumour Molecular Pathology Laboratory, Bologna, Italy, [5]University of Bologna, Anatomic Pathology - Department of Experimental, Diagnostic and Specialty Medicine, Bologna, Italy, [6]IRCCS Azienda Ospedaliero-Universitaria Di Bologna, Pathology Unit, Bologna, Italy, [7]University of Bologna, Department of Pharmacy and Biotechnology, Bologna, Italy

Background & Objectives: High-grade serous carcinoma (HGSC) is an aggressive ovarian malignancy, responsible for most ovarian cancer-related deaths. Despite advances in surgery and chemotherapy and the introduction of PARP inhibitors (PARPi), long-term outcomes remain poor, with most patients experiencing recurrence after an initial response. Immune evasion, particularly through downregulation of human leukocyte antigen (HLA), limits tumour immunogenicity contributing to treatment resistance.
This study evaluates the expression of Human Leukocyte Antigen (HLA) Class I, HLA Class II, and β2-microglobulin (β2M) in HGSC and their correlation with Homologous Recombination Deficiency (HRD) status, clinico-pathological features and patient outcomes.
Methods: A total of 132 formalin-fixed, paraffin-embedded (FFPE) samples from 66 HGSC patients (FIGO stage II-IV) were analysed. Samples were collected from primary adnexal lesions and metastatic sites. IHC staining assessed HLA I, HLA II, and β2M expression. HRD status was determined by Next-generation sequencing (NGS). Clinico-pathological features, including tumour morphology (SET vs classic), pattern of invasion, mitotic rate, extensive tumour necrosis, tumour-infiltrating lymphocytes (TILs), CA125 levels, and residual tumour, were correlated with HLA-I, HLA-II and β2M expression.
Results: Molecular profiling showed HRD status in 43.9% of cases and *BRCA* mutations in 32.3%. HRD-positive and *BRCA*-mutated tumours correlated with improved DFS (p<0.001). HLA I loss was associated with higher residual disease, baseline CA125 levels, extensive tumour necrosis and reduced CD8+ T-cell infiltration. HLA II and β2M expression showed similar patterns. Spatial Cancer-Immune Phenotype (SCI) compartmentation identified three immune infiltration patterns: desert, excluded, and inflamed. SCIs correlated with higher residual disease, CA125 levels, desmoplastic stroma and SET growth pattern and they were consistent across primary and metastatic sites.
Conclusion: These findings confirm that HLA downregulation plays a pivotal role in HGSC progression. Improving patient stratification through molecular and immune profiling can refine prognostic assessments and guide personalized therapeutic strategies targeting both tumour vulnerabilities and immunity.

E-PS-11-066
Bilateral vulval lactational adenomas, a very rare case report and review of literature
A. Qasim[1], F. Kubba[1], S. Fernandez[1], L. Kahn[2], R. Lyons[2]
[1]Ealing Hospital, London North West University Healthcare NHS Trust, Histopathology, London, United Kingdom, [2]Ealing Hospital, London North West University Healthcare NHS Trust, Obstetrics and Gynaecology, London, United Kingdom

Background & Objectives: The anogenital mammary-like glands (AGMLG) are sites of origin of vulval mammary-like lesions. We present a very rare case of bilateral vulval lumps (VL) in a lactating female showing histologic lactational breast tissue-like changes in the AGMLG.
Methods: A 34-year-old Asian woman presented complaining of bilateral VL associated with some creamy discharge. She first noticed them six days after her caesarean delivery. She was breast feeding on presentation. She had two previous pregnancies with no such complaint. Both VL were excised.
Results: Macroscopically the VL measured 15X12X11 mm and 15x6x6 mm. They had circumscribed homogeneous soft creamy white cut surface . Microscopically, the left VL showed a well-demarcated area of glandular lobules with back to back acini and central double-lined ducts. The acini showed increased amount of eosinophilic and clear cytoplasm, round nuclei and inconspicuous nucleoli. On the right side, there were more cystically-dilated ducts with eosinophilic secretions. These changes were similar to those seen in lactational mammary tissue. Immunohistochemistry showed GATA 3, ER and PR expression in the acini, while PAX 8 was negative. P63 and CK5/6 stained surrounding myoepithelial cells.
Native AGMLG were first described by Kazakov and colleagues in 2011. Previously, these were considered as ectopic breast tissue representing the caudal remnants of the milk ridges. AGMLG can show mammary-like lactational changes, lactational adenoma, fibrocystic changes, intraductal papilloma, pseudo-angiomatous stromal hyperplasia, fibroadenoma, phyllodes tumour and adenocarcinoma of mammary type.
Conclusion: We have presented a very rare case of bilateral vulval lactational adenomas arising from AGMLG in a young postpartum female. Although a few unilateral cases were reported, bilateral lesions have not been documented. It is imperative for the pathologists to be aware of the presence of native AGMLG. These lesions are no more considered ectopic to this site. Treatment is by surgical excision as these lesions may cause local discomfort.

E-PS-11-067
Clinicopathologic profiling of ovarian clear cell carcinoma: insights from a tertiary cancer centre of North India
Z. Chowdhury[1], S. Narain[1], R. Jethani[2], V. Anu[2], I. Dhal[1], S. Patne[1], P. Paul[1], S. Haiyat[1], B. Sansar[3]
[1]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Oncopathology, Varanasi, India, [2]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Gynec-Oncology, Varanasi, India, [3]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Medical Oncology, Varanasi, India

Background & Objectives: Ovarian clear cell carcinoma (OCCC) is a rare epithelial ovarian cancer with overlapping histopathological characteristics with other ovarian tumours. Unfortunately, there seems to be a paucity of clinicopathological data pertaining to OCCC from the Indian subcontinent.
Objective: To comprehensively evaluate the entire spectrum of the clinical, histopathological, immunohistochemical, and survival characteristics of OCCC treated at our centre.
Methods: A retrospective analysis of OCCCs diagnosed over a period of 6 years was conducted.
Results: Median age of the 39 identified patients of OCCC was 50.8 years (range 31-74 years), presenting with chief complaints of abdominal mass and pain. The mean baseline serum CA-125 level was 508.5 U/ml (range 5.9-3907.6 U/ml). Histomorphology revealed papillary, tubulocystic, and solid patterns with variable number of clear cells. NapsinA reactivity on immunohistochemistry was evinced in 91.4%, HNF1β in 100%, and mutant type p53 in 27.3% cases. Majority of the patients presented in FIGO Stage III (43.6%), followed by stage I (35.9%), IV (15.4%), and II (5.1%). 74.4% patients underwent surgical resection, chemotherapy was administered in 84.6% patients while radiation therapy was mandated in a single patient. On a median follow-up of 26 months (range 6–63 months), the mean overall survival time was estimated at 49 months (95% CI: 41.2-57.0 months) and the 3-year overall survival rate 62.8±11.2%. The median progression-free survival (PFS) for stages I & II patients was at 33 months (95% CI: 11.8 to 54.2 months), followed by stages III & IV patients at 20 months (95% CI: 5.7 to 34.3 months).
Conclusion: Majority of the patients presented at a late stage, and the mean serum CA-125 level was higher compared to Western literature. Early-stage patients demonstrated a better PFS than late-stage ones. Such findings highlight the aggressive behaviour of this rare condition, underscoring the vital need for accurate histopathological diagnosis and effective therapeutic management.

E-PS-11-068
Detection of microplastics in human placental tissue using nile red staining and fluorescence microscopy
M. Bollová[1], P. Janega[1], M. Vrždiak[1]
[1]Institute of Pathological Anatomy, Faculty of Medicine, Comenius University in Bratislava and University Hospital Bratislava, Bratislava, Slovakia

Background & Objectives: The presence of microplastics in human tissues has raised concerns regarding their potential health effects. Previous studies have primarily focused on microplastic identification using Raman microscopy, flow cytometry, or homogenized tissue samples, often relying on animal models. However, these approaches do not allow precise histological localization of microplastics within tissue structures. This study aimed to detect microplastics in placental tissue using a fluorescence-based method that preserves tissue architecture.
Methods: Formalin-fixed, paraffin-embedded placental tissue samples were deparaffinized and stained directly on slides. Nile Red staining solution was prepared by dissolving the dye in dimethyl sulfoxide (DMSO), which was diluted with denatured ethanol to achieve an optimal concentration for microplastic labelling. The samples were incubated at 50–60°C to enhance staining efficiency and fluorescence signal. All procedures were conducted under controlled conditions to minimize external plastic contamination. Fluorescence microscopy was used to analyse the stained sections and identify microplastic particles based on their characteristic fluorescence.
Results: Fluorescence microscopy revealed an increased signal corresponding to microplastics in various placental structures. Microplastics were observed in the intervillous space, villous and extravillous trophoblast, and decidua. In the villi, microplastics were frequently associated with vascular walls. The particles were well-defined and ranged in size from 5 to 15 µm.
Conclusion: The identification of microplastics in placental structures highlights the need for further investigation into their potential impact on pregnancy. While this study does not establish a direct link between microplastic presence and placental pathology, future research should explore potential correlations and underlying mechanisms.

Funding: VEGA 1/0646/25 "Alterations in the placental tissue glycocode related to maternal glucose metabolism affecting the course of pregnancy"

E-PS-11-070
Isolated Langerhans cell histiocytosis of the vulva: case report
E. Hijazi[1], M. Al-Hussaini[2]
[1]Islamic Hospital, Pathology Department, Amman, Jordan, [2]Khcc, Amman, Jordan

Background & Objectives: Langerhans Cell Histiocytosis (LCH) is a rare disorder characterized by the proliferation of Langerhans cells, most commonly affecting the skin, bones, and lymph nodes. Isolated vulvar involvement is extremely rare and often mimics chronic inflammatory or neoplastic conditions, leading to diagnostic challenges.
Methods: We report the case of a 55-year-old female who presented with chronic vulvar ulcerations and pruritus, unresponsive to standard treatments. Clinical examination revealed erythematous, ulcerated plaque on the vulva.
Results: Histopathological examination showed an infiltrate of histiocytes with characteristic nuclear grooves, accompanied by numerous eosinophils. Immunohistochemical staining confirmed the diagnosis of LCH, with positive expression of CD1a, S100, and Langerin. A systemic workup excluded multisystem involvement.
Vulvar LCH is an uncommon presentation that requires a high index of suspicion. The presence of abundant eosinophils is a hallmark histopathologic feature that aids in differentiation from other conditions, such as squamous cell carcinoma, lichen sclerosus, and chronic infectious diseases. Immunohistochemistry plays a crucial role in confirming the diagnosis. Treatment strategies depend on disease extent, with options including local corticosteroids, surgical excision, or systemic therapy in disseminated cases.

Conclusion: This case highlights the importance of considering LCH in the differential diagnosis of chronic vulvar lesions. Early recognition, supported by histopathology and immunohistochemistry, is essential for accurate diagnosis and optimal patient management.
E-PS-11-071
STIC, high-grade serous, and neuroendocrine carcinomas: evidence of a unified pathogenetic origin
C.M. Alfonso Rosa[1], J. Machuca Aguado[1], A. Alvarez Muñoz[1], E. Rodriguez Zarco[1], T. Cano Barbadillo[1], A. Garcia Escudero[1]
[1]Hospital Universitario Virgen Macarena, Pathology, Seville, Spain

Background & Objectives: High-grade neuroendocrine carcinoma of the uterine tube is a rare neoplasm, with limited cases documented in literature. We present a case of a 77-year-old woman diagnosed with this carcinoma, alongside high-grade serous carcinoma and a precursor lesion of the STIC type, supporting a shared origin.
Methods: The patient underwent excisional biopsy after identifying a hypermetabolic lesion. Histopathological examination revealed a high-grade neuroendocrine carcinoma, with immunohistochemistry showing neuroendocrine markers. Complete tissue embedding confirmed multifocal secondary high-grade serous carcinoma, with a concurrent STIC precursor lesion.

Results: Histology revealed a high-grade small-cell neuroendocrine carcinoma involving the fallopian tube. The tumour exhibited hyperchromatic nuclei, mitotic activity, and lymphovascular invasion. Immunohistochemistry demonstrated positivity for neuroendocrine markers (INSM-1, synaptophysin, chromogranin) and mutations in p53. The fallopian tube also showed multifocal high-grade serous carcinoma, with areas of STIC precursor lesions. The two carcinoma types were adjacent, suggesting a potential biological link. Detailed histopathology indicated a transition zone between neuroendocrine and serous carcinoma components, sharing immunohistochemical characteristics, including mutated p53 and block positivity for p16.
Conclusion: This case highlights the rarity of high-grade neuroendocrine carcinoma of the fallopian tube, particularly in combination with high-grade serous carcinoma and STIC lesions. The presence of these components suggests a common origin and supports the hypothesis that neuroendocrine differentiation may arise from a pre-existing carcinoma. This finding provides insight into the tumour's pathogenesis and emphasizes the importance of thorough histological examination to identify all components of such rare cases. Continued documentation is essential to improve diagnostic and therapeutic strategies.

E-PS-11-072

Second opinion in gynaecologic pathology: evaluating diagnostic concordance and its effect on patient management

P. Rodrigues Veiga[1], C. Perez Duque[1], C. Bartosch[1]
[1]Portuguese Oncology Institute of Porto (IPO-Porto), Department of Pathology, Porto, Portugal

Background & Objectives: In pathology, second opinion allows cases to be reviewed by experienced pathologists, thereby increasing diagnostic accuracy and ensuring appropriate patient management. This study aimed to evaluate the frequency of diagnostic discrepancies in gynaecologic pathology at our institution and their impact on clinical management.
Methods: We analysed all gynaecological pathological second opinion reports conducted at our institution in 2024, and compared them with the original reports. Each patient clinical files were analysed to evaluate the clinical impact of discordances. Cases were categorized into five groups: no diagnostic disagreement, no diagnostic disagreement but pertinent information not included, diagnostic disagreement without clinical consequences (NoCS), diagnostic disagreement with minor clinical significance (MinorCS) and diagnostic disagreement with major clinical significance (MajorCS).
Results: A total of 182 cases was reviewed, including specimens from uterine corpus (n=98), uterine cervix (n=41), ovary/Fallopian tube/peritoneum (n=20), vulva (n=17) and vagina (n=6). The majority were biopsy specimens (n=135, 74.2%).
In 132 (72.5%) cases there was consensus between the original report and the one revised at our institution, but in a subset of these (n=11) second opinion added pertinent information for patient management. Diagnostic disagreement was present in 50 (27.5%) cases, including: 16(8.8%) MajorCS, 7(3.8%) MinorCS and 27 (14.8%) NoCS.
The higher rates of disagreement were similar in uterine corpus (30.6%) and ovary/Fallopian tube/peritoneum (30.0%), and lower in cervix (21.9%) and vulva (17,6%).
Conclusion: We report a higher discordance rate compared to literature, that may be explained by our role as a cancer referral centre for complex cases. Additionally, our access to advanced diagnostic tools, including genetic testing unavailable in local laboratories, enhances second opinion diagnostic precision. Our data reflects a selection bias, as currently only endometrial carcinomas undergo mandatory review, while other topographies are reviewed opportunistically. The discrepancies significantly impact patient care and institutional costs, highlighting the value of expert second opinion in pathology.

E-PS-11-073

FN-EDA fibronectin isoform: harnessing its expression for innovative therapeutic strategies

A. Piermattei[1], R. De Luca[2], P. Frederik[3], L. Pluss[3], E. Puca[2], N. D'Alessandris[4], A. Travaglino[5], F. Sillano[4], T. Pasciuto[6], D. Giannarelli[6], M. Buttarelli[6], G.F. Zannoni[4], A. Fagotti[4], D. Neri[2], C. Nero
[1]Fondazione Policlinico Gemelli IRCCS Rome, Anatomia Patologica Generale, Dipartimento di Scienze della Salute della Donna, del Bambino e di Sanità Pubblica, Rome, Italy, [2]Philogen, Zurich, Switzerland, [3]Philochem, Zurich, Switzerland, [4]Fondazione Policlinico Gemelli-IRCCS, Roma, Italy, [5]Università degli Studi dell' Isubria, Verona, Italy, [6]Università Cattolica del Sacro Cuore, Rome, Italy

Background & Objectives: Over 39,000 ovarian cancer deaths occur annually in Europe and the U.S., highlighting the need for improved diagnostics and treatments. This study evaluates four tumour markers—extra-domains A and B of fibronectin, fibroblast activation protein, and carcinoembryonic antigen—and expands to assess EDA-FN in epithelial ovarian cancer tissue samples.
Methods: An exploratory immunohistochemical analysis was performed on 60 FFPE tissue sections from 47 patients with epithelial ovarian cancer. The samples included 47 specimens collected at first diagnosis, along with 13 relapsed lesions. These tissue sections were stained using validated antibodies to evaluate the stromal immunoreactive score (sIRS) for biomarker expression in 'Exploratory Fase 1' of the study. After completing this phase, the study expanded to investigate EDA-FN. In 'Focus Fase 2', 204 FFPE tissue samples from 102 patients with High Grade Serous Ovarian Cancer (HGSOC) were analysed, including both primary and metastatic sites.
Results: Results of 'Exploratory Phase 1' showed stromal expression of EDA-FN, EDB-FN, and FAP in ovarian cancer, while their levels remained unchanged in matched primary and relapse tumour tissues. CEA was found exclusively in mucinous ovarian cancer. Our analysis revealed that EDA-FN was the most abundant antigen, prompting further analysis in a larger sample size of EOC (Focus Phase 2). When patients were stratified by (i) molecular status (BRCAwt vs BRCAmut), (ii) line of treatment (naive vs relapse), (iii) primary vs metastatic lesions, and (iv) prior bevacizumab treatment, EDA-FN was highly abundant in all cases. Moreover, elevated expression was found in metastases compared to primary tumours.
Conclusion: These findings highlight that EDA-FN is an excellent target for HGSOC, while CEA could serve as a potential target for MOC. Clinical investigations are warranted to validate innovative treatments in ovarian cancer targeting these antigens.

Funding: This work was partially supported by Philogen S.p.a

E-PS-11-074

Impact of molecular profiling in the management of high-grade serous carcinoma: a case of tumour heterogeneity

G. Scaglione[1], A. Santoro[1], B. Padial Urtueta[2], D. Arciuolo[2], N. D'alessandris[1], F. Addante[2], M. Valente[2], N. Narducci[2], A. Minucci[2], F. Camarda[3], C. Nero[3], A. Fagotti[3], G.F. Zannoni[1]
[1]Catholic University of Sacred Heart, Department of Pathology, Rome, Italy, [2]Fondazione Policlinico A. Gemelli, General Pathology, Rome, Italy, [3]Fondazione Policlinico A. Gemelli, Gynaecology, Rome, Italy

Background & Objectives: A 50-year-old woman presented to the emergency department with abdominal pain, and hematemesis for three days. A CT scan showed a 65 mm abdominal mass. She underwent emergency laparotomy, including total hysterectomy, bilateral adnexectomy, omentectomy, and resection of peritoneal nodules and diaphragmatic peritoneum (RT=0). The histology confirmed adnexal high-grade serous carcinoma, FIGO IIIB.

Methods: Two different tumour areas were evaluated, one by the in-house NGS tumour-only multigene panel, the other by FMI-Roche (MITO25.1 trial). In one area (morphological pseudoendometrioid features), NGS programme revealed the following: TP53 (p.R280*, c.838A>/T, VAF% 79.2); MUTYH (p.Y179C, c.536A>G, VAF% 49.8); HRD status by Sophia negative, with GI: -12.4; BRCA1-2 wild type. On the other FFPE block (usual morphological features), the FMI revealed: same TP53 mut; MUTYH (p.Y165C); HRD not detected; BRCA2 R3052Q, with VAF% 41; LOH: 4.7%. Germline testing for BRCA1/2 and MUTYH (p.Y165C) was performed with negative and positive results, respectively.
Results: These two molecular assays highlighted the intratumoral heterogeneity. To clarify this discrepancy, we examined the significance of the BRCA2 R3052Q mutation on ClinVar, where it is classified as VUS/likely benign (if germline) or without clinical impact (if somatic). A review of the literature suggested that this variant may be hypomorphic, with minimal prognostic impact. We reached out to the FMI for clarification with the following response: 'This variant has conflicting evidence listed in ClinVar. Studies by Mesman et al. provided in vitro evidence suggesting that BRCA2 R3052Q may be considered a hypomorphic variant, meaning it leads to partial loss of function in the homologous recombination repair pathway".
Conclusion: The CT scan showed no residual disease. The patient received 5 cycles of chemotherapy (carboplatin AUC5 + paclitaxel 175 mg/m²). Given the molecular heterogeneity observed, the best maintenance therapy remained uncertain. After tumour board review, the patient was considered for MITO 25.1, with liquid biopsy testing ongoing.

E-PS-11-075

Diagnosis of peritoneal tuberculosis from primary peritoneal cancer

N. Karmous[1,2], A. Masmoudi[1], B. Bouguerra[1,2]
[1]Charles Nicolle Hospital, Gynaecology and Obstetrics Department B, Tunis, Tunisia, [2]Faculty of Medicine of Tunis - University Tunis el Manar, Tunis, Tunisia

Background & Objectives: Peritoneal tuberculosis (PTB) is a rare extrapulmonary infection that can mimic primary peritoneal cancer (PPC). This study aimed to identify clinical, radiological, and biomarker differences between PTB and PPC to enable earlier and more accurate diagnosis of PTB.
Methods: Medical records of patients diagnosed with PTB from January 2016 to 2024 were reviewed. PTB was confirmed by pathology or Mycobacterium tuberculosis culture/ polymerase chain reaction in ascitic fluid or lymph nodes. A comparison group of PPC patients was included, diagnosed based on histopathology using Gynaecologic Oncology Group criteria.
Results: We analysed data from 7 women with PTB and 15 with PPC. Key differentiators for PTB included a body temperature above 38°C ($p < 0.001$), lower body mass index (BMI) ($p = 0.003$), lower white blood cell (WBC) count ($p < 0.001$), and lower CA-125 levels ($p < 0.001$). Imaging showed more pulmonary infiltration and consolidation ($p < 0.001$) and less omental or mesenteric involvement ($p < 0.001$) in PTB compared to PPC. Patients who underwent surgery received treatment earlier ($p = 0.010$).
Conclusion: The clinical spectrum of PTB includes fever, lower BMI, reduced WBC count, and modestly elevated CA-125 levels. Chest X-rays may show infiltrative lesions, and computed tomography scans are less likely to reveal omental nodules. Early suspicion of PTB in patients with these features should prompt laparoscopy for biopsy, which offers a quicker diagnosis and initiation of antituberculosis therapy. We propose an algorithm to enhance the differentiation between PTB and PPC, emphasizing early laparoscopic biopsy for timely diagnosis and treatment.

E-PS-11-076

Implementation and validation of FOLR1 (clone FOLR1-2.1) immunohistochemistry in high-grade serous ovarian carcinoma: diagnostic experience and quality control considerations

J. Durślewicz[1,2], Ł. Szylberg[1]
[1]Franciszek Łukaszczyk Oncology Centre, Department of Tumour Pathology and Pathomorphology, Bydgoszcz, Poland, [2]Bydgoszcz University of Science and Technology, Department of Animal Biotechnology and Genetics, Bydgoszcz, Poland

Background & Objectives: **FOLR1 (folate receptor alpha)** is a potential diagnostic and predictive biomarker in high-grade serous ovarian carcinoma (HGSC). In recent years, its relevance has increased, especially in the context of targeted therapies. The aim of this study is to present our experience with the implementation of FOLR1 immunohistochemical staining (clone FOLR1-2.1) in routine pathological diagnostics.
Methods: Prior to diagnostic implementation, 50 cases of HGSC were analysed using the VENTANA® FOLR1 (clone FOLR1-2.1, Roche) ready-to-use assay on the BenchMark ULTRA platform. The staining protocol included standard CC1 heat-induced epitope retrieval, application of the primary antibody as per manufacturer's instructions, and detection with the OptiView DAB IHC Detection Kit. Positive controls (fallopian tube epithelium) and negative controls (non-serous ovarian tumours and normal tissues) were used. FOLR1 expression was assessed semi-quantitatively, focusing on membranous staining intensity (0, 1+, 2+, 3+) and the percentage of positive tumour cells. High FOLR1 expression (FOLR1-high) was defined as ≥75% of tumour cells with ≥2+ membranous staining.
Results: Optimization of the staining protocol was necessary to reduce background noise and cytoplasmic staining. The selection of appropriate internal and external controls proved essential for reliable interpretation. In several cases, non-specific staining patterns were observed, requiring cautious evaluation, especially in samples with borderline intensity or focal expression. The proportion of FOLR1-high cases was 44%, with variability in staining distribution and intensity.
Conclusion: Implementation of FOLR1 immunohistochemistry using clone FOLR1-2.1 requires careful validation, including the use of standardized protocols and well-defined scoring criteria. The presence of non-specific staining underlines the importance of adequate controls and experience in interpretation. FOLR1 evaluation may support patient stratification for targeted therapies and should be further explored in a clinical context.

E-PS-11-077

A novel *MLLT10::C10orf67* gene fusion detected in a uterine leiomyosarcoma with aggressive behaviour

R. Bakkar[1], M. Afkhami[1], J. Carlson[1], D. Bell[2]
[1]City of Hope Comprehensive Cancer Centre, Pathology, Duarte, USA, [2]University of Pittsburgh, Pathology, Pittsburgh, USA

Background & Objectives: Leiomyosarcoma is an aggressive malignant mesenchymal uterine tumour. Distinguishing high grade mesenchymal uterine neoplasms can be challenging. Molecular diagnostics therefore can be a valuable tool to establish a definitive diagnosis. We describe for the first time a novel *MLLT10::C10orf67* gene fusion, detected in a uterine leiomyosarcoma, with peculiar histologic features.
Methods: A 64-year-old healthy female with sudden onset right lower quadrant pain was found to have a fibroid uterus with pressure effect on pelvic organs. She underwent a supracervical hysterectomy and bilateral salpingo-oophorectomy at an outside hospital and was diagnosed with 18 cm leiomyosarcoma. One month later, she presented at our institution for consultation and was found to have diffuse pulmonary,

osseous, peritoneal, and pelvic metastases. Microscopic examination, immunohistochemical (IHC) and comprehensive next generation sequencing (NGS) studies were performed on her primary tumour.
Results: Tumour consisted of sheets of polymorphic cells with spindled, epithelioid, focal rhabdoid morphology, ill-defined fascicular pattern, moderate light eosinophilic cytoplasm, scattered lymphocytes, and peculiar numerous scattered small hyaline plaques. Brisk mitotic activity (33/10 hpf) and extensive tumour necrosis were identified. IHC results showed positive caldesmon (diffuse), SMA and CD10, with negative desmin, SMMHC, myogenin, MYO-D1, Melan A, HMB-45, ALK-1, AE1/3, S-100, CD117, and ER. NGS showed a novel fusion of the *MLLT10* (exon 7) gene to the *C10orf67* (exon 3) gene, arising from t(10;10) translocation. Other significant molecular findings included mutations in *TP53*, *CHEK2*, and *PALB2* genes. The patient was started on doxorubicin-trabectedin chemotherapy, however, died of disease 4 months after the initial diagnosis.
Conclusion: Fusions of *MLLT10* with KMT2A or *PICALM* have been described in hematologic malignancies, with reported high-risk features, and with other partners in solid tumours, such as intestinal, lung and skin cancers. To our knowledge, this is the first report of *MLLT10::C10orf67* fusion detected in the literature, including the gynaecologic tract, with aggressive clinical behaviour.

E-PS-11-078
Primary vaginal gastric-type adenocarcinoma arising from sporadic vaginal adenosis: a case report
S. Hacıoğlu Erşahan[1], S. Kevser Dursun[1], S. Altınay[1]
[1]Basaksehir Cam and Sakura City Hospital, Department of Pathology, Istanbul, Turkey

Background & Objectives: Vaginal adenosis is a benign metaplastic condition, typically associated with in utero diethylstilbestrol(DES) exposure but also occurring sporadically. While most cases regress through squamous metaplasia, some persist and exhibit gastric differentiation, which may carry malignant potential. Although progression from adenosis to atypical adenosis, clear cell carcinoma, or gastric-type adenocarcinoma is rare, it is clinically significant. Gastric-type adenocarcinoma is an aggressive, HPV-independent subtype that often evades detection by routine screening. This report presents a rare case of primary vaginal gastric-type adenocarcinoma arising in the background of sporadic vaginal adenosis.
Methods: A 44-year-old woman presented with postcoital vaginal bleeding. Gynaecological examination revealed a friable, haemorrhagic mass on the right vaginal wall extending to the posterior cervix. Biopsies were obtained from both sites. Clinical and radiological findings favoured a vaginal rather than a cervical primary tumour. Histopathological and immunohistochemical analyses were performed.
Results: Cervical biopsies revealed glandular atypia and CIN1 without invasion, whereas vaginal biopsies demonstrated adenocarcinoma in situ and invasive adenocarcinoma with gastric morphology. Tumour cells were positive for CK7 and CAIX, with focal MUC6 expression. PAX8 and p16 negativity supported the HPV-independent nature of the tumour. The Ki-67 index was 15–20%. Based on clinical, radiological, and pathological findings, a diagnosis of primary vaginal gastric-type adenocarcinoma was established. Systemic evaluation revealed no distant metastases.
Conclusion: Although vaginal adenosis is generally considered benign, the presence of gastric differentiation may indicate malignant potential. While some adenotic lesions regress, others may progress to malignancy. This case highlights the importance of recognizing and monitoring vaginal adenosis with gastric differentiation as a potential precursor to aggressive malignancies. HPV-independent gastric-type adenocarcinoma can arise in sporadic vaginal adenosis. Given its rarity and aggressive nature, primary vaginal gastric-type adenocarcinoma requires meticulous diagnostic evaluation and clinical management. Heightened clinical awareness and thorough histopathological evaluation are essential for early diagnosis and improved patient outcomes.

E-PS-11-079
Evaluation of Mismatch Repair (MMR) status and breast cancer-1 (BRCA-1) in epithelial cancers of the ovary
P. Agarwal[1], R. Singh[1], E. Raman[2], S. Agrawal[2], V. Solanki[2], P. Prakash[3], M. Maurya[1], R. Jaiswal[1], S. Gupta[3]
[1]King George's Medical University, Pathology, Lucknow, India, [2]King George's Medical University, Obstetrics and Gynaecology, Lucknow, India, [3]King George's Medical University, Surgical Oncology, Lucknow, India

Background & Objectives: India contributes approximately 5.9% of global ovarian cancer cases. The standard treatment for surface epithelial ovarian cancers typically involves a combination of surgery and platinum- or taxane-based adjuvant chemotherapy. However, these therapies are often associated with relapse and early mortality.
BRCA1 (Breast Cancer 1) and Mismatch Repair (MMR) proteins play a critical role in guiding targeted therapy, offering chemo- and immunotherapeutic advantages. This study aims to evaluate BRCA1 and MMR protein expression using immunohistochemistry (IHC) in surface epithelial ovarian cancers. Additionally, it seeks to establish a clinicopathological correlation and assess the concordance between IHC findings and molecular analysis of MMR gene.
Methods: Immunohistochemistry (IHC) was performed on epithelial ovarian cancers for BRCA1, MLH1, MSH2, MSH6, and PMS2, and the results were analysed in relation to clinical and pathological variables. Additionally, 15 samples were processed in duplicate for sequencing studies, using a panel of 13 MMR gene markers, along with appropriate positive and negative controls.
Results: Our study, which included 49 cases of epithelial ovarian cancer, involved documentation of demographic details. According to our findings, 51% of epithelial ovarian cancers were dMMR. However, no significant correlation was observed between dMMR and pMMR tumours in terms of high-grade features. Notably, patients with dMMR exhibited better survival rates, likely due to an improved response to chemotherapy.
Total loss of BRCA1 was observed in 36.7% of cases. While BRCA1 loss was associated with aggressive tumour behaviour, it also correlated with a better response to chemotherapy.
No significant correlation was found between molecular testing and immunohistochemistry (IHC) results for microsatellite instability (MSI) in this study.
Conclusion: Our study demonstrates that a significant proportion of epithelial ovarian cancers exhibit BRCA1 loss and dMMR. Therefore, incorporating IHC-based screening into routine practice could help identify patients who may benefit from targeted therapies.

E-PS-11-080
When metastasis tells the story: a case of lung metastatic extrauterine endometrial stromal sarcoma
F. Soares Nogueira[1], J. Rodrigues Alves[1], C. Branco[1], P. Sequeira[1], A. Oliveira[1], L. Viegas de Carvalho[1]
[1]ULS Almada-Seixal - Hospital Garcia de Orta, Pathology, Almada, Portugal

Background & Objectives: Endometrial stromal sarcoma (ESS) represents 1% of all uterine malignancies with known risk factors including prolonged oestrogen use, pelvic radiation and endometriosis. The aim is to report the diagnostic approach, imaging findings, histopathological and molecular features of this entity.
Methods: A 49-year-old woman presented with mild fatigue and pleuritic chest pain. Additional symptoms included dysmenorrhea, deep dyspareunia, irregular menstruation for less than a year, and heavy

menstrual flow. Her family history was notable for gastrointestinal and prostate cancers. Due to the respiratory symptoms, a thoracic CT scan was performed, revealing multiple bilateral pulmonary nodules, which were subsequently biopsied.
Results: Lung biopsy showed a neoplasm composed of oval small cells with scarce cytoplasm and indistinct boundaries, arranged in short, intersecting bundles within a rich capillary network. Some areas displayed perivascular concentric arrangements of neoplastic cells. The nuclei exhibited minimal pleomorphism, with variable chromatin distribution. Mitoses were scarce, and no haemorrhage or necrosis was observed.
Immunohistochemistry revealed neoplastic cells positive for vimentin, CD10, WT1, ER, and PR, focally for CD117 and were negative for inhibin, cytokeratin AE1/AE3, EMA, DOG1, pan-TRK, CD34, CD31, calretinin, actin, and desmin. These findings are consistent with a mesenchymal neoplasm, with features suggestive of Endometrial Stromal Sarcoma with the differential diagnosis with a sarcomatous component of a gynaecological mixed neoplasm.
Pelvic-RM was performed and showed a pelvic mass interposed between the uterus and left ovary.
Pelvic mass biopsy was performed, and both histological and immunohistochemical analysis, were overlapping with the lung lesion.
Next-generation sequencing identified a CTNNB1 translocation p.(Asp32Asn)/DN32N. Pathological study of the surgical specimen confirmed the final diagnosis of Extrauterine Endometrial Stromal Sarcoma.
Conclusion: This rare case highlights the diagnostic challenges of metastatic extrauterine ESS. Several genetic alterations have been reported in ESS, with the CTNNB1 translocation being linked to the presence of whorled and fibromixoid morphology and β-catenin pathway.

E-PS-11-081
Cervical adenocarcinoma with endometrial and fallopian tube metastasis: a case report
E.-L. Giannikaki[1], E. Chliara[1], G. Kazamias[1], E. Serpetsidaki[1], A. Alexopoulou[1], E. Vardaki[1], K. Pavlakis[2]
[1]Venizeleio General Hospital, Pathology, Iraklion, Greece, [2]IASO Womens' Hospital, Pathology, Athens, Greece

Background & Objectives: Adnexal and endometrial metastasis of cervical adenocarcinoma (ADC) is relatively uncommon. Most of the tubal metastases are associated with ovarian ones. Tubal metastasis that occurs alone is generally asymptomatic and grossly unidentifiable and only a few studies have been published.
Methods: We present a case of a 58-year old woman, diagnosed with HPV-associated AIS cervix in cervical biopsy and treated with total hysterectomy with BSO.
Histopathology showed an HPV-related AIS-like ADC (CK7+/CK20-/p16+/ER-/PR-/vimentin/WT-1-, p53wt), 30 mm in length, extending to the isthmus and endometrium, with areas of non destructive stromal invasion (type A Silva system) up to 1,6mm in depth and a polypoid/exophytic non infiltrating component, 5mm in high, identified in the transition of endocervical-isthmus. Lesions of the same immunohistochemical profil tumour were observed in endometrial fundus, and in mucosa of both fallopian tubes without stromal invasion, supporting the idea of metastasis from the endocervical carcinoma, rather than primary. Both ovaries were free from disease.
No lymph nodes or peritoneal lesions were identified during operation.
Results: According to AJCC 2017, the stage of the carcinoma is pT1A1. According to ISGyP proposal, 2021, and considering the exophytic component as part of the primary tumour and not as endometrial involvement, the stage is pTA2. Currently, the free carcinomatous lesions in endometrium and tubes do not change the stage.
The MDT proposed NAC.
Conclusion: - our case support the transuterine/transtubal spread of exfoliated tumour cells as a mechanism of spread of ADC to the upper genital tract.
- microscopic tubal metastases may happen in non-destructively ADC, warranting an extensive sampling
- tubal metastases from ADC should be distinguished from STIC
- follow up of the case, may contribute to the best treatment and prognosis of these rare cases.

E-PS-11-082
A rare case of carcinosarcoma arising from the Fallopian tube: a unique clinical presentation
F. Gundogdu[1], L. House[1]
[1]University Hospitals Sussex NHS Foundation Trust, Cellular Pathology, Chichester, United Kingdom

Background & Objectives: Carcinosarcomas of the gynaecological system are most commonly seen in the endometrium, followed by the ovary, while a Fallopian tube origin is exceptionally rare. These aggressive malignancies are often diagnosed at an advanced stage due to nonspecific symptoms. We present a rare case of carcinosarcoma arising from the left Fallopian tube with serous tubal intraepithelial carcinoma (STIC), providing strong evidence of tubal origin. The aim was to contribute further information on the clinicopathologic aspects of this rare disease.
Methods: A 71-year-old female presented with abdominal bloating, distension, and left-sided pain. MRI revealed bilateral adnexal masses with torsion features. She underwent total laparoscopic hysterectomy with bilateral salpingo-oophorectomy. Histopathological and immunohistochemical analyses were performed.
Results: Macroscopic examination showed a multinodular mass (50mm) at the fimbrial end of the left Fallopian tube. The left ovary contained a solid mass (28mm). Microscopically, the tumour comprised predominantly high-grade serous carcinoma and a minor sarcomatous component (<5%) with focal chondromatous differentiation, along with STIC in the left fimbrial end, confirming tubal origin. Immunohistochemistry showed positivity for PAX8, WT1, ER, and PR, with a mutant (null) p53 staining pattern. Tumour involvement was noted in the right ovary, both Fallopian tubes, and uterine serosa. The provisional stage was FIGO IIA. Due to comorbidities, restaging surgery was not performed, and platinum-based chemotherapy was initiated.
Conclusion: Primary Fallopian tube carcinosarcomas are exceptionally rare, with very few reported cases in the literature, and highly aggressive malignancies of the gynaecological system. The presence of STIC in the Fallopian tube reinforces its role as a precursor lesion and provides strong evidence of tubal origin. Early recognition and thorough histopathological assessment, including adequate sampling to detect minor sarcomatous components, are crucial for accurate diagnosis and prognostication

E-PS-11-083
Primary retroperitoneal mucinous borderline tumour: a case report
L. Boesch[1], A. Fleischmann[1]
[1]Spital Thurgau AG, Kantonsspital Münsterlingen, Pathologie Institut, Münsterlingen, Switzerland

Background & Objectives: Primary retroperitoneal mucinous tumours are exceedingly rare, and are classified into mucinous cystadenomas, mucinous borderline tumours (PRMBTs), and mucinous cystadenocarcinomas. To date, only 34 cases of PRMBTs have been documented in the literature. Here, we present the case of a 78-year-old female patient with such a tumour.
Methods: A 78-year-old Caucasian woman was referred for MRI of the lumbar spine due to fatigue, knee pain, and tingling sensations.

Upon detection of a newly developed Grade IV hydronephrosis on the right side and the sonographic confirmation of a mass, a CT scan of the abdomen was performed, raising suspicion of a large renal cell carcinoma. The patient subsequently underwent open nephrectomy on the right side. Intraoperative findings included a large tumour mass in the area of the caudal part of the kidney with pronounced adhesions between the tumour and the omentum, liver, duodenum, and vena cava.
Results: Pathological analysis identified a PRMBT of 10.3 cm in diameter adherent to the kidney and compressing the pyelon resulting in chronic active, localized, abscess-forming, destructive pyelonephritis. Of all reported PRMBTs, 29 involved female and 6 male patients. The median age for female patients was 42.4 years, making PRMTs a potential differential diagnosis for young women with retroperitoneal masses. The exact pathogenesis and genetic factors remain unclear due to the rarity of these cases. After complete surgical resection, five-year disease specific survival reaches 100% in patients with PRMBT.
Conclusion: Publication of individual cases is crucial for improving diagnostic attention to and understanding of this rare tumour over time.

E-PS-11-084

Embryonal rhabdomyosarcoma (*sarcoma botryoides*) mimicking a benign cervical lesion: a case report of a rare gynecopathological entity

M. Masevičienė[1,2], M. Karpavičiūtė[3], J. Kačerauskienė[4], M. Kuprytė[1], N. Valtienė[1], L. Poškienė[1,2]
[1]Hospital of Lithuanian University of Health Sciences Kauno Klinikos, Pathological Anatomy Department, Kaunas, Lithuania, [2]Lithuanian University of Health Sciences, Kaunas, Lithuania, [3]Lithuanian University of Health Sciences, Faculty of Medicine, Kaunas, Lithuania, [4]Hospital of Lithuanian University of Health Sciences Kauno Klinikos, Obstetrics and Gynaecology, Kaunas, Lithuania

Background & Objectives: Embryonal rhabdomyosarcoma (*sarcoma botryoides*), a rare mesenchymal cervical neoplasm, primarily affects paediatric and adolescent females, commonly arising in the vagina or cervix. The main peak incidence of embryonal rhabdomyosarcoma is <5 years old (y.o.), but it can also be diagnosed in older patients. Characterized by a polypoid, grape-like appearance, it often mimics benign lesions, complicating gynaecological diagnostics of cervical pathology.
Methods: A 16 y.o. female presented with a three-month history of a protruding vaginal mass. Her gynaecological history was unremarkable. Gynaecological examination revealed a 6 cm pinkish tissue mass with haemorrhages and ulcerations, likely extending from posterior cervical lip. Ultrasound demonstrated internal cystic structures, while a 8.5 x 4.8 x 2.7 cm mass prolapsing through vaginal introitus was detected during pelvic MRI. Initially suspected as a fibroepithelial polyp, a biopsy was sent for a morphological examination of gynaecological diagnosis.
Results: Findings in biopsy were initially interpreted as a benign soft tissue tumour, to be differentiated between fibroepithelial polyp and angiofibroma, consisting of hypocellular oedematous areas with accentuated thick-walled blood vessels and covered by non-dysplastic squamous epithelium. Following surgical excision with histological examination of surgical material revealed alternating hypocellular areas with myxoid or oedematous stroma admixed with hyaline-type cartilage foci and hypercellular regions (cambium layer) of primitive, small cells with hyperchromatic nuclei, mitotic activity and significantly increased Ki67 proliferation index (approx. 85%), mostly located in subepithelial zone and around cervical glands. Separate striated rhabdomyoblasts were morphologically identified and confirmed by applying Desmin and MyoD1 immunohistochemical markers. Positive expression of these immunohistochemical markers confirmed the pathology diagnosis of rhabdomyosarcoma.
Conclusion: Embryonal rhabdomyosarcoma (*sarcoma botryoides*) is a rare gynecopathologic mesenchymal malignancy in adolescent females. Complex clinical, morphological, and immunohistochemical evaluation of neoplastic tissue should be performed, including immunohistochemical testing for evidence of skeletal muscle differentiation in neoplastic cells, ensuring timely diagnosis and treatment for the patient.

E-PS-11-085

PTEN in endometrial cancer: evaluation of expression and correlation with histo-prognostic factors: a series of 77 cases

M. Alaya[1], G. Sahraoui[1], Z. Abdelkefi[1], E. Khemir[1], M. Mlik[1], R. Mecheri[1], R. Doghri[1], L. Charfi[1], K. Mrad[1]
[1]Salah Azaiez Institute, Pathology Department A, Tunis, Tunisia

Background & Objectives: Endometrial cancer (EC) is the third most common female gynaecological cancer in Tunisia, after breast and cervical cancer, with increasing incidence rates in recent decades. Several studies have demonstrated the prognostic importance of various surgical and pathological parameters in this cancer. Therefore, it is essential to identify new additional biomarkers for its prognostic prediction. Among these biomarkers, the PTEN gene has emerged as a prognostic and theragnostic factor for EC. In this work, we were interested in evaluating the immunohistochemical expression of PTEN as well as the correlation of its status with clinicopathological characteristics in EC.
Methods: It was a descriptive, retrospective and semi-quantitative study. All data were collected from the PCR Laboratory of the ISA between 2007 and 2017. These samples underwent anatomopathological study followed by an immunohistochemical study.
Results: Our series included 77 cases of EC. Low-grade endometrioid carcinomas represented the majority of cases (88,3%). On immunohistochemical study, PTEN expression was observed in tumour cells in 12% of cases and in the stroma in 29% of cases. PTEN expression status in tumour cells showed no statistically significant association with histo-prognostic parameters. However, PTEN expression in the stroma was significantly correlated with several important histo-prognostic features, such as tumour appearance (p=0.004), degree of differenciation (p=0.006), surgical margin invasion (p=0.032), and annexal infiltration (p=0.016).
Conclusion: The PTEN gene is emerging as a key biomarker in endometrial cancer, offering promising prospects for the development of targeted treatments and better risk stratification in patients.

E-PS-11-086

A rare case of Intravenous Leiomyomatosis (IVL) with extension into the inferior vena cava and right atrium

T. Navickis[1,2], I. Prikockytė[2], M. Kuprytė[1,2], L. Poškienė[1,2]
[1]Lithuanian University of Health Sciences, Kaunas, Lithuania, [2]Kaunas Hospital of Lithuanian University of Health Sciences, Pathology, Kaunas, Lithuania

Background & Objectives: Intravenous leiomyomatosis (IVL) is a rare and distinct type of smooth muscle tumour that, despite being histologically benign, exhibits malignant-like behaviour due to its ability to infiltrate the venous system. Smooth muscle cells extend intravascularly, typically originating from uterine leiomyomas. IVL may remain asymptomatic or present with non-specific pelvic symptoms, but can become life-threatening when it extends into large vessels such as the inferior vena cava (IVC) and right atrium.
Methods: A 41-year-old woman presented with a history of an intra-abdominal pelvic mass. The patient underwent a total abdominal hysterectomy with bilateral salpingo-oophorectomy. At the time of surgery, the tumour's aetiology was unclear. The tumour mass extended from the left corner of the cervix towards the iliac region and was localized beneath the left uterine appendages and the broad ligament.
Results: Morphological examination of tumour mass revealed multiple intramural leiomyomas and smooth muscle tumour invasion into the left uterine vein, with extension through the broad ligament and

surrounding pelvic structures. Immunohistochemical study demonstrated diffuse positive staining for desmin, Ki-67 proliferative index ~3%, indicating low proliferative activity. Two years after surgery, this patient underwent a CT scan, which revealed thrombosis in inferior vena cava (IVC) extending into the right atrium and left renal vein, pathological pelvic masses near the left lateral wall of the bladder, within the left retroperitoneal space, and extending along the anterolateral surface of the left psoas muscle, at the level of the renal arteries. No disease progress has been detected during continuous CT scan follow-ups every two years.
Conclusion: This case report emphasizes the malignant potential of histologically benign intravenous leiomyomatosis. While initial surgical treatment focused on uterine mass removal, delayed vascular extension and pelvic recurrence demonstrate the significance of extensive vascular evaluation and long-term follow-up in such patients diagnosed with rare, but potentially life-threatening condition.

E-PS-11-087
Comparative immunohistochemical assessment of SSEA-1, SOX-9, and CD117 in endometriosis and adenomyosis
R.A. Balan[1], T.A. Balan[1], I.D. Căruntu[1], I. Păvăleanu[2], T.A. Bușureanu[2], S.E. Giușcă[1], C. Amalinei[1]
[1]"Grigore T. Popa" University of Medicine and Pharmacy, Department of Morphofunctional Sciences I, Iasi, Romania, [2]"Grigore T. Popa" University of Medicine and Pharmacy, Department Mother and Child, Iasi, Romania

Background & Objectives: Adenomyosis and endometriosis are frequent gynaecological entities, yet their underlying mechanisms remain a topic of ongoing discussion. As stem cells are considered to play a crucial role in the initiation and progression of both lesions, different variants of the stem cell hypothesis have been proposed to explain their pathogenesis. This study aims to comparatively assess the immunohistochemical expression of endometrial stem cells markers, SSEA-1, SOX-9, and CD117, in adenomyosis and endometriosis.
Methods: Our retrospective study was conducted at "Elena Doamna" Clinical Hospital of Obstetrics and Gynaecology, Iasi, Romania and included 261 cases of adenomyosis and endometriosis, diagnosed and surgically treated between 2019-2024. The cases were histopathological diagnosed on standard H&E slides, and immunohistochemically assessed for SSEA-1, SOX-9, and CD117.
Results: The histopathological examination of the surgical specimens identified adenomyosis in 70.11% (n=183) of the cases, endometriosis in 24.13% (n=63) of the cases, 5.74% (n=15) presenting both lesions simultaneously, associating adenomyosis with different endometriotic lesions, with the following sites: ovarian (endometriotic cysts (n=47) and implants (n=10)), abdominal wall (n=12), tubal (n=6), and cervical (n=3). The stem cell marker SSEA-1 presented positive immunoexpression in both adenomyosis and endometriotic lesions. A higher diffuse cytoplasmic expression of SSEA-1 of glandular epithelial cells was found in adenomyosis compared to endometriosis. Nuclear immunoexpression of SOX-9 was positive in glandular epithelial cells from endometriotic lesions as well as in adenomyosis, but also with higher levels in adenomyosis. In the endometrial stroma, CD117 was significant elevated in endometriosis compared to adenomyosis, their distribution showing a periglandular pattern.
Conclusion: The study reveals that both entities contain the evaluated stem cells. However, the different immunoexpression profile of endometrial stem cells in endometriosis and adenomyosis may support the etiopathogenic differences between the two. Future studies are needed for a broader etiopathogenic characterization of these lesions, in order to develop new therapeutic strategies.

E-PS-11-088
Mammary-type Myofibroblastoma of the vagina: a case report of a rare polypoid lesion
N. Chiote[1], M. Zbronska[1], S. Neves[1], A. Duarte[1]
[1]Anatomic Pathology Service Genetics and Pathology Clinic Unidade Local de Saúde de Santo António (ULSSA)Largo Professor Abel Salazar, Porto, Portugal

Background & Objectives: Mammary-type Myofibroblastoma (MTMF) is a rare benign mesenchymal tumour, primarily described in the breast but also reported in extramammary sites, including the soft tissues, inguinal region, and lower female genital tract. It is part of the spectrum of the so called 13q/*RB1* family of tumours, which includes tumours such as spindle cell / pleomorphic lipoma and cellular angiofibroma. Its pathogenesis remains poorly understood, though hormonal influences are suggested by its frequent positivity for oestrogen and androgen receptors. Clinically, MTMF presents as a well-circumscribed, slow-growing mass, which may be mistaken for other mesenchymal neoplasms. This report aims to describe a rare case of vaginal MTMF, emphasizing its clinico-pathological features and differential diagnosis.
Methods: A 74-year-old woman presented with a 2 cm pedunculated vaginal polypoid lesion with a 0.9 cm base. The lesion was covered by whitish mucosa and had a firm, elastic consistency. Complete excision was performed, and the diagnosis of Mammary-type Myofibroblastoma was made.
Results: Histological examination revealed a subepithelial spindle-cell neoplasia with a "grenz zone," moderate cellularity, spindle and stellate-shaped cells with ocasional multinucleated cells. The stroma was collagenous with keloid-like fibres and hyalinized-walled blood vessels. There was no mitotic activity or necrosis. Immunohistochemistry showed strong desmin positivity, highlighting dendritic morphology of some spindle cells, and positivity for CD34, ER, AR, Bcl-2, CD99, and CD10. The lesion was negative for caldesmon, calponin, SMA, S100, and AE1/AE3.
Conclusion: Vaginal MTMF is an uncommon benign neoplasm that should be considered in the differential diagnosis of vaginal spindle-cell lesions. Given its indolent behaviour, conservative surgical excision is the treatment of choice. Recognition of this entity is crucial to avoiding unnecessary aggressive interventions and distinguishing it from malignant mesenchymal tumours.

E-PS-11-089
CPSF2 expression in endometrial carcinoma: analysis of 100 cases
R. Limani[1], V. Ademi Ibishi[2], R. Dreshaj Hoxha[3], L. Kondirolli[1], B. Blakaj Gashi[1], G. Sopa[2], D. Miftari Pazhari[1], L. Veliu[4], B. Curri[5]
[1]Faculty of Medicine, University of Prishtina, Kosovo, Anatomical Pathology, Prishtina, Kosovo, [2]Faculty of Medicine, University of Prishtina, Kosovo, Gynaecology and Obstetrics, Prishtina, Kosovo, [3]Faculty of Medicine, University of Prishtina, Kosovo, Prishtina, Kosovo, [4]Faculty of Medicine, University of Tetova, Anatomical Pathology, Tetovo, North Macedonia, The Republic of, [5]Faculty of Medicine, University of Prishtina, Kosovo, Forensic Medicine, Prishtina, Kosovo

Background & Objectives: Cleavage and Polyadenylation Specificity Factor 2 (CPSF2) is a component of the mRNA processing machinery, and its dysregulation has been implicated in various cancer types. However, the clinical significance of CPSF2 expression in endometrial carcinoma remains underexplored. We analysed CPSF2 expression in a cohort of endometrial carcinoma cases and to evaluate its potential correlation with key clinicopathological parameters.
Methods: Formalin-fixed, paraffin-embedded tissue samples from 100 patients diagnosed with endometrial carcinoma were assessed for CPSF2 expression via immunohistochemistry. Expression levels

were scored semi-quantitatively, and patient data were retrospectively reviewed to correlate CPSF2 status with tumour type, grade and stage.
Results: Most endometrial carcinoma samples demonstrated varying degrees of CPSF2 immunoreactivity, and preliminary analyses suggest that its expression may be linked to specific pathologic features, including tumour stage and histological grade.
Conclusion: We report that CSF2 is frequently expressed in endometrial carcinoma. Nevertheless, the significance of CPSF2 expression, including potential prognostic implications and underlying biological mechanisms require larger prospective studies and mechanistic analyses will help clarify the clinical relevance of CPSF2 in endometrial carcinoma.

Prognostic implications of microsatellite instability and p53 expression in endometrial carcinomas: an immunohistochemical study
N. Abdessayed[1], Z. Nfikha[1], M. Kouira[2], S. Yacoub[1], M. Mokni[1]
[1]Farhat Hached University Hospital, Pathology, Sousse, Tunisia, [2]Farhat Hached University Hospital, Gynaecology, Sousse, Tunisia

Background & Objectives: The study of microsatellite instability (MSI) and mutations of the TP53 gene is part of the new molecular classification of endometrial carcinomas (EC) adopted by the latest edition of the WHO classification of tumours of the female genital tract. Our work aimed to evaluate, through immunohistochemistry, the microsatellite status and p53 expression in a series of EC and to determine their clinico-pathological features.
Methods: This was a retrospective descriptive study involving 76 cases of EC collected at the pathology department of FarhatHached Hospital over seven years (2014-2020). Immunohistochemical analysis was performed using a tissue microarray (TMA) block with p53, MLH1, MSH2, MSH6, and PMS2 antibodies.
Results: The average age of the patients was 58.9 years. The majority of cases were EC (89.5%), with low-grade tumours (48.7%) and early FIGO stage (69.8%). Microsatellite instability was found in 35.5% of cases. Abnormal p53 expression was observed in 11.8% of cases. MSI patients were older and had endometrioid tumours in 96.7% of cases, although no significant association was found. Overexpression of p53 was statistically correlated with advanced age (p=0.010), non-endometrioid type (p=10^-3), high-grade FIGO (p=10^-3), and advanced FIGO stage (p=0.001). The survival rates (overall survival and relapse-free survival) of MSI/p53-wild type patients were reduced compared to those of the MSS/p53-wild type group (p=0.767; p=0.990). The overexpression of p53 decreased both overall survival (p=10^-3) and relapse-free survival (p=0.003) and was identified as an independent poor prognostic factor for overall survival.
Conclusion: The study of the microsatellite status and p53 expression allowed us to determine three subgroups in our series: the MSS/p53-wild type subgroup had the most favourable prognosis, the MSI/p53-wild type subgroup had an intermediate prognosis, and the MSS/p53-abnormal subgroup had the poorest prognosis. This "immunohistochemical" classification brought us closer to the molecular classification of EC, emphasizing the role of immunohistochemistry in prognostic studies of EC.

E-PS-11-091
Endometrial sampling in women aged 40 and under: an institutional experience of an increasing caseload
H. Ashe[1], G. Neville[2], M. Buckley[1]
[1]Cork University Hospital, Pathology, Cork, Ireland, [2]Cork University Hospital, Cork, Ireland

Background & Objectives: The incidence of endometrial sampling of women under 40 has steadily increased in our institution over recent years, requiring significant pathology resources. We aimed to audit practices regarding endometrial sampling in this age group. To compare the incidence, indications, and significant findings of endometrial sampling in women aged 40 and under in our institution between two time periods, ten years apart, to better understand the core reasons for the increase observed. To examine whether indications for endometrial sampling are in keeping with current guidelines, and whether the risk of neoplasia/preneoplasia is changing in our younger patients over time.
Methods: All endometrial biopsies in women aged 40 and under were identified from Cork University Hospital pathology department electronic records database using search codes for endometrial biopsies for 2008-2012 (T1) and 2018-2024 (T2). Clinical details, macroscopic, and microscopic reports were analysed. All data was recorded and analysed using Microsoft Excel.
Results: 2582 cases were identified, 271 cases from T1 (21% of total number sampled), and 2311 (19% of total number sampled) cases from T2. T1 had an average of 54.2 cases per year, T2 had an average of 330.1 cases per year. The average age in T1 was 35.5 and 34.8 in T2. No significant difference between sampling indications were identified. The most common indication was AUB (76% of T1, 74% of T2). A small but non-statistically significant difference in diagnosis of ATH/EIN and endometrial carcinoma was identified (0% ATH/EIN, 0% endometrial carcinoma in T1, 1% ATH/EIN, 1% endometrial carcinoma in T2).
Conclusion: A small, non-statistically significant increase in the incidence of ATH/EIN and endometrial carcinoma was observed between time periods. Relative stability compared with a large increase in overall number sampled suggests consistency in management of these women. The continuing increase in cases may reflect a growing baseline population in our region.

E-PS-11-092
Heterogeneity in mesonephric adenocarcinoma: clinicopathological and immunohistochemical analysis of two cases
M. Toker[1], Ö. Erdem[1], M.A. Onan[2], M. Erdem[2]
[1]Gazi University, Faculty of Medicine, Pathology, Ankara, Turkey, [2]Gazi University, Faculty of Medicine, Obstetrics and Gynaecology, Ankara, Turkey

Background & Objectives: Mesonephric carcinomas of the uterine cervix are rare tumours believed to originate from mesonephric remnants. We present two cases of mesonephric adenocarcinoma in patients from different age groups.
Methods: **First Case:** A 40-year-old female patient presented with spotting-type bleeding. Ultrasound revealed no abnormalities in the vagina, cervix, uterus, or adnexa. Pelvic examination identified uterine prolapse and cystocele. The patient underwent cervical amputation due to uterine prolapse, which led to the diagnosis of mesonephric adenocarcinoma. A subsequent total hysterectomy was performed, and no residual tumour was detected.
Second Case: A 75-year-old female patient presented with postmenopausal bleeding at an external centre and underwent curettage. Histopathological evaluation of both the initial and repeat curettage samples confirmed the diagnosis of mesonephric adenocarcinoma, leading to a decision for hysterectomy.
Results: In the first case, examination of the cervical amputation specimen revealed back-to-back acini lined with low cuboidal cells containing intraluminal eosinophilic secretions, surrounded by desmoplasia. The acini exhibited invasive features within the muscle layer. Immunohistochemically, the tumour cells were positive for GATA-3 and PAX8 but negative for CD10 and the oestrogen receptor.

In the second case, examination of the curettage and hysterectomy specimens showed similar acinar structures, along with papillary formations containing true fibrovascular cores with hierarchical branching, lined by cuboidal/columnar cells. Immunohistochemical analysis demonstrated negativity for the oestrogen receptor, positivity for GATA-3, PAX8, CD10, and TTF-1, wild-type p53 expression, and patchy p16 positivity.
In both cases, the invasive appearance of these structures ruled out mesonephric remnants. The combination of oestrogen receptor negativity, wild-type p53 expression, and p16 negativity helped exclude endometrioid-type adenocarcinoma and serous carcinoma. No sarcomatous component was present.
Conclusion: Mesonephric adenocarcinoma is a rare cervical tumour that requires both morphological and immunohistochemical differentiation from benign mesonephric remnants and other, more common cervical tumours.

E-PS-11-093
Identification of new diagnostic and therapeutic targets in endometrial carcinoma
T. Kuracinová[1], P. Janega[1], A. Janegova[1]
[1]Institute of Pathological Anatomy, Faculty of Medicine, Comenius University in Bratislava and University Hospital Bratislava, Bratislava, Slovakia

Background & Objectives: Endometrial carcinoma (EC) originates from the epithelial lining of the endometrium and is histologically classified into Type I (low-grade, favourable prognosis) and Type II (high-grade, poor prognosis). Molecular classification defines four prognostically significant subgroups: POLE-mutated, microsatellite instability (MSI), low copy number, and high copy number tumours. The PTEN gene, frequently mutated in EC, plays a key role in the PI3K/Akt signalling pathway, regulating tumour growth, invasion, and apoptosis. Additionally, alterations in glycosylation significantly influence tumour progression by modulating cell adhesion, migration, and proliferation. This study aims to characterize changes in surface glycoconjugates in EC and correlate them with the molecular classification, as well as to investigate alterations in the PI3K/Akt/PTEN pathway and their association with protein sialylation.
Methods: Formalin-fixed, paraffin-embedded EC biopsy samples were analysed using lectin histochemistry to assess alterations in surface glycoconjugates. Lectins specific for distinct carbohydrate motifs (ECL, PNA, PSA, UEA, SNA, LCA, MAL, RCA, AAL, PHA) were utilized to obtain a comprehensive glycosylation profile. Immunohistochemistry was performed to evaluate PI3K/PTEN/AKT pathway activity, focusing on PTEN expression and phosphorylated AKT.
Results: PTEN expression was higher in microsatellite stable tumours compared to MSI tumours. AKT strong positivity in invasive front foci was observed in 31%, suggesting a role in invasion and progression. Weak diffuse AKT positivity was more frequent in G3 tumours, indicating its involvement in early carcinogenesis or less aggressive tumours. SNA positivity (α2,6-sialylation) predominated, while MAL expression (α2,3-sialylation) was weak, emphasizing the role of sialylation in EC pathogenesis.
Conclusion: The observed AKT positivity at invasive fronts and the predominance of α2,6-sialylation suggest a potential role of glycosylation in EC progression. These findings provide new insights into EC tumour biology and may inform future diagnostic and therapeutic strategies. Further research using additional lectins is needed to confirm the correlation between glycosylation patterns and molecular characteristics of EC.

E-PS-11-094
High-grade serous carcinoma arising from a bilateral micropapillary serous borderline tumour: a rare case of malignant transformation
S. Çalışkan[1], Ş. Çebi[2]
[1]Samsun University, Faculty of Medicine, Pathology, Samsun, Turkey, [2]Samsun Training and Research Hospital, Gynaecologic Oncology, Samsun, Turkey

Background & Objectives: Serous borderline tumours (SBTs) of the ovary are non-invasive epithelial neoplasms with generally favourable outcomes. However, progression to high-grade serous carcinoma (HGSC) is extremely rare, especially following micropapillary variants. We present a unique case of HGSC developing three years after the initial diagnosis of bilateral micropapillary-type SBT with microinvasion.
Methods: A woman in her 60s underwent total hysterectomy and bilateral salpingo-oophorectomy for bilateral ovarian masses. Histopathological evaluation revealed bilateral micropapillary-type serous borderline tumours with microinvasion. The patient received adjuvant chemotherapy and was followed for a period. During follow-up, elevated CA-125 levels and ascites were noted, but she was later lost to follow-up. Three years after the initial diagnosis, she presented with abdominal distension and pain. Imaging revealed an omental "cake-like" appearance. Diagnostic laparoscopy and biopsy confirmed extensive infiltration of high-grade serous carcinoma.
Results: While the progression of SBTs to low-grade serous carcinoma is a recognized phenomenon, transformation into HGSC remains exceedingly uncommon and raises important questions regarding the pathogenesis and molecular evolution of these tumours. The micropapillary subtype and microinvasive foci in this case may represent early indicators of potential aggressive transformation.
Conclusion: This case highlights a rare but significant clinical course where a micropapillary serous borderline tumour with microinvasion progressed to high-grade serous carcinoma over a prolonged interval. It underscores the importance of long-term surveillance and consideration of the micropapillary pattern as a potential risk factor for malignant transformation.

New rodent models of atypical implantation and placentation: cons and pros
N. Tikhonova[1], V. Aleksankina[1], A. Milovanov[1], L. Mikhaleva[1], A. Elchaninov[1]
[1]Petrovsky National Research Centre of Surgery, Moscow, Russia

Background & Objectives: Elucidating pathogenesis of placenta accreta spectrum (PAS) is the key foundation for improving the pregnancy outcome of PAS patients clinically. Appropriate animal models could facilitate comprehensive research on the pathogenesis of PAS. We investigated the possible role of adipocyte clusters in uterine scar in PAS development.
Methods: In the right horn of the uterus of the Sprague-Dawley rats (n=10) was inserted a strip of autologous fat tissue. On the left horn, a full-thickness surgical incision of uterine wall was made and stitched (control). Three weeks after the operation, males were put in the cages with these females. The gross pathological and histopathological examination of implantation and placentation in both horns was carried out on the 16th day of pregnancy.
Results: In the right horn, 3-4 embryos have been found at the site of the incorporated adipose tissue in 7 cases. In the control left horn, no implantion was found at the incision site. The number of embryos in the right horn was significant higher than in the control left in all observations ($p<0.05$). The placenta of foetus implanted in adipose site were atypical and different from the normal placenta. Signs of

invasion of the foetal vessels in the metrial gland were detected in several observations.
Conclusion: Our developed rat model can be useful for research on pathogenesis of PAS and the effect of uterine scar adipocytes on PAS development or caesarean scar pregnancy.

Funding: The work was carried out within the framework of FSBSI. "Petrovsky National Research Centre of Surgery", 119991 Moscow, Russia, No. 123030700105-0 (FURG-2023-0046)

Atypical polypoid adenomyoma: a diagnostic masquerader in young women with abnormal uterine bleeding
M. Karakuş[1], G. Turan[1], G.G. Gurel[1], B. Yaprak Bayrak[1]
[1]Kocaeli University School of Medicine, Department of Pathology, Kocaeli, Turkey

Background & Objectives: Atypical polypoid adenomyoma (APA) is a rare benign uterine lesion composed of atypical endometrioid glands and fibromuscular stroma, often accompanied by squamous morules. It commonly affects women of reproductive age and may mimic atypical hyperplasia or low-grade endometrioid carcinoma on biopsy. This case series aims to emphasize the diagnostic challenges of APA and the importance of histopathological and immunohistochemical evaluation in avoiding overtreatment.
Methods: We retrospectively analysed three cases of APA diagnosed between 2022 and 2024. Clinicopathological features, radiological findings, and immunohistochemical profiles (ER, PR, p63, CD10) were reviewed. All cases were diagnosed on endometrial sampling and/or hysterectomy specimens.
Results: The first case involved a 49-year-old woman with abnormal uterine bleeding. Hysterectomy revealed a 0.8 cm APA in the myometrium, along with mucinous cystadenoma in the ovary and leiomyoma. The second and third cases were younger women (26 and 34 years) presenting with heavy bleeding. Endometrial curettage specimens revealed irregular, crowded endometrioid-type glands with squamous morules embedded in fibromuscular stroma, consistent with APA. All cases showed diffuse ER and PR positivity in both glands and stroma. p63 expression was confined to squamous morules, and CD10 highlighted the periglandular stromal component. None of the patients showed evidence of malignant transformation or recurrence during short-term follow-up.
Conclusion: APA poses significant diagnostic challenges, particularly on limited biopsy material where it can mimic premalignant lesions. Recognition of its characteristic morphology, supported by a focused immunohistochemical panel, is essential for appropriate diagnosis and management. This is especially important in reproductive-age women, where fertility preservation is a key consideration.

E-PS-11-097
Wrong hormonal status during hysterotomy can cause problems with uterine scar formation
N. Tikhonova[1], V. Aleksankina[1], A. Aleksankin[1], E. Kuznetsova[1], M. Aksenova[1], Z. Gioeva[1], A. Elchaninov[1], A. Milovanov[1]
[1]Petrovsky National Research Centre of Surgery, Moscow, Russia

Background & Objectives: Preventing and treating caesarean scar defects is important task to decrease pregnancy complications. Animal models are an important tool for pre-clinical trials of methods and drugs aimed at the prevention and treatment of pregnancy complications. Our objective was to investigate how the sexual cycle phase during surgery affects the quality of healing after a thorough incision of the uterine wall.
Methods: Surgical incision (10 mm in length) were carried out on both uterine horns of Sprague-Dawley rats in different phases of estrous cycle: proestrus (n=5), estrous (n=5), metestrous (n=5) and diestrous (n=5). The incision on the right horn was stitched, but the incision on the left horn was left unsealed. On the 5th and 10th day after the operation, gross pathology and histopathology examinations were performed.
Results: By 5th day after surgery, the animals operated in the estrous phase had the damaged area covered with fat tissue on both sutured and unsutured horns. The wound space was filled by connective tissue. The operated rats in the diestrus had an unsealed incision of left horn and the incision of right horn wasn't covered with adipose tissue. By 10 days after the operation, the greatest delay in healing was observed in animals operated in the diestrous phase. The best healing was found in rats operated in the estrous phase. The attachment of adipose tissue to the damaged area was dependent from estrous phase in which was carried out the operation and correlated with healing quality. The parameters of the healing after the surgery in the metestrus and the proestrus were intermediate between the parameters for the estrus and the diestrus.

Conclusion: The level of sex hormones affects the healing of the uterine wound and the scar formation. The important role of visceral fat tissue in the healing efficiency of the uterine wound was discovered.

Funding: The work was carried out within the framework of FSBSI "Petrovsky National Research Centre of Surgery", 119991 Moscow, Russia, No. 123030700105-0 (FURG-2023-0046)

E-PS-11-098
Single nucleotide polymorphisms associated with cervical cancer susceptibility in Georgian women
K. Kankava[1,2], S. Surmava[1], B. Davitashvili[1], N. Vardiashvili[3], N. Kharebashvili[4], M. Zarandia[1], E. Abzianidze[1], E. Kvaratskhelia[1]
[1]Tbilisi State Medical University, Tbilisi, Georgia, [2]Megalab, Tbilisi, Georgia, [3]Inova Medical Centre, Tbilisi, Georgia, [4]New Hospitals, Tbilisi, Georgia

Background & Objectives: Cervical cancer (CC) is the third most common malignancy in women worldwide. Genome-wide-association studies (GWAS) have identified multiple single nucleotide polymorphisms (SNPs) that are associated with an increased risk of cervical cancer. In this study, we aimed to investigate the association between 13 SNPs and overall cervical cancer risk in Georgian population.
Methods: 50 patients diagnosed with cervical cancer and 50 healthy women had enrolled in this study. We genotyped 10 SNPs rs11263763, rs7726159, rs6897196, rs2853672, rs148261157, rs7579014, rs687289, rs635634, rs231775, rs2304204. These SNPs are described in association with different gynaecologic tumours and are mapped to cancer-related genes: HNF1B, TERT, BCL11A, ABO, CTLA4, IRF3. TaqMaq assays were used for the investigation.
Results: Our analysis, which utilised the GraphPad Prism 9.3.1 software package showed that there was a significant association of rs7579014 (BCL11A G/A), rs7726159 (TERT C/A) and rs687289 (ABO T/A) SNP risk genotypes with cervical cancer risk in Georgian population (p=0.02, p=0.04 and p=0.02, respectively). At the same time no significant association was found with other studied SNPs. Among them are CTLA4 and IRF polymorphysms, previously found to increase CC risk in other population groups.
Conclusion: These results are preliminary with a small sample size and relatively few SNPs analysed. However the tendency has been identified and it allows planning further investigations.

Funding: This study was supported by Shota Rustaveli National Science Foundation of Georgia (grant #FR-21-17599)

E-PS-12-001
Primary Rosai Dorfman disease of bone: a case series
C. Wijegunarathna[1], P. Kasilingam[1], S.R. Constantine[1], R. Punchihewa[1]
[1]National Hospital of Sri Lanka, Colombo, Sri Lanka

Background & Objectives: Rosai Dorfman disease (RDD) is a histiocytic disorder which predominantly involves nodal sites with uncommon extranodal presentation. Primary osseous RDD is very rare and it is reported in 2-8% of cases. In this case series we are describing three cases of primary RDD in bone, in which the diagnosis has been confirmed by the novel marker cyclin D1.
Methods: NA
Results: Case 1 is a 16-year-old female who presented with right knee pain for 6 months with metaphysial lytic lesions in distal femur and proximal tibia on MRI. Case 2 is an 11-year-old male with a raised tender scalp lump for 1 year with well-defined lytic lesion is noted left occipital bone. Case 3 is a 14-year-old with a painful scalp lump for 3months. Radiologically, a lytic lesion is observed in the scalp occipital region. All three patients were previously healthy.
Histologically, sheets of large histiocytes with emperipolesis is noted in all three cases which showed S100 positivity along with diffuse strong nuclear Cyclin D1 positivity. Case 2 and 3 showed prominent sclerotic areas. Predominant plasma cell infiltration is seen in Case 1 while case 2 and 3 showed predominant neutrophil infiltration.
All three patients were treated with surgery and case 1 was initially treated with steroids. To date all three patients do not show evidence of extraoeesous RDD.
Conclusion: RDD should be considered as a differential diagnosis in bone lesions with inflammatory/histiocytic infiltrate or with fibrosis. Prominent stromal fibrosis in extranodal RDD can lead to misdiagnosis. Osteomyelitis, Langerhan cell histiocytosis and Erdhein Chester are differential diagnosis which cannot be reliably differentiated with S100. Therefore, Cyclin D1 is a useful marker in RDD.

E-PS-12-002
Primary cutaneous peripheral T-cell lymphoma with follicular helper T-cell phenotype: an indolent phase of a systemic disease?
A. Molina-Alvarez[1], N. Planella-Fontanillas[2], C. Lome-Maldonado[1], A. Pazmiño-Arias[1], D. Lopez-Segura[1], A. Herrera-Galera[1], F. David[1], F. Gallardo[2], R.M. Pujol[2], L. Colomo[1]
[1]Hospital del Mar, Pathology Department, Barcelona, Spain, [2]Hospital del Mar, Dermatology Department, Barcelona, Spain

Background & Objectives: Primary cutaneous peripheral T-cell lymphoma with T-follicular helper cell phenotype (pcPTCL-TFH) is uncommon, and was proposed as a lymphoma subtype (M. Battistella, Arch Dermatol 2012). It's characterised by persistent skin disease without nodal involvement, although circulating cells and bone marrow involvement can occur. Recently, targeted mutational analyses have revealed overlapping profiles with primary nodal peripheral T-cell lymphoma with a T-follicular helper cell phenotype (nPTCL-TFH), raising questions about the classification of these cases.
Methods: We present a case of pcPTCL-TFH with overlapping genetic features and peripheral blood involvement, characteristic of nPTCL-TFH.
Results: An otherwise healthy 82-year-old woman presented with asymptomatic erythematous papulo-nodular lesions on extremities and face, showing an autoinvolutive and recurrent course for weeks. No constitutional syndrome, lymphadenopathies or visceromegaly were present. Histopathology revealed an atypical lymphohistiocytic infiltrate in the mid and deep dermis with granulomatous features, paired with an atypical lymphoid population of medium-sized cells with monocytoid appearance and plasma cells aggregates. Immunohistochemical studies showed a predominant T-cell component with TFH phenotype closely related to cellular aggregates expressing B-cell markers. Monoclonal expansions were confirmed for both the B (FR1/FR2/FR3) and T (TCRγ/TCRβ) cell components. The p.G17V mutation in the *RHOA* gene was also detected. Complete staging studies, including bone marrow biopsy, showed no nodal or visceral involvement. The diagnosis of PTCL-TFH with cutaneous involvement was made. NGS studies confirmed the same *RHOA* mutation an identified 3 *TET2* mutations and a *DNMT3A* mutation. A minimal population (0.11%) of atypical T-cells with surface CD3 loss and CD4+/PD1+/CD200+ in peripheral blood was detected. The patient was treated with CVP (cyclophosphamide, vincristine and prednisone) scheme, with no response, being alive with disease limited to the skin after 24 months of follow-up.
Conclusion: The present case raises the questions of how to classify and manage such lymphomas according to the current classifications and therapeutic tools.

E-PS-12-003
Littoral cell angioma: a surprising tumour of spleen
B. Işik[1], A. Kilitci[1]
[1]Düzce University, Pathology, Düzce, Turkey

Background & Objectives: Littoral cell angioma (LCA) is a rare, benign vascular neoplasm unique to the spleen, characterized by the proliferation of vascular channels exhibiting a hybrid endothelial-histiocytic phenotype. It is often discovered incidentally. This report presents a case of LCA and highlights its diagnostic challenges.
Methods: A 50-year-old male with a past history of right calf pain and a previously identified popliteal lymph node enlargement on MRI and ultrasound presented without current complaints. Subsequent MRI revealed a 45x36 mm splenic mass exhibiting no elevated FDG uptake on PET/CT.
Results: Macroscopic examination of the enlarged spleen (160 mm in diameter) revealed a solitary, well-circumscribed, blackish-brown lesion measuring 7.5×7×6.5 cm. The lesion displayed a spongy, haemorrhagic, and encapsulated appearance on cross-section. Microscopically, the lesion was located in the red pulp and comprised anastomosing, blood-filled vascular channels resembling hypertrophic splenic sinuses. These channels were lined by a single layer of plump or elongated endothelial cells with abundant eosinophilic cytoplasm, lacking cellular atypia or necrosis, and no mitotic figures were observed. Immunohistochemical analysis demonstrated positivity for CD31, CD68, and Langerin, and negativity for CD34, CD8, SMA, and HHV-8. The Ki-67 proliferation index was low. Finally, the diagnosis of LCA was made.
Conclusion: The differential diagnosis of LCA includes hemangiomatosis, hamartoma, angiosarcoma, lymphoma, sarcoidosis, splenic cyst, inflammatory pseudotumor, sclerosing angiomatoid nodular transformation, and metastasis. In this case, the microscopic features of the tumour, characterized by monolayer-lined vascular channels with plump, cuboidal or elongated cells lacking atypia, necrosis, or mitotic figures, along with the immunohistochemical profile (CD31+, CD68+, Langerin+), supported the diagnosis of LCA. Pathologists should consider rare splenic tumours and integrate macroscopic, histomorphologic, and immunohistochemical findings with clinicoradiologic data for accurate diagnosis.

E-PS-12-004
Light chain deposition disease: a series of diagnostically challenging cases
K. Boulogeorgou[1], C. Topalidis[1], P. Hytiroglou[1], T. Koletsa[1]

[1]AHEPA University Hospital, Aristotle University of Thessaloniki, Departement of Pathology, Thessaloniki, Greece

Background & Objectives: Light chain deposition disease (LCDD) constitutes a rare disease defined by abnormal deposition of non-amyloid monoclonal chains in organs and tissues leading to their dysfunction. Despite the well-established renal involvement, reports of extrarenal manifestations are scarce. We present 3 cases of LCDD diagnosed at unexpected sites, aiming to underscore the need for clinicopathological vigilance.
Methods: We retrieved three cases of extrarenal LCDD from the archives of our Pathology Department over a period of 5 years (2020-2024) and reviewed the histochemical and immunohistochemical stained sections.
Results: Among 3 patients, 2 were female and 1 male. The male patient was a 65-year-old with known steatohepatitis, who underwent liver biopsy due to increased liver stiffness on elastography. The second case was a 46-year-old female with multiple subcutaneous nodules and papules and clinical suspicion of systemic autoimmune disease, who underwent skin punch biopsies. Finally, a female patient of 62 presented with dyspnea; PET/CT revealed a hypermetabolic nodule in the left upper lobe. Lung segmentectomy was performed. Histological examination in all cases revealed amorphous deposits, positive on PAS and Masson trichrome stains, and negative for Congo red stain. These were accompanied by histiocytic, lymphocytic and plasma cell infiltrates. Immunoreactivity to kappa light chains was established in two cases, whereas lambda depositions were identified in the case involving skin. Diagnosis of LCDD was set. No evidence of renal involvement was present. Bone-marrow biopsy was conducted in all patients, and plasma cell neoplasm was diagnosed in two.
Conclusion: LCDD is an underdiagnosed entity, usually unsuspected by clinicians, especially when it concerns unusual sites. Clinical and laboratory findings may be nonspecific, demanding a high level of awareness on part of the pathologists. Furthermore, the fact that LCDD may be the first manifestation of a plasma cell neoplasm or other lymphoproliferative disease emphasizes the crucial need for early diagnosis and treatment.

E-PS-12-005
Paediatric-type follicular lymphoma: case report
M.-Ş. Preda[1], G.B. Molnár[1], M.I. Chinceșan[2], E. Horváth[1]
[1]University of Medicine, Pharmacy, Science and Technology George Emil Palade of Târgu Mureș, Pathology, Târgu Mureș, Romania, [2]University of Medicine, Pharmacy, Science and Technology George Emil Palade of Târgu Mureș, Târgu Mureș, Romania

Background & Objectives: Paediatric-type follicular lymphoma (PTLF) is a relatively rare neoplasm, first recognized as a distinct entity in the 2016 WHO classification. Despite its characteristic high-grade histology, it differs from that found in adults due to its clinical behaviour and excellent prognosis.
Methods: We report a case of PTFL diagnosed in a 5-year-old male patient with no significant medical history and B symptoms who was admitted to the Oro-maxillo-facial surgery department with a slowly growing and apparently unique lymph node developed in the right submandibular region. All preoperative laboratory tests were normal. The removed lymph node measuring 2.5 cm × 1.5 cm × 1.5 cm was sent for histopathology.
Results: The lymph node was completely processed, and microscopically, under low-power microscope, the lymph node structure was partially destroyed, replaced by follicles of variable size with regular contour, packed, closely arranged with attenuated/disappeared mantle zone. At high magnification, the follicles were composed of centrocyte-like cells mixed with centroblasts and with persistence of a starry sky appearance. These cells expressed CD20, PAX5, CD79a and CD10, BCL6, with a high Ki-67 index (60-70%). Bcl-2 and MUM1 were negative. CD23 and CD21 highlight the dendritic follicular cell network, IgD confirms attenuation of the mantle zone. The diagnosis of PTCL was developed based on clinical and paraclinical data, i.e. nodule architecture and immunophenotype of cells of follicular structures. For therapeutic management, pET-CT examination was performed, which revealed multiple lymph nodes less than 2 cm located laterocervically and submandibularly, without compression phenomena on surrounding structures.
Conclusion: Based on the above imaging and pathologic findings, the diagnosis of PTFL in this case requires molecular confirmation by immunoglobulin (IG) gene rearrangement. To avoid misdiagnosis, differential diagnosis plays a crucial role in clinical practice.

E-PS-12-006
Idiopathic multicentric Castleman disease in a tertiary hospital: a diagnostic challenge
R. Mora[1], A.M. Montaña Ramirez[1], A. Lopez Prieto[1], A. Gutierrez Domingo[1]
[1]University Hospital Virgen Macarena, Pathology, Seville, Spain

Background & Objectives: Multicentric Castleman disease (MCD) was first described in 1978 and is classified into subgroups based on aetiology: human herpesvirus 8 (HHV8)-associated, POEMS syndrome-associated, or idiopathic. Clinically, it is characterized by generalized lymphadenopathy, hepatosplenomegaly, renal dysfunction, and laboratory abnormalities such as hypergammaglobulinemia and elevated C-reactive protein.
Methods: This is a retrospective observational study of cases diagnosed as idiopathic multicentric Castleman disease (iMCD) by the Pathology Department of our institution between 2014 and 2024. The study exclusively included lymph node excision samples, excluding fine-needle biopsy specimens.
Results: Initially, nine cases of iMCD were identified; however, two were excluded after completing the clinical assessment, as they were found to be HHV8-associated in HIV-positive patients. The remaining seven cases included four males and three females, with a median age of 59 years. All cases met the major histopathological diagnostic criteria established by the NCCN Clinical Practice Guidelines in Oncology. Histopathological analysis revealed that 57.1% (4 cases) corresponded to the plasmacytic subtype, 28.6% (2 cases) to the hyaline-vascular subtype, and 14.3% (1 case) presented a mixed pattern.
Among all cases, six patients (85.7%) received anti-IL6 therapy with siltuximab. The only untreated patient died 42 days after diagnosis. Among the treated patients, one died (16.7% of treated cases), with the number of treatment cycles ranging from 6 to 52. In three cases, treatment was discontinued due to poor tolerance, two of whom had the hyaline-vascular histopathological subtype. Additionally, one patient showed no response after four treatment cycles and was subsequently diagnosed with progression to low-grade follicular lymphoma upon histological re-evaluation.
Conclusion: iMCD is a rare entity, often underdiagnosed due to its morphological variability and heterogeneous clinical presentation. Despite its uncertain aetiology, treatment with anti-IL6 siltuximab and the establishment of standardized histopathological diagnostic criteria have contributed to improved diagnostic accuracy and, consequently, better prognosis.

E-PS-12-007
Onions, Lollipops and HHV8: a recipe for Castleman disease, with a side of Kaposi Sarcoma in a HIV-negative patient
A.-M. Vasile[1], R.-M. Closca[1,2], A.-R. Bucur[1,2], A. Armega-Anghelescu[1,2], M. Iordache[3], F. Zara[1,2]
[1]Emergency City Hospital, Department of Pathology, Timisoara, Romania, [2]Victor Babes University of Medicine and Pharmacy,

Department of Microscopic Morphology, Timisoara, Romania, [3]Victor Babes University of Medicine and Pharmacy, Department of Haematology, Timisoara, Romania

Background & Objectives: Human Herpesvirus 8-associated Multicentric Castleman disease is a rare lymphoproliferative disorder characterized by recurrent episodes of systemic inflammation. Pathogenesis is driven by dysregulated cytokine activity, particularly human and viral interleukin 6. Additionally, these individuals have a significantly increased risk of developing concurrent Kaposi Sarcoma. Definitive diagnosis requires histopathologic confirmation through lymph node biopsy.
Methods: The patient was admitted to the Haematology Department of the Emergency City Hospital in Timisoara, Romania, presenting with fever, night sweats, palpitations, weight loss, and general deterioration. The symptoms had appeared approximately three months prior, with gradual progression. Clinical examination revealed bilateral lymphadenopathy in the cervical and inguinal regions. Laboratory tests showed elevated C-reactive protein, elevated IL-6, pancytopenia, hypergammaglobulinemia, hypoalbuminemia, hyponatremia, and HIV negative serology. CT imaging revealed generalized lymphadenopathy and splenomegaly. Further excisional biopsy of the inguinal lymphadenopathy was performed.
Results: Microscopic examination using Haematoxylin-eosin staining revealed a spindle cell proliferation with slit-like vascular spaces and moderate atypia. The remaining lymphoid tissue presented atrophic germinal centres, onion ring and lollipop follicular architecture, consisting of hyalinized penetrating vessels and thickened mantle zones. Additionally, hyperplastic follicles with plasma cell aggregates were observed. Immunohistochemical staining with the following antibodies: anti-HHV8, anti-CD34, anti-CD31, anti-D2-40, anti-Ki-67 was performed and the diagnosis of Human Herpesvirus 8 associated multicentric Castleman disease, concomitant with Kaposi sarcoma was established. The patient is currently undergoing oncological treatment.
Conclusion: Human Herpesvirus 8-associated Multicentric Castleman Disease is predominantly observed in HIV-positive patients, but there is evidence of its occurrence in HIV-negative individuals, presenting distinct epidemiological and pathological characteristics. Early and precise diagnosis is essential, as the disease can progress rapidly and may lead to severe or fatal outcomes.

E-PS-12-008
Lactylation in B-cell lymphomas: a novel epigenetic signature?
E. Ozsagir[1], N. Ozsan[1], M. Hekimgil[1], D. Demir[1]
[1]Ege University Faculty of Medicine, Pathology, Izmir, Turkey

Background & Objectives: Lactylation, a newly identified post-translational modification, introduces a novel layer to epigenetic regulation. Cancer cells often undergo metabolic reprogramming, like the Warburg effect, producing excess lactate. Lactate-driven lactylation can alter gene expression, promoting tumour growth. Here, we investigate lactylation-related genetic alterations in B-cell lymphomas.
Methods: Next-generation sequencing data from cBioPortal (5,245 samples, 5,139 patients across 17 studies) were analysed, covering both low-grade and aggressive B-cell lymphomas. We performed a literature review identifying 57 lactylation-related genes. After filtering for somatic mutations and queried gene profiles, we included 3,779 samples (3,752 patients). Further selection incorporating copy-number alterations (CNA) resulted in 170 samples (128 patients). Patients were grouped by genetic alterations; survival analysis (Kaplan-Meier) and Chi-square tests compared altered versus unaltered groups.
Results: *CREBBP* (10%), *SF3B1* (7%), and *EP300* (4%) were the most frequently altered genes. Including CNAs revealed additional alterations in *HDAC2, ABCF1, ATAD3A, LARS2,ALDOB*, and *H2AZ2* (3–4%), while SF3B1 alterations were 1.6%. Genetic alterations of lactylation-related genes across B-cell lymphomas, were detected in more than 40% of high-grade B-cell lymphomas, follicular lymphoma, and germinal centre B-cell-type diffuse large B-cell lymphoma (GCB-DLBCL); approximately 20% in activated B-cell-type DLBCL (ABC-DLBCL), Burkitt lymphoma, primary central nervous system DLBCL, chronic lymphocytic leukaemia (CLL), and marginal zone lymphoma; and less than 10% in mantle cell lymphoma. *CREBBP* and *SF3B1* mutations were mutually exclusive, while *EP300* alterations co-occurred with *CREBBP*. Initial survival analysis showed a non-significant benefit for lactylation-related alterations in aggressive lymphomas. However, the integration of mutations with CNAs revealed a statistically significant survival advantage in patients with alterations ($p=0.003$).
Conclusion: Our findings underscore lactylation's emerging role in regulating cancer-associated gene expression, potentially surpassing traditional DNA methylation. Integrating mutation and CNA analyses was essential for identifying clinically relevant alterations, especially in GCB-derived lymphomas. This study positions lactylation as a promising epigenetic-driver and therapeutic target in B-cell lymphomas.

E-PS-12-009
Intravascular lymphoma: a case series about a silent killer
H. Galindo-Guzmán[1], M. Arias Duart[1], M.A. Salcedo Armijos[1], B.B. Ardaya López[1], V. Parra Blanco[1], F.J. Menarguez Palanca[1], F.J. Diaz Crespo[1]
[1]Hospital General Universitario Gregorio Marañón, Pathology, Madrid, Spain

Background & Objectives: Intravascular lymphoma is a rare extranodal non-Hodgkin lymphoma with a poor prognosis. Its diagnosis is challenging due to its clinical presentation. Most reported cases are B-cell lymphomas, although T-cell variants have also been described. The estimated incidence is approximately 0.09 cases per million people. This study presents a clinicopathological review of nine patients diagnosed at our hospital over the past 20 years.
Methods: We conducted a retrospective review of patients diagnosed with intravascular lymphoma by biopsy or autopsy between 2004 and 2022. Nine patients met the inclusion criteria, and their clinical data, biopsies, immunohistochemical studies, and molecular analyses were reviewed.
Results: A biopsy confirmed the diagnosis in 78% of cases, while 22% were diagnosed postmortem. Fever of unknown origin (FUO) was the most common presentation (78%), followed by skin lesions (22%). All cases showed intravascular infiltration of large lymphocytes with vesicular nuclei, prominent nucleoli, and a discohesive growth pattern. Anaplastic and immunoblastic morphologies were observed in 11% each, while 78% had conventional morphology. Among FUO cases, 78% were classified as the classical subtype, and 22% as the cutaneous subtype.
Immunophenotyping showed that 78% expressed B-cell markers (CD20, CD79a), while 22% had a T-cell phenotype (CD30+, ALK-). Among B-cell cases, 40% were CD5+ and 60% CD5-. Germinal centre and non-germinal centre phenotypes were found in 43% and 57% of cases, respectively. Clonality studies (IGH and TCR) were performed in 44% of patients, detecting clonality in 22%.
All living patients received treatment; however, 72% died due to disease-related complications, while 28% remain alive.
Conclusion: Intravascular lymphoma is an aggressive neoplasm with an exclusive intravascular distribution, predominantly exhibiting a B-cell phenotype. It primarily affects elderly patients without gender predisposition. Its rarity and nonspecific clinical presentation make diagnosis complex, requiring close clinicopathological correlation.

E-PS-12-012

Sclerosing angiomatoid nodular transformation of spleen: case report in cancer staging

J. Bonfitto[1], M. Bonfitto[2], N. Gonçalves[1], L. Freitas[1], J. Loureiro[3], M. Ferreira[3], E. Ataide[4], S. Perales[4]
[1]State University of Campinas, Laboratório de Anatomia Patológica - Hospital das Clínicas da Unicamp (HC-UNICAMP), Campinas, Brazil, [2]State University of Campinas, Laboratório de Anatomia Patológica - Gastrocentro, Campinas, Brazil, [3]State University of Campinas, Hospital das Clínicas da Unicamp (HC-UNICAMP), Campinas, Brazil, [4]State University of Campinas, Departamento de Gastrocirurgia - Hospital das Clínicas da Unicamp (HC-UNICAMP), Campinas, Brazil

Background & Objectives: Sclerosing angiomatoid nodular transformation (SANT) is a rare, benign vascular lesion of the spleen. It reveals itself morphologically and phenotypically as a nodular red pulp vascular proliferation surrounded by fibrous tissue.
The aim of this study is to report a case diagnosed in the context of a cancer staging process.
Methods: A 59-year-old female patient who underwent caudal pancreatectomy for a neuroendocrine tumour was admitted suspected of having splenic metastasis, eligible for total splenectomy.
Results: Gross findings revealed a firm, whitish subcapsular nodular spleen lesion measuring 1.5cm and demonstrating a stellate central scar. Histopathological examination showed angiomatoid nodules composed of slit-like, ectatic, and irregularly shaped vascular channels, surrounded by concentric layers of collagen and fibrinoid material, with red blood cells within and outside the lumina. The lesion centre was essentially fibrotic. Immunohistochemical analysis revealed a population of phenotypically variable blood vessels, including sinusoids (CD31 and CD8 positive), capillaries (CD31 and CD34 positive) and veins (CD31 positive).
Conclusion: According to the World Health Organization Classification of Tumours (5th ed.), SANT is often asymptomatic and mostly detected incidentally by imaging studies in middle-aged adults. The definition is a circumscribed lesion composed of multiple angiomatoid nodules containing blood vessels as seen in splenic red pulp, with intervening fibrosclerotic stroma. It has been suggested for the pathogenesis that a disruption of the local microcirculation could be caused by a fibrotic stromal proliferation, leading to transformation of red pulp into angiomatoid nodules. Molecular studies support either its reactive nature or the presence of a benign neoplasm. Although IgG4-related disease and EBV infection have been previously linked to this entity, they are not supported by current studies.
Since knowledge is limited, additional effort could be made to understand its nature and whether reactive or neoplastic processes are related to its origin.

Funding: Educorp - State University of Campinas

Thyroid MALT Lymphoma with Extreme Plasmacytic Differentiation and Dense Fibrosis Mimicking IgG4-Related Disease

X.C.A. Goh[1], M.L. Oon[1]
[1]National University Hospital, Department of Pathology, Singapore, Singapore

Background & Objectives: Extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue (MALT lymphoma) of the thyroid typically arises in the setting of chronic lymphocytic thyroiditis. This hematolymphoid neoplasm can show extensive plasmacytic differentiation. We present a case of thyroid MALT lymphoma with extreme plasmacytic differentiation and unusually dense fibrosis, mimicking IgG4-related disease of the thyroid gland. We discuss the morphologic features and immunohistochemical workup of this uncommon presentation of MALT lymphoma.
Methods: A 59-year-old female with longstanding Hashimoto's thyroiditis on thyroxine presented with a diffuse goiter and compressive symptoms. She underwent a total thyroidectomy, which revealed a large, multinodular thyroid.
Results: Gross examination of the thyroid gland revealed a firm, homogenously pale tan-whitish cut surface with vague lobularity. Histology revealed diffuse replacement of thyroid parenchyma by dense fibrosis and a dense plasma cell infiltrate. The degree of fibrosis was marked in some areas, mimicking IgG4-related disease of the thyroid gland. Residual atrophic thyroid follicles and focal lymphoepithelial lesions were identified. Despite the morphologic resemblance to IgG4-related disease of the thyroid gland, immunohistochemistry for IgG and IgG4 showed no increased IgG4-positive plasma cells or IgG4:IgG ratio. In-situ hybridization for kappa and lambda light chains demonstrated a monotypic, kappa-restricted plasma cell proliferation. Lymph nodes from both central neck compartments also exhibited kappa-restricted plasma cell aggregates, supporting disease involvement. Clinical, biochemical and radiological findings did not support multiple myeloma or plasmacytoma. The final diagnosis was thyroid MALT lymphoma with extensive plasmacytic differentiation.
Conclusion: We report an uncommon histomorphological appearance of thyroid MALT lymphoma mimicking IgG4-related disease of the thyroid gland. Judicious use of ancillary investigations including in-situ hybridization for immunoglobulin light chains is crucial to further interrogate thyroid specimens with dense plasmacytic infiltrate. Other lymphomas with plasmacytic differentiation should also be considered. Accurate diagnosis and classification are essential for treatment and prognostication.

E-PS-12-015

Composite nodal T-follicular helper cell lymphoma and marginal zone lymphoma – a case report of a rare disease

A. Tan Garcia[1], C.L. Cheng[1]
[1]Singapore General Hospital, Anatomical Pathology Department, Singapore, Singapore

Background & Objectives: Nodal T-follicular helper cell lymphoma (nTFHL) is a group of mature T-cell neoplasms comprising angioimmunoblastic-type, follicular-type and not otherwise specified (NOS), with their normal counterpart being TFH cells within lymphoid follicles. Generalised lymphadenopathy is the most common clinical presentation, but myriad features related to immune dysregulation can be seen. Histologically, this is reflected by the frequent presence of a prominent B-cell lymphoproliferative response and reactivation of Epstein-Barr Virus (EBV) within large B-immunoblasts. While the association between nTFHL and B-cell neoplasms has been widely documented, composite marginal zone lymphoma (MZL) occurring in nTFHL is rare. Here, we present a case of an 82-year-old female with metastatic lung adenocarcinoma who developed a right elbow soft tissue mass which was diagnosed as extranodal MZL. Following localised radiotherapy with radiological resolution of disease, she then developed multiple subcutaneous masses in the left arm and right thigh, including new hilar and lower paratracheal lymphadenopathy. Excision of a left arm lesion revealed a diagnosis of composite MZL and nTFHL-NOS. The mechanistic association between nTFHL and B-lymphoproliferations and the related diagnostic challenges are discussed.
Methods: N/A
Results: N/A
Conclusion: N/A

Critical analysis and summary of the study on 10-colour flow cytometry in Multiple Myeloma (MM)

M. Zhu[1], P. Feng[2]

[1]The First Affiliated Hospital of Soochow University, Jiangsu Institute of Haematology, Key Laboratory of Thrombosis and Hemostasis of Ministry of Health, Suzhou, China, [2]The Second Affiliated Hospital of Soochow University, Clinical Laboratory, Suzhou, China

Background & Objectives: This study aimed to evaluate the clinical utility of **10-colour flow cytometry** in identifying immunophenotypic aberrations in clonal plasma cells (cPCs) of multiple myeloma (MM) patients, with a focus on diagnostic and therapeutic monitoring applications.
Methods:

- **Gating Strategy:** Plasma cells were isolated using CD45/SSC (low CD45, moderate side scatter) and CD38/CD138 (high expression) markers.
- **Markers Analyzed:** Surface antigens (CD19, CD56, CD117, CD81, CD27) and cytoplasmic immunoglobulin light chains (cKappa/cLambda) were assessed in **118 MM patients** (pre- and post-treatment) and **40 healthy controls**.

Results: A clonal plasma cell population was identified in **99.2% of MM patients**, demonstrating high sensitivity for malignancy detection.**Immunophenotypic Aberrations in MM vs. Normal Plasma Cells:CD19**: Rarely expressed in MM (2.4% positive) compared to normal plasma cells.**CD56**: Overexpressed in **87.6% of MM cases** (aberrant marker of malignancy).**CD81**: Heterogeneous expression (58.3% ±).**CD117 and CD27**: Low positivity rates (17.6% and 22.6%, respectively), distinct from normal plasma cell profiles.

Conclusion: 10-colour flow cytometry effectively identifies cPCs, distinguishes malignant from normal plasma cells, and provides valuable insights for MM diagnosis and treatment monitoring.

E-PS-12-017
Mantle cell lymphoma in a 14-year-old patient with Nijmegen breakage syndrome: a rare case report
L. Kašpar[1], V. Campr[1], J. Zámečník[1]
[1]Motol University Hospital, Department of Pathology and Molecular Medicine, 2nd Faculty of Medicine, Charles University and Motol University Hospital, Prague, Czech Republic

Background & Objectives: Mantle cell lymphoma is a subtype of B-cell lymphoma that is relatively common in adults but extremely rare in the paediatric population. Nijmegen breakage syndrome is a genetic disorder associated with impaired DNA repair and a predisposition to malignancies, particularly lymphoproliferative diseases. We present a unique case of a paediatric Nijmegen breakage syndrome patient who developed two distinct lymphoproliferative disorders in the lungs: lymphomatoid granulomatosis, a rare but known complication in immunodeficient individuals, and mantle cell lymphoma, an entity almost unheard of in children. By presenting this case, we aim to highlight the possibility of MCL in the paediatric population and share our insights into the diagnostic process of such a rare case.
Methods: A 14-year-old female with a known diagnosis of Nijmegen breakage syndrome presented with cough and dyspnea. Chest X-ray revealed bilateral infiltrates. After excluding infectious and other non-malignant causes, a biopsy of the pulmonary lesions was performed. The final diagnosis was established through histopathological examination using H&E and Giemsa stains, a panel of immunohistochemical markers, fluorescence in situ hybridization, and molecular pathology techniques.
Results: Histopathological examination revealed two distinct morphological patterns: dispersed large cells (CD30+, CD20+, LMP+) in a T-cell-rich background with blood vessel wall infiltration, and dense infiltrates of small lymphocytes (CD20+, CD5+, cyclin D1+). Clonality of the lymphoid population was confirmed by multiplex PCR. The diagnosis of mantle cell lymphoma was further supported by fluorescence in situ hybridization, which detected the t(11;14)(q13;q32) IGH/CCND1 translocation. Next-generation sequencing using Archer VariantPlex and FusionPlex Lymphoma panels revealed no additional genetic abnormalities in the tumour.
Conclusion: The final diagnosis was a coexistence of mantle cell lymphoma and lymphomatoid granulomatosis in a paediatric patient with Nijmegen Breakage Syndrome. This case highlights the complexity of lymphoproliferative disorders in immunodeficient patients and reports the exceptionally rare occurrence of mantle cell lymphoma in a child.

E-PS-12-018
Myelofibrosis-induced erythropoietin-resistant anaemia due to renal osteodystrophy
Z. Koca[1], E. Karakuş[1]
[1]Ankara Bilkent City Hospital, Pathology, Ankara, Turkey

Background & Objectives: We present a case of myelofibrosis secondary to renal osteodystrophy caused by primary hyperparathyroidism (PHPT), a rare clinical entity. The pathogenesis involves prolonged stimulation of bone marrow stromal cells by elevated parathyroid hormone (PTH) levels, resulting in fibrosis and abnormal bone remodelling. PHPT, characterized by elevated PTH levels due to parathyroid adenoma or hyperplasia, can lead to haematological abnormalities such as pancytopenia, anaemia, and splenomegaly through collagen deposition in the bone marrow. Early detection and treatment are critical, as myelofibrosis may be reversible in some cases.
Methods: The patient's clinical history, laboratory findings, and imaging studies were systematically analysed. Myelofibrosis was confirmed via bone marrow biopsy. Imaging modalities, including MRI and CT, were utilized to identify the underlying cause of PHPT.
Results: A 19-year-old woman with end-stage renal disease on hemodialysis for 6 years presented with erythropoietin-resistant anaemia. Laboratory analyses revealed hypercalcemia and significantly elevated PTH levels. Imaging confirmed a parathyroid adenoma as the cause of PHPT. Parathyroidectomy resulted in significant improvement in laboratory parameters; however, the bone marrow fibrosis persisted during follow-up. Bone marrow biopsy revealed hypo-grade 3 nonuniform, patchy peritrabecular myelofibrosis with increased osteoclastic and osteoblastic activity. In the context of hyperparathyroidism resulting from long-standing chronic kidney disease and the absence of other underlying causes, the bone marrow findings were consistent with non-malignant myelofibrosis secondary to hyperparathyroidism and renal osteodystrophy.
Conclusion: Myelofibrosis secondary to PHPT is rarely documented, particularly in paediatric populations. This case highlights that PHPT can cause haematological complications, including erythropoietin-resistant anaemia, even in early life stages. Early detection and treatment are essential, as myelofibrosis may be reversible. PHPT should be considered in the differential diagnosis of myelofibrosis, especially in paediatric cases.

E-PS-12-019
Myeloid sarcoma, a diagnostic challenge: the experience of a tertiary hospital
I. Fernández de la Prieta[1], N. Arbide del Río[1], G. Cancho Galán[1], L. Aguirrezabal Marcotegui[1], R.I. Alvarado Cuenca[1], P. Calvo Torio[1], I. Menéndez Lora[1], A. Gaafar[1]
[1]Basurto University Hospital, Bilbao, Spain

Background & Objectives: Myeloid sarcoma (MS) is a rare tumour with a highly variable immunophenotypic profile. Therefore, its differential diagnosis is wide and it is often misdiagnosed, especially in cases without known history of acute myeloid leukaemia (AML). The

aim of this study is to analyse these diagnostic difficulties, revising our collection of cases.
Methods: In the last ten years, 8 cases of MS have been diagnosed in our department, one of them without any available material left. A wide panel of immunohistochemistry was performed for all cases. Finally, clinical, histological and immunophenotypic characteristics have been compiled.
Results: In our case series, skin is the most often involved organ (20%), followed by lymphoid tissues, soft tissue, thyroid and gastrointestinal tract. Histologically, almost all cases showed diffuse architecture effacement by a dense proliferation of intermediate sized cells with irregular nuclear contours, occasional nucleoli and atypical mitoses. Immunohistochemically, all cases were positive for CD45, CD43, CD68, and Lysozyme. Almost all cases were positive for CD4 (87,5%), CD163 (85%), Myeloperoxidase (62,5%), and CD117 (62,5%). Meanwhile, CD34, CD7, CD56, and CD15 were less commonly positive (37,5%). Only one case showed co-expression of TdT and CD38. The rest of antibodies (CD20, CD79a, PAX-5, CD3, and CD8) were always negative. Clinically, only one of the eight cases had a prior diagnosis of AML.
Conclusion: MS is a rare disease with heterogeneous immunohistochemical characteristics. In our series, most of the cases lacked a previous diagnosis of AML, making the diagnosis even more challenging. Therefore, a broad differential diagnosis is essential. Our results highlight the importance of a wide and adequate immunohistochemistry study, which can be helpful in ruling out other entities, and reduce misdiagnoses caused by aberrant expression of B, T or NK-cell markers.

E-PS-12-020
Revisiting the classification of histiocytic and dendritic cell neoplasms: a retrospective review based on the 2022 WHO update
M. Sable[1], P. Mishra[1], S. Purkait[1], A. JN[1]
[1]All India Institute of Medical Sciences, Pathology & Lab Medicine, Bhubaneswar, India

Background & Objectives: Histiocytic and dendritic cell neoplasms represent a distinct and diverse group of tumours originating from monocytic or dendritic cell precursors. The WHO5 Classification of Hematolymphoid Tumours introduces a hierarchical classification structure. The aim of this study is to revisit the histiocytic and dendritic cell neoplasms diagnosed at a tertiary care centre to reclassify according to the most recent (2022) WHO classification.
Methods: We reviewed all hematolymphoid malignancies diagnosed according to the 4th edition of the WHO from 2015 to 2023 at our centre. The cases were then reclassified using the 2022 update of the WHO classification. Demographic data, including the site of involvement (nodal vs extra-nodal) was collected.
Results: Forty-nine (4.08%) were initially diagnosed as histiocytic/dendritic cell neoplasms according to the 4th edition of the WHO classification. Upon reclassification, these cases were divided into two groups: histiocytic/dendritic neoplasms (Group 1, n=38, 77.55%) and stroma-derived mesenchymal tumours (Group 2, n=11, 22.44%). Group 1 included Langerhans Cell Histiocytosis (LCH, n=27), Rosai-Dorfman Disease (RDD, n=6), Xanthogranuloma (n=3), Histiocytic Sarcoma (n=2), Plasmacytoid Dendritic Cell Neoplasm (n=1). Group 2 consisted of stroma-derived neoplasms of lymphoid tissues: Follicular Dendritic Cell Sarcoma (FDCS, n=8), Cytokeratin-positive Interstitial Reticulum Cell Sarcoma (CIRCS, n=2), Littoral Cell Angioma (n=1).
A majority of cases in both groups were extra-nodal (Group 1: 72%, Group 2: 80%). All cases in Group 2 were adult patients (mean-38 years), while most cases in Group 1 were paediatric (63.15%, mean-15 years). All Group 2 cases were male. Tumours involving the skin (n=13) and bone (n=6) were all classified in Group 1, while all gastrointestinal tumours (n=4) were classified in Group 2. Both CIRCS cases involved the gastrointestinal tract. At nodal site, RDD(n=6), LCH(n=4), and FDCS(n=2) were diagnosed.
Conclusion: Histiocytic and dendritic cell neoplasms represent a distinct and diverse group of tumours of extranodal site.

E-PS-12-021
Systemic chronic active Epstein-Barr virus disease: three case report
B.S. Pacheco Martínez[1], M.D.C. Martinez Roca[1], A. Pinedo Estalayo[1], V. Cancer Huerva[1], M.G. Canchola Aguilar[1], B. Fuertes Negro[1], A. Armengou Arxe[1], C.A. Vasquez Dongo[1], H. Iliev Iliev[1], F.X. Pozo Ariza[1], R. Ortiz Duran[1], C. Melendez Muñoz[1]
[1]Hospital Universitari de Girona Doctor Josep Trueta, Departmen of Pathology, Girona, Spain

Background & Objectives: Chronic active Epstein–Barr virus disease (CAEBV) is a rare condition characterized by persistent systemic inflammation and clonal proliferation of EBV-infected T or NK cells. It predominantly affects East Asian and indigenous Central and South American populations. Diagnosis requires four criteria to be met: mononucleosis-like symptoms lasting over three months, EBV-DNA viral load >10,000 IU/mL, EBV-infected T/NK-cell infiltration in peripheral blood or tissues, and exclusion of known immunodeficiency, autoimmune disorders or malignancies.
Methods: A retrospective review of three CAEBV cases analysed age, sex, origin, affected organs, EBV copy number, T/NK lymphocyte infection, progression to lymphoma/leukaemia, and survival time.
Results: The median age was 22 years. All patients were men, one from Africa and two from South America. Liver involvement was present in all, while two had bone marrow and lung involvement. One patient had an end-stage chronic kidney disease, which made the therapeutic approach very challenging. This patient suffered from a digestive bleeding and died. Autopsy also revealed multiple organ involvement by CD3- expressing lymphocytes along with EBV RNAs detected by in situ hybridization. Another patient developed EBV-associated T/NK-cell lymphoma/leukaemia (with ARID1A and STAT3 mutations), and another developed EBV+ T-cell lymphoma (withDDX3X and STAT3 mutations). Interestingly, different mutations of unknownsignificance in SETD2 gene were detected in two cases of CAEBV. The median survival time was 24 months. Allogeneic Stem Cell Transplantation is considered the only curative option; however, none of our patients was able to receive it.
Conclusion: CAEBV, which follows a variable course, often leading to hematologic malignancies, should be suspected in Asian and Central American patients with persistent fever, systemic symptoms, and positive EBV serology. This study underscores the importance of early diagnosis and further research into disease progression and treatment. Untreated, CAEBV disease carries a high mortality rate. However, determining the optimal time to start treatment remains a challenge.

E-PS-12-022
Gaucher's disease-case report
J. Ilić Sabo[1,2], A. El Fara[3,4], I. Perčić[3,4], Ž. Panić[1]
[1]University of Novi Sad, Faculty of Medicine, Department for Histology and Embryology, Novi Sad, Serbia, [2]University Clinical Centre of Vojvodina, Centre for Pathology and Histology, Novi Sad, Serbia, [3]University of Novi Sad, Faculty of Medicine, Department for Internal Medicine, Novi Sad, Serbia, [4]University Clinical Centre of Vojvodina, Clinic for Haematology, Novi Sad, Serbia

Background & Objectives: Gaucher disease is a lysosomal storage disease caused by genetic mutations in GBA gene. The main characteristic is a deficiency of the enzyme ß-glucocerebrosidase. The consequence of the deficit of the enzyme is the accumulation of

glucocerebroside in macrophages which becomes specific cells-Gaucher cells which infiltrate bone marrow, liver, spleen and lymph nodes.
Methods: Histopathological diagnoses imply the detection of Gaucher cells-large lipid-laden macrophages, sized 20-100μm. Cytoplasm is pale, "wrinkled tissue paper" like and nucleus is small eccentrically placed. Diagnosis is confirmed according to clinical symptoms, laboratory findings, bone marrow biopsy and genetic testing.
Results: We have received a mail patient aged 35 years with the clinical symptoms of hepatosplenomegaly, pancytopenia and osteopenia. Bone marrow biopsy reveals clustered and dispersed large macrophages with pale, "wrinkled tissue paper" cytoplasm and small eccentrically placed nucleus, which account about 40-50% of bone marrow cellularity. Immunohistochemistry was positive in CD68, CD163, Lysozome, HLADR, Fascin (week), CD14 (week). The main differential diagnoses in bone marrow consider Niemann-Pick disease, sea-blue histiocytosis, leukaemia or myelodysplastic syndromes. Genetic analysis was positive and indicated to type 1 with the mutation in CYP2D6 gene with phenotypic intermediate metabolizer activity.
Conclusion: The prompt and correct diagnoses is essential considering the treatment for those diseases is a different and for some types of Gaucher disease there is adequate treatment if we start on time.

E-PS-12-023
MALT lymphoma of the dura: a report of two cases with emphasis on histopathological features
A. Canastra[1], D. Gonçalves[1]
[1]CUF Descobertas Hospital, Pathology Department, Lisbon, Portugal

Background & Objectives: Primary dural lymphoma is a rare type of primary central nervous system lymphoma that often mimics meningioma or other dural-based lesions on imaging. Most cases are extranodal marginal zone lymphomas. We report two cases of primary dural MALT lymphoma with distinct histopathological features.
Methods: Two female patients, 60 and 48 years old, presented with neurological symptoms - facial hypoesthesia and upper lip ptosis in the former, and persistent bilateral headache in the latter. MRI imaging revealed dural-based extra-axial lesions, leading to craniotomy followed by surgical resection.
Results: Histopathology in both cases showed a diffuse infiltration of sclerotic meningeal tissue by small lymphoid cells with round to irregular nuclei, some exhibiting monocytic morphology and a subset demonstrating plasmacytic differentiation. There were also some regressive and colonized lymphoid follicles. Immunohistochemistry confirmed CD20 and BCL2 positivity, with CD10, CD5, CD3, CD23, and cyclin D1 negativity; plasma cells with monotypic light chain expression were identified. The first case exhibited scattered intermediate to large atypical cells with vesicular chromatin, not forming sheets, and the proliferation index (Ki-67) varied between 20% and 60% (vs. 10% in the other case). Systemic involvement was ruled out and a diagnosis of MALT lymphoma of the dura was rendered.
Conclusion: MALT lymphoma of the dura may exhibit significant histopathological variability, often posing diagnostic challenges, particularly with diffuse large B-cell lymphoma. While scattered large lymphoid cells may be present, this does not significantly impact prognosis or treatment response. Both patients achieved stable disease following treatment - rituximab plus radiotherapy in the first case and rituximab alone in the latter.

E-PS-12-024
Chronic myeloid leukaemia blast phase with concurrent t(9;22) and inv(16): a rare case of clonal evolution
K.M.M. Bandara[1], V. Mateescu[1]
[1]University of Missouri Kansas City, Pathology, Kansas City, USA

Background & Objectives: Chronic myeloid leukaemia (CML) is characterized by the t(9;22)(q34.1;q11.2) translocation, resulting in the Philadelphia (Ph) chromosome and BCR::ABL1 fusion gene. Progression to blast phase (CML-BP) is often associated with additional cytogenetic abnormalities such as extra Ph chromosome, trisomy 8, isochromosome 17q, or trisomy 19. Rarely, CML-BP acquires aberrations commonly seen in de novo acute myeloid leukaemia (AML), including t(8;21), t(15;17), and inv(16)/t(16;16). The coexistence of Ph and inv(16) in CML is extremely rare, with few reported cases.
Methods: We present a 31-year-old Portuguese-speaking male with no significant past medical history who presented with fever, gastrointestinal symptoms, and massive splenomegaly.
Results: Laboratory studies revealed hyperleukocytosis and thrombocytosis. Peripheral blood flow cytometry demonstrated left-shifted myeloid maturation with 19.4% CD34+ myeloblasts. Bone marrow biopsy showed marked hypercellularity (98%) with granulocytic hyperplasia, eosinophilia, and 10% blasts by CD34 immunostaining, while differential count of aspirate smears revealed approximately 13% blasts. The variation in blast percentages may reflect sampling differences and the effects of hydroxyurea. FISH of peripheral blood was positive for BCR::ABL1 fusion gene, specifically the p210 transcript. Bone marrow karyotyping revealed 46,XY,t(9;22)(q34.1;q11.2)[6]/46,idem,inv(16)(p13.1q22)[14], consistent with CML-BP with rare clonal evolution involving inv(16). Molecular genetic testing on bone marrow was negative for FLT3 and c-KIT mutations.
Conclusion: De novo AML with inv(16) is associated with a favourable prognosis, however older age and FLT3 and KIT mutations are associated with a worse outcome. Inv(16) presence in CML-BP typically portends an aggressive clinical course marked by rapid progression and treatment resistance. Most reported cases have resulted in poor outcomes, underscoring the need for novel therapeutic strategies and vigilant disease monitoring. This case highlights the rare coexistence of acquired (Ph chromosome) and secondary chromosomal abnormalities (inv(16)) in CML-BP. Recognizing such combinations is crucial for understanding disease biology, guiding prognosis, and tailoring treatment, especially in distinguishing these cases from conventional CML-BP.

E-PS-12-025
A case of occult mastocytosis
R. Brand[1], J. Rohrbeck[1], I. Simonitsch-Klupp[1]
[1]Clinical Institute of the Medical University of Vienna, Department of Pathology, Vienna, Austria

Background & Objectives: Systemic mastocytosis (SM) is characterised by the extracutaneous infiltration of morphologically and/or immunophenotypically aberrant mast cells (MCs) into at least one organ system, usually involving the bone marrow (BM). The condition is primarily driven by a somatic gain-of-function mutation in *KIT* and presents with a broad clinical spectrum.
Methods: Histology, immunohistochemistry and molecular pathology were performed.
Results: We report the case of a 61-year-old female patient who presented to the Department of Haematology for further clarification of an IgA lambda paraprotein found in routine examinations. BM biopsy revealed a discrete infiltration of lambda monotypic plasma cells with concomitant CD56 expression and scattered MCs with an aberrant immunophenotype (partial CD25 and CD2 expression) and 40% spindle cell morphology, comprising approximately 5% of the BM cellularity. The patient's history included eosinophilic colitis with intestinal cramps, food intolerance and episodes of flushing symptoms following alcohol consumption, raising the suspicion of intestinal involvement by SM. Colonoscopy showed several flat, white-yellowish lesions with prominent infiltrates of eosinophilic granulocytes and dense aggregates of atypical MCs. Further testing revealed slightly elevated tryptase levels and evidence of a *KIT*

D816V mutation, establishing the diagnosis of SM with an associated haematological neoplasm (SM-AHN, WHO 2022). Given her stable general condition, treatment with famotidine and desloratadine was initiated and clinically followed. Laboratory tests showed slightly persistent elevated tryptase, IgA levels and IgA lambda paraprotein.
Conclusion: To our knowledge, plasma cell disorders associated with SM are rare, leading to the diagnosis of a SM-AHN of non-myeloid lineage. The discrete MC infiltration of the BM with simultaneous extensive intestinal involvement is another unusual finding. Thus, the presence of prominent eosinophilic infiltrates on endoscopic biopsies should raise the suspicion of occult SM, especially in patients with peripheral eosinophilia and concomitant haematological abnormalities.

E-PS-12-026
EBV-positive mucocutaneous ulcer: a comparison of histological and clinical findings of four cases from Istanbul University-Cerrahpasa with the literature
C.S. Sucubulak[1], O.O. Kizilkaya[1], C. Turker Saricoban[1], A.M. Onenerk Men[1], E. Karaca[2], A.S. Demiroz[1]
[1]Istanbul University Cerrahpasa, Pathology, Istanbul, Turkey, [2]Istanbul University Cerrahpasa, Istanbul, Turkey

Background & Objectives: EBV-positive mucocutaneous ulcer (EBV-MCU) is a rare, recently described entity associated with immunodeficiency and immune dysregulation. It primarily affects the elderly due to immunosenescence but is also common in patients receiving immunosuppressive therapy. Microscopically, it presents with polymorphic infiltration and Reed-Sternberg-like cells, making differentiation from other EBV-positive lymphoproliferative (EBV-LP) diseases challenging.
Methods: Four EBV-MCU cases (2016–2024) from the Pathology Department archive of Istanbul University-Cerrahpasa were reviewed. H&E slides, IHC, and EBER in situ hybridization analyses were performed. 26 papers total of 235 cases (2010–2025) were reviewed for comparison.
Results: The mean age of the patients was 48 years (16, 43, 47, 78). Two were female, and two were male. Three lesions were located in the oral cavity, while one was in the anal canal. The youngest patient had systemic lupus erythematosus and was under immunosuppressive therapy, whereas the 78-year-old patient's condition was likely due to immunosenescence.
Microscopic examination revealed ulcer bases with heterogeneous inflammatory infiltrates. Atypical large cells were CD30-positive (4/4), CD20-positive (2/4), PAX5-positive (2/2), and MUM1-positive (2/2). EBER was positive in all cases. CD3-positive band-like T cell infiltration limiting the infiltration was present (4/4). The Ki-67 proliferative index was 10–25% in three patients and over 50% in one.
Compared to the literature (mean age: 67.3 years), our series had a younger mean age due to the inclusion of a paediatric case, which is rare. Only nine paediatric EBV-MCU cases have been reported. Despite this, none of our cases were HIV-positive. In contrast, the literature reports six HIV-positive cases, five of whom were under 60.
Conclusion: EBV-MCU is a benign disease that can resolve spontaneously or with immunosuppressive drug cessation. Misdiagnosis may lead to overtreatment, especially in immunosuppressed patients. Pathologists should recognize this entity when evaluating EBV-LP cases.

E-PS-12-027
Next-Generation Sequencing study of low grade B lymphomas after one year of implementation: usefulness as a diagnostic, prognostic and therapeutic tool
S. Moles Caparros[1], A.S. Veliz Dominguez[1], N. Cadavid Fernandez[1], A.G. Tenelanda Santillan[1], T. Caniego Casas[1], A. Salton Roldan[1], M.E. Reguero Callejas[1], M. Piris Villaespesa[2], M. Garcia-Cosio Piqueras[1]
[1]Hospital Universitario Ramon y Cajal, Department of Pathology, Madrid, Spain, [2]Hospital Universitario Ramon y Cajal, Department of Haematology, Madrid, Spain

Background & Objectives: The incorporation of Next-Generation Sequencing (NGS) in the study of lymphomas represents an advancement in their diagnosis and management. This innovative approach provides a detailed analysis of each patient's genetic profile, facilitating essential information for precise diagnosis, particularly in low grade lymphomas, personalized treatment, and identification of markers that can be monitored in liquid biopsy studies of minimal residual disease, ultimately improving the clinical outcomes. In 2024, this technique was implemented in our department, in collaboration with the Haematology Department.
Methods: NGS was performed in 16 paraffin-embedded low grade lymphomas: 5 marginal zone lymphomas, 5 follicular lymphomas, 5 small lymphocytic lymphomas and 1 mantle cell lymphoma. The NGS panel used was developed by the international Liverpool Lymphoid Network consortium (ThermoFisher Scientific), and based on amplicon technology that includes 60 relevant genes to both B and T lymphomas. In parallel, one case was analysed in peripheral blood.
Results: Out of the 16 samples, 15 were informative. Mutations were found in 87.6% of the cases. In 84.6% of them, mutations with prognostic utility were identified, in 46.2% had diagnostic utility and in 7.7% were useful for selecting targeted therapy.
In two cases, the technique was essential to support the diagnosis of marginal zone lymphoma over other types. In one patient with Richter's syndrome, clonal evolution between sequential biopsies was demonstrated, and in the case where both paraffin and liquid biopsy samples from the same patient were analysed, the same mutation was detected.
Conclusion: NGS in lymphomas is a useful tool for identifying diagnostic and prognostic biomarkers, as well as mutations related to resistance to targeted therapy, influencing therapeutic decisions and patient monitoring.
The collaboration between the Departments of Pathology and Haematology, has facilitated the implementation of NGS in lymphomas in our hospital, presenting it as an option to consider for implementation in other centres.

E-PS-12-028
Diagnostic challenges in HHV8 positive diffuse large B-cell lymphoma: a case report
S. Charfi[1], M. Mellouli[1], S. Makni[1], M. Triki[1], N. Gouiaa[1], C. Chaari[1], T. Sellami Boudawara[1], M. Bouhamed[1]
[1]CHU Habib Bourguiba, Pathology, Sfax, Tunisia

Background & Objectives: HHV8-positive diffuse large B-cell Lymphoma (DLBCL) is a rare and aggressive subtype of lymphoma caracterized by a monoclonal proliferation of HHV8 infected lymphoid cells that resemble plasmablasts. Its diagnosis can be challenging due to its overlap with other hematologic malignancies particularly with plasmablastic features. We report this case to highlight the diagnostic difficulties associated with HHV8-positive DLBCL and to emphasize the importance of considering this diagnosis in patients presenting with necrotic lymphadenopathy.
Methods: A 66-year-old male presented with cervical lymphadenopathy that had progressively enlarged over the course of one year. A first biopsy was performed.
Results: This biopsy showed large lymphoid cells with a plasmacytoid appearance and nuclear debris. A wide panel of antibodies was used, and the diagnosis of Kikuchi necrotizing lymphadenitis in its pseudotumoral form was made. Corticosteroid treatment was initiated and we noted further enlargement of lymph nodes. A second biopsy of the cervical lymph node was performed and processed in our laboratory. Histological analysis revealed sheets or confluent clusters of large

atypical cells with plasmablastic morphology with effacement of the lymph node normal architecture. Mitotic activity was high. Immunohistochemical analysis revealed positive staining for EMA, MUM1, and HHV8, while the tumour cells were negative for CD3, CD20, CD138, CD30, PAX5, and OCT2. These findings were consistent with a diagnosis of HHV8-positive DLBCL.
Conclusion: HHV8-positive DLBCL can present significant diagnostic challenges. Plasmablastic lymphoma and other histologically similar entities, including plasmablastic myeloma and reactive plasmacytic proliferations, must be considered in the differential diagnosis. The combination of clinical presentation, histological findings, immunohistochemistry, and HHV-8 detection is critical for accurate diagnosis.

E-PS-12-029
A rare case of intestinal T-cell lymphoma masquerading as B-cell lymphoma: a diagnostic pitfall
Y.-C. Zosmer[1], A. Dumitru[1], C. Alius[1], D. Dumitrescu[1], A. Tudorache[1]
[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background & Objectives: Enteropathy-associated T-cell lymphoma (EATL) is a rare, aggressive malignancy originating from intraepithelial T cells in patients with celiac disease, most commonly affecting the small intestine. It often presents with gastrointestinal symptoms and has a poor prognosis. In some cases, its morphology can resemble B-cell lymphomas, leading to potential misclassification without detailed immunophenotypic analysis.
Methods: We report the case of a patient who presented with acute abdominal pain and peritonitis, requiring an enterectomy. Histopathological examination revealed a massive transmural lymphocytic proliferation, infiltrating the intestinal wall and extending through the serosa into the mesentery. The tumour was composed of small mononucleated cells with scant clear cytoplasm, indented centrocytic nuclei, and scattered larger cells with centroblastic, immunoblastic, plasmacytoid, and monocytoid morphology. Based on these findings, an initial diagnosis of extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue (MALT lymphoma) was considered, pending immunohistochemical confirmation.
Results: Immunohistochemistry showed strong positivity for CD79a, but the absence of CD20, PAX5 and CD19 argues against a B-cell lineage, which contradicts the initial suspicion of MALT lymphoma. The strong positivity for CD3 and CD7, combined with CD2 negativity, suggests a T-cell neoplasm. The lack of BCL6 and MUM1 expression argues against a germinal centre or activated B-cell phenotype, while Cyclin D1 negativity excludes mantle cell lymphoma.
The immunohistochemistry results indicate a T-cell lymphoma, ruling out the initial diagnosis of MALT lymphoma. The absence of B-cell markers (CD20, PAX5, CD19) and the strong expression of T-cell and cytotoxic markers support the reclassification as Enteropathy-associated T-cell lymphoma.
Conclusion: This case highlights the importance of recognizing T-cell lymphoma, such as EATL, as a diagnostic consideration in gastrointestinal tumours with atypical morphology.
The initial misclassification as a B-cell lymphoma underscores the need for comprehensive immunohistochemical analysis that was crucial in establishing the correct diagnosis and guiding appropriate management.

E-PS-12-030
Cutaneous clues to a hidden malignancy: CD10-positive Hairy cell leukaemia presenting with Sweet syndrome
K.M.M. Bandara[1], V. Mateescu[1]
[1]University of Missouri Kansas City, Pathology, Kansas City, USA

Background & Objectives: Hairy cell leukaemia (HCL) is a rare indolent B-cell neoplasm that may trigger systemic inflammatory responses; however, its association with Sweet syndrome (SS) is rare and underrecognized. SS, an acute febrile neutrophilic dermatosis, may occur idiopathically or as a paraneoplastic manifestation, particularly in hematologic malignancies.
Methods: A 33-year-old woman with history of anxiety and endometriosis, chronic fatigue and drenching night sweats for one year presented with one-month history of painful, erythematous plaques and papules on the extremities, fever and severe arthralgia. Laboratory studies revealed microcytic hypochromic anaemia, leukopenia with absolute neutropenia, monocytopenia, and markedly elevated inflammatory markers, with normal liver and renal function. Autoimmune and infectious serologies, including ANA, hepatitis C, and HIV, were negative. CT imaging showed necrotic hilar and mediastinal lymphadenopathy and mild splenomegaly, raising concern for malignancy.
Results: Skin biopsy demonstrated a dense neutrophilic dermal infiltrate with suppurative liquefactive necrosis, consistent with Sweet syndrome. Peripheral blood smear revealed rare lymphoid cells with abundant cytoplasm and fine, circumferential villous projections, raising suspicion for HCL. Bone marrow flow cytometry identified monotypic CD20+ B-lymphocytes lambda light chain restricted, co-expressing CD11c, CD25, CD103 (subset), and CD10 (subset). Bone marrow biopsy and immunohistochemistry showed normocellular marrow (70%) with interstitial infiltration by CD20-positive/CD79a-positve B-lymphocytes with abundant cytoplasm (80% of marrow), CD10-positive (subset), negative for Cyclin-D1, LEF-1 and SOX-11. PCR detected BRAF V600E mutation, confirming the diagnosis. Although CD10 expression is uncommon in HCL, reported cases demonstrate similar morphological features to CD10-negative HCL. CD10-positive HCL may be associated with unfavourable prognosis.
Conclusion: This case underscores the importance of recognizing SS as a potential early or residual marker of hematologic malignancy. Recognition of atypical cutaneous findings in the context of systemic inflammation is critical for guiding timely hematopathologic evaluation. Recognizing the dermatologic signatures of hematologic disease may enable timely diagnosis and intervention, ultimately improving patient outcome.

E-PS-12-031
The importance of bone marrow biopsy in the diagnosis of splenic lymphoma
C.S. Sucubulak[1], O.O. Kizilkaya[1], C. Turker Saricoban[1], S. Cin[1], A.S. Demiroz[1]
[1]Istanbul University Cerrahpasa, Pathology, Istanbul, Turkey

Background & Objectives: Splenic lymphomas are rare B-cell malignancies involving the spleen and bone marrow. Bone marrow biopsy plays a crucial role in diagnosis, as splenectomy may not be available for every case.
Methods: Between 2010 and 2024, 56 cases of splenic lymphomas (splenic marginal zone lymphoma,red pulp lymphoma(hairy cell leukemia,splenic diffuse red pulp small B-cell lymphoma), mantle cell lymphoma)bone marrow biopsies have been reviewed based on their clinical and pathological data from Istanbul University-Cerrahpasa.
Results: The study included 33 male and 24 female patients (mean age:65, range 40–86). Splenomegaly was reported in 51 cases (140–290 mm). Twelve had B symptoms, and 20 had lymphadenopathy. Thrombocytopenia was observed in 35 cases, anaemia in 38, leukopenia in 15, pancytopenia in 9, and leukocytosis in 17. Paraproteinemia was detected in 6 patients.
Flow cytometry showed CD5 negativity in 15/19 cases, CD20 positivity in 17/17, and CD23 positivity in 9/15. Bone marrow cellularity ranged from 30% to 100%; 43 cases were hypercellular, and 12 were

normocellular for age. The marrow infiltration pattern was interstitial in 40 cases, nodular in 37 (9 paranodular/7 internodular), and intrasinusoidal in 34.
Reticulin fibrosis was grade 0 in 16 cases, grade I in 12, grade I–II in 14, grade II in 7, and grade II–III in 5. Morphologically, cells were mature in 47/48 cases; 6 also had medium-sized cells, and 1 had only medium-sized cells.
Splenectomy was performed in 27 cases (20 SMZL, 5 RPL, 2 MCL), with bone marrow biopsy diagnosing 11/20SMZL, 2/5 RPL, and 2/2 MCL cases. Although splenic lymphoma was suggested in the bone marrow of 12/27 cases, splenectomy was required for diagnosis. A correct diagnosis was obtained from bone marrow in 15 cases.
Conclusion: Splenic lymphomas often involve the bone marrow with diverse infiltration patterns, cell morphologies, and immunohistochemical profiles, making it a key diagnostic tool.

E-PS-12-032
Mastocytosis: morphological and immunohistochemical examination
E. Chupyatova[1,2], V. Chepikova[1], G. Setdikova[1]
[1]Regional Research and Clinical Institute ("MONIKI"), Pathological Anatomy (with a Prosector's Office), Moscow, Russia, [2]Patrice Lumumba Medical Institute of the Russian University of Medical Sciences (RUDN), Pathological Anatomy, Moscow, Russia

Background & Objectives: The term "mastocytosis" encompasses a group of rare diseases characterized by tumorigenic proliferation of clonal mast cells (MCs) and infiltration of one or more organs. Mastocytosis is separated from the group of myeloproliferative disorders as a nosological entity in the 5th edition of the WHO. Cutaneous mastocytosis (CM) usually manifests during the first year of life. Systemic mastocytosis (SM) is a group of hematologic oncohematologic diseases based on proliferation of tumour-associated mast cells (MCs) with involvement of one or more organs. Bone marrow (BM) trepanobiopsy is a mandatory examination in newly diagnosed mastocytosis, regardless of its form. The criterion for diagnosis is the formation of multifocal accumulations of MC in the BM (more than 15 cells) and/or in organs other than the skin. Other criteria for mastocytosis include the presence of a mutation in codon 816 of the KIT gene, elevated serum tryptase levels above 20 ng/mL, and aberrant expression of CD2 and/or CD25 by immunochistochemistry (IHC).
Clinical and morphologic analysis of patients with different forms of mastocytosis from viewpoint of modern classification (WHO, 2024).
Methods: Mastocytosis cases diagnosed in 2021-2024 were retrospectively analysed using histological and immunohistochemical methods with determination of CD117, CD25 expression based on data from the database of the Pathological anatomy department of the Clinical Institute ("MONIKI").
Results: Mastocytosis was diagnosed in 16 patients, age range 2.9 - 74 years, median age - 46 years, female:male ratio= 1.8:1. In all cases, mastocytosis was associated with cutaneous manifestations. Systemic mastocytosis was diagnosed in 7/16 patients by bone marrow trephine biopsy including IHC. As of 01.01.2025, all patients are alive.
Conclusion: Most patients with CM remain in an indolent stage for many years. However, in our population, in 44% cases SM was found with aggressive course. That's why bone marrow biopsy with IHC and molecular analysis is necessary for all patients.

E-PS-12-033
Histopathological and immunohistochemical features of inguinal region lymphomas: a singlecentre experience
H. Erdoğan[1], N.S. Şeker[1]
[1]Eskişehir Osmangazi Üniversitesi Tıp Fakültesi, Tıbbi Patoloji, Eskişehir, Turkey

Background & Objectives: Lymph nodes located in the inguinal region are among the most important components of the lymphatic system and can be sites of either primary or secondary lymphoma involvement. The most common type observed is follicular lymphoma (FL), followed by diffuse large B-cell lymphoma (DLBCL), Hodgkin lymphoma (HL), and mantle cell lymphoma (MCL). Lymph nodes in the inguinal region, particularly those previously affected by inflammatory processes, may exhibit architectural alterations, leading to diagnostic challenges.
This study aims to clarify whether inguinal lymphoma cases differ from those in other regions, as well as to define their morphology and immunophenotype.
Methods: The clinical and demographic characteristics, as well as the histopathological, immunohistochemical, and genetic features, of 18 lymphoma cases diagnosed from inguinal lymph node excision materials in our department between 2020 and 2024 were recorded.
Results: Among the cases, 50% (9 cases) werediagnosed with follicular lymphoma (FL), 44.4% (8 cases) with diffuse large B-cell lymphoma (DLBCL), and 5.5% (1 case) with Hodgkin lymphoma (HL). Bcl-6 gene rearrangement detected in 4 of theDLBCL cases. CD23 positivity was observed in 2 Grade 2 FL cases, whereas none of the DLBCL casesexhibited CD23 positivity.
The gender distribution, age range, and frequency of histopathological subtypes in our cases were found tobe consistent with the literature. However, differingfrom previous reports, CD23 positivity, which is commonly observed in Grade 1 follicularlymphomas, was detected in Grade 2 cases in ourstudy.
Conclusion: Follicular lymphomas exhibiting CD23 positivityremain a subject of debate in the literature. Theclinical significance of this finding has not yet beenclearly established and requires further studies forvalidation.

E-PS-12-034
Clinicopathological characteristics of plasmablastic lymphoma: a retrospective single-centre analysis
N. Bulut[1], D. Demir[1], A. Yilmazer[2], A. Gunes[2], M. Hekimgil[1], N. Ozsan[1]
[1]Ege University, Department of Pathology, Izmir, Turkey, [2]Ege University, Department of Haematology, Izmir, Turkey

Background & Objectives: Plasmablastic lymphoma (PBL) is a rare and aggressive large B-cell lymphoma, typically associated with immunosuppression, particularly HIV. However, increasing evidence suggests its occurrence in immunocompetent individuals as well. This study aims to characterize the clinicopathological and immunophenotypic features, treatment responses, and survival outcomes.
Methods: A retrospective review was conducted on 66 patients diagnosed with PBL at a single tertiary centre between 2006 and 2024. Demographic, clinical, pathological, and laboratory data were analysed. Immunohistochemical markers, HIV status, and survival data were evaluated.
Results: The median age was 65 years (range: 19–95), with a male predominance (69.7%). The most common tumour sites were bone and soft tissue (n=14), head and neck (n=13), and nodal regions (n=13). Other affected sites included the gastrointestinal tract (n=11), medullary region (n=7), spleen (n=4), and testis (n=3), with one case involving renal involvement. Immunohistochemistry showed frequent expression of CD138 (80.7%), MUM1 (91.5%), and CD38 (76.9%), while CD20 was negative in 88.9% of cases. MYC and EBER positivity were seen in 62.5% and 61.7%, respectively. Only 10% of 20 tested patients were HIV-positive. Bone marrow involvement was seen in 28.6%, and 54.5% were diagnosed at clinical stage IV. High Ki-67 proliferation index (mean 74.3%) and elevated LDH levels (mean 1229 IU/L) reflected aggressive disease. Despite

treatment in 76.2% of cases, the objective response rate was only 20%. The median survival time was 26.2 months.
Conclusion: In conclusion, PBL demonstrates a highly aggressive clinical course with poor response to conventional therapies. Although commonly linked to immunodeficiency, our data emphasize that a significant proportion of PBL cases arise in immunocompetent individuals. High proliferative index, MYC and EBER expression, and frequent extranodal involvement reflect the unique biology of PBL and underscore the urgent need for improved therapeutic strategies.

E-PS-12-035
Nodular lymphocyte predominant Hodgkin lymphoma: a clinicopathologic appraisal based on a single institution experience of North India
Z. Chowdhury[1], T. Ravikumar[1], A. Singh[2], R. Ranjan[3], A. Krishnan[4], S.A. Saraf[5], S. Nanda[4]
[1]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Oncopathology, Varanasi, India, [2]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Medical Oncology, Varanasi, India, [3]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Paediatric Oncology, Varanasi, India, [4]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Radiation Oncology, Varanasi, India, [5]V G Saraf Memorial Hospital, Pathology, Kochi, India

Background & Objectives: Nodular lymphocyte predominant Hodgkin lymphoma (NLPHL) is a rare indolent lymphoma traditionally considered a subtype of Hodgkin lymphoma, accounting for <5% of Hodgkin lymphoma with an incidence of approximately 0.1-0.2/100.000/year, even lesser in Asia. NLPHL however differs from Classic Hodgkin lymphoma (CHL) with the tumour cells expressing B-cell antigens and hence, is now regarded as a B-cell lymphoma. Most patients present with early-stage disease and display an excellent prognosis.
Objective: To chronicle the clinic-pathological profile of NLPHLs diagnosed and treated at our centre.
Methods: All cases diagnosed as NLPHL over a period of 5 years at a tertiary cancer centre were explored. The relevant clinical details and survival data were obtained from hospital electronic medical records and analysed.
Results: Of the 36 patients included in the study, the median age of presentation was 45 years with 3 patients (8.33%) less than 18 years of age. age. Male to female ratio was 2.27:1, with predominant nodal presentation except one. Clinical stage of the patients was as such: Stage I (19.4%), Stage II (27.7%), Stage III (27.7%), and Stage IV (25%). Bone marrow was involved in a single case. The closest differential was CHL, with immunohistochemistry markers such as CD20, PAX5, and LCA proving handy in accurately diagnosing NLPHL. On a median follow-up of 18 months (1-58 months), 5 patients expired and the 3-year overall survival rate was 79.1±8.7%.
Conclusion: NLPHL has varied histological patterns with close differentials like Lymphocyte-rich CHL, T-cell/histiocyte-rich large B cell lymphoma, EBV-positive Diffuse large B cell lymphoma, and Progressive transformation of germinal centres. The chemotherapeutic regimen for NLPHL is different and has a more favourable prognosis than its mimickers. Therein lies the significance of histopathological and immunohistochemical expertise, especially on core biopsy samples, in veracious detection of this rare entity, paving the way for precise therapeutic management.

E-PS-12-036
Classical Hodgkin lymphoma with marked necrotising granulomatous reaction: diagnostic difficulty
Z. Sagnak Yilmaz[1], B.M. Polat[1]
[1]Karadeniz Technical University Faculty of Medicine, Department of Pathology, Trabzon, Turkey

Background & Objectives: Hodgkin lymphoma (HL) is a lymphoid malignancy characterised by the presence of large mononuclear and multinucleated neoplastic Hodgkin and Reed-Sternberg cells surrounded by lymphoid and non-lymphoid inflammatory cells. The incidence of necrotizing granuloma is 1.8% and the incidence of necrotizing granuloma in HL has been reported in studies to be 9%. Granulomatous reaction may easily mask the presence of lymphoma. Therefore, the differential diagnosis should be made very carefully.
Methods: An excisional biopsy of the lymphoid nodule was performed. The specimen was formalin fixed and paraffin embedded. The sections were stained with routinary haematoxylin and eosin staining. Immunohistochemistry was performed.
Results: A 26-year-old female presented with a painless, palpable mass in the right cervical region. Ultrasonography showed multiple atypical lymphadenopathies in the right cervical region segment 3-4a, the largest measuring 40 mm. Disrupted lymph node structure and multiple necrotic epithelioid granuloma-like formations were observed on haematoxylin and eosin staining. In addition, these granuloma-like changes were separated from the lymphocyte-rich stroma. Scattered large multinucleated Hodgkin and Reed-Sternberg cells were seen in these areas. Epithelioid cells expressed CD68. High expression of CD30 and MUM1 was seen in the Hodgkin and Reed-Sternberg cells, and weak expression of PAX5 was identified. Based on the combination of histological examination and immunohistochemical results, classic HL was diagnosed.
Conclusion: Lymphoma is one of the potential underlying causes of granuloma. In particular, some prominent granulomatous lesions may mask the changes in lymphoma. Immunohistochemical staining can be used to exclude infectious changes during the clinicopathological diagnosis process. In young patients with lymph node granulomatous lesions, HL should be excluded first.

E-PS-12-037
MISREAD Network Project: a multicentre retrospective study for the identification of undiagnosed cases of idiopathic multicentric Castleman Disease based on suggestive histological findings
N. Rausell Fontestad[1], C. Rodríguez García[1], J. Castellvi Vives[2], J.A. Todoli Parra[3], R. Andreu Lapiedra[4], M.T. Martínez Honrubia[2], S. Escriva Felix[1], A. Hernandiz Senent[1], E. Mayordomo Aranda[1]
[1]Instituto Investigación Sanitaria La Fe, Pathology, València, Spain, [2]Hospital Universitario Vall d'Hebron, Pathology, Barcelona, Spain, [3]Instituto Investigación Sanitaria La Fe, Internal Medicine, València, Spain, [4]Instituto Investigación Sanitaria La Fe, Haematology, València, Spain

Background & Objectives: Idiopathic multicentric Castleman disease (iMCD) is a rare disorder marked by abnormal lymph node proliferation, mimicking various diseases, mainly lymphoma. Accurate diagnosis is crutial to avoid mismanagement. The MISREAD Project aims to identify undiagnosed iMCD cases by reviewing previous lymph node biopsies using newly published diagnostic and grading criteria from the Spanish Haematopathology Group.
Methods: This retrospective multicentre study identifies lymph node biopsies with CD-like features through searches in pathology databases (Laboratory Information System) using predefined keywords (Castleman, plasmacytosis, regressive centres, and follicular hyperplasia). Fine-needle aspiration biopsies and cases with conditions excluding

iMCD were excluded. Reviews focus on histological grading, clinical history, and outcomes. The study has two phases: Phase 1 (review and checklist development by two hospitals) and Phase 2 (checklist implementation across 15 centres).
Results: In Phase 1, 66 cases were reviewed (39 in Centre-A, 27 in Centre-B); 1case (1,5%) met both histological and clinical criteria for iMCD, and was previously missdiagnosed as reactive follicular hyperplasia NOS.
The phase 2 is ongoing. Systematic biopsy review applying the standardized checklist is being applied during the next months. Findings from this expanded cohort will be evaluated once data collection and review are completed.
Conclusion: Accurate iMCD diagnosis requires accurate histological criteria application. Without proper grading, diagnoses may be overlooked, as seen in 1,5% of cases in Phase 1. Phase 2 will assess nationwide diagnosis improvements using the checklist, enhancing iMCD detection and clinical decisions.

E-PS-12-039
Molecular heterogeneity in paediatric Langerhans cell histiocytosis: BRAF V600E and KRAS mutational spectrum with VE1 immunohistochemical concordance analysis
N. Moulai[1], R. Bennoui[1], M. Guermi[1], A. Zammouchi[1], W. Ouahioune[1]
[1]Laboratory of Cancer Research, Faculty of Medicine of Blida, Saad Dahlab University, Blida-1, Blida, Algeria

Background & Objectives: Paediatric Langerhans cell histiocytosis (LCH) is a rare clonal neoplastic disorder of Langerhans-type cells. The BRAF V600E mutation is a key oncogenic driver, while KRAS mutations are emerging as alternative pathogenic events. This study explores the clinicopathological and molecular features of paediatric LCH, focusing on the concordance between BRAF V600E mutation and VE1 immunohistochemical expression.
Methods: We conducted a retroprospective analysis of 10 paediatric LCH cases. Clinical and pathological data were reviewed. Histological diagnosis was established according to WHO criteria and confirmed by CD207 (Langerin, Ventana) immunoreactivity. VE1 monoclonal antibody (Ventana) was used to assess BRAF V600E expression. Molecular testing was performed via real-time PCR using TheraScreen BRAF and KRAS (Qiagen) assays. Statistical analyses included Fisher's exact and Mann-Whitney U tests, with $p < 0.05$ considered significant.
Results: The cohort comprised 10 patients (7 males, 3 females; median age: 6 years, range: 1–11), all with osseous involvement. BRAF V600E mutations were identified in 6 cases (60%), KRAS mutations in 3 (30%), and 1 case (10%) was wild-type. Langerin was positive in all cases, validating the diagnosis of LCH. VE1 immunohistochemistry demonstrated 100% sensitivity and specificity for BRAF V600E mutational status, with moderate to strong cytoplasmic immunoreactivity exclusively observed in BRAF-mutated cases. No VE1 immunoreactivity was seen in KRAS-mutated or wild-type cases. No statistically significant differences in age distribution ($p = 0.48$) or gender predominance ($p = 1.00$) were observed between BRAF- and KRAS-mutated cohorts.
Conclusion: Our findings demonstrate perfect concordance between VE1 immunohistochemical profile and BRAF V600E mutational status, validating its utility as a reliable surrogate biomarker in paediatric LCH. The identification of KRAS mutations in 30% of cases underscores the molecular heterogeneity of this entity and suggests potential alternative therapeutic targets for BRAF-negative patients, warranting further investigation.

E-PS-12-040
Histiocytic sarcoma. A rare tumour review in the last 10 years
D. Bravo Blanco[1], I. García Miranda[1], K. Goncalves Villarreal[1], I. Orbegozo Arrizabalaga[1], L. Andrés Álvarez[1], M. Saiz Camin[1], Y. Aberasturi Plata[1]
[1]Hospital Universitario Cruces, Anatomía Patológica, Barakaldo, Spain

Background & Objectives: Histiocytic sarcoma (HS) is a rare and aggressive malignant neoplasm showing morphological and immunophenotypic features of macrophages. HS occurs in lymph nodes or extranodal sites, most commonly the gastrointestinal tract, spleen, soft tissue, skin, and CNS. It can be localized or disseminated. It represents a diagnostic challenge due to its prevalence and overlapping features with other hematolymphoid disorders and its diagnosis is usually by exclusion of different entities.
The objective is to review the cases diagnosed in our hospital in the last 10 years.
Methods: We retrospectively studied cases diagnosed as HS at Hospital Universitario de Cruces between 2014 and 2024. We reviewed clinical data and histopathological and immunohistochemistry findings.
Results: Four cases of HS were identified, all affecting adult patients, 2 were women, the mean age was 53, and the median was 54. Two were diagnosed in the gastrointestinal tract (ileum and rectum), and the others in the oral cavity and the lung. Histologically all of them were characterized by large, pleomorphic cells with abundant eosinophilic cytoplasm and vesicular nuclei. Immunohistochemistry (IHC) played a crucial role in confirming the diagnosis, with tumour cells that expressed CD68, CD163, CD4, lysozyme, and vimentin whereas lacking markers of dendritic CD1a, epithelial (CK AE1/AE3), lymphoid (CD3, CD10) and other lineages (HMB45, Melan-A). The proliferation index (Ki-67) ranged from 10% to 20%. Two cases had necrosis (<50% of the tumour) and vascular invasion but this was not reported in other cases. Two patients deceased one year after the diagnosis and the others are still alive.
Conclusion: - Histiocytic sarcoma remains a rare and aggressive entity that requires a thorough histopathological and immunohistochemical approach for accurate diagnosis.
- Due to its rarity, case series like this contribute to a better understanding of its clinicopathological spectrum and may aid in future diagnostic and therapeutic strategies.

E-PS-12-041
Aberrant expression of epithelial marker in a follicular dendritic cell sarcoma: a case report highlighting diagnostic pitfalls
H.-N. Li[1], C.-H. Chen[2]
[1]Taichung Veterans General Hospital, Department of Pathology and Laboratory Medicine, Taichung, Taiwan, [2]Taichung Veterans General Hospital, Department of Medical Imaging, Taichung, Taiwan

Background & Objectives: Follicular dendritic cell sarcoma (FDCS) is a rare neoplasm originating from specialized antigen-presenting cells normally located in the germinal centres of lymphoid tissue. A subset of FDCS cases has been reported in association with Castleman disease, a lymphoproliferative disorder involving follicular dendritic cells. We report an unusual case of FDCS arising in the setting of Castleman disease, marked by a spectrum of progressive morphologic changes—ranging from follicular dendritic cell (FDC) hyperplasia and dysplasia to neoplasia—and an aberrant immunophenotypic profile.
Methods: Follicular dendritic cell sarcoma (FDCS) is a rare neoplasm originating from specialized antigen-presenting cells normally located in the germinal centres of lymphoid tissue. A subset of FDCS cases has been reported in association with Castleman disease, a lymphoproliferative disorder involving follicular dendritic cells. We report an unusual case of FDCS arising in the setting of Castleman disease, marked by a spectrum of progressive morphologic changes—ranging from hyperplasia and dysplasia to neoplasia—and an aberrant immunophenotypic profile.
Results: Histologic examination revealed a lymph node with partially preserved architecture encased in a fibrous capsule. Proliferative lymphoid follicles composed of atypical epithelioid FDCs

displayed marked nuclear pleomorphism, vesicular chromatin, prominent nucleoli, and occasional binucleation or multinucleation. These follicles were surrounded by small lymphocytes in an "onion-skin" arrangement, with prominent hyalinized vasculature. Immunohistochemically, the atypical FDCs were strongly positive for AE1/AE3, fascin, D2-40, and PD-L1, but negative for other epithelial markers (EMA, CK7, CK20). Focal positivity for FDC markers, including CD21, CD23, and CD35, was also observed. CD20 staining highlighted surrounding concentric mantle zone lymphocytes.
Conclusion: This case represents a rare instance of FDCS arising in a background of Castleman disease with associated FDC hyperplasia and dysplasia. Aberrant expression of epithelial marker may complicate the diagnosis by mimicking metastatic carcinoma, emphasizing the importance of comprehensive histologic and immunophenotypic evaluation.

E-PS-12-042
B-lymphoblastic leukaemia with co-occurrence of BCR::ABL1 p190/p210, t(12;21) ETV6-RUNX1, and ETV6 exon 5 deletion: a case report
K.J. Quintero-Gil[1,2], F.V. Diaz-Pupo[1], J.A. Mora-Quimbayo[1,3], J.E. Rojas-Salcedo[1,2], L.A. Chacón-Zambrano[2,1], M.L. Romero-Prieto[1]
[1]University Hospital Fundación Santa Fe de Bogota, Bogotá, Colombia, [2]Universidad de Los Andes, Bogotá, Colombia, [3]Universidad Colegio Mayor de Cundinamarca, Bogotá, Colombia

Background & Objectives: B-cell acute lymphoblastic leukaemia (B-ALL) is an aggressive hematologic malignancy in adults. The most prevalent genetic alteration is the BCR::ABL1 p210 fusion. However, the simultaneous presence of BCR::ABL1 p190 and additional rearrangements, such as t(12;21)(p13;q22) ETV6::RUNX1, is exceptionally rare. This co-occurrence suggests underlying molecular reprogramming and increased clonal heterogeneity in B-ALL. Given its clinical and therapeutic implications, comprehensive molecular characterization is essential.
Methods: A 52-year-old female patient presented with lower limb cellulitis. Laboratory findings revealed marked hyperleukocytosis (217,300/mm³) with 83.6% circulating blasts. Flow cytometry confirmed a diagnosis of common B-ALL. RT-qPCR identified the concurrent expression of BCR::ABL1 p210 and p190 transcripts. The presence of the t(12;21) ETV6-RUNX1 translocation and a 57 bp deletion in exon 5 of the ETV6 gene was detected through RT-PCR, capillary electrophoresis, and in silico analysis. The patient was initiated on the GRAAPH treatment protocol in combination with dasatinib. After the second induction cycle, molecular remission for the BCR::ABL1 p190 transcript was achieved, enabling allogeneic hematopoietic stem cell transplantation.
Results: The molecular characterization of B-ALL provides critical prognostic and therapeutic insights. The co-occurrence of BCR::ABL1 p190/p210, observed in fewer than 10% of cases, has been associated with adverse outcomes due to its high oncogenic potential. The t(12;21)(p13;q22) ETV6-RUNX1 translocation is exceedingly rare in adults, with an unclear prognostic significance. Additionally, the exon 5 deletion in ETV6 may impair hematopoietic differentiation and proliferation, potentially contributing to a more unfavourable disease course.
Conclusion: The co-occurrence of BCR::ABL1 p190/p210 in B-ALL is an uncommon event that may significantly influence leukemogenesis and treatment response. Its association with t(12;21) ETV6-RUNX1 and ETV6 exon 5 deletion suggests increased clonal complexity. Given the clinical and therapeutic implications of these genetic alterations, comprehensive molecular profiling with prognostic relevance is crucial for optimizing treatment strategies and patient management.

E-PS-12-043
Marginal zone lymphoma of the liver: pathology and molecular profiling of three cases
I.A. Montes Mojarro[1], J. Bosch Schips[1], R. Rolim[2], L. Frauenfeld[1], S. Kieninger[1], A.B. Mankel[1], F. Fend[1]
[1]Institute of Pathology and Neuropathology and Comprehensive Cancer Centre Tübingen, Eberhard-Karls-University, Tübingen, Germany, [2]Instituto Português de Oncologia de Lisboa, Francisco Gentil, Pathology Department, Lisboa, Portugal

Background & Objectives: Marginal zone lymphoma (MZL) is a B-cell non-Hodgkin lymphoma that typically arises in mucosa-associated lymphoid tissue (MALT). While MZL can involve various extranodal sites, primary hepatic MZL lymphoma is exceedingly rare, with only a few reported cases. This study aims to characterize the clinical, pathological, and genetic features of hepatic MZL.
Methods: We retrospectively analysed three cases of hepatic MZL diagnosed at our reference centre. Clinical and histopathological data were reviewed. Molecular studies included whole-exome sequencing (WES), targeted sequencing using a custom B-cell lymphoma panel, and fluorescence in situ hybridization (FISH) analysis for *MALT1–IgH* rearrangement using a break-apart probe.
Results: We identified three cases of primary hepatic MZL. One patient had Sjögren's disease. All cases presented with a liver mass as the primary manifestation. One patient also exhibited enlarged cervical and axillary lymph nodes on further imaging. Histopathological examination of the liver showed a nodular to diffuse infiltration of small to medium-sized lymphocytes, with focal lymphoepithelial lesions involving interlobular bile ducts. Immunophenotyping showed a B-cell phenotype consistent with MZL ($CD20^+/CD5^-/CD23^-$). One case demonstrated lambda light chain restriction. Bone marrow involvement was absent in all patients. Notably, one patient developed an indolent systemic T-cell lymphoproliferative disorder. FISH analysis in two cases showed no evidence of the *MALT1–IGH* t(14;18)(q32;q21) translocation. Sequencing data identified mutations in *KMT2D* (p.Q1213H), *PRDM1* (p.L144Rfs, p.S405L), *KLF2* (c.75+1G>A), *NFKBIA* (p.E40K, p.A4T), and *NOTCH1* (p.P1410S).
Conclusion: The mutational landscape of hepatic MZL in our series included alterations in the NOTCH pathway (*NOTCH1*), transcription factors (*KLF2*), and epigenetic regulators (*PRDM1*, *KMT2D*), but no *PTPRD* mutations were detected. This profile overlaps more with nodal and splenic MZL than with MALT lymphomas, reinforcing the biological heterogeneity of MZL. The characterization of primary hepatic MZL remains limited, but its biology appears to be linked to antigen stimulation and BCR signalling.

E-PS-12-044
Myeloid sarcoma localized in the stomach as a progression of chronic myelomonocytic leukaemia
C. Baraddi[1], F. Folini[1], G. Di Stefano[2], R. Santi[1]
[1]University of Florence, Pathology Section, Florence, Italy, [2]Careggi University Hospital, Histopathology and Molecular Diagnostics, Florence, Italy

Background & Objectives: Myeloid Sarcoma (MS) is an aggressive and highly heterogeneous haematological malignancy characterized by myeloid blasts in an extramedullary location, occurring either before or after leukaemia diagnosis. The occurrence of MS in association with myelodysplastic/myeloproliferative neoplasms is rare. In this report, we present the case of an 80-year-old woman who exhibited extramedullary localization of MS following a diagnosis of chronic myelomonocytic leukaemia (CMML).

Methods: A gastric biopsy was performed due to suspicion of gastric carcinoma. Formalin-fixed paraffin-embedded (FFPE) tissue was routinely prepared, and a comprehensive immunohistochemical panel, including CD68 PGM1, CD68 KP1, CD163, CD14, CD45, myeloperoxidase (MPO), CD15, CD34, CD117, CD3, CD20, CD2, CD25, CD30, ALK, CD138, CK AE1/AE3, CK7 and S100, was applied.
Results: Microscopic examination of the gastric mucosa revealed atypical small to medium-sized elements with blastic features. These characteristics included scant cytoplasm, irregular nuclear profiles, and fine chromatin with indistinct nucleoli. Immunohistochemical analysis indicated a histiocytic phenotype (CD68 PGM1+, CD68 KP1+, CD163+, CD14-/+) with CD15 and CD45 positivity, and a high proliferation index (Ki-67: 90%). The neoplastic cells tested negative for MPO, CD34, CD3, CD20, CD2, CD117, CD25, Tryptase, CD30, ALK, CD138 and S100. A diagnosis of MS secondary to CMML was established, and the patient died shortly after histopathological diagnosis.
Conclusion: Diagnosis of extramedullary myeloid sarcoma is challenging in routine practice. This case highlights a rare manifestation of disease progression in CMML, seldom reported in gastric biopsies.

E-PS-12-045
Comparative analysis of mediastinal lymphomas diagnosed at a tertiary medical centre over a 25-year period
S. Kaymaz[1], S. Cin[1], A.S. Demiröz[1], S.H. Aki[1]
[1]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Pathology Department, Istanbul, Turkey

Background & Objectives: Mediastinal lymphomas represent a diagnostic challenge due to overlapping morphologic and immunophenotypic features, particularly between classical Hodgkin lymphoma (CHL), primary mediastinal large B-cell lymphoma (PMBCL), diffuse large B-cell lymphoma (DLBCL), and mediastinal gray zone lymphoma (MGZL). This study aims to comparatively evaluate these subtypes based on cases diagnosed over a 25-year period in a single tertiary centre.
Methods: We retrospectively analysed 40 cases (10 per entity) diagnosed between 2000–2025 at Cerrahpasa Medical Faculty. Histopathologic and immunohistochemical features were re-evaluated using archival slides and pathology reports.
Results: Reed-Sternberg (RS) or RS-like cells were seen in all CHL and MGZL cases, frequently binucleated with prominent eosinophilic nucleoli, but not in DLBCL or PMBCL. Prominent inflammatory background was typical for CHL (10/10) and MGZL (9/10), while rare in DLBCL (1/10) and PMBCL (2/10). Fibrosis was frequent in PMBCL (8/10) and CHL (7/10). CD30 was positive in all CHL and MGZL, and in most PMBCL (9/10), but rare in DLBCL (2/10). CD15 was seen mainly in CHL (9/10). CD20 was expressed in all DLBCL and PMBCL, variably in MGZL (6/10), and rarely in CHL (2/10). High Ki-67 (>70%) was common in DLBCL (9/10), PMBCL (8/10), MGZL (7/10), but less frequent in CHL (3/10). EBV was positive in 4/10 CHL and 2/10 MGZL.
Conclusion: Despite overlapping features, certain histologic and immunophenotypic patterns can help distinguish between mediastinal lymphoma subtypes. While RS morphology, CD30&CD15 positivity and inflammatory background favour CHL and MGZL, strong B-cell markers and high proliferation index support DLBCL and PMBCL diagnoses.

E-PS-12-046
Clinicopathological profile of tonsillar diffuse large B-cell lymphoma NOS, in younger patients: a six-year single-centre study
N. Moulai[1], M. Guermi[1], R. Bennoui[1], S. Ahmed Allal[1], G. Ifaidi[1], W. Ouahioune[1]
[1]Faculty of Medicine, Blida Universität 1, Laboratory of Cancer Research, Blida, Algeria

Background & Objectives: Diffuse Large B-Cell Lymphoma (DLBCL) of the tonsil represents a distinct entity among extranodal lymphomas with unique clinicopathological features. This study aims to characterize tonsillar DLBCL in younger patients (aged <50 years) and compare their profile with older counterparts, focusing on cell-of-origin classification and its potential prognostic implications.
Methods: We retrospectively analysed 50 consecutive cases of primary tonsillar DLBCL diagnosed at our department between January 2019 and December 2024. Cases were classified into germinal centre B-cell-like (GCB) and non-germinal centre B-cell-like (non-GCB) subtypes using the Hans algorithm (CD10, BCL6, MUM1).BCL2 and c-MYC immunostaining and EBER in situ hybridization were performed for all cases. Clinical and pathological data were statistically analysed (significance: $p < 0.05$).
Results: Among the 50 patients, 13 (26%) were under 50 years of age, with a mean age of 34.0 years (range: 15–46). The younger cohort showed a male predominance (61.5%) that was less pronounced than in older patients (≥50 years: 73.0% male). Notably, the GCB subtype was significantly more frequent in younger patients (61.5%) compared to older individuals (16.2%; $p = 0.002$). In contrast, the non-GCB subtype predominated in patients aged ≥50 years (78.4% vs. 38.5% in younger patients). Three double-hit cases (MYC and BCL2 co-expression) were identified exclusively in older patients. EBER was negative in all cases. The annual incidence of cases remained stable over the study period, ranging from 5 to 13 cases per year.
Conclusion: Tonsillar DLBCL in younger patients displays a distinct molecular profile, with a significantly higher prevalence of the GCB subtype. This age-related molecular heterogeneity may reflect divergent pathogenic pathways and has potential prognostic implications, given the generally more favourable outcomes associated with the GCB phenotype. These findings underscore the importance of age-adapted diagnostic and therapeutic strategies in the management of tonsillar DLBCL.

E-PS-12-048
Blastic plasmacytoid dendritic cell neoplasm with unusual morphologic, phenotypic and cytogenetic features
G. Di Stefano[1], C. Baraddi[2], F. Folini[2], R. Santi[2]
[1]Careggi University Hospital, Histopathology and Molecular Diagnostics, Florence, Italy, [2]University of Florence, Pathology Section, Health Sciences, Florence, Italy

Background & Objectives: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare haematological malignancy characterized by the formation of cutaneous tumours and subsequent/simultaneous leukemic manifestations. Most of these haematological diseases exhibit chromosomal abnormalities and previous studies have detected BPDCN displaying an 8q24 rearrangement of the *MYC* locus. Herein, we describe two cases of BPDCN with *MYC* rearrangement.
Methods: Between 2024 and 2025, two cases of BPDCN were diagnosed from incisional skin biopsies. Formalin-fixed paraffin-embedded (FFPE) tissues underwent immunohistochemical analysis, including markers such as CD123, CD4, CD45, CD56, S100, CD207, CD34, CD117, and MYC. Furthermore, fluorescence in situ hybridization (FISH) was performed using a commercially available probe to identify the 8q24 rearrangement of the *MYC* gene.
Results: The patients were 83 and 75 years old. Skin biopsies showed a diffuse infiltrate in the dermis composed of large, atypical cells with round vesicular nuclei and centrally located nucleoli (immunoblasts). Both cases tested positive for CD123, CD4, CD45 and exhibited high expression of MYC (>90%) along with a high proliferation rate (Ki-67: 90%). CD56 was positive in only one of the cases. Additionally, CD34, CD117, MPO, and CD15 were negative. FISH analysis of tissue sections from the skin lesions confirmed *MYC* rearrangement. Both

patients experienced rapid clinical deterioration and died shortly after diagnosis.
Conclusion: These two cases highlight the complexities of diagnosing BPDCN due to unusual morphological (immunoblastoid vs. myelo-/lymphoblastic) and immunophenotypic features (CD56 negativity vs. CD56 positivity). Interestingly, neoplastic cells demonstrated intense and diffuse c-MYC immunohistochemical expression and harboured *MYC* rearrangement, consistent with previous reports of BPDCN immunoblastic variants and their aggressive clinical course. Therefore, these unique morphological and cytogenetic features in BPDCN should be recognized for diagnostic and prognostic purposes.

E-PS-12-049
Thinking out of the bone: extramedullary multiple myeloma in uncommon locations
A. Santos[1], R. Oliveira[1], F. Miranda[2], B. Lança[3]
[1]ULS Lisboa Ocidental, Serviço de Anatomia Patológica, Lisboa, Portugal, [2]ULS Lisboa Ocidental, Serviço de Hematologia Clínica, Lisboa, Portugal, [3]ULS Lisboa Ocidental, Serviço de Otorrinolaringologia, Lisboa, Portugal

Background & Objectives: Extramedullary involvement by multiple myeloma (MM) is rare, typically emerging during relapse and carrying a poor prognosis. It most frequently involves the skin and soft tissues, but it can rarely affect other organs. The main differential diagnosis is with solitary plasmacytoma, which has a different management and better prognosis.
Methods: We report two cases of extramedullary disease in two rare locations. The first case is of a 68 year old male, in remission from MM, who presented with a painful lesion in the right testicle measuring 53cm3, associated with biochemical relapse of MM. The patient accepted intervention with right orchiectomy.
The second case concerns a 72 year old male with MM diagnosed 3 years prior, in remission. A month after suspending lenalidomide, the patient presented with a painful mass in the right preauricular region measuring 6cm. A CT scan showed a well delimited lesion in the superficial lobe of the parotid gland, which was submitted to a Fine Needle Aspiration (FNA).
Results: In the first case, the testicular parenchyma was almost completely obliterated by sheets of plasmacytoid cells, with occasional Dutcher bodies, immunohistochemistry positive for CD56 and CD138; lambda light chain restriction was noted (by in situ hybridization).
In the second case, the FNA cytology revealed a sheet of plasmacytoid cells positive for CD138, CD56 and MUM1, with lambda light chain restriction and a high Ki-67 index.
Conclusion: These cases highlight both the importance of correlation with the patient's clinical information and the necessity of considering rare diagnoses due to their impact on patient management and outcomes.

E-PS-12-050
Clinicopathological and molecular diversity of large B-cell lymphoma across extranodal sites: a comparative analysis of 160 cases from the tonsil, stomach, and mediastinum
N. Moulai[1], R. Bennoui[1], M. Guermi[1], A. Zammouchi[1], W. Ouahioune[1]
[1]Laboratory of Cancer Research, Faculty of Medicine of Blida, Saad Dahlab University, Blida-1, Blida, Algeria

Background & Objectives: Large B-cell lymphoma (LBCL) frequently arises in extranodal sites, particularly the gastrointestinal tract, exhibiting site-specific biological and molecular profiles. This study compares the clinicopathological, immunophenotypic, and molecular features of DLBCL across three distinct extranodal locations, with emphasis on cell-of-origin classification and age-related patterns.
Methods: We retrospectively analysed 160 cases of primary extranodal DLBCL diagnosed between 2019-2024 (50 tonsillar, 88 gastric, 22 mediastinal). Cell-of-origin classification utilized the Hans algorithm (CD10, BCL6, MUM1). Immunohistochemical assessment included BCL2, c-MYC, PD-L1, CD30, and CD23. EBER in situ hybridization was performed for all cases. Comparative statistical analyses were performed between the different anatomical sites, with a p-value < 0.05 considered.
Results: Median age varied significantly across sites: tonsillar (65 years), gastric (60 years), and mediastinal (36 years; $p < 0.001$). Male predominance characterized tonsillar (56.0%) and gastric (54.2%) cases, while mediastinal DLBCL, consistent with primary mediastinal large B-cell lymphoma (PMBCL), predominantly affected females (68.4%; $p = 0.02$). The GCB subtype was significantly enriched in younger patients across sites, particularly in tonsillar DLBCL (61.5% in <50 years vs. 21.6% in ≥50 years; $p = 0.03$). Non-GCB phenotype predominated in older patients (78.4% in tonsillar, 77.0% in gastric DLBCL aged ≥50 years). Three double-hit cases (MYC/BCL2 co-expression) were identified exclusively in older patients. EBER positivity was observed in 4 gastric cases (4.8%) but was negative in all tonsillar and mediastinal cases. Mediastinal DLBCLs demonstrated typical PMBCL features with younger age and female predominance.
Conclusion: LBCL demonstrates distinct site-specific and age-dependent clinicopathological profiles. The significant enrichment of GCB subtype in younger patients, particularly in tonsillar DLBCL, suggests age-related molecular heterogeneity with divergent pathogenic mechanisms. PMBCL exhibits a unique demographic profile, while gastric DLBCL shows occasional EBV association. These findings underscore the importance of anatomical site and patient age in DLBCL molecular stratification and support site-adapted and age-adapted diagnostic and therapeutic approaches.

E-PS-13 E-Posters Head and Neck Pathology

E-PS-13-001
Clinicopathological correlations in medication-related osteonecrosis of the jaw: a retrospective histopathological study
B. Mülayim[1], I. Atak Secen[1], S.E. Gultekin[1]
[1]Gazi University, Faculty of Dentistry, Oral Pathology, Ankara, Turkey

Background & Objectives: Medication-related osteonecrosis of the jaw (MRONJ) is a severe complication associated with antiresorptive and antiangiogenic therapies, particularly in patients with malignancies. Histopathological features of MRONJ remain underexplored and unstandardized, limiting their clinical utility. This study aimed to investigate the correlation between clinical variables and histopathological parameters in MRONJ cases to identify potential prognostic indicators.
Methods: Among 101 MRONJ cases diagnosed between 2013 and 2025 and archived in the Department of Oral Pathology at Gazi University, 32 cases associated with malignancy-related medication use were retrospectively selected. Demographic, clinical, and radiographic data were recorded. Variables such as soft tissue changes, inflammation, haemorrhage, presence of microorganisms, bone resorption, proportion of viable bone, cement line integrity, and presence of osteoclasts were assessed. Histochemical stains were applied to further characterize microorganisms. Statistical analyses were performed to assess correlations between clinical and histopathological findings.
Results: The most frequent clinical trigger was tooth extraction, and the most commonly used drug was zoledronic acid. All cases showed classic features of osteonecrosis; Actinomyces was detected in 62.5% of cases. Inflammation was higher in male patients ($p < 0.0001$), those with metastases ($p < 0.0001$), and following tooth extraction ($p < 0.0001$). Denosumab use was linked to increased inflammation ($p = 0.0008$) and osteoclast activity ($p = 0.0287$) compared to zoledronic acid. Actinomyces presence correlated with metastasis, tooth

extraction, and inflammation ($p < 0.05$). The type of primary tumour and treatment regimen significantly influenced bone vitality and inflammatory response. Notably, age was the only variable significantly correlated with all histopathological parameters, suggesting a potential role of advanced age in disease severity.
Conclusion: Histopathological findings in MRONJ correlate with key clinical variables. Age, drug type, metastasis, and local risk factors may influence disease severity. These findings support the potential prognostic value of histopathology and underscore the need for standardized evaluation criteria in MRONJ.

E-PS-13-002
The mystery of long-standing pleomorphic adenoma
B. Anghel[1], L. Lozneanu[1,2], C. Andriescu[1], R. Andriescu[3]
[1]"Sf. Spiridon" Emergency County Hospital, Department of Pathology, Iași, Romania, [2]"Grigore T. Popa" University of Medicine and Pharmacy, Department of Morphofunctional Sciences I - Histology, Iași, Romania, [3]"Grigore T. Popa" University of Medicine and Pharmacy, Iași, Romania

Background & Objectives: Pleomorphic adenoma is the most common benign salivary tumour, rarely undergoing malignant transformation. Carcinoma ex pleomorphic adenoma (CEPA) is a rare malignancy that affects the major and less frequently, minor salivary glands. Recent studies suggest that apocrine changes within pleomorphic adenoma may represent a premalignant stage and intraductal carcinoma is a preinvasive lesion of CEPA. We present a case of a 53-year-old patient with 20-year-evolving pleomorphic adenoma of genian region with areas of low-grade apocrine intraductal carcinoma, highlighting the importance of thorough diagnostic evaluation of benign tumours.
Methods: A 53-year-old man presented with a painless, firm, slow-growing nodular tumour located in the left cheek, involving its entire thickness. Ultrasound evaluation shows a solid, well-demarcated vascularized lesion located at a depth of 3 mm. The tumour formation was surgically removed and was sent to the pathological anatomy laboratory for histopathological and immunohistochemical evaluation.
Results: Macroscopic examination reveals a well-demarcated nodular tumour formation, encapsulated with a lobulated contour that presents a solid, multinodular, white-gray appearance on section with brown-haemorrhagic and yellowish areas. The tumour formation is in contact with the surgical resection margin macroscopically. Microscopic evaluation shows a nodular tumour proliferation consisting of three elements: predominantly chondromyxoid stroma, epithelial and myoepithelial elements. The epithelial component presents a tubular or cribriform architecture, with reduced cellular pleomorphism with eosinophilic nucleoli and reduced mitotic activity. Immunohistochemistry was performed for CK7, CK5, p63, p53, GCDFP15 and androgen receptor, which were positive, confirming the presence of areas of apocrine intraductal carcinoma, as well as SOX10 which was negative in the carcinoma area.
Conclusion: This case highlights the potential for malignant transformation of long-standing pleomorphic adenomas. The histopathological and immunohistochemical approach is important for an accurate diagnosis, since early recognition of malignant components affects the clinical management and prognosis of the patient.

E-PS-13-003
Reclassification of squamous cell carcinomas of the tongue according to the 8th edition of the TNM classification: prognostic impact of the new T stage
S. Kamoun[1,2], A. Rais[1], A. Methnani[3], A. Goucha[1], I. Bettaieb[1], S. Ferchichi[1], Y. Houcine[1], M. Driss[1,2], S. Kedous[3]
[1]Salah Azaiez Institute, Pathology Departement B, Tunis, Tunisia, [2]Salah Azaiez institute, Research Laboratory LR21SP01, Tunis, Tunisia, [3]Salah Azaiez Institute, Department of ENT and Head and Neck Surgery, Tunis, Tunisia

Background & Objectives: Tongue squamous cell carcinoma (TSCC) is a common and aggressive form of oral cavity cancer, often diagnosed at advanced stages with poor prognosis. The 8th edition of the TNM classification introduces updated criteria, especially concerning tumour size and depth of invasion (DOI). This study aimed to reclassify the T stage of TSCC using the new TNM classification and assess the prognostic impact of DOI.
Methods: We analysed 67 cases of TSCC diagnosed at Salah Azaiez Institute between 2012 and 2018. Tumours were reclassified according to DOI, and survival analysis was performed using Log Rank test.
Results: The mean age of patients was 68 years [49–98], with a male-to-female ratio of 0.9. Tobacco use was reported in 35% of cases, and alcohol use in 25%. The mean tumour size was 27mm (range 8–64).
Re-evaluation of the T stage based on the 8th edition of TNM led to the upgrading of 22 cases, with no downgrades. Specifically, 20 of 27 cases initially classified as T1 with a DOI >5mm were reclassified as T2, and 10 of 29 cases initially classified as T2 with a DOI >10mm were reclassified as T3. Two cases initially classified as T3 with a DOI >10mm were upgraded to T4a.
Survival analysis revealed that DOI>10mm and T3-T4 stages were significantly associated with lymph node metastasis and 5-year disease-free survival ($p=0.000$ and $p=0.005$, respectively). In multivariate analysis only DOI was independently associated with lymph node metastasis (OR 11.8, CI [3.2-43.3]).
Conclusion: In conclusion, the 8th edition of the TNM classification has a significant impact on the reclassification of TSCC, with DOI emerging as a key prognostic factor in staging and patient outcomes. This new classification allows better risk stratification and more rigorous mentoring of OTC who were earlier considered at risk-free.

E-PS-13-004
Unusual case of sinonasal carcinosarcoma on inverted papilloma – case report
M.-A. Cerbu[1], G. Halcu[2,3], M. Bara[2]
[1]University Emergency Hospital Bucharest, Department of Pathology, Bucharest, Romania, [2]Coltea Clinical Hospital, Department of Pathology, Bucharest, Romania, [3]University of Medicine and Pharmacy "Carol Davila ", Bucharest, Romania

Background & Objectives: Sinonasal (Schneiderian) papillomas are benign epithelial neoplasms and the most common tumours of the nasal cavity and paranasal sinuses. These lesions are well known for their tendency to recur and malignant transformation.
Malignancies arising in sinonasal papillomas are rare and almost always described as in situ or invasive squamous cell carcinoma. An exceedingly rare situation is the coexistence of carcinomatous and sarcomatous components.
Methods: We report the case of a 42-year-old male who presented with recurrent nasal obstruction, bleeding and an enlarging sinonasal mass in the left nasal vestibule.
Our pathology department received a piecemeal resection of the tumour. The blocks were sectioned and stained with Haematoxylin and eosin, and blank slides were prepared for immunohistochemical stains.
Results: Histopathological examination revealed a lesion that exhibited a biphasic morphology, with areas demonstrating moderately differentiated squamous cell carcinoma and regions showing a spindle cell component. Immunohistochemical analysis revealed strong positivity for CK34bE12 and p40 in the squamous cell carcinoma areas, confirming their epithelial origin. The sarcomatous component was positive for vimentin, desmin, h-caldesmon and actin, suggesting mesenchymal differentiation. Additionally, both components were negative for S100 and CD34. The transition from the inverted papilloma to the malignant

components was evident, with dysplastic epithelium at the periphery of the papilloma, indicating a stepwise progression to carcinoma and sarcoma.
Conclusion: This case underscores the importance of thorough histopathological and immunohistochemical evaluation in diagnosing rare malignancies like sinonasal carcinosarcoma, particularly in the context of pre-existing inverted papillomas. It also highlights the potential for malignant transformation in these lesions, necessitating vigilant follow-up in patients with Schneiderian papillomas.

E-PS-13-005
Mesenchymal chondrosarcoma: an illustrative case
K.A.J. Curso[1], C.V. Mirhan[1], E.M. Yturralde[1], J. Carnate, Jr[1]
[1]Philippine General Hospital, Laboratories, Manila, Philippines

Background & Objectives: Malignant small round blue cell tumours encompass a diverse group of aggressive neoplasms with overlapping histological features, complicating diagnosis. This report presents a case of mesenchymal chondrosarcoma (MCS) in a 6-year-old female, emphasizing diagnostic challenges and differential considerations.
Methods: An incisional biopsy from the left maxillary alveolar bone revealed soft, cream-tan tissue fragments. Histopathological examination demonstrated undifferentiated small round blue cells with hyperchromatic nuclei, scant cytoplasm, and slit-like vascular spaces resembling staghorn vessels. Abrupt transitions to mature hyaline cartilage were noted. Immunohistochemical studies revealed strong NKX3.1 staining in the undifferentiated component and S100 positivity in the cartilaginous component. SATB2 was weakly positive in the undifferentiated cells but absent in the cartilage. Pancytokeratin and desmin were negative. These findings supported a diagnosis of MCS, with molecular testing for HEY1::NCOA2 fusion recommended for confirmation.
Results: MCS is a rare sarcoma comprising 2-10% of all chondrosarcomas, with 20-30% occurring in the head and neck, particularly affecting young individuals. It exhibits biphasic histology with undifferentiated mesenchymal cells and mature cartilage. Diagnosing MCS is challenging when the cartilaginous component is absent in limited biopsies, leading to potential confusion with Ewing's sarcoma, desmoplastic small round cell tumour, small cell osteosarcoma, and rhabdomyosarcoma. NKX3.1, a novel marker, is absent in these differentials, aiding distinction. The HEY1::NCOA2 gene fusion further supports diagnosis, particularly in cases lacking characteristic cartilage.
Conclusion: Due to its aggressive nature, MCS requires long-term follow-up. Craniofacial tumours in paediatric patients tend to have better outcomes post-surgical resection and chemotherapy. This case highlights the importance of integrating histology, immunohistochemistry, and molecular studies for accurate diagnosis and appropriate management of MCS.

E-PS-13-006
Laryngeal salivary duct carcinoma with pagetoid spread: a very rare case report
R.R. Askin[1], S. Ozturk Sari[1], C. Sen[2], G. Yegen[1], D. Vuralli Bakkaloglu[1], Y. Ozluk[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Pathology, Istanbul, Turkey, [2]Istanbul University, Istanbul Faculty of Medicine, Otorhinolaryngology, Istanbul, Turkey

Background & Objectives: Paget disease is a rare carcinoma characterized by an intraepithelial growth of neoplastic cells originating in the skin or representing the intraepithelial spread of an underlying visceral carcinoma. It usually is located in the breast or apocrine-rich areas.
Methods: Here, we present a rare case of laryngeal salivary duct carcinoma (SDC) with pagetoid spread in a 71-year-old male. The patient had a 2-year history of hoarseness and new-onset stridor, which led to the decision to perform a tracheostomy, followed by a laryngeal biopsy. Further imaging revealed a 1.5 cm soft tissue lesion in the neck that infiltrates thyroid tissue, which was also biopsied, with no other masses identified elsewhere. Both biopsies were sent for histopathological examination with a one-week interval.
Results: The first biopsy revealed intraepithelial carcinoma cells, with no additional lesions identified in the subepithelium, aside from some inflammatory cells. The second biopsy from the neck mass demonstrated neoplastic infiltration consisting of cells with eosinophilic cytoplasm and large, round, and pleomorphic nuclei, organized in irregular clusters within a desmoplastic stroma. Immunohistochemical analysis showed positivity for cytokeratin 7, EMA, CEA, and androgen receptor, while cytokeratin 20, p40, TTF-1, PAX8 and S100 were negative. Identical immunohistochemical findings were observed for both biopsies. Laryngoscopic findings showing submucosal mass localized in the subglottic area and histopathological findings supported a diagnosis of laryngeal SDC.
Conclusion: This case is particularly intriguing and rare for several reasons. Paget's disease in the head and neck region is exceedingly uncommon, with the majority of reported cases involving the oral mucosa. Additionally, SDC, typically associated with major salivary glands, was found in the minor salivary glands of the larynx in this instance. To the best of our knowledge, this represents the first documented case of laryngeal SDC with pagetoid spread in the literature.

E-PS-13-007
Molecular characterization and biomarkers in salivary gland carcinomas through NGS: diagnostic and therapeutic implications
A.S. Veliz Dominguez[1], S. Molés Caparrós[1], N. Cadavid Fernández[1], A.G. Tenelanda Santillán[1], T. Caniego Casas[1], A. Santón Roldán[1], M.E. Reguero Callejas[1], M. Garcia-Cosío Piqueras[1], E. Moreno Moreno[1]
[1]Hospital Ramón y Cajal, Pathology, Madrid, Spain

Background & Objectives: Salivary glands carcinomas shows genotypic diversity, complicating their management in advanced cases. Next-generation sequencing (NGS) allows for the detection of genetic alterations, improving accurate diagnoses and offering therapeutic targets. Since 2020, our service has implemented NGS in advanced cases of salivary gland carcinoma.
Methods: We analysed ten paraffin tissue samples: five adenoid cystic carcinomas (AdCC), three ductal carcinomas (SDC), one myoepithelial carcinoma (MECA), and one epithelial-myoepithelial carcinoma (EMC). We used three custom panels: Oncomine™ Precision Assay (50 genes) for five cases, Oncomine™ Focus Assay (52 genes) for four cases and Oncomine™ Dx Express Test (46 genes) for one case. Three cases underwent NGS at an external laboratory (Foundation One, FOne). Immunohistochemical biomarkers (Her-2, PDL-1, androgen receptors, and c-kit) and fluorescence in situ hybridization (FISH) were performed.
Results: Molecular alterations were detected in two cases with diagnostic utility: EMC (*HRAS* and *PIK3CA*) and SDC (*FGFR1*). The three analysed cases with FOne, showed diagnostic alterations: two AdCC (*MYB* and *NOTCH-1*, respectively) and one SDC (*PTEN, TP53* and *NOTCH-1*). We did not detect these genes because they were not included in our panels.
FISH detected a *MYB* fusion in a AdCC case. Immunohistochemical staining detected two CD117+ cases (AdCC), five androgen receptors+ cases (three SDC and two AdCC), of which four received antiandrogenic treatment; one PD-L1 CPS 6 (AdCC), treated with Pembrolizumab, and one HER2+++ (SDC), without related treatment. In cases without alterations, the treatments included RT-chemotherapy and tyrosine kinase inhibitors.

Conclusion: NGS is valuable for identifying molecular alterations, improving diagnostic accuracy and offering therapeutic targets, with treatment options. It is important to highlight the need of a broad panel that includes the main genes involved in salivary glands carcinomas. Our study found that small percentage of cases showed significant results for the diagnostic process, while immunohistochemical biomarker studies had a greater impact on therapeutic decision-making.

E-PS-13-008

Cytomegalovirus sialadenitis: a diagnostic mousetrap

R. Yaakoubi[1], S. Makni[1], M. Mellouli[1], M. Bouhamed[1,1], I. Saguem[2], T. Boudaouara[1], O. Boudaouara[1]
[1]Habib Bourguiba University Hospital, Pathology, Sfax, Tunisia, [2]Saguem Pathology Lab, Gabes, Tunisia

Background & Objectives: Sialadenitis is the inflammation of the salivary glands. It can be caused by various infectious, obstructive, and auto-immune processes. Cytomegalovirus (CMV) sialadenitis is extremely rare and occurs mainly in immunocompromised patients.
Methods: A 32-year-old healthcare worker woman presented with a left submandibular tumour-like mass. Imagery showed a pseudotumour appearance. Therefore, a fine-needle aspiration was carried out, the specimen contained small lymphoid-like cells and large cells with abundant, granular cytoplasm and a large nucleolated nucleus. The exact type of these cells could not be determined and a biopsy proved to be necessary for a definitive diagnosis.
Results: The biopsy showed atrophic salivary tissue, with a few residual acini dissociated by a dense lymphoplasmacytic infiltration, without a recognizable lymphoid follicle or an obvious lymphoepithelial complex; several salivary epithelial cells contained granular basophilic cytoplasm and a large intra-nuclear inclusion of the CMV type; there were no granulomas or giant cells.
An immunohistochemical study was performed using antibodies to CD3, CD20, and CK; CK identified acini and salivary ducts without a lymphoepithelial complex; the lymphoid cells were polymorphic with a predominance of T lymphocytes (CD3+), which are thought to be reactive to CMV infection.
These findings prompted a more in-depth investigation, which ultimately revealed that the patient was HIV-positive.
Conclusion: The deceptive imagery and cytological appearance make this pathological entity easily mistaken for benign or malignant tumours. Therefore, the patient's immune status is a crucial factor in diagnostic orientation, and biopsies should be widely considered even after a fine-needle aspiration. Although rare, this entity should be included in the differential diagnosis of suspicious submandibular masses, particularly in immunocompromised patients.

E-PS-13-009

Watch carefully! Perineural invasion in adenoid cystic carcinoma proves once again to be a negative prognostic marker for metastasis even without local recurrence post-R0 resection. A case report

A.-A. Neamtu[1,2,3], A. Dema[1,4,5], C. Duta[6,7], S. Taban[1,4,5]
[1]"Pius Brinzeu" County Clinical County Emergency Hospital, Department of Pathology, Timisoara, Romania, [2]"Victor Babes" University of Medicine and Pharmacy, Department of Toxicology, Timisoara, Romania, [3]"Victor Babes" University of Medicine and Pharmacy, Research Centre for Pharmaco-Toxicological Evaluation, Timisoara, Romania, [4]"Victor Babes" University of Medicine and Pharmacy, Department of Microscopic Morphology-Morphopathology, Timisoara, Romania, [5]"Victor Babes" University of Medicine and Pharmacy, ANAPATMOL Research Centre, Timisoara, Romania, [6]"Pius Brinzeu" County Clinical County Emergency Hospital, Surgery Clinic 2, Timisoara, Romania, [7]"Victor Babes" University of Medicine and Pharmacy, X Surgery Department, Timisoara, Romania

Background & Objectives: Adenoid cystic carcinoma (ACC) of the parotid gland is a rare and aggressive malignancy, representing approximately 1% of head and neck cancers, with MYB-NFIB fusion gene playing a crucial pathophysiological role. ACC has a propensity for perineural invasion (PNI) – parotidean tumours particularly along facial nerve branches – complicating detection and management as they are mostly clinically indolent. Despite unclear mechanisms linking PNI to distant metastasis, PNI is a recognized negative prognostic marker. This presentation aims to discuss a rare case of ACC that, following an R0 resection and radiotherapy, presented with delayed extensive metastases but no local recurrence, underscoring how critical clinical history and robust surveillance are.
Methods: A 54-year-old female patient initially presented with facial asymmetry due to a tumour in the right parotid gland. The patient underwent surgical excision of the tumour, facial nerve and lymph nodes (jugulo-carotid chain and spinal levels III/IV). Pathology confirmed ACC, staged IVA pT4aN0M0, with perineural invasion (PNI) and no lymphovascular invasion (LVI), achieving clear margins (R0). Post-surgery, adjuvant radiotherapy was administered. Three years later, the patient experienced acute abdominal symptoms. Imaging revealed metastatic masses in the lungs, liver, stomach, intestines, colon, and bones. An emergency laparotomy confirmed a perforated gastric ulcer and multiple peritoneal masses, which were biopsied for origin confirmation and corroboration with the initial diagnosis of ACC.
Results: Histopathological examination showed well-circumcised nodular tumours consisting of metastatic lesions with cribriform pseudoglandular pattern; cysts surrounded by cuboidal and, at the periphery, myoepithelial cells, with monomorphic small round nuclei, infrequently larger/hyperchromic/discretely vesicular; low mitotic activity. Immunohistochemistry was consistent with metastatic ACC: CK7 positivity (ductal component); p63 positivity (myoepithelial cells); CK20 and TTF1 negativity.
Conclusion: Due to its significance as prognostic marker of delayed distant metastatic behaviour, documenting PNI is crucial for the clinical management and surveillance of ACC patients, even after achieving local disease control.

E-PS-13-010

Low grade fibromyxoid sarcoma arising in the parotid gland - a pitfall in salivary gland cytopathology

E. Pereira[1], I. Brandão[2], D. Doutel[1], A. Félix[1,3]
[1]Instituto Português de Oncologia de Lisboa Francisco Gentil, Anatomic Pathology, Lisbon, Portugal, [2]Nova Medical School, Lisbon, Portugal, [3]Nova Medical School, Anatomic Pathology, Lisbon, Portugal

Background & Objectives: Low grade fibromyxoid sarcoma (LGFMS) is a rare malignant neoplasm, most commonly found in the extremities or trunk. In the literature, we found reports of 49 head and neck LGFMS, 3 in the parotid gland. These neoplasms have spindle and deceptively bland cells, often with an alternating myxoid and collagenous background. We report the clinicopathologic features of one case of LGFMS in the parotid gland.
Methods: A 58-year-old woman previously been submitted 5 years ago to a superficial parotidectomy elsewhere with unknown diagnosis, presented with a *de novo* hard, painful and palpable nodule on the same location. Fine needle aspiration citology (FNAC) of the lesion was followed by total parotidectomy.
Results: FNAC revealed a hypocellular lesion composed of bland spindle cells dispersed in a chondromyxoid-like matrix. A diagnosis biphasic neoplasia compatible with pleomorphic adenoma (PA) was established. On the surgical specimen the findings were of a multinodular myxoid-yellowish tumour with gross infiltration of the salivary gland and soft tissues. Histological evaluation revealed dispersed neoplastic spindle cells with poorly defined cytoplasm and no atypia

in a collagenous and myxoid stroma with hypocellular and hypercellular areas. The neoplastic cells were MUC4 positive and fluorescence in situ hybridization (FISH) revealed *FUS* gene rearrangement. A final diagnosis of LGFMS was made.
Conclusion: This case demonstrates that LGFMS is a difficult diagnosis, especially in citology and in uncommon locations like the head and neck, where other matrix-rich tumours like PA are commonly found. High suspicion for a myxoid mesenchymal neoplasm is necessary to properly choose complementary studies like immuno-histochemistry and FISH analysis.

E-PS-13-011
Ewing-like sarcoma of the oral cavity: a rare diagnostic challenge
N.-S. Orosz-Bogya[1], A. Orosz[1], A. Vigdorovits[1], S.-A. Vese[1], M.-M. Muresan[1], A.-C. Pop[1], A. Camarasan[1], A.-V. Pascalau[1], O.-L. Pop[1]
[1]Bihor County Emergency Clinical Hospital, Department of Anatomical Pathology, Oradea, Romania

Background & Objectives: Ewing-like sarcomas are a subset of undifferentiated round cell sarcomas that pose significant diagnostic challenges due to their histological and immunophenotypic overlap with other malignancies. Metastases to the oral cavity are extremely rare, comprising only 1% of orofacial malignancies, with the lung being the most common primary site. Distinguishing metastatic Ewing-like sarcoma from primary oral tumours is critical for appropriate management.
Methods: A 64-year-old female with multiple comorbidities, including a history of lung adenocarcinoma with multiple metastases presented with intraoral ulcerative, haemorrhagic mass. Chest and neck CT scans were followed by palliative surgical excision of the intraoral mass. Histopathological and immunohistochemical analyses, including markers CK7, CK20, Vimentin, CD99, CD34, TTF-1, CD56, Ki-67, Synaptophysin, SATB2 and TLE-1 were performed.
Results: CT scans revealed a multilobulated parenchymal-density mass in the left central hilar region along with an osteolytic lesion in the horizontal branch of the left mandible with infiltration of adjacent structures. H&E examination demonstrated diffuse, infiltrating atypical cells arranged in trabeculae, sheets, and small clusters with frequent atypical mitoses. Immunohistochemical analysis revealed CD99, CK7, synaptophysin, CD56, SATB2 and TLE-1 positivity. BCOR::CCNB3 fusion testing was unavailable, limiting further molecular characterization.
Conclusion: Although rare, oral cavity metastases should be considered in patients with a history of lung malignancy. A thorough immunohistochemical workup is crucial for distinguishing Ewing-like sarcoma from other malignancies. This case underscores the importance of recognizing atypical metastatic patterns and employing a systematic diagnostic approach for accurate classification and optimal patient care.

E-PS-13-012
Anatomopathological diagnosis of tumours of the oral cavity: a retrospective study of 10 years, from 2013 to 2023
B. Chafiaa[1], R. Hanane[1]
[1]University Hospital Centre, Anatomie Pathologic, Marrakech, Morocco

Background & Objectives: Oral cavity tumours present with a wide range of clinical and histopathological features, posing challenges in diagnosis and treatment. This study provides a comprehensive overview of oral cavity tumours over a decade from 2013 to 2023 at the University Hospital Centre of Marrakech and proposes a standardized diagnostic report template to enhance diagnostic accuracy and therapeutic strategies.
Methods: This retrospective study reviewed a total of 98 cases of oral cavity tumours diagnosed over a 10-year period at the CHU of Marrakech. The tumours were categorized based on their clinical presentations and histopathological findings. To improve diagnostic consistency and quality, a new report template was developed based on the recommendations of the College of American Pathologists (CAP).
Results: The analysis of 98 cases revealed a diverse range of clinical and histopathological presentations. Based on this, the proposed report template, grounded in the latest recommendations from the College of American Pathologists (CAP) in 2023, aims to standardize diagnostic reporting. This approach is expected to lead to more accurate diagnoses and optimized therapeutic strategies.
Conclusion: This study emphasizes the importance of standardizing diagnostic reporting for oral cavity tumours. By implementing the proposed CAP-based report template, the quality of diagnoses and therapeutic strategies at the CHU of Marrakech can be significantly improved, ultimately leading to better patient outcomes.

E-PS-13-013
Expression of immune checkpoint regulators PDL-1, VISTA, LAG3, TIM3, Nectin-2 and CD8 in adenoid cystic carcinoma
A.H. Üstündağ[1], Z.D. Ayhan[2], M.İ. Gündüz[2], N. Akyürek[2]
[1]Gazi University, Department of Oral Pathology, Ankara, Turkey, [2]Gazi University, Department of Pathology, Ankara, Turkey

Background & Objectives: Adenoid cystic carcinoma (ACC) is characterized by frequent recurrence and metastasis, highlighting the need for novel therapeutic strategies, especially immunotherapies. This study aimed to evaluate the molecular characteristics of ACC cases and assess the expression of immune checkpoint markers PD-L1, VISTA, LAG3, and TIM3, as well as CD8 and Nectin-2 in tumour-infiltrating lymphocytes (TILs), to explore potential targets for immunotherapy.
Methods: We performed immunohistochemical staining for PD-L1, VISTA, LAG3, TIM3, CD8, and nectin on 27 ACC cases diagnosed between 2019 and 2025. TILs were semi-quantitatively assessed in the most densely infiltrated areas. Expression was considered high when ≥4% of TILs were positive for PD-L1, VISTA, and CD8, and >1% for LAG3, TIM3, and nectin. Retrospective molecular analyses included testing for c-erbB-2 and androgen receptor expression, microsatellite instability, BRAF, KRAS, and EGFR mutations, and gene fusions (NTRK, RET, ALK, ROS1), as well as MET amplification.
Results: Of the 27 cases (14 female, 13 male; age 34–74), high PD-L1 expression was seen in one case, VISTA in 15, TIM3 in 8, and LAG3 in 6. CD8 was highly expressed in all cases. Nectin-2 expression in TILs was absent, though a unique PDL-1 positive case showed tumour cell expression. No cases showed c-erbB-2, androgen receptor positivity, microsatellite instability, or relevant gene fusions. One case each had a BRAF exon 11 G469E mutation, a KRAS exon 2 mutation, and a BRAF V600E mutation.
Conclusion: Co-expression of VISTA, TIM3, and LAG3 was observed in 3 cases, despite no significant molecular mutations. These findings support the potential role of immune checkpoint markers in ACC and suggest that better biomarkers are needed to understand immune evasion and resistance, paving the way for personalized immunotherapy.

E-PS-13-014
Beyond HPV: the role of invasion pattern and stromal signals in oral cavity squamous cell carsinoma
M. Toker[1], B. Mülayim[2], A. Yeniçeri[3], D. Pula[4], M. Akalın[4], B. Öğüt[1], M. Düzlü[4]
[1]Gazi University, Faculty of Medicine, Department of Pathology, Ankara, Turkey, [2]Gazi University, Faculty of Dentistry, Department of Oral Pathology, Ankara, Turkey, [3]Ankara Bilkent City Hospital, Department of Otorhinolaryngology Head & Neck Surgery, Ankara, Turkey, [4]Gazi University, Faculty of Medicine, Department of Otorhinolaryngology Head & Neck Surgery, Ankara, Turkey

Background & Objectives: The Worst Pattern of Invasion (WPOI) has emerged as a critical histopathological parameter in oral cavity squamous cell carcinomas (OCSCC), with significant prognostic and therapeutic implications. This study evaluated the relationship between WPOI and various clinicopathological and microenvironmental features in patients with oropharyngeal carcinoma.
Methods: A retrospective cohort of 53 patients diagnosed with OCSCC was analysed. WPOI was classified into low-risk (types 1–3) and high-risk (types 4–5) categories. Associations between WPOI and key variables—including p16 status (as a surrogate for HPV association), perineural invasion (PNI), lymphovascular invasion (LVI), tumour budding, tumour-infiltrating lymphocytes (TILs), stroma-tumour ratio (STR), depth of invasion (DOI), tumour differentiation, nodal metastasis, and recurrence were evaluated using Pearson's chi-square test. Survival outcomes were assessed via Kaplan-Meier analysis with log-rank tests for statistical significance. Histopathologic parameters were evaluated in haematoxylin and eosin-stained sections.
Results: The cohort included 53 patients (26 male, 27 female) with a median age of 63.84 years (range: 41-86). High-grade WPOI showed statistically significant correlations with several adverse pathological features: perineural invasion ($p = 0.0002$), lymphovascular invasion ($p = 0.0020$), high tumour budding grade ($p < 0.0001$), stromal predominance (>50% stroma; $p = 0.0006$), poor differentiation ($p = 0.0404$), and cervical lymph node metastasis ($p = 0.0068$). However, no significant associations were found between WPOI and p16 status ($p = 0.452$), TIL density (20% cutoff; $p = 0.317$), or anatomical subsite ($p = 0.189$). Survival analysis demonstrated significantly worse outcomes for high-WPOI cases (log-rank $p = 0.0039$), while higher tumour budding showed a trend toward increased nodal metastasis ($p = 0.0166$).
Conclusion: WPOI strongly correlates with adverse features (PNI, LVI, stromal response, tumour budding) and poor survival in OCSCC, reflecting critical tumour-host interactions. These findings support integrating WPOI into routine pathology reporting and risk stratification, offering valuable HPV-independent prognostic information.

E-PS-13-016
Oropharyngeal/tonsillar NUT carcinoma – an important differential diagnosis to non-keratinizing squamous cell carcinoma
J.J.H. Chng[1], N.J.H. Tan[1], F. Petersson[1]
[1]National University Hospital, Department of Pathology, Singapore, Singapore

Background & Objectives: NUT carcinoma is an uncommon and highly aggressive malignant tumour which may arise in a wide range of anatomical locations. Rare primary NUT carcinomas of the oropharynx may be misdiagnosed as HPV-associated non-keratinizing (NK) squamous (SCC) or undifferentiated cell carcinoma. We present a case of NUT carcinoma originating from the left posterior oropharyngeal wall/left tonsil, with cervical nodal metastases, which displayed morphological features overlapping with NK-SCC, both on cytology and histomorphologically.
Methods: Histology from the oropharyngeal tumour showed nests of medium-sized neoplastic cells with surrounding inflammation and central necrosis. The tumour cells displayed monotonous nuclei, increased nuclear-to-cytoplasmic ratios, vesicular nuclei, prominent nucleoli, and brisk mitotic activity. No keratinization was identified. An enlarged left level 2 cervical lymph node underwent fine-needle aspiration biopsy, which contained tumour cells arranged in syncytial crowded sheets and occasionally dispersed singly, with scattered atypical, keratinized and non-keratinized tumour cells, with necrotic and karyorrhectic debris in the background.
Results: On immunohistochemistry (IHC), the tumour cells in both the oropharynx tumour and cervical lymph node showed p63/p40 expression and focal p16 positivity. Given the tumour origin, relatively monotonous appearance of the cells, and lack of distinct light microscopical squamous differentiation, an impression of metastatic HPV-associated NK-SCC was entertained. However, the absence of block-positive p16 expression prompted further IHC testing, and we detected diffuse speckled nuclear positivity for NUT in the tumour cells in both sites.
Conclusion: Oropharyngeal NUT carcinoma is a rare neoplastic event entity that can be easily missed and misdiagnosed as other more common cancers of the oropharynx. Given the highly aggressive nature and poor prognosis compared to oropharyngeal HPV-associated NK-SCC, this distinction is of utmost clinical importance. Awareness that NUT carcinoma may arise in the oropharynx and applying IHC for NUT is critical in avoiding this mistake.

E-PS-13-018
The periostin immunoexpression in histological preparation of 100 nasal polyps
E. Koniaris[1], K. Chrysouli[2], D. Riga[1], S. Ritsatou[1], A. Aktselis[1], E. Stoupi[1], T. Nikolopoulos[3], A. Delides[3], P. Maragkoudakis[3], G. Kafiri[1]
[1]Hippocration General Hospital, Pathology, Athens, Greece, [2]Sismanogleio Hospital, Athens, Greece, [3]'Attikon' University Hospital, Athens, Greece

Background & Objectives: Periostin is an extracellular matrix protein that contributes to the remodelling of the upper respiratory system in chronic rhibosinusitis (CRS). Our aim is to investigate the periostin in nasal polyps (NPs).
Methods: NPs from 100 patients were studied. The positivity and intensity of periostin immunoexpression was evaluated. Detection of periostin was performed with the rabbit polyclonal anti-periostin anti-rabbit antibody from Abcam International Inc. (Cambridge, UK, ab14041) at a dilution of 1:100.
Results: The immunostaining score was calculated for each case using H-score with values ranging from 0 to 300 and was calculated by multiplying the percentage of positively stained cells by the staining intensity using the following formula: [1× (% weakly positive area) + 2× (% moderately positive area) + 3× (% strongly positive area)]. The results were then divided into three categories, <100, 100-200 and >200. 58% of the selected patients were male and 42% female. From the histopathological data, 70% of nasal polyps belonged to the oedematous, 20% to the adeno-cystic (ductal) and 10% to the fibrous type respectively. Periostin was expressed in all samples. The total mean immunostaining score was 136,1. 10% of nasal polyps had > 200, 68% 100- 200 and 22% <100 H-score.
Conclusion: Periostin is highly expressed in chronic Th2 inflammation such as asthma and its overproduction in the nasal mucosa is reported to contribute to polyp formation (Stankovic KM, 2008). Periostin is involved in inflammatory procedures in nasal polyps and appears to be a novel molecular biomarker for the categorization of CRS into at least 2 distinct molecular endotypes. Based on our study, periostin may serve as a new target for future therapeutic interventions in CRS with nasal polyps.

E-PS-13-020
Salivary gland tumour with ductal differentiation: A rare malignancy with HMGA2: WIFI fusion mimicking secretory carcinoma
O. Oyegbile[1], C. Natasha[2], O. Zalay[3], B. Perez[4], S. Smith[5], I. Weinreb[5], Y. Gong[6], C. E. Orr[6]
[1]Queens' university, Diagnostic and Molecular Pathology, Kingston Ontario, Canada, [2]Queens University, Otolaryngology, Kingston, Ontario, Canada, [3]Queens University, Oncology, Kingston, Ontario, Canada, [4]University of Toronto, Laboratory medicine-Anatomic Pathology, Toronto, Canada, [5]University of Toronto, Laboratory Medicine-Anatomic Pathology, Toronto, Canada, [6]Queens' university, Diagnostic and Molecular Pathology, Kingston, Ontario, Canada

Background & Objectives: Salivary gland neoplasms are a diverse group of tumours with ductal and myoepithelial differentiation and varying stromal features. Their overlapping histological and immunohistochemical characteristics can challenge pathologists in making accurate diagnoses. Recent studies have explored their molecular characteristics for diagnostic purposes. Notably, the HMGA2:WIF1 fusion was identified in pleomorphic adenomas of the parotid gland, which resemble canalicular adenomas and have a greater risk of recurrence and progression to carcinoma. Secretory carcinoma, a rare tumour featuring the ETV6-NTRK3 fusion, and its differential diagnosis includes mucoepidermoid carcinoma, salivary duct carcinoma, pleomorphic adenoma, and acinic cell carcinoma. This study aims to highlight a case of salivary gland tumour initially diagnosed as secretory carcinoma, later identified as a different malignancy due to molecular analysis
Methods: A 75-year-old woman with a slow-growing mass in the left parotid gland underwent a left subtotal parotidectomy. Imaging showed a multilobulated lesion measuring 1.4 x 2.4 x 2.2 cm. Histology revealed an epithelioid neoplasm extending beyond the capsule, with duct formation and eosinophilic secretions. Immunohistochemistry showed strong CK7, Sox10, and patchy mammaglobin positivity, initially diagnosed as secretory carcinoma. However, molecular testing identified the HMGA2-WIF1 fusion, reclassifying the diagnosis to an HMGA2 rearrangement salivary gland tumour, consistent with a benign ductal adenoma or pleomorphic adenoma.
Results: The HMGA2-WIF1 fusion reclassified the tumour from secretory carcinoma to a salivary gland tumour with an HMGA2 rearrangement, resembling a benign ductal adenoma or pleomorphic adenoma. This molecular finding clarified the diagnosis, which would have otherwise been missed
Conclusion: This case underscores the importance of molecular testing in diagnosing salivary gland tumours, particularly when histological and immunohistochemical findings are ambiguous. The HMGA2-WIF1 fusion reclassification highlights the need for combining histological, immunohistochemical, and molecular approaches to accurately diagnose these challenging tumours. Molecular profiling can prevent misdiagnosis and guide appropriate treatment, improving patient outcomes

E-PS-13-022
High grade sinonasal adenosquamous carcinoma with focal ciliated and apocrine features
M. Bundele[1]
[1]Tan Tock Seng Hospital, Pathology, Singapore, Singapore

Background & Objectives: Sinonasal Adenosquamous carcinoma is rare. Further clinicopathologic studies should be considered.
Methods: 48-year-old Chinese female nonsmoker nondrinker presented with facial pain and intermittent epistaxis. No occupational exposure to leather or wood dust was present. Patient had history of Asthma and Graves disease on Carbimazole. Nasal endoscopy showed mass involving inferior turbinate long the nasal floor. MRI showed tumour epicentre at the medial wall of left maxillary sinus infiltrating into the nasal cavity. Patient underwent left maxillectomy and left level I-V lateral neck dissection. Histology showed poorly differentiated non-keratinizing carcinoma with formation of nests and islands with areas of comedonecrosis. Focal squamous differentiation with keratinization in some solid nests and areas of glandular lumina formation with focal ciliated and apocrine features were seen. No goblet cells or sinonasal papilloma component seen. Tumour infiltrated into subcutaneous tissue through the maxillary wall (pT3). Perineural invasion was noted. No lymph node metastases were seen. Resection margins were close.
Results: Immunostaining profile:
AE1/3- moderate to strong positive staining
P40- positive in squamous areas
Androgen Receptor- patchy positive within solid nests and areas of apocrine differentiation
GATA3, Desmin, NKX2.2, NUT and p16 were negative.
SMARCA4 (BRG1) and SMARB1 (INI1) were intact.
Conclusion: High Grade Sinonasal carcinoma with glandular and squamous differentiation are rare. Unusual features such as presence of Ciliated tumour cells as well as apocrine differentiation were seen. The differential considered included apocrine adenocarcinoma of minor salivary gland origin however GATA3 was negative. Postresection patient received proton beam (radiation) therapy and is currently disease free at 3 months follow up. PET scan did not show any evidence of metastasis. The prognosis of Adenosquamous carcinoma, in general, has been found to be worse than that for conventional Squamous Cell Carcinoma (SCC) or HPV associated SCC. These cases should be studied further for appropriate classification, further refining treatment and prognostication.

E-PS-13-023
Case report: GNAQ mutation in a blue nevus of the nasal cavity
R. Rafiq[1], M. Carter[1], M. Taylor[2], M. Bullock[1]
[1]Queen Elizabeth II Health Science Centre, Department of Pathology, Halifax, Canada, [2]Dalhousie University, Department of Surgery, Division of Otolaryngology Head & Neck Surgery, Halifax, Canada

Background & Objectives: A common blue nevus typically presents as a blue-black macule or papule, often found on the extremities. Histologically, it is made up of elongated melanocytes containing cytoplasmic melanin within the dermal collagen in the mid and upper dermis. Molecular profiling of a common blue nevus may identify GNAQ or GNA11 mutations and immunohistochemistry (IHC) is often positive for SOX10, HMB45, MelanA/MART1, and S100. Here, we describe a case of a blue nevus of the nasal cavity in a 25-year-old female which was found to have a GNAQ Q209L variant.
Methods: The clinical, microscopic, immunohistochemical, and molecular features were reviewed. Next-generation sequencing (NGS) had been performed using the Ampliseq for Illumina NGS panel on the Illumina MiSeq instrument.
Results: This patient had a longstanding and increasingly firm pigmented lesion on the right caudal medial septum on the mucocutaneous junction. Histologically, the lamina propria to the deep margin contained a heavy melanocytic pigmentation of macrophages and a fascicular proliferation of spindled and epithelioid cells, also with pigmentation. There were intervening bands of thick collagen. IHC showed positivity of the spindled cells for SOX10 and MelanA/MART1, with focal HMB45 staining, and low Ki67 labelling (<2%). BRAF IHC (for V600E mutation) was negative. Beta catenin IHC was normal. Molecular testing by NGS was positive for GNAQ variant Q209L (18% allele frequency). Activating variants in GNAQ, almost always present at Q209, occur in up to 83% of blue nevi and up to 46% of uveal melanomas.
Conclusion: This rare finding within the nasal cavity may have diagnostic and therapeutic implications, including the consideration of metastatic uveal melanoma, a tumour which often has activating GNAQ and GNA11 variants. To the authors' knowledge, this is the first study to characterize the molecular profile of a blue nevus within the nasal cavity, thereby broadening our understanding of these lesions.

E-PS-13-024
Assessment of tumour-infiltrating lymphocytes predicts the behaviour of oral tongue cancer: which cut-off to choose?
S. Kamoun[1,2], A. Rais[1], A. Methnani[3], S. Mhalli[1], A. Goucha[1], I. Bettaieb[1], Y. Houcine[1], M. Driss[1,2], S. Kedous[3]
[1]Salah Azaiez Institute, Pathology Departement B, Tunis, Tunisia, [2]Salah Azaiez Institute, Research Laboratory LR21SP01, Tunis, Tunisia, [3]Salah Azaiez Institute, Department of ENT and Head and Neck Surgery, Tunis, Tunisia

Background & Objectives: The role of the tumour microenvironment in cancer prognosis has sparked interest among pathologists in recent years. Immune infiltrates around tumours have been worldwide studied. However, routine pathology reports do not assess the immune response in oral tongue carcinoma (OTC). Therefore, it is clinically important to identify histopathological criteria that can effectively evaluate the immune response. This study aims to evaluate tumour-infiltrating lymphocytes (TILs) in OTC to determine whether TILs is a prognostic factor, and to identify which cut-off point would be most useful.
Methods: We report 67 cases of OTC diagnosed at department of pathology B of Oncology Institute of Tunis during 8years. Lymphocytic infiltration was assessed according to the recommendations of the International Immuno-Oncology Biomarker Study Group (IIOBSG) for the evaluation of lymphocytes infiltrating solid tumours. To facilitate the interpretation of the results, TILs were classified into two categories using cut-off points of 30% and 60%.
Results: The distribution of TILs patterns showed that 75% of cases had TILs<30%, while 25% had TILs>30%. Survival analysis revealed that TILs>30% was associated with better overall survival(OS), although this was not statistically significant (p=0.36). The mean OS for TILs>30% was 85 months, compared to 74 months for TILs<30%. On the other hand, 94% of cases had TILs<60%, and 6% had TILs>60%. Survival analysis showed that TILs>60% was not associated with better prognosis. The mean OS for TILs >60% was 46 months, compared to 47months for TILs<60%.
Conclusion: In conclusion, this study represents the first evaluation of TILs in OTC in our institution. The method introduced by the IIOBSG can be used for the standardized determination of TILs in OTC. A cut-off of 30% is more reliable than a cut-off of 60%. Further studies with larger cohorts are required to validate these findings and clarify the role of TILs in OTC management.

E-PS-13-025
A Morphomolecular perspective on a rare phenomenon: malignant melanoma in the tonsil
M. Büyükgök[1], O. Savaş[2], Ç. Atakan[2], B. Pehlivanoglu[3]
[1]Dokuz Eylul University, Department of Medical Pathology, İzmir, Turkey, [2]Dokuz Eylul University, Department of Otorhinolaryngology, Izmir, Turkey, [3]Dokuz Eylul University, Department of Medical Pathology, Izmir, Turkey

Background & Objectives: Malignant melanoma (MM), one of the deadliest skin cancers, may rarely occur in mucosa either as a primary or metastatic tumour. To date, less than 50 cases of primary/metastatic tonsillar MM have been reported.
Methods: Here, a case of malignant melanoma located in the right tonsil is presented.
Results: A 67-year-old man who had previously been diagnosed with acral lentiginous MM on the right heel presented with complaints of weight loss and difficulty in swallowing 16 years after the initial diagnosis. A 4.5 cm, black, indurated mass was detected on the right tonsil in physical examination. The patient underwent tonsillectomy. In microscopic examination, a tumour infiltrating the tonsil mucosa and submucosa with spindle and epithelioid morphology, containing brownish pigment was detected. The tumour was positive for HMB45, Melan-A, Sox10, and negative for Keratin. Then, next generation sequencing (NGS) was performed to reveal any mutations that might be targeted during therapy. However, no mutation was detected.
Conclusion: Considering the previous history of MM, the tumour in this case represents a metastatic lesion. Mucosal metastasis of skin melanoma, including metastatic tonsillar melanoma is rare. However, it should be kept in mind in differential diagnosis in cases diagnosed with melanoma, even in the long-term follow-up.

E-PS-13-027
Splenic metastasis of parotid acinic cell carcinoma
J. Lages dos Santos[1], M.J. Germano de Sousa[2], R. Caetano Oliveira[2]
[1]Unidade Local de Saúde Gaia Espinho, Department of Anatomic Pathology, Porto, Portugal, [2]Centro de Anatomia Patológica Germano de Sousa, Coimbra, Portugal

Background & Objectives: Acinic cell carcinoma is a salivary gland neoplasm representing around 10% of all salivary gland malignancies, developing in the parotid gland in 85% of cases. Despite most cases having a favourable prognosis, as evidenced by mean 5-year-survival rates of approximately 95-97.2%, the prognosis worsens considerably with the presence of distant metastasis, dropping survival rates to around 22%. Acinic cell carcinoma most commonly metastizes via lymphatic spread and is more frequent in high-grade tumours.
Splenic metastases are rare and of hematogenous origin, as the spleen has no afferent lymphatic vessels. In this report we present a rare case of splenic metastasis of acinic cell carcinoma.
Methods: We report the case of a 53-year-old man with history of acinic cell carcinoma of the parotid gland for which he was surgically interventioned in 2018 and followed at the Instituto Português de Oncologia de Coimbra, with evidence of disease progression in 2024 in the form of lung and bone metastases, as well as a single splenic metastasis which was surgically excised.
Results: We received a surgical specimen of total splenectomy weighing 310g, measuring 13.5 x 10.5 x 4.5 cm with a smooth and continuous capsule. On cut section exhibits a heterogeneous nodule with 1.5 x 1.3 cm, with white and pink areas, tangential to the capsule.
On microscopic examination we observed an expansive nodule of acinic cells with central haemorrhage within the splenic parenchyma. The acinic cells showed diffuse and strong immunoreactivity to DOG1, focal, heterogenous staining for EMA and SOX-10, and no staining for p40.
Conclusion: As acinic cell carcinoma typically metastasize via lymphatic spread, this case is evidence of hematogenous spread to the spleen, highlighting the need for a more thorough staging process, particularly in the case of high-grade tumours.

E-PS-13-028
SMARCA4 deficient malignancies of the head and neck region: focusing on 6 new cases of SMARCA4 deficient carcinomas
M. Bradová[1,2], A. Agaimy[3], L. Hauer[4], P. Martínek[1], K. Pivovarcikova[1,2], B. Prchlikova[5], M. Farkasz[6], R.H. Simpson[7], M. Rito[8], P. Slavík[1,2], M. Michal[1,2], A. Skálová[1,2], M. Svajdler[1,2,9]
[1]Bioptic Laboratory, Ltd, Plzen, Czech Republic, Pilsen, Czech Republic, [2]Department of Pathology, Faculty of Medicine in Plzen, University Hospital Plzen, Charles University, Pilsen, Czech Republic, [3]University Hospital Erlangen, Friedrich-Alexander University Erlangen-Nürnberg (FAU), Comprehensive Cancer Centre (CCC) Erlangen-EMN, Erlangen, Germany, Institute of Pathology, Erlangen, Germany, [4]University Hospital and Faculty of Medicine in Pilsen, Charles University, Faculty of Medicine in Plzen, Plzen, Czech Republic, Department of Oral and Maxillofacial Surgery, Pilsen, Czech Republic, [5]Rudolf and Stefanie Hospital Benešov, Inc., Benešov, Czech Republic., Department of Pathological Anatomy, Brno, Czech Republic, [6]Onco Team Diagnostic, București, Romania, Bucurest, Romania, [7]Department of Pathology, University of Calgary, Calgary, Alberta, Canada, Calgary, Canada, [8]Serviço de Anatomia Patológica, Instituto Português de Oncologia de Lisboa, R. Prof. Lima Basto, 1099-023, Lisbon, Portugal., Lisbon, Portugal, [9]Cytopathos, Ltd, Bratislava, Slovakia, Bratislava, Slovakia

Background & Objectives: SMARCA4-deficient neoplasms are rare and highly aggressive malignancies characterized by inactivation or

loss of the SMARCA4 gene, which encodes BRG1, a core component of the SWI/SNF chromatin remodelling complex**.** These neoplasms exhibit a pattern-based association with specific cancer types rather than a random cancer distribution. In the head and neck (H&N), SMARCA4-deficient malignancies include SMARCA4-deficient sinonasal carcinoma and most of the teratocarcinosarcomas. Only one case of SMARCA4 deficient carcinoma was reported outside the sinonasal region.
Methods: Six cases of SMARCA4-deficient carcinomas of the H&N, were identified in the authors' archives. Their clinicopathological features were reviewed and documented. All cases with available tissue block were investigated by molecular genetic methods.
Results: The cohort consisted of six new cases localized in sinonasal (3/6) and non-sinonasal locations (3/6). The non-sinonasal tumours were present in the tongue, oral floor and the upper jaw submucosa, affecting 66- and 81-year old men and 61-years old woman, respectively. Lymph node metastasis were documented in two cases. Histologically, two cases were poorly differentiated malignancies with small cell morphology and one case showed morphology resembling salivary duct carcinoma. A novel fusion *SLC66A1::PLCB1 (exon 1::exon 31)* was found in one case, one case showed multiple copy number variations and in the third case had *KRAS* gene mutation.
Conclusion: The presence of SMARCA4-deficient carcinoma in the H&N outside the sinonasal tract is extraordinary**.** We present 3 cases of sinonasal SMARCA4-deficient carcinomas and three new cases outside the sinonasal tract widening the topographic distribution of SMARCA4-deficient carcinomas. These tumours are highly aggressive and are often diagnosed at an advanced stage. In the sinonasal region, they can mimic olfactory neuroblastoma, while in other head and neck sites, they may resemble neuroendocrine carcinoma. SMARCB1 immunohistochemistry is essential for evaluating poorly differentiated neoplasms throughout the head and neck to ensure accurate diagnosis.

Funding: This study was in part supported by study grant SVV 260652 from the Ministry of Education, Czech Republic, the Cooperatio Program, research area SURG, and the project National Institute for Cancer Research – NICR (Programme EXCELES, ID Project No. LX22NPO5102) - Funded by the European Union - Next Generation EU

E-PS-13-029

Human papillomavirus infection as a prognostic factor in carcinomas of the oral cavity

M. Alaya[1], S. Kamoun[1,2], M. El Faires[2,3], R. Abir[1], S. Dhambri[4], A. Goucha[1], I. Bettaieb[1], R. Jeridi[1], Y. Houcine[1], M. Driss[1], S. Kedous[4]
[1]Salah Azaiez Institute, Pathology Department B, Tunis, Tunisia, [2]Salah Azaiez Institute, Research Laboratory LR21SP01, Tunis, Tunisia, [3]Faculty of Sciences of Bizerte, Bizerte, Tunisia, [4]Salah Azaiez Institute, Department of ENT, Head and Neck Surgery, Tunis, Tunisia

Background & Objectives: Oral cavity squamous cell carcinomas account for 0.8% of cancers according to the North Tunisia Cancer Registry and affect more men than women. The main risk factors are alcohol and tobacco use. Human papillomavirus (HPV) infection is also a risk factor for squamous cell carcinoma (SCC). Its detection can be performed using various techniques. This study aims to determine whether p16 expression is a prognostic factor.
Methods: The is descriptive and retrospective study, including 60 cases of oral cavity SCC collected in Pathology Department B of the Salah Azaiez Institute over 11 years, from January 2012 to November 2022. It examines clinical features and histological features, alongside p16 expression determined by immunohistochemistry.
Results: The mean age of patients was 64 years [18-85], with a sex ratio of 2.75. Tumour locations were as follows: 23% lip, 12% cheek, 13% palate, 13% gum, and 38% tongue. p16 positivity was statistically correlated with gum location ($p = 0.023$). Alcoholic and/or tobacco use was present in 49% of cases. 18% of cases tested positive for p16, with intense staining in 80% of cells in 3 cases and in 100% of cells in the remaining 8 cases. Regarding patient follow-up, 20% had recurrences after treatment, with only one case of metastatic relapse, and 5% of patients died. P16 positivity was statistically associated with the absence of recurrence ($p<0.000$), but it was not correlated with lymph node metastasis or mortality.
Conclusion: HPV infection remains an emerging factor in squamous cell carcinoma of the oral cavity. However, in our country, it is still preceded by other major risk factors such as smoking and alcohol consumption. Our study demonstrates that HPV-infected patients have a better prognosis and fewer recurrences. Further investigations using other tools, such as PCR or in situ hybridization, should be conducted to confirm HPV infection.

E-PS-13-030

Immunohistochemical study of p16 in sinonasal carcinomas and correlation with anatomo- clinical and prognostic factors

M. Alaya[1], S. Kamoun[1,2], H. Ouled Nassr[3], A. Ghazouani[4], A. Methnani[5], A. Goucha[1], I. Bettaieb[1], N. Aloui[1], Y. Houcine[1], M. Driss[1,2], S. Kedous[5]
[1]Salah Azaiez Institute, Pathology Department B, Tunis, Tunisia, [2]Salah Azaiez Institute, Research Laboratory LR21SP01, Tunis, Tunisia, [3]Faculty of Science of Tunis, Tunis, Tunisia, [4]Salah Azaiez Institute, Surgical Oncology, Tunis, Tunisia, [5]Salah Azaiez Institute, Department of ENT, Head and Neck Surgery, Tunis, Tunisia

Background & Objectives: Sinonasal squamous cell carcinomas (SCC) are rare malignancies that arise in the nasal and paranasal regions, with a complex aetiology influenced by factors such as tobacco and alcohol use, as well as potential viral infections like Human Papillomavirus (HPV). However, the role of p16 expression, which is often linked to HPV infection, in sinonasal SCC remains poorly understood. This study explores the overexpression of the tumour suppressor protein p16 in sinonasal carcinomas and its correlations with clinical and prognostic factors.
Methods: This is a monocentric, descriptive, cross-sectional, and retrospective study that includes 32 Tunisian patients with sinonasal SCC, collected at the Pathology Department B of the Salah Azaiez Institute from 2010 to 2022. It examines clinical features (age, sex, tobacco/alcohol use, tumour characteristics) and histological features (subtypes, degree of keratinization), alongside p16 expression determined by immunohistochemistry.
Results: The average age at diagnosis was 60 years, with a male predominance. The tumour stage was advanced in 69% of cases, and the average tumour size was 48 mm. Tobacco use was observed in 37% of cases, and alcohol-tobacco use was noted in 19% of cases. In this study, 31% of cases were p16-positive. No association was found between p16 overexpression and age, gender, tobacco use, alcohol-tobacco use, tumour size, clinical tumour stage (T), presence of lymphadenopathy, or distant metastases. However, the histological types of adenoid cystic morphology and non-keratinizing subtypes were significantly associated with positive p16 expression ($p=0.006$, $p=0.03$).
Conclusion: p16 overexpression is statistically more commonly observed in adenoid cystic morphology and non-keratinizing squamous cell carcinoma. These results suggest that histological morphology may provide insight into p16 status and, by extension, HPV status. Further investigations using additional tools, such as PCR or in situ hybridization, should be conducted to confirm HPV infection.

E-PS-13-031

Aberrant expression of IRF1 promotes the proliferation and tumorigenicity of oral squamous cancer cells

H.-W. Chuang[1], Y.-J. Li[1], J.-S. Liang[1], T.-C. Yuan[2]
[1]Kaohsiung Veterans General Hospital, Pathology and Laboratory Medicine, Kaohsiung, Taiwan, [2]National Dong Hwa University, Department of Life Science, Hualien, Taiwan

Background & Objectives: Interferon regulatory factor 1 (IRF1) is a transcription factor that belongs to the family of interferon regulatory factors. IRF1 plays regulatory roles in type I interferon production, lymphocyte development, and immune responses. Some studies show the antitumor properties of IRF1 in different cancer types. However, its tumour-promoting effects have also been reported. It is unclear what the expression profile and functional role of IRF1 are in oral squamous cell carcinoma (OSCC).
Methods: We initially examined the immunoexpression of IRF1 protein in 40 paraffin-embedded OSCC tissue samples, including tumour and non-cancer epithelial tissues, from our archives. Next, we performed the RNA-sequencing and western blot analysis of OSCC cell lines, including OECM-1, SAS, and HSC-3, comparing them to immortalized human oral keratinocytes (HOK). We further knocked down IRF1 expression in OECM-1, SAS, and FaDu cells to determine the potential of IRF1 to affect OSCC proliferation, migration, and invasion capability in vitro.
Results: IRF1 was primarily detected on the cell membrane and cytoplasm of OSCC cells, with increased nuclear staining in strong immunoreactivity. In thirty-three patients with paired normal and cancerous tissues, IRF1 showed greater positive expression in tumours than in normal epithelia. However, there was no significant difference between the survival times and IRF1 expression in 40 patients. A heat map showed the relative expression of *IRF1-3*, *IRF5-7*, and *IRF9* genes. Among *IRF* genes, only the *IRF1* gene was highly expressed in all three OSCC cells. Western blot analysis further indicated that OSCC cells exhibited a higher level of IRF1 proteins than HOK. Decreased cell proliferation in IRF1-knockdown OECM-1, SAS, and FaDu cells was found, and silencing IRF1 expression in those cells also reduced cell migration and invasion.
Conclusion: Our results suggest that IRF1 may serve as a prognostic biomarker associated with the tumorigenesis and aggressiveness of OSCC.

E-PS-13-032

Pd-L1 expression in head and neck squamous cell carcinomas (HN-SCC)

A. Nalwa[1], A. Visakhan[1], P. Elhence[1], M. Rao[1], V. Vishwajeet[1]
[1]All India Institute of Medical Sciences, Pathology & Lab Medicine, Jodhpur, India

Background & Objectives: PD-L1 molecule responsible for immune evasion, and p16, a surrogate marker of HPV. Study aimed to assess expression of PD-L1 in HN-SCCs. Authors studied PD-L1 expression in tumour and tumour infiltrating lymphocytes with clinico-pathologic parameters:age, gender, histologic subtype, histologic grade, nodal status, stage, lymphovascular and extranodal extension; & compared PD-L1 expression in HPV-positive and HPV-negative HN-SCCs using p16 immunohistochemistry.
Methods: IHC for PD-L1 was evaluated using combined proportion score (CPS). CPS ≥1:low positive,CPS ≥20:strong positive. CPS <1 or no expression in tumour or immune cells was scored as negative. Diffuse and strong nuclear and cytoplasmic expression of p16 in ≥70% tumour cells was considered positive (block) expression.
Results: Total 188 cases of HN-SCCs were included. Buccal mucosa(49%) was the commonest site.Of n=188 cases, 162(87%) showed PD-L1 positivity and 26(13%) did not show PD-L1 expression. In well-differentiated SCCs 69.6%(n=16) showed a CPS score >20, and in high-grade (moderate & poorly-differentiated SCC),66.1% (109)showed a CPS>20. 29 (17.1%) were low positive and 27(16.4%) were negative.A p-value of 0.894 was observed, suggesting no significant statistical correlation with PD-L1 expression with tumour grade. Among early stages (pT1&pT2), 47 (59.5%) were strong positive,15 (19.0%) were low positive and 17 (21.5%) were negative for PD-L1. Among advanced stage (pT3&pT4),78 (71.6%) were strong positive,17(15.6%) were low positive and 14 (12.8%) were negative for PD-L1 withp-value of 0.182 suggesting no significant statistical correlation between PD-L1 expression and tumour stage.Among 136 cases with p16 positivity, 91 were strongly positive for PD-L1,20 were low positive and 20 were negative for PD-L1 with no significant statistical correlation between p16 and PD-L1.
Conclusion: In current era of personalized cancer treatment & targeted immunotherapy role of PD-L1 is becoming relevant in management of HN-SCC.Studies with a bigger sample size are required to establish correlation of PD-L1 with clinico-pathological parameters and HPV association especially in Indian population.

E-PS-13-033

Craniofacial vascular malformation with *PIK3CA* activating mutation in a 15-year-old patient

A. Syrnioti[1], A. Loukousia[1], V. Kotoula[1], S. Sotiriou[1], S. Balaska[1], A. Tragiannidis[2], K. Chatzopoulos[1]
[1]Department of Pathology, School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece, [2]Childhood & Adolescent Haematology Oncology Unit, 2nd Paediatric Department, School of Medicine, Aristotle University of Thessaloniki, AHEPA University Hospital, Thessaloniki, Greece

Background & Objectives: Vascular malformations are congenital anomalies arising from defects during vascular development. *PIK3CA* mutations, known to drive overactivation of the phosphoinositide 3-kinase (PI3K)/AKT pathway, have been implicated in a subset of vascular malformations, with potential therapeutic implications. We report a case of a 15-year-old male with a combined lymphatic and venous malformation harbouring an activating/oncogenic *PIK3CA* mutation, discussing its histopathological characteristics and clinical relevance.
Methods: A 15-year-old male presented with multiple polycystic lesions in the right frontal and orbital region. Biopsy of the lesions was performed, which was sent for histopathological examination, followed by targeted next-generation sequencing (NGS). Haematoxylin-eosin, histochemical, and immunohistochemical stained sections were examined. Molecular profiling was performed using the Oncomine Precision Assay on a Genexus Integrated Sequencer (CE-IVD).
Results: Microscopic examination revealed thin-walled lymphatic and venous-type vascular formations of various size and shape, within fibroadipose and striated muscle tissue. Lymphatic-type vascular formations were lined by a layer of podoplanin (D2-40)-positive endothelial cells. Venous-type formations exhibited a well-developed, continuous smooth muscle wall, whereas lymphatic-type formations had only focal smooth muscle fibres within their walls, as demonstrated by Masson's trichrome histochemical staining and caldesmon immunohistochemistry. No cytologic atypia, pleomorphism, or mitotic activity were observed. NGS analysis demonstrated an oncogenic *PIK3CA* p.H1047R (c.3140A>G) mutation, a hotspot variant in the kinase domain of the catalytic subunit of PI3K known to activate the PI3K/AKT pathway. This mutation has been reported in vascular malformations and is druggable with AKT (miransertib) and PI3K (alpelisib) inhibitors. No additional pathogenic variants were detected.
Conclusion: This case underscores the role of *PIK3CA* mutations in vascular malformations and their potential therapeutic relevance. Molecular profiling in vascular anomalies can guide therapeutic

decisions, offering new treatment avenues for patients with refractory or symptomatic lesions. Further research is needed to establish standardized molecular-driven treatment strategies for these conditions.

E-PS-13-035

EBV-positive mucocutaneous ulcer: a case report

S. Papadopoulou[1], I. Emmanouil[1], I. Dimitriadis[1], N. Pastelli[1], P. Eskitzis[2], K. Domvri[1], P. Pantelidou[1], S. Papaemmanouil[1]
[1]General Hospital of Thessaloniki George Papanikolaou, Pathology, Thessaloniki, Greece, [2]Assistant Professor, Western Macedonia University, Obstetrics Department, Ptolemaida, Greece

Background & Objectives: Epstein-Barr virus-positive mucocutaneous ulcer (EBVMCU) is a rare, indolent B-cell lymphoproliferative disorder, first described in 2010 by Stefan D.Dojcinov et al., characterized by solitary or multiple ulcers in the oral cavity, skin, gastrointestinal tract. It is often associated with immunosuppression, aging, or underlying immunodeficiency.
Methods: **Case report:** A 56-year-old woman presented with a persistent, non-healing ulcer on her buccal mucosa. The ulcer was approximately 1.5 cm in diameter, with a fibrinous base and irregular borders. The patient reported no significant medical history. An incisional biopsy was performed. Histopathological examination revealed a dense polymorphic inflammatory infiltrate including abundant lymphocytes, polyclonal plasma cells, scattered histiocytes, neutrophils and eosinophils. Among these, numerous large cells with vesicular nuclei, sometimes lobulated, and a prominent nucleolus were recognized, resembling Hodgkin-Reed Sterberg cells. These were positive to CD30, CD20, MUM-1 and EBV (LMP-1 protein) but negative to CD3, CD5, CD15 and Bcl-6. The histological findings in relation with the clinical information and the absence of lymphadenopathy, were compatible with an EBV-positive mucocutaneous ulcer. Further testing showed no evidence of systemic EBV-associated lymphoproliferative disorders.
Results: **Discussion:** EBVMCU is a challenging diagnosis due to its rarity and variable clinical presentation. The differential diagnosis includes lymphoma, squamous cell carcinoma, and other infectious or inflammatory processes. The diagnosis of EBVMCU may be a challenge to pathologists, as the presence of large pleomorphic cells are suggestive of malignant lymphoproliferative processes, such as classic Hodgkin lymphoma, DLBCL associated or not with EBV, anaplastic large cell lymphoma (ALCL) or lymphomatoid granulomatosis. The absence of a clear immunodeficiency state in this case is noteworthy, highlighting that EBVMCU can occur in immunocompetent individuals.
Conclusion: This case underscores the importance of considering EBVMCU in the differential diagnosis of persistent mucocutaneous ulcers, even in the absence of overt immunosuppression. Comprehensive histopathological and immunohistochemical evaluation is essential for accurate diagnosis.

E-PS-13-036

A pathological series of 30 ameloblastoma

R. Ben Essalah[1,1], S. Khalifa[1], B. Belbachir[1]
[1]University Hospital of Oran, Pathology, Oran, Algeria

Background & Objectives: Ameloblastoma is defined as an odontogenic tumour. classified as benign, it behaves in a localy agressive maner and it's tendancy to recur. Pathology plays a key role not only in diagnosing but also prognosing by providing critical insights related to histological characteristics that can influence the treatment strategy .in this presentation we collected 30 cases from our pathology department from January 2023 to december 2024, we show case the distribution according to sexe, age, histological sub-types and other variables.
Describe the epidemiological and pathological profile of ameloblastoma.
Methods: For our describtive study, we collected a series of 30 cases including: 17 mandibulectomy specimens, 3 maxilectomies and 10 biopsies.
Results: - The males were commonly involved with a sex ratio of 1.72.
- The affected age group : 20 to 55 years old . mean age 35 yo.
- 05 cases of ameloblastoma unicystic type and 20cases of peripheral type.
- The histological types of ameloblatome found were:
follicular sub-type (22 cases), plexiform (3 cases), desmoplasic (2 cases), acanthomatous (2 cases).
metastatic ameloblastoma (1 case).
- No intravascular tumour emboli was found nor perineural invasion.
- 04 cases only involved spongy bone invasion.
- The R- classification resection results shows: -10 cases of R-2,06 cases of R-1 and 14 cases of R0.
Conclusion: Ameloblastoma is a frequent bone lesion, considering its radiological aspcets wich lacks pathognomonic features, it's diagnosis remains histological.

E-PS-13-040

Lymphoid stroma in a salivary gland pleomorphic adenoma case

A.C. Faur[1], L.A. Ghenciu LA[2], A.M. Sisu[1], H. Urechescu[3], C. Prodan-Barbulescu[1], A.-M. Pusztai[1]
[1]"V. Babes" University of Medicine and Pharmacy, Anatomy and Embryology, Timisoara, Romania, [2]"V. Babes" University of Medicine and Pharmacy, Department of Functional Sciences, Timisoara, Romania, [3]"V. Babes" University of Medicine and Pharmacy, Oro-Maxillo-Facial Surgery Department, Timisoara, Romania

Background & Objectives: Pleomorphic adenomas (PAs) are common benign salivary gland tumours mostly situated in the superficial lobes of the parotid glands. We present a unique case of a PA with lymphoid stroma.
Methods: A 77-year-old female presented to the Oro-Maxillo-Facial Surgery Department, City Hospital of Timisoara, with a right parotid painless mass. A resection of the mass with tumour-free margins was performed. The patient was previously surgically treated for a synchronous squamous cell carcinoma of the gingivae of the left oral cavity.
Results: Macroscopically the tumour was a circumscribed 4.5/3/1.6 cm, white elastic mass with irregular capsule. The microscopic examination revealed a tumour with a mixture of myoepithelial cells, ductal cells and extracellular stroma. The stromal component was myxochondroid and rich in lymphoid cells. The histochemical examination with Periodic-Acid-Schiff (PAS) revealed positive stain within the lumen of ductal areas of the PA. Slides were stained immunohistochemically for CD20, CD3, CD8, and Multi (AE1/AE3) antibodies. The epithelial areas show a positive reaction for cytocheratins. In the lymphoid component, there were a population of cells positive for CD20, CD3 and CD8. The population of CD8 and CD3 positive cells was quantitatively richer than the CD20 positive one.
Conclusion: To best of our knowledge, this is the first case of PA with a lymphoid stromal component reported in the English language literature.

E-PS-13-041

Endoglin expression in vascular endothelial cells and its role in angiogenesis and pathogenesis of nasal polyps

E. Koniaris[1], K. Chrysouli[2], A. Kataki[1], D. Riga[1], S. Ritsatou[1], E. Stoupi[1], T. Nikolopoulos[3], A. Delides[3], P. Maragkoudakis[3], G. Kafiri[1]
[1]"Hippocration" General Hospital, Pathology, Athens, Greece, [2]Sismanogleio Hospital, Athens, Greece, [3]'Attikon' University Hospital, Athens, Greece

Background & Objectives: CD105/Endoglin, is a transmembrane glycoprotein and ancillary receptor of TGF-β, mainly expressed on

vascular endothelial cells. Antibodies against CD105 react preferentially with endothelial cells in tissues with active angiogenesis. Thus CD105 is a valuable angiogenic biomarker in the diagnosis and prognosis of cancer. CD105 is also related to inflammatory diseases: its expression is strongly upregulated in endothelial cells of inflammed tissues.Vascularity is a prognostic indicator of inflammation. Aim of this study is to evaluate the vascularity in histological preparation of 100 nasal polyp tissues.
Methods: Tissue from 100 operated patients was used for evaluation of the nasal polyp vascularity. The polyclonal anti-CD105 antibody was used. Then, the vascularity was assessed by counting CD105-stained vessels and calculating the Microvessel Density (MVD), through a Digital Image Analysis System, in order to obtain more objective results.
Results: CD105 was expressed in all tissue samples. Nasal polyps were associated with a high MVD, as revealed by CD105 immunostaining; the mean MVD value was 19,65.Of the total number of vessels counted in each section, the average number of small vessels was 90,45, while the average number of large vessels was 38,27.Moreover, the diameter of small vessels (min vessel area) ranged from 10 to 45 μm, with an average of 20,62 μm, while the diameter of large vessels (max vessel area) ranged from 87 to 1615 μm, with an average of 405,81 μm, respectively.
Conclusion: Recently, a significant association was found between CD105 expression and the size of nasal polyps, hypothesizing a role for CD105 and angiogenesis in the development of chronic rhinosinusitis with nasal polyps (CRSwNP). This study supports that CD105 expression in vascular endothelial cells may contribute to the angiogenesis and pathogenesis of nasal polyps.

E-PS-13-042

A challenging case of giant oral undifferentiated pleomorphic sarcoma uncovering a novel *SPECC1L::TERT* gene fusion

M. Della Mura[1], J. Sorino[1], E. Maiorano[1], G. Cazzato[1], A. Manfuso[2], C. Caporusso[1], C. Copelli[2], E. Cascardi[1]
[1]University of Bari "Aldo Moro", Section of Molecular Pathology, Department of Precision and Regenerative Medicine and Ionian Area (DiMePRe-J), Bari, Italy, [2]University of Bari "Aldo Moro", Maxillofacial Surgery Unit, Interdisciplinary Department of Medicine, Bari, Italy

Background & Objectives: Undifferentiated pleomorphic sarcoma (UPS) is a type of soft tissue sarcoma consisting of a patternless growth of pleomorphic bizarre tumour cells without identifiable line of differentiation. It can rarely involve the maxillo-facial region, constituting both a diagnostic and therapeutic challenge. Herein, we report a novel case of UPS of the oral cavity, characterized by exceptionally large size, aggressive clinical course and novel molecular finding, further deepening our knowledge about this entity.
Methods: Patient's clinical history was retrieved. Tissue samples were formalin-fixed and paraffin-embedded. Haematoxylin-eosin and immunohistochemical stainings (including CKAE1/AE3, CKMNF116, EMA, p63, p40, vimentin, SMA, SMMS-1, desmin, CD10, CD34, ERG, Melan-A, S-100, MDM2) along with RNA-based NGS were performed. A comprehensive literature review was conducted on public scientific databases (2002-present) to contextualize our findings.
Results: A 54-year-old woman presented with a rapidly enlarging, 10 cm oral mesenchymal neoplasm involving the left maxilla, unresponsive to neoadiuvant chemotherapy. Complete surgical excision was performed. Histopathology revealed a high-cellular, necrotic mass, composed of highly pleomorphic cells with brisk mitotic activity, arranged in a vaguely storiform pattern. Immunohistochemistry didn't show a specific lineage of differentiation, revealing an "only vimentin" positive phenotype; Ki-67 was 80%. RNA-based NGS found a novel gene fusion transcript: *SPECC1L::TERT*. After 6 months, patient is disease-free.
Conclusion: Only 53 oral UPSs have been reported so far. Male predominance, geographic predilection for middle-east Asia, history of trauma and aggressive course are common features. Differential diagnosis requires exclusion of other mesenchymal/non-mesenchymal neoplasms. Although complete surgical resection is critical, the role of chemotherapy remains undefined. Our case represents the largest documented oral UPS and, for the first time, NGS molecular evaluation was performed, with the discovery of *SPECC1L::TERT* gene fusion. While its functional implication requires further investigation, its identification provides new insights into the molecular pathogenesis of UPS, potentially informing future targeted therapies for this aggressive neoplasm.

E-PS-13-043

The role of chemokine receptors in salivary gland tumours

V. Ruhdorfer[1], M. Leoni[1], S. Schauer[1], J. Pock[2], A. Deutsch[3], A. Aigelsreiter[1]
[1]Diagnostic and Research Institute of Pathology, Medical University of Graz, Graz, Austria, [2]Institute of Otorhinolaryngology, Medical University of Graz, Graz, Austria, [3]Institute of Haematology, Department of Internal Medicine, Medical University of Graz, Graz, Austria

Background & Objectives: Chemokine receptors (CRs) are G-protein-coupled-receptors that play a key role in the recruitment of immune cells, tumour progression and metastasis. Tumour cells exploit chemokine receptors to create a favourable microenvironment for immune evasion, angiogenesis, and therapy resistance. Data concerning chemokine receptors in salivary gland tumours are sparse. Therefore, we designed this study to comprehensively study the mRNA expression profile of 10 CRs in our cohort of salivary gland tumours.
Methods: We performed mRNA profiles of 10 CRs (CCR1, CCR2, CCR3, CCR4, CCR6, CCR8, CCR9, CXCR4, CXCR6, and CXCR7) of 70 paraffin-embedded salivary gland tumours by a semiquantitative realtime-PCR. Non-neoplastic lymphatic tissue specimens (tonsils, lymph nodes) known to express all the CRs were included as positive controls.
Results: The mRNA levels of the 10 CRs were detectable in nearly all included salivary gland tumours. Interestingly, no significant differences were observed between squamous and glandular tumours. However, hierarchical cluster analysis revealed two distinct tumour clusters: one characterized by high expression of the investigated CRs and the other by low expression. Moreover, survival analysis indicated that low expression of CCR6 and CCR10 was associated with shorter survival, confirming already published data.
Conclusion: Our data indicates that the expression patterns of the CRs are not influenced by the subtype of salivary gland tumour. Furthermore, we showed that hierarchical clustering identified two tumour groups based on CR expression, suggesting biological heterogeneity. Notably, low CCR6 and CCR10 expression correlated with reduced survival, highlighting their potential prognostic value. These findings warrant further investigation into the role of CRs as therapeutic targets.

E-PS-13-044

Palisading adenocarcinoma of the sublingual gland: a report of two cases of a recently described entity

A.N. Yuksel[1], A. Aydogdu Yesiloglu[2], G. Acar Yüceant[3], B.U. Durmus[1], A.H. Uguz[2], K. Basak[1]
[1]Kartal Dr. Lutfi Kirdar City Hospital, Department of Pathology, Istanbul, Turkey, [2]Cukurova University, Department of Pathology, Adana, Turkey, [3]Kartal Dr. Lutfi Kirdar City Hospital, Otorhinolaryngology, Head and Neck Surgery, Istanbul, Turkey

Background & Objectives: In recent years, a new tumour named palisading adenocarcinoma, which is characteristically and uniquely located in the sublingual gland and has a unique histological pattern, has been described. We would like to report two cases from more than one centre in Türkiye to better define the demographic and histopathological features of this particular type of carcinoma.
Methods: Two female patients, aged 39 and 54 years, presented with sublingual masses located in the floor of the mouth. MRI showed a mass not clearly demarcated from the normal sublingual gland for the first case and a well delineated mass for the second case. Macroscopically the mass dimensions were 3x3x2 cm and 2x2x1.8 cm. The capsule structure could not be clearly evaluated macroscopically in the first case. The second case was described as a well-circumscribed, solid encapsulated mass.
Results: Histopathological examination shows that both tumours are composed of 2 cell components. First and dominant component were consisted of cells with predominantly round, pale eosinophilic cytoplasm, prominent nucleoli and some nuclei has shown salt-pepper chromatin-like appearance. Secondary component was consisted of tubule forming cells and some irregular single infiltrating cells with small cytoplasm. Dominant component formed trabecular, mostly solid nests, palisading array around the nests and pseudorosette formation in some areas. While chromogranin, synaptophysin, S100, Sox10, INSM1 expression was not observed in the first component, CD56 was diffusely positive. Strong CK(AE1/AE3) positivity is observed in the ductal components and pale diffuse positivity in the other component. No mutation is observed in the Pan Cancer Fusion Panel containing 137 genes applied to the first case.
Conclusion: Our findings were strikingly similar with the previous cases and histopathological features support the claim that this is a new tumour entity.

E-PS-13-045
The lonely tumour of the salivary gland: sialolipoma, two case reports
H. Aknar[1], S. Ozlu[1], S. Yuksel[1]
[1]Ankara University, Pathology, Ankara, Turkey

Background & Objectives: Sialolipoma is a rare benign tumour of the salivary gland, first described by Nagao et al. in 2001. According to the 2022 WHO Classification of Head and Neck Tumours, sialolipoma is the only mesenchymal tumour of the salivary gland. Accounting for approximately 0.3% of all salivary gland tumours, sialolipoma is a rare entity with only a limited number of reported cases in the literature. Here, we present two cases of sialolipoma diagnosed in our department to further contribute to the existing literature.
Methods: **Case 1:** A 59-year-old female patient presented in 2020 with a gradually growing, painless swelling on the right side of her face, present for nine years. Imaging studies revealed a well-defined, fat-containing lesion in the right parotid gland, measuring 31×44×14 mm. Gross examination of the excised specimen revealed a well-circumscribed, homogeneous yellow lesion measuring 44×31×10 mm, consistent with adipose tissue. Histopathological analysis demonstrated salivary glandular and ductal structures embedded within mature adipose tissue.
Results: **Case 2:** A 44-year-old male patient presented in 2024 with a swelling in the neck that had been present for 1.5 years. Radiological examination revealed a tumour-like lesion in the right parotid gland, measuring approximately 25×15 mm. Gross examination of the excised specimen revealed a tumour-like lesion with a homogeneous yellowish colour, measuring 42×32×22 mm, surrounded by a thin fibrous capsule. Histopathological analysis demonstrated enlarged ectatic vascular structures along with salivary glandular and ductal structures trapped within mature adipose tissue.
Conclusion: Sialolipoma is a rare and benign neoplasm of the salivary glands, classified as the only mesenchymal tumour in this region. There is limited information available about this tumour. Differentiation from pleomorphic adenomas with extensive lipomatosis and soft tissue lipomas is crucial for accurate diagnosis.

E-PS-13-046
Uncommon location, familiar pathology: papillary thyroid carcinoma in a thyroglossal duct cyst – case report and literature review
S.-P. Simion[1], O.S. Cotoi[1,2], E.A. Szasz[1,3]
[1]Mureș Clinical County Hospital, Pathology, Targu Mures, Romania, [2]"George Emil Palade" University of Medicine, Pharmacy, Science and Technology of Targu Mures, Pathophysiology, Targu Mures, Romania, [3]"George Emil Palade" University of Medicine, Pharmacy, Science and Technology of Targu Mures, Histology, Targu Mures, Romania

Background & Objectives: Thyroglossal duct cyst (TGDC) is the most common congenital neck anomaly, yet it harbours malignancy in fewer than 1% of cases, predominantly papillary carcinoma. Other variants, including squamous, follicular, Hürthle cell, insular, or anaplastic carcinoma, are exceedingly rare, with no reported medullary carcinoma. Because TGDC typically mimics a benign cyst clinically, diagnosis is often established incidentally by histopathological examination.
Methods: We report the case of a 28-year-old female presenting with a 40×33×25 mm multilocular cystic mass located in the midline of the anterior cervical region, characterized by a smooth, intact wall and containing brownish-black fluid. The internal lining had a thickened, brownish papillary area measuring 20×20×10 mm. A simple excision was performed, removing only the cystic lesion without extending to surrounding structures.
Results: Microscopically, the cyst wall contained multiple foci of papillary and follicular tumour proliferations, along with numerous cystic spaces. These papillae, follicles, and cysts were lined by tumour cells displaying mildly eosinophilic cytoplasm and nuclei with features characteristic of papillary thyroid carcinoma: enlarged, overlapping, irregular contours, grooves, and a "ground-glass" appearance. Numerous reactive thyroid follicles lined by simple cuboidal epithelium were also observed. Immunohistochemically, the tumour cells were positive for cytokeratin AE1/AE3, CK7, TTF1, thyroglobulin, and PAX8, confirming their thyroid origin.
Conclusion: Papillary thyroid carcinoma arising within a TGDC is exceedingly rare, typically discovered incidentally after surgery, and generally demonstrates a favourable prognosis. With approximately 250 such cases reported in the literature, there is no definitive management consensus, though the Sistrunk procedure is widely regarded as sufficient for low-risk patients. More aggressive interventions may be warranted in high-risk scenarios. In our case, only a simple cyst excision was performed, underscoring the need for close follow-up. Additional case reports and series are crucial for refining diagnostic and therapeutic strategies for this uncommon malignancy.

E-PS-13-047
Middle Ear Neuroendocrine Tumour with extensive glandular pattern in a young woman
E. Özoğul[1], A. Noyan[1]
[1]Hacettepe University Faculty of Medicine, Pathology Department, Ankara, Turkey

Background & Objectives: Middle ear neuroendocrine tumours (MeNETs) are rare epithelial neoplasms with neuroendocrine differentiation. Formerly labeled as adenomas or carcinoid tumours, they are now classified as well-differentiated neuroendocrine tumours (NETs) according to the 2022 WHO classification. These tumours may exhibit variable architecture and unpredictable biological behaviour.

Methods: A 22-year-old woman presented with progressive unilateral conductive hearing loss and tinnitus. Imaging studies raised suspicion for a glomus tumour, leading to an exploratory tympanotomy and surgical excision of the mass.
Results: Histopathological examination revealed an epithelial neoplasm with a striking glandular architecture and tubules lined by a uniform single layer of cuboidal to columnar cells with eosinophilic cytoplasm and round to oval nuclei. The neoplastic cells appeared cytologically bland, with no evidence of mitosis or necrosis. Mucin production was noted in some of the glandular structures. The Ki-67 proliferation index was focally elevated (5–6%). Immunohistochemical analysis demonstrated positivity for INSM1, synaptophysin, chromogranin A, and CK7, while S100, SOX10, and CD117 were negative.
Conclusion: This case highlights a morphological spectrum of MeNET with extensive glandular architecture and focal proliferation. The absence of cytologic atypia and diffuse neuroendocrine marker expression supports a diagnosis of well-differentiated NET, despite elevated Ki-67. Accurate classification and long-term follow-up are critical, as recurrence may occur even in histologically low-grade lesions.

E-PS-13-048
Infection mimicking malignancy in the head and neck area. Report of three cases
P. Tamiolakis[1], G. Hall[1]
[1]King's College London, Head and Neck Pathology, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Background & Objectives: Infectious disease with serious or significant consequence to the patient arising in the Head and Neck area are not so common with mucosal candidosis, dental infection and herpes simplex related ulceration regularly encountered. Destructive invasive fungal infections are easily recognised, albeit as a rare event and typically in immunosuppressed individuals. Occasionally, head and neck lesions might be the first or even the only manifestation of rarer and more significant infectious disease and can present with a more confusing clinical and radiological picture that is suspicious for neoplastic disease processes. The purpose of this study is to present cases of rarely encountered infectious diseases with respect to our local population that arise in the Head and Neck area, and in which the clinical presentation was alarming for malignancy.
Methods: Historical search in the authors' archives to identify cases with clinical and/or radiological suspicion for malignancy but with infectious aetiology as the final diagnosis.
Results: Three cases were retrieved. One 59-year old male patient and two female patients aged 33 and 61 years old without relevant medical history known to the pathologists at the time they received the cases. The histopathological findings in combination with the results of special stains and further testing as well as an algorithmic approach to approach these cases is presented. The diagnoses include syphilis, a rhinoscleroma-like reaction to bacteria and leishmaniasis.
Conclusion: Although extremely rare, uncommonly encountered infectious diseases can be mimickers of malignancy in the Head and Neck area causing difficulty in diagnosis even amongst experienced specialist pathologists.

E-PS-13-049
Breast metastasis from nasopharyngeal carcinoma: a case report with literature review
R. Aouadi[1], A. Khemir[1], A. Rais[1], G. Sahraoui[2], N. Boujelbene[3], I. Abbes[1], L. Charfi[2], K. Mrad[2]
[1]Salah Azaiez Institute, Pathology, Tunis, Tunisia, [2]Salah Azaiez Institute, Faculty of Medicine, University of Tunis Al Manar, Precision Medicine and Oncology Investigation Laboratory (LR21SP01), Pathology, Tunis, Tunisia, [3]Salah Azaiez Institute, Faculty of Medicine, University of Tunis Al Manar, Pathology, Tunis, Tunisia

Background & Objectives: Metastases to the breast are rare, accounting for only 0.4-2% of all mammary malignant tumours. Melanoma and lymphoma are the most common two malignancies metastasizing to the breast. Non-keratinizing undifferentiated nasopharyngeal carcinoma (NPC) rarely metastasizes to the breast.
Methods: We report a case of breast metastasis from a non-keratinizing undifferentiated NPC in a male patient with literature review.
Results: We report the case of a 38-year-old man previously treated for NPC who consulted for breast swelling. Imaging survey revealed multiple breast masses. An ultrasound-guided biopsy was performed. Microscopic examination showed a tumour with solid and trabecular growth patterns. Tumour cells were medium to large sized with irregular nuclei. Immunohistochemical staining showed positivity for cytokeratin and p63 antibodies and negativity for GATA3 and hormone receptors antibodies. Based on patient's history and pathologic examination findings the diagnosis of NPC metastasizing to the breast was established.
Conclusion: The breast is an extremely rare site of metastasis for NPC and represents a diagnostic challenge due to the radiographic similarities with primary breast cancer. According to literature review, only 15 cases of NPC metastasizing to the breast have been reported until this date. Breast metastases may be revealed as palpable masses or as incidental findings on imaging. They can often be misdiagnosed as a mammary primary tumour, due to their morphological similarities. In such cases immunohistochemistry is of a great help.

E-PS-13-050
Fibroblastic and myofibroblastic benign tumours of head and neck location
M. Alaya[1], S. Kamoun[1], F. Loued[1], Y. Loukil[1], S. Ferchichi[1], M. Dhaha[2], A. Goucha[1], E. Bettaieb[1], Y. Houcine[1], M. Driss[1], S. Kedous[2]
[1]Salah Azaiez Institute, Pathology Department B, Tunis, Tunisia, [2]Salah Azaiez Institute, Department of ENT and Head and Neck Surgery, Tunis, Tunisia

Background & Objectives: Head and neck fibroblastic/myofibroblastic tumours (HNFMT) are rare and often overlooked benign tumours. They can be of osseous origin, often resulting in craniofacial deformity such as fibrous dysplasia, or of a vascular origin such as angiofibromas.
Methods: Our study is retrospective, involving 31 cases of HNFMT collected at the Pathology Department of the Salah Azaiez Institute over a 20-year period from 2004 to 2024.
Results: Our series consisted of 17 men and 14 women. Nine tumours were of bone origin and represented fibrous dysplasia lesions. Histological examination revealed a proliferation consisting of anastomosing bone trabeculae without osteoblastic margins, on a densely cellular fibrous background composed of spindle cells.Fourteen cases represented nasopharyngeal angio-fibromas. Histological examination demonstrated benign mesenchymal proliferation rich in vessels and capillaries with a thick, hyalinized wall. All around, there was an abundant fibrous component associated with a mononuclear inflammatory infiltrate. One case was a juvenile fibroma occurring in 16-year-old boy whose biopsy revealed a well-circumscribed mass with a regular respiratory-type coating, sometimes with squamous cell metaplasia. One case was an ossifying fibroma in a 26-year-old man. Five cases corresponded to fibromatosis. Histological examination revealed a spindle cell proliferation made up of cells with eosinophilic cytoplasm and unclear boundaries. The nuclei were monomorphic, finely nucleolated, wavy and without mitotic figures. The tumour cells expressed Beta cathenin.
Conclusion: Fibroblastic tumours often arise diagnostic difficulties, which mainly come from the "head and neck" location leading to an uncertain recognition of the benign or malignant nature of the lesion, especially on biopsies (e.g. desmoid tumour versus fibromyxoid sarcoma of low degree of malignancy). The diagnostic approach must be

based first on the clinical presentation (age and clinical history of the patient, gender, location of the lesion) and then on the morphological study. Immunohistochemistry is only a complement to diagnosis, however it can be sometimes decisive.

E-PS-13-051

Histopathological diagnostic markers of otitis media with ANCA associated vasculitis

T. Miyazaki[1], N. Suzui[2], M. Matsumoto[1], K. Kobayashi[3], A. Ishizu[4]
[1]GIfu University Hospital, Department of Pathology, Gifu-city, Japan, [2]Gifu University Hospital, Department of Pathology, Gifu-city, Japan, [3]Fujita Health University Hospital, Centre for Clinical Pathology, Toyoake, Japan, [4]Hokkaido University, Faculty of Health Sciences, Department of Medical Laboratory Science, Sapporo, Japan

Background & Objectives: Among refractory otitis media in adults, there exhibit otitis media with ANCA associated vasculitis (OMAAV), which develops by the same mechanism, and its difference from GPA has been debated. OMAAV is difficult to diagnose early and can cause serious complications . However, the histological characteristics and diagnostic criteria for OMAAV have not yet been established. Therefore, we extracted the histological parameters of OMAAV and validated them to formulate diagnostic criteria.
Methods: A total 81 cases were analysed including 34 cases of OMAAV, 32 cases of chronic sinusitis, 5 cases of non-specific chronic otitis media and 10 cases of laryngeal granuloma . As a preliminary analysis, histological parameters were qualitatively or semi-quantitatively evaluated in a double-blind manner. Histological parameters including erosion, oedema, fibrosis, type of nflammatory cells, inflammatory cell infiltration in small vessel walls, cell anchoring to vascular endothelium, occlusion of muscular arteries/veins, qualitative evaluation of vasculitis, irregular vascular thickening, etc. Next, to verify the validity of candidate parameters revealed in the preliminary study, we divide the above cases into a Training Set and a Testing Set, then share the whole slide images with the research collaborators.
Results: In the preliminary analyses, significant differences were found in: 1) manifestation of arteritis/phlebitis; 2) arterial/venous occlusion as positive findings in OMAAV, on the other hand, 3) oedema; 4) eosinophil infiltration and 5) plasma cell infiltration were found to be negatively correlated candidate histological parameters. In order to verify the validity of each of these parameters, the cases were divided into a training set and a testing set. The male to female ratio was almost the same, and the average age was within ±2 years. Using this set, we conducted the validity of extracted parameters.
Conclusion: We successfully obtained effective histological biomarker of OMAAV with statistical validity. We expected those parameters will be established as the diagnostic criterion.

Funding: This work was funded by Japan Research Committee of the Ministry of Health, Labor and Welfare for intractable vasculitis (JPVAS)

E-PS-13-052

Clinicopathological spectrum of intestinal-type sinonasal adenocarcinoma: a retrospective study

T. Sharma[1], K. Kante[1], S. Rane[1], N. Mittal[1], M. Bal[1], A. Patil[1]
[1]Tata Memorial Centre, Pathology, Mumbai, India

Background & Objectives: Sinonasal adenocarcinomas (SNAC) are categorised into two subtypes: Intestinal-type (ITAC) and Non-intestinal-type (non-ITAC). ITACs are rare and exhibit a morphology and immunoprofile similar to primary intestinal adenocarcinoma. We present findings from a retrospective analysis of the clinicopathological characteristics of ITAC.
Methods: We identified and reviewed all cases of ITAC diagnosed at our institute between January 2012 and April 2024 from the pathology archives. Clinical details were obtained from electronic medical records.
Results: A total of 48 cases of ITAC were included in this study. The mean age was 47 years (Range, 19-81 years), with a male-to-female ratio of 3:1. The most common symptoms were epistaxis, followed by nasal obstruction, with the nasal cavity being the most affected site. Most patients presented at advanced stages of the disease, with T4 being the most prevalent stage (27/39, 56.3%). Histologically, the majority of tumours showed a mixed architectural pattern, with the papillary pattern being the most common component, followed by tubular and solid patterns. Mucin (intracellular and/or extracellular) was observed in 39.58% of the cases. The majority of tumours were classified as high grade (60.4%). Nodal and distant metastases were noted in 13.3% (2/15) and 33.3% (6/18) cases, respectively. Immunohistochemistry for p53 was done in 33 cases; 15 (45.5%) of them showed strong diffuse mutational type staining, 3 cases (9.0%) cases showed null-type mutation staining pattern, while the rest of the 15 cases (41.5%) showed a wild-type staining for p53. Most patients (40.7% of cases) were treated with surgery, followed by adjuvant therapy (radiotherapy, chemotherapy, or chemoradiation). Immunohistochemistry results were available for 43/48 cases.
Conclusion: We present one of the largest series of ITAC cases, including 48 cases. In our cohort, we observed a male predominance with a majority of cases presenting at advanced stage, exhibiting higher grade tumours, necessitating multimodality treatment.

E-PS-13-053

Papillary carcinoma arising in thyroglossal duct cyst. A case report

G. Kafiri[1], E. Koniaris[1], S. Ritsatou[1], A. Aktselis[1], N. Triantafilou[1], E. Tsafa[1], C. Markogiannakis[2]
[1]''Hippocration'' General Hospital, Pathology, Athens, Greece, [2]''Hippocration'' General Hospital, Athens, Greece

Background & Objectives: Papillary carcinoma originating in a thyroglossal duct cyst (PCTDC) is a very rare entity, with a frequency less than 1% of all cases in that location, usually presenting within an otherwise benign developmental cyst of the neck. The thyroglossal duct cysts usually arise as cystic expansion of the remnants of the thyroglossal duct tract, and are mainly incidental findings.
Methods: A 44-year-old female patient presented to our hospital with a slow growing, soft, cervical mass, in the vicinity of the hyoid bone, measuring 3,6 cm on U/S showing suspicious sonographic features. The FNA cytologic findings, revealed a papillary carcinoma of the thyroglossal cyst, with papillary and solid components. Serological laboratory findings were compatible with an autoimmune Hashimoto thyroiditis.
Results: Histologically the lesion was well circumscribed, with a thin fibrous capsule, was composed of papillary structures as well as a centrally placed solid component with mainly a follicular growth pattern. The neoplastic cells were highly atypical, with nuclear features compatible with papillary carcinoma, and more specifically the neoplastic cells presented with overlapping, clearing of the nuclei and nuclear grooves. The tumour presented with a highly desmoplastic stroma and with mild inflammatory infiltrate. Part of the hyoid bone was also included in the specimen, which was decalcified and didn't reveal any signs of infiltration
Immunohistochemistry revealed positivity in HMBE1, CK19, TTF1 and Galectin.
Conclusion: PCTDCs are infrequent incidental findings, with higher prevalence rate in women (2.5:1). Main presenting symptoms include dysphagia, hoarseness and a slow growing mass. PCTDCs are either direct metastases of a papillary thyroid carcinoma or more often (up

to 65%) are generated de novo from ectopic thyroid tissue in the thyroglossal cyst.

E-PS-13-054

Tumours metastasizing to the jawbones, oral cavity and salivary glands: a retrospective study

A.H. Üstündağ[1], İ. Atak Seçen[1], B. Öğüt[2], B. Toközlü[1]
[1]Gazi University, Department of Oral Pathology, Ankara, Turkey, [2]Gazi University, Department of Pathology, Ankara, Turkey

Background & Objectives: Distant metastasis to the oral cavity is rare, comprising approximately 1–1.5% of all oral malignancies. The most frequent primary sites are the breast and lung, with a jawbone-to-soft tissue ratio of 2:1. The study aims to evaluate the clinicopathological features of tumours metastasizing to the jaw bones, salivary glands and soft tissues of the oral cavity in the Central Anatolia region.
Methods: This study is a retrospective analysis spanning 25 years, covering the period from January 2000 to January 2025. Clinicopathological data were obtained from electronic medical records.
Results: A total of 43 cases (28 males, 15 females; M:F ratio 1.75:1) with a mean age of 60 years (range 25–85) were analysed. Metastases were located in the oral soft tissue (67%), salivary glands (28%), and jawbone (5%). Adenocarcinomas were the most common metastatic tumours (44%), primarily from the lung, gastrointestinal tract, colon, oesophagus, and prostate. Other tumour types included lymphomas (11%), squamous cell carcinoma/malignant epithelial tumour (9%), renal cell carcinoma, malignant melanoma, sebaceous carcinoma, and myeloid sarcoma (each 5%), and various others (16%). Adenocarcinoma and sebaceous carcinoma metastases were more frequent in males, while all malignant melanoma cases occurred in females. Survival data were available for 30 patients: 12 were alive, and 18 had died at the time of analysis.
Conclusion: Metastasis to the oral cavity is a rare occurrence and is characterized by a poor prognosis. Any lesion found in the oral cavity should undergo biopsy and thorough evaluation, as metastatic tumours can mimic benign conditions clinically. The challenging diagnosis requires a multidisciplinary approach. Oral and maxillofacial pathologists play a vital role in the early detection of oral cancers and in recognizing metastatic lesions affecting the maxillofacial region.

E-PS-13-055

Calcifying odontogenic cyst: a case series and literature review

A.H. Üstündağ[1], B. Toközlü[1]
[1]Gazi University, Department of Oral Pathology, Ankara, Turkey

Background & Objectives: The calcifying odontogenic cyst (COC) is an uncommon, benign developmental cyst derived from odontogenic epithelium, characterized by its potential to undergo calcification and accounting for approximately 0.3–0.8% of all odontogenic cysts. The Aim of the study was evaluating clinical and pathologic characteristics of a case series of COC.
Methods: This study reports an 11-year (2014–2025) case series from our oral pathology department, comprising a total of 15 cases of COCs. Demographic data and histopathological diagnoses were evaluated descriptively. Additionally, a literature review of case series was conducted using PubMed.
Results: The average patient age was 36 years (range: 13–70), with 8 males and 7 females. The cysts were most frequently located in the posterior mandible, followed by the anterior maxilla, anterior mandible, and posterior maxilla. Clinically, most cases were asymptomatic, while a few presented with swelling or tooth mobility. Radiologically, all lesions appeared as well-defined, unilocular radiolucencies with an average size of 1.5 cm. Histologically, ghost cells, dystrophic calcifications, reverse polarization, and remnants of odontogenic epithelium were commonly observed. In two cases, palisaded, hyperchromatic ameloblast-like cells were noted. Notably, one case was a hybrid lesion exhibiting features of both a calcifying odontogenic cyst and an adenomatoid odontogenic tumour, with epithelial cells forming rosette- and duct-like structures within a hyalinized matrix.
Conclusion: COC is a rare developmental odontogenic cyst with a historically debated nature. It can present with a variety of clinical features and outcomes, appearing as a solid tumour, a unilocular cystic lesion, or, in rare cases, as a carcinoma. The distinguishing feature is the odontogenic cystic epithelium, which may include calcifications and ghost cells. In the differential diagnosis, it is important to distinguish it from dentinogenic ghost cell tumour and ghost cell odontogenic carcinoma.

E-PS-13-056

Morphologic diversity and clinicopathologic features of HPV-associated sinonasal carcinomas

I. Laklouk[1]
[1]David Geffen School of Medicine at UCLA, Pathology &Laboratory Medicine, Los Angeles, USA

Background & Objectives: To explore the morphologic spectrum and clinicopathologic characteristics of HPV-associated sinonasal carcinomas, with an emphasis on histologic diversity, HPV subtypes, and their potential diagnostic significance.
Methods: We reviewed 102 cases of sinonasal carcinoma from the pathology archive with corresponding in-situ hybridization (ISH) for low-risk and/or high-risk HPV. Nineteen cases (18.6%) tested positive for HPV, and clinicopathologic data were collected.
Results: Among the 19 HPV-associated sinonasal carcinomas, 6 (31.6%) were squamous cell carcinomas and variants, 10 (52.6%) were HPV-related multiphenotypic sinonasal carcinomas, 2 (10.5%) were high-grade carcinomas, and 1 (5.3%) was an adenocarcinoma. The median age of affected patients was 66 years (range: 37–89), with 8 (42.1%) women and 11 (57.9%) men. These tumours were predominantly located in the nasal cavity. The adenocarcinoma displayed heterogeneous morphology, with invasive growth forming two distinct architectural patterns: papillary structures and nests with a cribriform-like configuration. High-risk HPV positivity was observed by ISH, showing strong, diffuse nuclear staining in the papillary component and a dot-like expression pattern in the cribriform nests. Two cases (10.5%) of HPV-related multiphenotypic sinonasal carcinoma were positive for low-risk HPV but negative for high-risk HPV by ISH. One case presented as a high-grade small round blue cell tumour with immunophenotypic evidence of myoepithelial differentiation, exhibiting adenoid cystic-like features. Focally, the surface epithelium showed severe dysplasia/carcinoma in situ. Worse overall survival and progression-free survival were observed in HPV-associated carcinoma patients with high-grade morphology, although this difference was not statistically significant [p=0.06].
Conclusion: Our study highlights an unusual association between low-risk HPV and multiphenotypic sinonasal carcinoma, which has not been previously reported. Additionally, we describe a novel heterogeneous morphology in HPV-associated sinonasal adenocarcinoma, with distinct HPV expression patterns by ISH. Further research is needed to evaluate the clinical and prognostic significance of these findings and their implications in distinguishing HPV-associated sinonasal carcinomas.

E-PS-13-057

Salivary duct carcinoma: analysis of the clinicopathologic spectrum of a rare aggressive malignancy from a tertiary cancer centre of North India

Z. Chowdhury[1], Z.H. Fatima[2], S. Jha[1], K. Lamba[3], S. Nanda[4], S.A. Saraf[5], A. Kapoor[6]
[1]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Oncopathology, Varanasi, India, [2]Homi Bhabha

Cancer Hospital & Research Centre, Pathology, Muzaffarpur, India, [3]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Surgical Oncology, Varanasi, India, [4]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Radiation Oncology, Varanasi, India, [5]V G Saraf Memorial Hospital, Pathology, Kochi, India, [6]Mahamana Pandit Madan Mohan Malviya Cancer Centre & Homi Bhabha Cancer Hospital (Tata Memorial Centre), Homi Bhabha National Institute, Medical Oncology, Varanasi, India

Background & Objectives: Salivary Duct Carcinoma (SDC) is a rare and aggressive high-grade salivary gland malignancy, accounting for <1.8% of all major salivary gland tumours and about 10% of all salivary gland malignancies.
Objective: To comprehensively evaluate the entire clinicopathologic spectrum of SDCs treated at our centre.
Methods: A retrospective analysis of SDC patients treated at a tertiary cancer centre over a period of 5 years was undertaken.
Results: A total of 46 histologically confirmed cases of SDCs were identified. Mean age of the patients was 59.02 years (30-83 yrs) with a male predominance. Most common site involved was the parotid gland (74%), and the histology evinced was that of high-grade mammary ductal carcinoma with Androgen receptor (AR) positivity in 85% cases and HER2/neu expression in 41% cases. Perineural invasion was detected in 26%, lymphovascular invasion in 24%, regional lymph node involvement in 74% and distant metastases in 41% cases, with the most common metastatic site being lung followed by bones, non-regional nodes, brain and soft tissue. Majority of the patients presented at a higher stage (stage IV 69.5%). The chief modality of treatment was surgery (n=23) followed by adjuvant radiation, adjuvant chemo-radiation and adjuvant chemotherapy. On a median follow-up period of 11 months (1-43 months), the mean overall survival duration was 41 months, median time for distant metastasis 15 months and the 3-year progression-free survival rate 60.2±12%. Overall survival was perceived to be better for AR positive (42 months vs 9 months) and HER2/neu negative (39 months vs 10 months) patients, compared to their counterparts.
Conclusion: Distinction of SDC from other salivary neoplasms is of prognostic and therapeutic significance since it has a dismal prognosis. Analysis for AR and HER2/neu expression should be mandated on all SDC patients, as the benefits of androgen deprivation therapy and targeted HER2/neu therapy are becoming more evident.

E-PS-13-060

Spindle cell/Sclerosing and intra-osseous Rhabdomyosarcoma of the head & neck in adults: a tertiary care cancer centre case series

N. Mittal[1], M. Afsar[1], M. Jain[1], S. Rane[2], M. Ramadwar[1], B. Rekhi[1], P. Panjwani[1], M. Bal[1], U. Sakhdeo[1], A. Patil[2]
[1]Tata Memorial Centre, HBNI University, Pathology, Mumbai, India, [2]ACTREC TATA Memorial Centre, HBNI University, Pathology, Mumbai, India

Background & Objectives: Spindle cell/Sclerosing Rhabdomyosarcoma (SSRMS) is a rare subtype reclassified by the WHO as distinct from Embryonal RMS. Intraosseous (TFCP2 rearranged) RMS (IRMS) is a recently described entity with a unique histology and molecular profile. Rarity and the limited understanding of the clinical and pathological features, especially in adults, require further evaluation.
Methods: Retrospective observational clinicopathological study of 11 years duration (Jan 2014-March2025) of adult RMS patients (>/=18 years) with SSRMS and IPRMS histology and available material for review.
Results: 22 patients; 16 SSRMS and 6 IRMS, with a M:F ratio of 2.1:1 and mean age of 28.4 years were evaluated. SSRMS was characterised by upper alveolus as the most common site (31.2%), pure spindle morphology in 60% of cases, with sclerosis in 35%, mitoses >5/per mm² in 60%. MyoD1 (Diffuse/strong), desmin and myogenin expression was seen in 68%, 55% and 35% respectively. IRMS were characterised by M:F ratio of 2:1, mandibular involvement in 83.3%, unique morphology of round nuclei but spindle abundant eosinophilic cytoplasm (epithelioid leiomyosarcoma-like) in all, short fascicles in 80%, myxoid stroma in 70%, variable AE1/AE3 expression in all, ALK IHC positivity in all (n=5), myogenin in none, desmin in 20%, and EWSR1 gene rearrangement in 2 of 3 tested. 7 of 22 patients underwent resection. With a median follow up of 18.5 months, one patient is alive with no evidence of disease (disease-free survival: 74 months), three are alive with the disease, and two have died (one from recurrence, one from metastasis).
Conclusion: Adult SSRMS and IRMS share a male predilection, and MyoD1 positivity. They differ in spindle vs epithelioid histology, maxilla vs mandibular involvement, very focal vs diffuse keratin positivity, and none vs majority with ALK IHC positive. EWSR1 gene rearrangement is frequent in IRMS. Dismal outcomes in both necessitate accurate distinction and further research to improve treatment strategies.

E-PS-13-061

Glomangiopericytoma of the nasal cavity: a case report

A. Simoulis[1], G. Galanopoulos[2], N. Altarawneh[1], K. Panagiotou[1], S. Laskaris[3], O. Tzaida[1]
[1]Metaxa Cancer Hospital, Pathology, Piraeus, Greece, [2]Agia Olga - Regional General Hospital of Nea Ionia, Pathology, Nea Ionia, Greece, [3]Metaxa Cancer Hospital, Otolaryngology, Piraeus, Greece

Background & Objectives: Glomangiopericytoma is a rare vascular neoplasm of the sinonasal tract, accounting for <0.5% of neoplasms in this region. It typically affects patients aged 40–70 years, with a slight female predominance. Classified by the World Health Organization as a borderline/low-malignant-potential tumour, it is distinguished by its indolent behaviour and unique histopathological features. This case report aims to describe the clinical presentation, diagnostic approach, and management of glomangiopericytoma in a 74-year-old patient.
Methods: A 74-year-old woman presented with recurrent epistaxis and unilateral nasal obstruction. Endoscopic examination revealed a polypoid, friable mass in the nasal cavity. The lesion was excised via endoscopic surgery, yielding soft, elastic tissue fragments measuring 0.5–1.5 cm. Histopathological analysis was performed to evaluate the tumour's morphology, while immunohistochemical studies assessed its molecular profile.
Results: Histopathological examination revealed respiratory epithelium overlying a submucosal mesenchymal neoplasm composed of monomorphic spindle-shaped cells arranged in a perivascular growth pattern with a prominent branching ("staghorn") vascular network. No nuclear atypia, mitotic activity, or necrosis was observed. Immunohistochemistry demonstrated diffuse positivity for smooth muscle actin (SMA), vimentin, β-catenin, and cyclin-D1, confirming myoid perivascular differentiation. CD31 and CD34 highlighted endothelial cells within vascular channels. The Ki-67 proliferation index was <1%.
Conclusion: Glomangiopericytoma is characterized by somatic β-catenin mutations and lacks NAB2-STAT6 gene fusions seen in conventional hemangiopericytomas. Key diagnostic features include SMA positivity, absence of pleomorphism or necrosis, and low Ki-67 index. Endoscopic resection with clear margins remains the gold standard treatment. Long-term follow-up is essential due to recurrence risks (17%–50% after incomplete resection), though metastases

are exceptionally rare.Accurate diagnosis of glomangiopericytoma is crucial for appropriate management and requires integration of clinical, histopathological, and immunohistochemical findings. Complete surgical excision remains the gold standard and ensures optimal outcomes.

E-PS-13-062

Laryngeal liposarcoma: a challenging diagnosis

M. de Uribe Viloria[1], S. Quinones[2], E.P. Sánchez-López[2], G. Escuer-Albero[2], V. Macarrón[2], E. Ruíz-Bravo Burguillos[2]
[1]Clínico de Valladolid University Hospital, Pathology, Valladolid, Spain, [2]La Paz University Hospital, Pathology, Madrid, Spain

Background & Objectives: Laryngeal and hypopharyngeal liposarcomas are exceedenly rare entities. They represent approximately 10% of all head and neck liposarcomas. Dyspnea and dysphagia often are the only symptoms present at diagnosis. The main differential diagnoses are lipoma and spindle cell/pleomorphic lipoma (SCL/PL). We present the case of an 81-year-old man who consulted for dyspnea and dysphagia. Two tumours were identified, one in the hypopharynx and another in the right piriform sinus.
Methods: The hypopharyngeal mass was biopsied and diagnosed as a lipoma. Then the pyriform sinus lesion was removed and diagnosed as a spindle cell lipoma. Following a recurrence, the pyriform sinus lesion was removed once again. After macroscopic, microscopic, immunohistochemical and molecular studies the diagnosis of low-grade liposarcoma/atypical lipomatous tumour (LGLS/ALT) was achieved.
We reviewed all laryngeal and hypopharyngeal biopsies diagnosed as lipoma, SCL/PL and LGLS/ALT at our hospital from January 2013 to February 2025. Clinical and epidemiological data were collected from the medical records.
Results: A total of two cases were identified, male 81 years and male 85 years, both presented with dyspnea and dysphagia at the time of diagnosis. One of them was diagnosed as a SCL . The second one was a diagnostic challenge being first diagnosed as lipoma, then as a SCL before reaching the diagnosis of LGLS/ALT. Inmunohistochemical studies with CD34, MDM2 and CDK4 were positive. Nuclear expression Rb protein was preserved. Amplification of MDM2 and CDK4 was evidenced using fluorescence in situ hybridization (FISH).
Conclusion: Laryngeal and hypopharyngeal LGLS/ALT are a diagnostic challenge. Atypical cells or other indicators of malignancy may not be observed in a biopsy. To date there have been no specific recommendations for molecular testing in lipomatous tumours in the head and neck region, but based on our experience it may be advisable to perform molecular studies in all lipomatous tumours in this location.

E-PS-13-063

Paediatric adenoid cystic carcinoma of the submandibular gland: a rare case report

B. Mülayim[1], B. Culluoglu[2], F.S. Gurevin[3], G. Esendaglı[3]
[1]Gazi University, Faculty of Dentistry, Oral Pathology, Ankara, Turkey, [2]Trinity College, Medical Student, Dublin, Ireland, [3]Gazi University, Faculty of Medicine, Pathology, Ankara, Turkey

Background & Objectives: Adenoid cystic carcinoma (ACC) is a rare malignant salivary gland tumour of epithelial and myoepithelial origin, typically occurring between the ages of 40 and 60, with a median of 57 years. ACC is often characterized by perineural invasion and a high risk of local recurrence. This case report presents a paediatric patient diagnosed with ACC of the left submandibular gland at an unusually early age, emphasizing its pathological features and treatment approach.
Methods: A 7-year-old patient with a six-month history of a palpable mass in the left level 2 cervical region underwent imaging, revealing a 13×11 mm lesion in the left submandibular gland. An incisional biopsy confirmed ACC. Surgical management included left level 1B neck dissection and tumour excision. Histopathological evaluation assessed tumour size, perineural invasion, lymphovascular invasion, and lymph node involvement. Immunohistochemical staining for c-MYB expression was performed.
Results: Histopathology confirmed a 1.5 cm ACC confined to the salivary gland capsule (pT1), with perineural invasion and absence of lymphovascular invasion. Four reactive submandibular and 13 cervical lymph nodes were identified. Lymphoepithelial lesions were observed in non-neoplastic salivary gland tissue, particularly in periductal regions. Immunohistochemistry demonstrated strong nuclear c-MYB positivity in tumour cells. Surgical margins were clear. Postoperatively, the patient received adjuvant radiotherapy. Regular clinical and radiological follow-up was recommended due to the high risk of local recurrence. Given the paediatric age, molecular and genetic evaluation may be warranted to assess potential predisposition or hereditary association.
Conclusion: This case highlights the sporadic nature of ACC, with no known hereditary or other predisposing factors. The presence of perineural invasion underscores the need for close follow-up to monitor for recurrence. Additionally, lymphoepithelial lesions raise the possibility of an associated immunological condition. Further molecular studies may provide insights into the pathogenesis and contribute to the development of targeted therapies for paediatric ACC.

E-PS-13-064

Sinonasal mucosal melanoma: a case report highlighting diagnostic and therapeutic challenges

A. Simoulis[1], G. Galanopoulos[2], N. Altarawneh[1], K. Panagiotou[1], S. Laskaris[3], O. Tzaida[1]
[1]Metaxa Cancer Hospital, Pathology, Piraeus, Greece, [2]Agia Olga - Regional General Hospital of Nea Ionia, Pathology, Nea Ionia, Greece, [3]Metaxa Cancer Hospital, Otolaryngology, Piraeus, Greece

Background & Objectives: Sinonasal mucosal melanoma (SNMM) is an extremely rare malignancy, accounting for 0.5–2% of all melanomas and approximately 4% of sinonasal malignancies. Its pathogenesis involves mucosal melanocytes derived from neural crest cells during embryogenesis. SNMM predominantly affects males over 60 years of age and is often diagnosed at advanced stages due to nonspecific symptoms, leading to a poor prognosis (median survival: 18 months). The molecular profile of SNMM is distinct from that of cutaneous melanomas, presenting challenging therapeutic considerations. This study presents a rare case of SNMM in a young patient, highlighting diagnostic challenges and therapeutic considerations.
Methods: A 34-year-old Asian male with a history of smoking and drug use presented with nasal congestion, recurrent epistaxis, and nasal swelling. Imaging revealed a 5.5 cm soft-tissue mass involving the nasal cavity, paranasal sinuses, and intracranial extension. Biopsies measuring 0.7–1 cm were obtained for histopathological examination. Immunohistochemical (IHC) analysis for melanoma markers (S100, HMB45, Melan-A, SOX10), proliferation index (Ki-67), and vimentin was performed.
Results: Histology revealed a malignant epithelioid neoplasm beneath the respiratory-type mucosal epithelium, characterized by marked nuclear atypia, high mitotic activity, and abundant melanin production. IHC confirmed positivity for melanoma markers with a high Ki-67 index (50%). The presence of intraepithelial atypical melanocytes supported the primary mucosal origin. The patient underwent combined modality therapy (CMT) with immunotherapy and showed a partial clinical response at follow-up.
Conclusion: SNMM is a rare and aggressive malignancy requiring early recognition and multidisciplinary management to improve outcomes. This case highlights the importance of biopsy in patients with

atypical nasal symptoms and underscores the need for further research into effective treatment strategies for this challenging disease.

E-PS-13-066

Pseudoendocrine sarcoma: a case report of a newly described soft tissue tumour

A. Shalaby[1], S. Al Jahdhami[1], H. Al Farii[2], Y. Mahfouz[3], M. Al Riyami[1], A. Qureshi[1]
[1]SQU, Pathology, Muscat, Oman, [2]SQU, Surgery, Orthopedics, Muscat, Oman, [3]SQUH, Radiology, Muscat, Oman

Background & Objectives: Pseudoendocrine sarcoma (PES) is a recently reported tumour that usually arises in paravertebral deep soft tissues and shares histological similarities with well-differentiated neuroendocrine tumours, but it lacks epithelial and neuroendocrine marker expression. Most of the reported PES exhibited aberrant nuclear β-catenin expression with confirmed mutations in the CTNNB1 gene. We here describe the clinicopathological, immune histochemical, and molecular findings of one case.
Methods: **Case presentation:** A 70-year-old man presented with left posterior neck mass that was discovered on surveillance imaging for a previously diagnosed colorectal carcinoma. Imaging revealed an enhanced left paraspinal soft tissue mass measuring 5x6.2x7 cm. The mass is separate from the adjacent bone and nerve roots.
Results: Histologically, a relatively circumscribed neoplasm with lobular invasion into the adjacent tissue. The tumour is made up of epithelioid cells with uniform, central round nuclei with speckled chromatin and pale cytoplasm with focal clear cell change. The cells are arranged in sheet-like, trabecular, organoid, and/or nested patterns. Occasional pseudo-glycular architecture, eosinophilic hyaline globules and psammomatous calcifications are noted. Immune histochemical staining showed negative expression of Pan-cytokeratin, CK7, CK8/18, CK20, EMA, p63, synaptophysin,chromogranin A, GFAP, and SOX10 with weak S100 positivity. Strong nuclear β-catenin expression was observed throughout the tumour. The Ki-67 labelling index was 10–15% in areas with increased mitotic activity. DNA-based targeted next-generation sequencing (NGS) confirmed the presence of a CTNNB1 (p.S37F) mutation.
Conclusion: The prominent epithelioid morphology and predilection for deep soft tissues in the paravertebral region of PES may raise the possibility of other tumour types such as paraganglioma, ependymoma, glomus tumour and some round cell sarcomas such as Ewing sarcoma and so it may represent a diagnostic pitfall. Accurate diagnosis is challenging on morphology alone, and it mandates immune histochemical and molecular evaluation. This is very important because of the varied biological behaviours and clinical outcomes.

E-PS-14 E-Posters History of Pathology

E-PS-14-001

The fall of the old guard - evolving perceptions on the origin of disease in the Early Modern period

H. O'Shea[1]
[1]Galway University Hospital, Galway, Ireland

Background & Objectives: To explore the evolution of medical philosophy and perspectives on the origins of disease in the Early Modern period, its resulting controversies, and its influence on modern pathology.
Methods: Robert Hooke first described the cell as seen under his microscope in 1665, but it would not be for nearly another two hundred years before Virchow's 'Cellular Pathology' would be published. For much of the Early Modern period, medical theory and practice was predominately shaped by the works of Galen and Hippocrates. Any challenge to these ancient authorities was considered a direct attack on the medical, and even religious, orthodoxy of the day.
Results: However, new schools of thought did begin to emerge. Empiricists such as Lord Francis Bacon condemned the unquestioning adherence to Galen's teaching, and instead promoted direct observation and experimentation. William Harvey's description of circulation typified a new mechanical philosophy of the human body, and while his main focus was on physiology, he did explore how disturbances in the circulation could lead to disease. Others, such as the iatrochemists, believed that disease arose from disturbances in chemical reactions in the body, and that specific chemical remedies were required to treat them – though unfortunately making frequent use of mercury and arsenic. These deviations from the medical establishment were not without their critics however – Lord Bacon and his "Baconical" followers were denounced as "pretender[s] to Physick", whose ignorance made them "unfit to be entrusted with the life of any man".
Conclusion: While many of the theories developed in this period would be ultimately superseded in the following centuries, the willingness to question entrenched tradition and embrace experimentation laid the groundwork for modern medicine. As we enter into this new epoch of precision medicine, we too must not fall into the trap of clinging to the familiar at the expense of progress.

E-PS-14-002

Pathology through the legacy of the sanctuary of asclepius in epidaurus: integrating ancient wisdom into modern medicine

D. Moissidou[1]
[1]Queen Mary University of London, Malta Campus, School of Medicine, Gozo, Malta

Background & Objectives: This historical case presents the Sanctuary of Asclepius in Epidaurus as a significant centre for healing in the ancient Mediterranean world, blending mystical and systematic medical practices. Dedicated to Asclepius, the divine healer, it promoted a holistic approach to health, considering physical, psychological, and spiritual well-being. The sanctuary's natural environment, purification rituals, physical activities, and artistic engagement contributed to the healing process.
The aim is to highlight the sanctuary's role in early medical practices and its influence on modern healthcare. It emphasises the importance of holistic healing, the integration of psychological and physical treatments, and the lasting impact of Epidaurus on medical ethics, preventive medicine, and integrative healthcare approaches.
Methods: Treatment methods started at the natural setting of Epidaurus, with its serene landscape and fresh water sources, contributed significantly to the healing process. Patients engaged in purification rituals, physical exercise, dietary regulations, and artistic activities, such as attending performances at the renowned Epidaurus theatre, reinforcing the link between emotional and physical health. A key element of the healing practice was 'incubation' or 'enkoimesis,' where patients slept in a sacred space, seeking divine guidance in dreams. This method, blending psychological suggestion with religious belief, prefigures modern psychosomatic and placebo-based healing techniques.
Results: The sanctuary's emphasis on treating the whole person, rather than just symptoms, aligns with contemporary medical principles. The World Health Organization's definition of health as complete physical, mental, and social well-being echoes these ancient practices. Furthermore, modern integrative medicine, which combines conventional treatments with alternative therapies, reflects the holistic approach of Epidaurus.
Conclusion: Beyond its religious function, the sanctuary served as a foundation for medical science, influencing ethics, preventive medicine, and the integration of psychological and social aspects in healthcare. Its enduring legacy affirms the relevance of ancient medical wisdom in shaping contemporary healthcare practices.

E-PS-14-003

Prevalence of *concha bullosa* in the natural mummies of a monastic community in central Italy (17th-18th century)

L. Ventura[1], F. Bruno[2], L. Cirella[1], V. Forte[1], I. Faenza[3], E. Petrella[4], G. Pasquinelli[5], M. Traversari[5]

[1]San Salvatore Hospital, Pathology, L'Aquila, Italy, [2]San Salvatore Hospital, Neuroradiology and Interventional Radiology, L'Aquila, Italy, [3]University of Bologna, DIBINEM, Bologna, Italy, [4]Morgagni-Pierantoni Hospital, Radiology, Forlì, Italy, [5]University of Bologna, DIMEC, Bologna, Italy

Background & Objectives: *Concha bullosa* (CB) is the pneumatization of the middle turbinate and the most common anatomical variant of the sinonasal complex. The prevalence of CB in the modern population ranges from 13 to 72%, and this condition is frequently associated with nasal septal deviation (NSD). CB can be classified as unilateral, bilateral symmetric, and bilateral asymmetric. CB may be easily identified in skulls by inspection, but is under-reported in archaeological collections due to the poor preservation of nasal bones. CB has only been demonstrated in mummified heads by endoscopy.

Methods: The aim of this study was to investigate the prevalence of CB in 17 mummified bodies and 1 mummified head from the monastic community of the Poor Clares Hermits of Fara in Sabina, who followed the First Rule of Saint Clare combined with strict seclusion and absolute loyalty to ecclesiastical hierarchies. After a careful external examination, the mummies were investigated by computed tomography (CT) scanning with multiplanar reconstruction and 3D rendering. The nasal cavities, turbinates, and septum were examined to detect their significant morphological variations.

Results: Due to the presence of mummified nasal pyramids, no alteration of the structures could be visualized by external examination. CT scans revealed pneumatization of the middle turbinates in 5 out of 18 individuals (27.78%). Age at death of the subjects ranged from 40 to >60 years. Unilateral CB with contralateral NSD was observed in 2 cases (1 left, 1 right), bilateral asymmetric CB with NSD contralateral to the larger CB was observed in 2 cases, and bilateral symmetric CB with right NSD was observed in 1 case.

Conclusion: Our study represents the first investigation of CB in a series of natural mummies. CT scanning represents an essential tool to disclose this condition in mummified bodies. Our data confirm the close relationship between CB and NSD.

E-PS-14-004

Reviving autopsy reports from Baroque era

J. Gulczynski[1,2], P. Paluchowski[3], A. Szarszewski[3], E. Izycka-Swieszewska[1,2]

[1]Medical University of Gdansk, Div. of Pathology and Neuropathology, Gdańsk, Poland, [2]Copernicus Hospital Gdansk, Dept. of Pathology, Gdansk, Poland, [3]Medical University of Gdansk, Department of History & Philosophy of Medical Sciences, Gdansk, Poland

Background & Objectives: Post mortem was already settling in European medicine and autopsy reports were giving more and more information concerning pathologies found. The objective was to set the proces of transformation of ancient medical language (Latin) and terms into contemporary.

Methods: We analysed two chosen post mortem reports from beginnning of 17th and 18th centuries. After transliteration from original texts, Latin was translated to Polish and English. Anatomical and pathological terminology was correlated with contemporary knowledge and nomencalture. We also analysed the style of those professional medical documents, noting nevertheless distinct differences between two reports almost 100 years apart.

Results: Analysed reports differed in style though not in the anatomical and pathological approach. First from 1613 was devoid of linguistic embellishments, referred strictly to description of external view with detailed, and divided into separate chapters description of internal organs noting every pathology found. Information included was similar to present autopsy reports. The second performed in 1724 described thorough analysis of conjoined twins, though we see no information concerning mother who died before the foetuses were extracted. The language of the report printed afterwards in a form of a little book was more baroque, rich in embellishments, with introduction addressed to City Hall members and nobility present during the public autopsy.

Conclusion: The analysis let us compare two reports published after procedures performed in the same facility 100 years apart. Translation from Baroque Latin showed us different approach to the body with full profesionalism in performance maintained. Vocabulary like „arteria aspera" was new to us. But description of the foetus malformation let us state that it was the first presentation of Limb Body Wall Complex in literature, quoted shortly afterwards by Caspar Bauhin in his „*De hermaphroditorum et monstrosorum partuum natura"*

E-PS-14-005

The enigma of death of Barbara Radziwill – wife of the last king of Jagiellonian dynasty

J. Gulczynski[1,2], P. Paluchowski[3], A. Szarszewski[3], E. Izycka-Swieszewska[4,2]

[1]Medical University of Gdansk, Div. of Pathology and Neuropathology, Gdansk, Poland, [2]Copernicus Hospital Gdansk, Dept. of Pathology, Gdansk, Poland, [3]Medical University of Gdansk, Department of History & Philosophy of Medical Sciences, Gdansk, Poland, [4]Medical University of Gdansk, Div. of Pathology and Neuropathology, Gdańsk, Poland

Background & Objectives: Barbara was king's second wife. Sources negate any maladies until 1547. She died less than six months after her coronation... Before her death, she suffered with high fever, cachexia and growing growth/tumour in her abdominal area present.

Methods: We analysed available historical sources including family letters and published articles. The data show progressive weakness, specific and nonspecific symptoms. We can hypothesize the possible course of disease of King's wife leading to her demise. Additional information include her previous life, helath conditions and other possible threats of the court enviroment inlcluding her mother-in-law, Bona Sforza.

Results: We had to deal with several hypotheses, sometimes contradicting each other, including the risk of poisoning, puerperal fever, concequences of treatment of possible syphylis with mercurium, SIRS (systemic inflammatory response syndrome) and last but not least malignancy of the uterus. Differential diagnosis is rather difficult as no autopsy was performed, only the report after analysis of remains of her body, mainly skeleton, centuries later. On the other hand we have quite detailed medical history and course of disease basing on the rich correspondence, where continuous deterioration and appearing new symptoms are reported. Some of them let us narrow the possible final diagnosis.

Conclusion: The analysis of body remains proved no trace of mercurium which could exclude syphilis, as Barbara Radziwill came from nobility and would be treated with best possible methods of the time. There is no evidence of any malformation of skeleton, nor trace of metastases. The reports stating increasing foul odour, deterioration, progressive weakness, foul smelling discharge from vagina indicate malignancy of the uterus. In this case squamous cel carcinoma seems to be most probable, nevertheless other types cannot be excluded.

E-PS-15 E-Posters Infectious Diseases Pathology

E-PS-15-001
Pathological features of lung tissue as a major finding in COVID-19 deaths

M. Semko[1], Y. Kuzyk[1]
[1]Danylo Halytsky Lviv National Medical University, Pathological Anatomy and Forensic Medicine, Lviv, Ukraine

Background & Objectives: Understanding the characteristics of fatal COVID-19 cases is crucial for comprehending the pathogenesis of severe complications and identifying effective treatment methods.
This study aims to investigate the morphological features of fatal COVID-19 cases.
Methods: A retrospective analysis was conducted on the results of 3,744 postmortem examinations of patients who died from COVID-19 at the Lviv Regional Pathology Bureau between 2020 and 2021. Histological examination of lung tissue samples utilized the standard haematoxylin-eosin method, the modified Zerbino—Lukasevich MSB method, Masson's trichrome, and immunohistochemical studies using inflammatory and proliferative antibodies.
Results: A significant predominance was observed in young and middle-aged men compared to women, who showed a higher prevalence among the elderly ($p < 0.001$). The highest mortality rates were noted from 1 to 14 days ($72.92 \pm 0.73\%$) and from the 15th to the 21st day ($68.71 \pm 1.45\%$).
Among patients, the highest mortality (72.89%) occurred in the first 14 days, with 16.05% dying on days 15-21, and 11.06% passed on day 22 and later.
During the exudative phase, signs of haemorrhagic interstitial pneumonia were observed, characterized by a predominance of CD3, CD31, and CD34-positive T-lymphocytes, CD20-positive B-lymphocytes, and CD163-positive macrophages. Additional findings included intraalveolar oedema, hyaline membranes, pronounced plethora, and multiple thrombi. The proliferation phase was characterized by inflammation, marked by clusters of CD68- and CD163-positive cells and CD8-positive cytotoxic T cells. There was a thickening of the interalveolar septa due to the proliferation of fibroblasts and the hyperplasia of pneumocytes II (TTF1-positive). During the organization phase, a predominance of CD68- and CD163-positive macrophages was observed, accompanied by a small number of T-lymphocytes and solitary B-lymphocytes. Additionally, pneumofibrosis with arteriosclerosis also progressed.
Conclusion: The described lung histology indicates the progression of diffuse alveolar damage from an exudative to a fibrotic phase, leading to severe disease with potentially fatal consequences.

E-PS-15-003
Ecthyma gangrenosum in an immunosuppressed patient post-liver transplant: a diagnostic challenge

J. Alvarez Figueroa[1], M. Rolon[1], L. Chacon Zambrano[1]
[1]Fundacion Santa Fe de Bogotá, Pathology, Bogotá, Colombia

Background & Objectives: Ecthyma gangrenosum is a rare and severe cutaneous infection, most often associated with Pseudomonas aeruginosa and typically observed in immunocompromised patients. Early recognition and targeted therapy are critical due to its potential for rapid progression and high mortality. This report highlights the diagnostic and therapeutic approach in a 67-year-old post-liver transplant patient with ecthyma gangrenosum, emphasizing the importance of timely intervention.
Methods: The patient presented with a chronic necrotic lesion on the left foot, initially suspected to be of vascular origin. Clinical and histopathological findings revealed extensive ulceration with lymphohistiocytic and neutrophilic inflammation, capillary proliferation, interstitial haemorrhage, and fibrosis extending into the subcutis. Vessel walls showed marked thickening without occlusion, and PAS staining identified gram-positive bacterial colonies. These findings confirmed the diagnosis of ecthyma gangrenosum. Multidisciplinary management included targeted antibiotics, wound care, and adjustment of immunosuppressive therapy.
Results: The patient responded well to treatment, with significant ulcer healing and no systemic complications. The early histopathological diagnosis was pivotal in guiding therapy. This case underscores the challenges of managing infections in immunosuppressed patients, particularly with concerns of antibiotic resistance in Pseudomonas aeruginosa.
Conclusion: Ecthyma gangrenosum is a critical diagnosis to consider in necrotic ulcers, especially in high-risk patients. Early detection is essential to prevent severe complications and improve outcomes. Antibiotic resistance and the potential involvement of other pathogens demand a broader understanding of the disease. Reporting cases like this emphasizes the need for precise diagnostic tools, multidisciplinary collaboration, and careful antibiotic stewardship to address this life-threatening condition.

E-PS-15-004
Cerebral sparganosis: intracranial parasitic infection with diagnostic challenges and histopathological insights

O.C. Eren[1], H. Akturk[2], I. Solaroglu[3], I. Kulac[1]
[1]Koç University Hospital, Department of Pathology, Istanbul, Turkey, [2]Koç University Hospital, Department of Paediatrics, Istanbul, Turkey, [3]Koç University Hospital, Department of Neurosurgery, Istanbul, Turkey

Background & Objectives: Sparganosis is a parasitic infection caused by migration of the plerocercoid larvae of *Spirometra*. It is among the understudied entities in pathology, especially due to its rarity and occurrence at unexpected locations. We hereby depict a case of cerebral sparganosis to increase awareness and emphasize diagnostic clues.
Methods: An 11-year-old female without relevant previous medical history presented with recurrent seizures. Magnetic resonance imaging revealed a mass in the right parietal lobe, measuring 13x7 millimeters. Together with multiple calcifications and peripheral contrast enhancement, the preliminary radiological differential diagnoses were glioneuronal tumours and paediatric diffuse gliomas. The parietal mass is resected for pathological evaluation.
Results: Entire specimen was submitted for evaluation. Histology revealed reactive gliosis, perivascular and parenchymal lymphoplasmacytic cells along with scattered eosinophils as well as multiple foci of microcalcification. Only on one of the sections a parasite, morphologically compatible with helminth was detected. Measuring 12 millimeters in the greatest piece, the parasite was characterized by an eosinophilic tegument and underlying pale myxoid matrix with characteristic longitudinal smooth muscle fibres, suggestive of sparganosis. No scolex was observed. Systemic imaging showed no signs of involvement in any other site.
Conclusion: Sparganosis is a parasitic zoonosis transmitted by contaminated water or consumption of raw snakes/frogs. With larvae characterized by outer tegument, inner calcareous corpuscles and longitudinal muscle fibres, sparganosis differs from cysticercosis. It is seen more commonly in superficial soft tissue but also rarely in internal organs, including the brain. Complete surgical removal, accurate diagnosis and antihelminth treatment remain crucial in management.

E-PS-15-005
Kaposi Sarcoma a case series of unusual locations

O. El Mnif[1], A. Zehani[1], A. Khadhar[1], I. Chelly[1], H. Azouz[1], K. Bellil[1], S. Haouet[1]

[1]La Rabta University Hospital, Pathology, Tunis, Tunisia

Background & Objectives: Kaposi sarcoma (KS) is an angioproliferative malignancy associated with Human Herpesvirus 8(HHV8), predominantly affecting immunocompromised individuals. Its incidence is highest in HIV/AIDS patients, but also occurs in transplant recipients and endemic populations. KS can manifest in various anatomical regions, typically affecting the skin but occasionally extending to the gastrointestinal tract and lungs.
We present a case series of KS with atypical anatomical locations diagnosed in our department.
The aim of the study was to investigate the clinical and pathological characteristics of KS cases particularly focusing on atypical presentation.
Methods: We present a retrospective study of five cases of KS diagnosed at LaRabta department of pathology between 2021 and 2025. Clinical, radiological, and endoscopic findings led to gastric, hypopharynx biopsies, lymphadenectomy and parotidectomy. All of the specimens underwent examination using Haematoxylin and Eosin staining and Immunohistochemistry using CD34 and HHV8 antibodies.
Results: There were 5 males aged between 47 and 81 years with a mean age of 57. Four out of five patients were HIV-positive, One patient was HIV-negative and non-immunocompromised. Three patients had multiple locations of KS. The affected sites were lymph nodes both cervical and inguinal (n=2), gastric antrum (n=2), gastric fundus (n=1), oesophagus (n=1), parotid gland (n=1), and hypopharynx (n=1) with n referring to the number of affected locations. Histopathological evaluation of all the specimens showed typical features of KS revealing nodular and diffuse spindle cell proliferation with elongated cells, hyperchromatic nuclei, eosinophilic cytoplasm, cytonuclear atypia, and mitoses. Hemorrhage was noted between tumour cell bundles (n=6).
Immunohistochemistry showed intense and diffuse nuclear positivity using HHV8 antibody (n=8) and CD34 antibody (n=1).
Conclusion: This case series is one of the few that highlights the atypical locations of Kaposi sarcoma and also reports a sporadic, HIV-negative case in an immunocompetent patient, underscoring the importance of considering KS in any difficult-to-classify spindle cell lesions.

E-PS-15-006

A case of pulmonary echinococcosis mimicking neoplasm in a patient from the Amazon Region, Brazil

D. Feitosa Junior[1], G. Tabosa[1], C. Bandeira[1], J. Furlaneto Junior[1], T. Neotti[1], R. Silva[1], R. Brito[1], M. Ortiz Rocha[2], A. Avertano Rocha[2], C. Silva[1]
[1]Instituto de Patologia Cirúrgica e Molecular, Belém, Brazil, [2]Hospital Regional Abelardo Santos, Belém, Brazil

Background & Objectives: Echinococcosis, a parasitic zoonosis caused by the larval stage of Echinococcus tapeworms, is a global health concern, particularly in regions with close contact between humans and infected canids. The disease can manifest as cystic lesions in various organs, most commonly the liver and lungs, often mimicking neoplastic processes in clinical and radiological assessments. This report presents a case of pulmonary echinococcosis in a patient from the Amazon region of Brazil, highlighting the diagnostic challenges and the importance of considering this parasitic infection in the differential diagnosis of lung nodules.
Methods: A 55-year-old male indigenous patient from the Amazon region presented with cough and pulmonary nodules. Initial investigations led to a referral to an oncology centre. Following a lung segmentectomy, a definitive diagnosis of echinococcosis was confirmed through histopathological examination of the resected tissue.
Results: The patient underwent surgical resection of a pulmonary lesion initially suspected to be a neoplasm. The histopathological analysis revealed the characteristic features of a hydatid cyst, confirming the diagnosis of pulmonary echinococcosis. This finding underscores the potential for this parasitic disease to mimic malignancy, necessitating careful consideration in endemic areas.
Conclusion: Pulmonary echinococcosis should be included in the differential diagnosis of lung nodules, especially in patients from endemic regions like the Amazon. This case highlights the challenges in distinguishing parasitic infections from neoplastic processes based on clinical and radiological findings alone. Accurate diagnosis through histopathological examination is crucial for appropriate patient management and to avoid misdiagnosis that could lead to inadequate or delayed treatment. The awareness of pathologists regarding this disease is paramount for accurate diagnosis and appropriate clinical approach.

E-PS-15-007

Herpetic hepatitis in a young, immunocompetent patient

L. Budding[1,2], B. Apleni[3,2], D.L. Le Grange[1,2], S. Maphumulo[4,5], J.C. Kotze[6,7], H. Pieters[8], A. van Wyk[9,10], J. Goedhals[11,12]
[1]National Health Laboratory Service, Department of Anatomical Pathology, Bloemfontein, South Africa, [2]University of the Free State, Bloemfontein, South Africa, [3]Department of Health, Department of Forensic Pathology, Bloemfontein, South Africa, [4]National Health Laboratory Service, Department of Virology, Pretoria, South Africa, [5]University of Pretoria, Pretoria, South Africa, [6]National Health Laboratory Service, Department of Virology, Bloemfontein, South Africa, [7]University of the Free State, Department of Virology, Bloemfontein, South Africa, [8]National Health Laboratory Service, Electron Microscopy Unit, Cape Town, South Africa, [9]National Health Laboratory Service, Department of Anatomical Pathology, Cape Town, South Africa, [10]Stellenbosch University, Bellville, South Africa, [11]PathCare, Department of Anatomical Pathology, Bloemfontein, South Africa, [12]University of the Free State, Department of Anatomical Pathology, Bloemfontein, South Africa

Background & Objectives: Herpes simplex virus (HSV) is a double-stranded deoxyribonucleic acid (DNA) virus that is rarely implicated in the pathogenesis of hepatitis, especially in immunocompetent patients. Herpetic hepatitis accounts for less than 1% of fulminant hepatic failure and, due to its rarity, is often underrecognised in clinical practice. Of the approximately 1% of patients who develop herpetic hepatitis, around 25% are immunocompetent. Unfortunately, herpetic hepatitis is fatal in up to 74% of cases, with the majority of cases diagnosed on postmortem examination.
Methods: In this report, an interesting case of herpetic hepatitis in a previously healthy male of 19-years-old is described. The patient presented to a tertiary hospital in Bloemfontein, South Africa, with a 1-week history of intermittent fever, vomiting, nausea and epigastric pain. No travel history was noted and the patient did not present with mucocutaneous lesions. He was anicteric and haematological and chemical investigations revealed that he was in fulminant hepatic failure, of unknown aetiology, complicated by hepatorenal syndrome and hepatic encephalopathy. His transaminases were markedly elevated with an aspartate transaminase of 20 437 U/L and ammonia of 393 umol/L was recorded. Whilst awaiting admission, he demised. A post-mortem was requested to ascertain the cause of death.
Results: On gross examination, the patient had a markedly enlarged, yellow liver and haemorrhagic mucous membranes in the gastrointestinal tract. Microscopic examination showed features of herpetic hepatitis that were confirmed by immunohistochemical stains. Despite the absence of HSV IgM and IgG positivity, virologic investigations verified the presence of HSV-1 associated hepatitis. Electron microscopy showed HSV within the hepatocytes, even though the tissue was formalin-fixed.

Conclusion: This case serves as an important reminder to consider the possibility of herpetic hepatitis in young, previously healthy patients who present with acute hepatic failure, severely deranged liver functions and features of disseminated intravascular coagulopathy.

E-PS-15-008

Hyperinfestation syndrome of Strongyloides Stercolaris: when the biopsy leads to diagnosis

A. Nogales-Moro[1], M.R. Vázquez-Carnero[1], L. Camacho-Abascal[1], I. Gallego-Gutiérrez[1], S. Gómez-de Frutos[2], M. Gómez-Márquez[1], N. Dimas-Vasquez[1], M.V. Domínguez-Martínez[1], M. Chao-Crecente[1], C. Ariño-Palao[1]
[1]Hospital Universitario Severo Ochoa, Pathology, Leganés (Madrid), Spain, [2]Hospital Universitario Severo Ochoa, Microbiology, Leganés (Madrid), Spain

Background & Objectives: Strongyloidiasis is caused by the penetration of infective mature filiform larvae through the skin and/or the ingestion of immature forms (eggs and rhabditiform larvae) of the nematode Strongyloides Stercolaris, endemic to tropical and warm regions. Clinically, the disease progresses from an acute cutaneous phase, during which the host's unprotected skin is penetrated, to a chronic systemic phase which ends with the migration of the parasite from the organs of the gastrointestinal tract, via the host's bloodstream, to the respiratory and lymphatic systems. Asymptomatic cases which remain undiagnosed until reaching advanced stages, carry a high mortality rate.
Methods: We present the case of a 59-year-old apparently immunocompetent woman from Colombia with no relevant medical history. She was admitted to our hospital due to persistent vomiting, diarrhoea, and weight loss, associated with unexplained eosinophilia and hyponatremia. Stool cultures were negative. CT scan showed ascites, pleural effusion and consolidations in addition to diffuse gastroenterocolitis. Gastroscopy from oesophagus to duodenum was non-specific with oedema, thickening and friable mucosa suggesting an inflammatory origin.
Results: Biopsies were performed from the oesophagus, stomach, and duodenum, showing acute inflammatory response associated with parasitic forms of Strongyloides Stercolaris at different stages of development. Only the duodenum was ulcerated. Following the pathology report, a bronchial aspirate sample was obtained with evidence of mature filiform larvae confirming the diagnosis. Although the patient was immediately started on antiparasitic treatment, she died in less than 24 hours. Post-mortem serology for HTLV-1 virus turned out positive, justifying the clinical picture.
Conclusion: Although culture or serology are the usual diagnostic methods, the importance of an adequate histopathological diagnosis remains crucial, as it can directly identify the parasite. Just as in our case, hyperinfestation syndrome should be taken into consideration as a differential diagnosis in apparently immunocompetent patients from endemic areas with severe chronic gastrointestinal symptomatology.

E-PS-15-009

Leprosy does not disappear: remembering its reality beyond Europe

A. Diez[1], M.C. Mota[2], M.C. Garrido[2], J.L. Rodriguez Peralto[2]
[1]Hospital 12 Octubre, Madrid, Spain, [2]Hospital Universitario 12 Octubre, Madrid, Spain

Background & Objectives: Leprosy although it is very rare in our continent, it continues to be endemic in Africa. Diagnosis requires clinical assessment,Acid-resistant bacilli are not always identified. Leprosy was classified by Ridley-Jopling into tuberculoid leprosy (with epithelioid cell aggregates), lepromatous leprosy (with Virchow cells), and a borderline spectrum. The New Indian classification introduced indeterminate leprosy, which shows only lymphohistiocytic infiltrates localized around nerves and appendages, without the presence of bacilli.
Methods: We received 42 cases for diagnosis at the end of 2024 from various regions of Malawi through the NGO "DERMALAWI". Clinical histories, histological preparations, and immunohistochemical/histochemical techniques were reviewed for suspected infectious dermatoses. A bibliographical review of leprosy was conducted.
Results: 4 cases of tuberculoid leprosy: These showed a well-defined granulomatous inflammatory infiltrate with epithelioid cells, giant cells, and macrophages without necrosis, and a lymphocytic crown. The distribution was perineural and perianexial in both superficial and deep dermis.
2 cases of lepromatous leprosy: These showed a perineural accumulation of foamy macrophages in an "onion skin" pattern in the dermis, with a visible Grenz zone and atrophic epidermis.
1 case of borderline tuberculoid leprosy: This case showed poorly defined granulomas with fewer lymphocytes and macrophages. The epidermis was atrophic, and the nerves did not show complete destruction.
5 cases of indeterminate leprosy: These showed a lymphocytic inflammatory infiltrate, both superficial and deep in the dermis, surrounding blood vessels, appendages, and nerves, with few macrophages.
Conclusion: Despite not being in an endemic zone, it is important to understand its histology, as cases may be referred to us at any time, and proper identification is crucial. We emphasize the importance of international collaboration and monitoring in endemic areas for proper diagnosis and timely intervention in vulnerable populations. There are two histological forms that may overlap with other conditions, making it essential to rely on diagnostic clues.

E-PS-15-010

Hydatidosis infection in an unusual sites: an ongoing diagnostic problem in the 21st Century

R. Ayadi[1], R. Yaiche[1], Y. Barbirou[1], S. Jedda[1], E. Braham[1], O. Ismail[1], N. Ben Jamaa[1], A. Ayadi[1]
[1]Abderrahmane Mami Hospital, Pathology, Tunis, Tunisia

Background & Objectives: Hydatidosis is a zoonotic disease caused by the larval form of *Echinococcus granulosus*. Tunisia is an endemic country, with an incidence of 15.1 per 100,000 inhabitants. The disease typically affects the liver and/or lungs. However, in exceptional cases, hydatid cysts can develop in atypical locations, posing diagnostic challenges.
The aim of this study was to report the epidemiological, clinical, and histological features of hydatid cysts of uncommon hydatid cyst localizations.
Methods: This is a retrospective study conducted in our department of pathology between 2004 and 2024, including cases of hydatid cysts diagnosed in rare anatomical sites.
Results: Twenty-six patients were included (female/male=1) aged between 18 and 76 years with a mean of 44. The most frequently involved organ werechest wall (n=18) and spleen (n=4) followed by pancreas (n=2). The other localizations female genital and peritoneum were noted in one cases each. For chest wall, the most common site was costal (n=13), followed by vertebral (n=2), clavicular (n=1), and sternal (n=1) involvement. The most frequently affected ribs were the 7th (n=6) and 8th (n=6), followed by the 3rd, 5th, 6th, and 9th ribs (each in 2 cases). Clinical presentations varied based on cyst location. Bone cysts typically presented with chest pain. While splenic cysts presented with mild abdominal discomfort and pancreatic cysts were associated with episodes of acute pancreatitis. Radiological investigations revealed cysts appearing as multiple opacities. All patients underwent surgical treatment. Histopathological examination confirmed hydatidosis infection of by identifying the

hydatid membrane and its multivesicular nature. The postoperative course was favourable in all patients, with no reported recurrences.
Conclusion: This case series emphasizes the importance of considering hydatid cysts in the differential diagnosis of cystic lesions in unusual locations. Imaging aids in preoperative evaluation, but histopathology remains the key diagnostic tool for confirmation. Surgery remains the preferred curative treatment for this condition.

E-PS-15-011

Mycobacterium tuberculosis complex: an unexpected cause of necrotizing granulomatous epididymo-orchitis mimicking malignancy

S. Horvath[1], L. Mejdoubi[1], R. Weichselbaum[1], A. Nader[1]
[1]Hanusch Hospital, Institute of Pathology and Microbiology, Vienna, Austria

Background & Objectives: We present a case of a 67-year-old immunocompetent man, born in Austria, who was referred to the urology outpatient clinic, because of an enlarged right testicle for the last 9 months. The patient did not report any tenderness of the testis, fever, weight loss or night sweats. Because of suspected malignancy, a radical orchiectomy was scheduled. Blood analysis showed no signs of lymphoma and no elevated tumour biomarkers. Performed thoracic and abdominal computational tomography (CT) revealed unspecific retroperitoneal lymphadenopathy and no metastatic lesions.
Methods: Right radical orchiectomy was performed and the tissue was analysed at the institute of pathology.
Results: The histology revealed extensive necrotizing granulomatous infection of the epididymis and testis with interspersed Langhans giant cells and no evidence of malignancy. A Ziehl-Neelsen staining was performed, in which no acid-fast bacilli were detected. PCR from the tissue was positive for *Mycobacterium tuberculosis* complex (MTBC). No culture was obtained as repeated sputum and urine samples were negative for MTBC. Chest X-ray did not show any abnormalities. After surgery, the patient developed active lesions in his left testicle, which were observed by ultrasound. The patient was started on standard treatment. After 4 months, follow-up ultrasound showed a significant improvement.
Conclusion: Necrotizing granulomatous epididymo-orchitis can mimic malignancy and is caused by a myriad of pathogens such as *Brucella* spp., *Salmonella typhimurium*, *Histoplasma capsulatum* and MTBC. Some cases have been reported after Bacillus Calmette-Guérin (BCG) instillation. Literature suggests that the majority of cases are caused by MTBC or *Brucella* spp. and should be tested in order to provide adequate treatment.

E-PS-15-012

Chronic cutaneous infection by dematiaceous fungi: a case report of chromoblastomycosis with leprosy-like features

K. Cruz[1], J.D. Serrano[1], M. Rolon[1], L. Chacon Zambrano[2]
[1]University Hospital Fundacion Santa Fe de Bogota, Pathology Department, Bogota, Colombia, [2]Third-Year Pathology Residency University Hospital Fundacion Santa Fe de Bogota, Pathology Department, Bogota, Colombia

Background & Objectives: Chromoblastomycosis is a chronic fungal infection that affects the skin and subcutaneous tissue, caused by dematiaceous fungi. This disease is predominantly found in tropical and subtropical regions, particularly in areas with warm and humid climates. Infection is typically acquired through traumatic inoculation of fungal spores present in the environment. Cutaneous lesions can be easily mistaken for other infectious and non-infectious conditions, making early diagnosis challenging. In this report, we present the case of a 50-year-old male farmer with a chronic leg lesion following an injury, who was initially treated under the clinical suspicion of leprosy. Through this case, we aim to highlight the diagnostic and clinical features of chromoblastomycosis, a rare and under-recognized disease.
Methods: A skin biopsy obtained from the patient was evaluated through histopathological analysis. The specimen was subjected to several special stains, including Haematoxylin and Eosin (H&E), Periodic Acid-Schiff (PAS), silver stain, and Ziehl-Neelsen (ZN), in order to identify characteristic fungal structures and to rule out other potential infections.
Results: Microscopic examination revealed pseudoepitheliomatous hyperplasia with intraepidermal abscesses and pigmented fungal sclerotic bodies (Medlar bodies) located in both the superficial and reticular dermis. Fungal elements were clearly visualized with PAS and silver stains, confirming the presence of dematiaceous fungi. Ziehl-Neelsen staining was negative, effectively ruling out the presence of mycobacteria.
Conclusion: The histopathological findings, in conjunction with the patient's clinical history, are consistent with a diagnosis of chromoblastomycosis. Consideration of epidemiological factors and the clinical presentation is critical in reaching an accurate diagnosis. In tropical countries, a wide range of microorganisms must be included in the differential diagnosis. Therefore, early and accurate recognition of this disease is essential for initiating timely treatment and preventing complications.

E-PS-15-013

Non-tuberculous mycobacterial nasal cavity infection caused by mycobacterium simiae in an immunocompetent 86-year-old female patient

J. Kim[1], H. Son[1], J. Lee[2]
[1]Daejeon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Pathology, Deajeon, Republic of Korea, [2]Daejeon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Otolaryngology, Deajeon, Republic of Korea

Background & Objectives: *Mycobacterium simiae* is a non-tuberculous mycobacterium (NTM) primarily associated with pulmonary disease and rarely presents as localized lesions. We report a case of *M. simiae* infection manifesting as a nasal cavity mass in an immunocompetent 86-year-old woman with a history of hypertension and a prior left pontine infarct. She experienced recurrent right-sided epistaxis for 20 days in February 2022. Laryngoscopic examination revealed a soft, non-tender, pea-sized mass originating from the right nasal septum. Paranasal sinus computed tomography identified a 1 cm-sized nodular lesion in the right anterior nasal cavity. The mass was excised via laryngoscopic examination. Routine laboratory tests were unremarkable, and a nasal swab for COVID-19 was negative.
Methods: The excised tissue underwent haematoxylin-eosin staining for histopathological evaluation and acid-fast bacilli staining for mycobacterial detection. Real-time polymerase chain reaction (PCR) and sequencing analysis were performed to identify NTM species.
Results: Histopathologic examination revealed poorly defined, irregularly shaped, chronic granulomatous inflammation with extensive foamy macrophages and suppurative inflammation. Acid-fast bacilli staining and PCR for NTM yielded positive results. An atypical mycobacterial infection was diagnosed. Real-time PCR, followed by sequencing, identified *Mycobacterium simiae* strain MH4 based on 16S-23S ribosomal RNA analysis. The patient remained asymptomatic following mass excision and did not require additional antimicrobial therapy. She continues routine follow-up for preexisting condition.
Conclusion: *Mycobacterium simiae* infections can closely mimic tuberculosis and other granulomatous diseases. As NTM infections are increasingly recognized worldwide, heightened awareness and the

use of molecular diagnostic tools are essential for accurate diagnosis and management. This case underscores the importance of considering *M. simiae* as a differential diagnosis in localized granulomatous nasal lesions, even in immunocompetent patients.

E-PS-15-014

Hydatid cyst in an unusual sites: a challenging diagnosis

Y. Dhouibi[1], R. Ayadi[1], R. Yaiche[1], S. Jedda[1], Y. Barbirou[1], E. Brahem[1], O. Ismail[1], N. Ben jemaa[1], A. Ayadi[1]
[1]Abderrahmen Mami Hospital, Department of Pathology, Ariana, Tunisia

Background & Objectives: Hydatid disease, caused by Echinococcus granulosus, typically affects the liver and lungs, but rare atypical localizations pose diagnostic challenges. This study presents cases of uncommon hydatid cyst sites, highlighting their clinical and pathological features.
Methods: We retrospectively reviewed cases of hydatid cysts diagnosed in rare anatomical sites over 15 years in our pathology department. Diagnosis was confirmed by histopathology following surgical excision. Clinical, imaging, and histopathological characteristics were analysed.
Results: Eight cases were included (age range: 24–65 years, F/M ratio: 3:1). Uncommon localizations included the spleen (4 cases), pancreas (2), uterus (1), and peritoneum (1). Clinical presentations varied: splenic cysts were mostly incidental or caused mild discomfort, while pancreatic cysts were associated with acute pancreatitis. The uterine cyst appeared as a solid-cystic pelvic mass with pain, and the peritoneal cyst was incidentally discovered. Imaging findings showed well-defined, hypoechoic splenic cysts (4 cases), with a "water lily" sign on CT (2 cases). Pancreatic cysts exhibited ductal dilatation and multiple cystic lesions, while the uterine cyst appeared solid-cystic on ultrasound and CT. Cyst sizes ranged from 7 to 18 cm. Macroscopic examination revealed fibrous and calcified cyst walls with hydatid membranes in most cases. Histologically, all cases showed fibrous cyst walls with granulomatous inflammation. One splenic case lacked hydatid membranes, suggesting degeneration.
Conclusion: Hydatid cysts should be considered in the differential diagnosis of cystic lesions in unusual locations. Imaging is valuable for preoperative assessment, but histopathology remains essential for definitive diagnosis.

E-PS-15-015

Unusual hydatid cysts: 5 cases report with heart, brain, kidney, muscle and bone localization

E. Yilmaz Eşsiz[1], S. Özekinci[1]
[1]Dicle Üniversity Medical Faculty, Medical Pathology, Diyarbakir, Turkey

Background & Objectives: Cyst Hydatid, the causative agent of which is Ecinococcus Granulosus, is a zoonotic disease that causes significant public health problems and serious economic losses, especially in developing Mediterranean countries. The parasite lives in the small intestines of dogs. Humans ingest the eggs, which are spread to the environment through dog feces; the ingested eggs hatch in the human intestine and first reach the liver via blood, where they most frequently form cysts. Those that manage to pass through the liver sinusoids cause disease by forming cysts in other organs, especially the lungs.
Methods: In this report, cases of hydatid cysts localized in the tibia in a 70-year-old male patient, intramuscular localization in the cruris in a 37-year-old female patient, cardiac localization in a 45-year-old male patient, renal localization in a 44-year-old female patient, and brain parenchymal localization in a 30-year-old male patient will be presented.
Results: Almost any anatomic location can be the host site of the parasitic cysts. Hydatid cysts in the liver and lung constitute 90-95% of all hydatid cyst cases. Hydatid cysts with unusual localization are extremely rare, even in endemic areas.
Conclusion: The disease may have many different clinical presentations. The widespread use and development of imaging methods such as CT and MRI make our job easier in diagnosis. Although it is a benign disease, sometimes it can cause serious morbidity and even mortality. It is for this reason that it should definitely be kept in mind in differential diagnosis. Surgery is the mainstay of treatment. Albendazole is used in drug therapy.

E-PS-15-017

Morphological changes in lung vessels in Covid-19

B. Magrupov[1,2], K. Murotov[1]
[1]Center for the Development of Professional Qualification of Medical Workers, Department of Patanatomy and Forensic Medicine, Tashkent, Uzbekistan, [2]Republican Research Centre of Emergency Medicine, Department of Cardiac Surgery, Vascular Surgery with Microsurgery, Tashkent, Uzbekistan

Background & Objectives: Covid-19 infection has caused a large number of complications and deaths. Studying the causes of the disease is a very urgent task.
Methods: The study examined histological lung sections from 68 deceased COVID-19 patients, autopsied in August-September 2021. Samples were processed, embedded in paraffin, and stained with haematoxylin and eosin for microscopic analysis. Significant pathomorphological changes in pulmonary vessels were documented.
Results: COVID-19 induces severe endothelial damage due to high ACE2 expression. This results in endotheliosis, endotheliitis, coagulopathy, and vasculitis. Vessels of varying calibers show fibrinoid necrosis, thrombus formation, and haemorrhagic-fibrinous inflammation. Microscopic examination reveals dilated capillaries, perivascular haemorrhage, and thickened alveolar walls. The proliferative phase shows lymphohistiocytic infiltration, vessel wall oedema, and sclerosis. Some vessels display fibrin thrombi and destroyed endothelial layers. During the proliferative phase, vessel walls thicken, showing mucoid and fibrinoid degeneration with perivascular lymphohistiocytic infiltration. Severe infiltration by histiocytes extends into alveolar tissue. The alveolar walls become airless and indistinguishable due to deventilation and haemorrhagic inflammation. Fibrin thrombi are commonly found in small pulmonary vessels.
Conclusion: SARS-CoV2-induced endothelial damage and ACE2 receptor abundance result in severe discirculatory changes, including endotheliosis, coagulopathy, vasculitis, and thrombus formation. The proliferative phase is marked by lymphohistiocytic infiltration, vessel wall destruction, and subsequent sclerosis.

E-PS-15-018

Unveiling granulomatous skin lesions story

R. Ranjan[1], P. Shelke[1], P. Doshi[1], K. Jagdale[1], M. Karandikar[1], R. Bharadwaj[1]
[1]Bharati Vidyapeeth Deemed to be University, Pathology, Pune, India

Background & Objectives: Granulomatous skin lesions present a diagnostic challenge, displaying varied clinical forms with overlapping histopathology. Accurate diagnosis requires clinical correlation and tests. India, endemic to TB and Leprosy, sees many infectious skin diseases like these presenting as granulomatous lesions. A systematic approach helps distinguish infectious, inflammatory, and immune causes. This case series aims to study the diagnosis and incidence of such lesions reported to our department.
Methods: This case series of 20 granulomatous skin lesions at Bharati Vidyapeeth Deemed University, a tertiary centre in Western Maharashtra, analyzes age, gender, histopathology, and final diagnosis after special staining.

Results: The mean age of 20 cases was 38.3 years (range: 14–70). There were 7 females (35%) and 13 males (65%). Swelling was the most common feature (9 cases, 45%). Lesions were on the upper limb in 13 cases (65%) and head-neck in 7 (35%). Histopathology showed 15 granulomatous lesion (75%) —3 suggestive of TB (20%). 5 of foreign body granuloma (25%)- 02 infected epidermoid cyst with foreign body granuloma(10%), 03 only showing foreign body granuloma(60%). Special staining confirmed 10 cases (50%), including 5 tuberculoid (25%) and 4 borderline tuberculoid leprosy (20%).
Conclusion: Our case series highlights the diagnostic complexity of granulomatous skin lesions, emphasizing the need for a systematic approach incorporating histopathology and ancillary tests for accurate identification. While most cases were correctly diagnosed histopathologically, special staining played a crucial role in confirming infections such as tuberculoid leprosy and fungal granulomas. A multidisciplinary correlation remains essential to differentiate between infectious and non-infectious causes, ensuring appropriate patient management.

E-PS-15-019
Histopathological diagnosis of rhinosinusitis-mucormycosis during the COVID-19 Pandemic. A cases serie from Venezuela
G. Arismendi Morillo[1]
[1]University of Deusto, Faculty of Health Sciences, Bilbao, Spain

Background & Objectives: Mucormycosis is a potentially fatal infection.
Methods: Cases of rhinosinusitis-mucormycosis during 2021 are studied. Pathological diagnosis was done by means H&E, Grocott´s methenamine silver, and PAS stains in rhinosinusal biopsies.
Results: Four patients were male (51-71 years old), two were female (38-59 years old). Three cases develop a mucormycosis-actinomycosis co-infection. All cases exhibited a necrotizing process. Radical surgical debridement was performed in all cases.
Conclusion: Pathological diagnosis was fundamental for specific antifungal-antibacterial treatment. Favorable clinical outcome was observed.

E-PS-15-021
Unmasking the unseen enemy: a retrospective study of the clinicopathological spectrum of histoid leprosy at a tertiary care hospital in South India
E. Edwin[1], M. Thomas[1]
[1]Christian Medical College, Department of General Pathology, Vellore, India

Background & Objectives: Leprosy is one of the oldest chronic infectious diseases known to man caused by Mycobacterium leprae. Leprosy has been declared eliminated (<1 case/ 10,000 population) in our country on December 31st, 2005. However, cases continue to be reported with varying prevalence all over India. Histopathological study in clinically suspicious cases plays a critical role in confirming the diagnosis, subtyping, prognostication and assessment of disease in patients. Histoid leprosy is a highly bacilliferrous type of lepromatous leprosy. It was previously believed to manifest after failure of long-term dapsone monotherapy or due to irregular and/or inadequate therapy. However, we now know that it sometimes arises de novo.
To study the incidence and clinicopathological characteristics of histoid leprosy.
Methods: All histopathologically confirmed cases of Hansen's disease received over a period of 5 years (January 2020-December 2024) were examined. Haematoxylin and Eosin and Fite-Faraco stained sections of all the cases were examined. Clinical details and corresponding slit-skin smears, wherever available, were also reviewed.
Results: 590 new cases of leprosy were registered in the Department during the study period. Histoid Leprosy was seen in 16 patients (0.027%). The mean age of 42.25 years along with male preponderance (68.7%) was observed. Skin nodules were seen in half the cases, but only one patient had deformity during their first visit. One patient developed type II lepra reaction (erythema nodosum leprosum). None of these patients had received any anti-Hansen's disease treatment prior to presentation and the lesions all appeared de novo.
Conclusion: Histoid leprosy is a rare subtype of Hansen's disease. Mimics, lack of knowledge of this variant with high bacillary load among pathologists and medical officers may lead to misdiagnosis. Histological awareness of this entity and use of special stain is warranted to differentiate it from its mimics for early treatment and prevention of deformities.

E-PS-15-022
Secondary syphilis – condyloma lata: an unusual clinical manifestation of secondary syphilis. Case report
P.C. Castro-Quiroga[1], B. Díaz-Gómez[1,2], C. Pineda[2], M. Reyes[2], P.A. Vega[2], R. Rodríguez[3]
[1]University Hospital Fundacion Santa Fe de Bogota, Pathology Department, Bogota, Colombia, [2]University of the Andes, School of Medicine, Bogota, Colombia, [3]Clínica Vida, Pathology Department, Medellin, Colombia

Background & Objectives: Syphilis, caused by Treponema pallidum, is resurging globally, particularly in developing regions. Secondary syphilis presents with varied mucocutaneous manifestations. Condyloma lata—broad-based, moist, gray-white papules in the anogenital region—is rare but highly contagious. In endemic areas like Colombia, underreporting and clinical misdiagnosis remain common due to atypical presentations.
Methods: A 77-year-old illiterate, widowed male from rural Colombia presented with weeks-long hematochezia and progressive, painless perianal verrucous lesions. He denied pruritus, systemic symptoms, or high-risk sexual behaviour. Colonoscopy revealed grade II internal hemorrhoids. Differential diagnoses included condyloma acuminata, squamous cell carcinoma, and rectal carcinoma.
Results: Skin biopsy showed psoriasiform epidermal hyperplasia, plasma cell-rich infiltrates, endothelial proliferation, and spirochetes highlighted by IHC using anti-Treponema pallidum antibody. Serologic tests (VDRL, FTA-ABS) were positive; HIV was negative, confirming secondary syphilis.
Conclusion: Though uncommon, condyloma lata is highly infectious and clinically relevant. Its resemblance to viral or fungal lesions can mislead clinicians and delay appropriate treatment. Histopathology and serology are essential for definitive diagnosis. In endemic, underserved areas, awareness of such atypical syphilitic manifestations is critical for early intervention and public health efforts.
This case underscores the importance of considering condyloma lata in the differential diagnosis of perianal lesions, even in immunocompetent patients without classic risk factors. Timely recognition through histopathology and serologic confirmation is vital to ensure treatment and reduce transmission, especially in resource-limited settings.

E-PS-15-023
Differential expression of TLRs in HPV-related oral benign lesions with and without concomitant *Candida* infection
P. Pina[1], E. Dos Santos[1], S. Sousa[1]
[1]University of Sao Paulo, School of Dentistry - Department of Stomatology, Sao Paulo, Brazil

Background & Objectives: Human Papillomavirus (HPV) is a DNA virus with over 200 genotypes, transmitted through skin or mucosal contact. It can cause both low-risk and high-risk lesions, with low-risk types leading to benign epithelial lesions such as squamous papillomas, condyloma acuminatum, verruca vulgaris, and focal epithelial

hyperplasia. HPV can disrupt the innate immune system, particularly by impairing cytokine production and Toll-like Receptor (TLR) signalling, which has made TLRs a target for immunotherapy research. HPV infects basal keratinocytes, and these cells express TLRs, which act as the body's first line of defense against pathogens. In our Oral Pathology Service, we observed that some of these HPV-related lesions are also infected by Candida. This study aimed to examine the relationship between HPV-induced benign oral lesions, Candida infection, and TLRs 1, 2, and 3 expressions.
Methods: We reviewed 129 HPV-related cases from our archives, including 107 papillomas, 21 cases of condyloma acuminatum, and 2 cases of papillary hyperplasia. We used PAS staining for Candida detection and immunohistochemistry to assess TLR expression.
Results: Out of 129 cases, 13 (12 papillomas and 1 condyloma) showed Candida infection. The tongue was the most commonly affected site. Histologically, all cases showed papillomatosis, koilocytes, exocytosis, and elongated rete ridges. Immunohistochemistry revealed that in Candida-infected lesions, TLRs 1 and 2 expression was completely lost, while TLR3 expression remained unchanged.
Conclusion: Our study suggests that HPV-related benign oral lesions, when associated with Candida infections, alters the expression of TLRs 1 and 2, but not TLR3.

E-PS-15-024
Cutaneous Leishmaniasis in an immunocompetent patient: a clinical and pathological case report
L. Chacon Zambrano[1], S. Zuluaga[2], V. Zapata[2], R. Rodríguez[3], B. Díaz-Gómez[4]
[1]School of Medicine - Universidad de Los Andes - Fundación Santa Fe de Bogotá, Department of Pathology and Laboratories, Bogota, Colombia, [2]School of Medicine, Universidad de Los Andes, Bogota, Colombia, [3]Clínica Vida, Fundación de Cancerología, Department of Pathology, Bogotá, Colombia, [4]School of Medicine - Universidad de Los Andes - Fundación Santa Fe de Bogotá, Department of Pathology and Laboratories, Bogotá, Colombia

Background & Objectives: Cutaneous leishmaniasis (CL) is a parasitic infection caused by protozoa of the Leishmania genus, transmitted by sandflies. It is endemic in tropical and subtropical areas, including Latin America, the Middle East, North Africa, and South Asia. In the Americas, Colombia, Brazil, Peru, and Bolivia report the highest cases. While immunosuppression increases susceptibility, CL can also occur in immunocompetent individuals, where it may present diagnostic challenges, particularly in urban or non-endemic settings.
We report the case of a 66-year-old retired woman living in a Colombian city at an elevation of 959 meters above sea level, with no history of immunosuppression. She presented with a 2-week history of a non-healing, painless, ulcerated lesion measuring 5 cm on the left cheek. Physical examination revealed a well-demarcated ulcer with raised, indurated borders and a granulating base.
Methods: A skin biopsy was performed for histopathological analysis. Haematoxylin and eosin staining revealed a dermal infiltrate of lymphocytes, plasma cells, and histiocytes containing intracellular amastigotes. In these cases, re-cuts of thin paraffin sections (3 microns) with H&E are considered to be enough and highlight the presence of Leishmania spp. within macrophages; Giemsa staining was not used. The patient was treated accordingly and showed significant clinical improvement within two weeks. PCR confirmation was not available due to resource limitations.
Results: This case illustrates the typical presentation of CL in an immunocompetent host in an endemic region. CL can mimic other infectious or neoplastic conditions, emphasizing the importance of clinical suspicion and histopathological confirmation, particularly in settings with limited access to molecular diagnostics.
Conclusion: CL remains a public health concern in endemic regions. Early recognition and biopsy-based diagnosis in immunocompetent patients are crucial for timely treatment and improved outcomes.

E-PS-15-025
Molecular diagnosis of parasites in formalin-fixed paraffin-embedded tissue: lessons from a national parasitology reference laboratory in South Africa
C. Sriruttan-Nel[1], S. Boughan[1], J. Ratabane[1], B. Moodley[1], J. Frean[1]
[1]National Institute for Communicable Diseases (NICD), Parasitology Reference Laboratory, Centre for Emerging Zoonotic and Parasitic Diseases, Johannesburg, South Africa

Background & Objectives: A wide variety of parasites is encountered in human tissue, including arthropods, protozoa and helminths. Many parasites cannot be cultured in vitro and often, a formalin-fixed paraffin-embedded (FFPE) tissue specimen is the only sample submitted for assessment. In general, the microscopic anatomic morphology of each of the major groups of parasites is sufficiently different to enable discrimination with the aid of a few key features; however, further genus and species-level identification may be required to guide appropriate treatment. Here we describe a few clinical cases referred to a national and regional parasitology reference laboratory in South Africa that warranted molecular testing.
Methods: Tissue specimens with suspected parasitic infections referred over a three-year period (2022 to 2025) were investigated at the reference laboratory following clinical consultation and referral by histopathologists from across the private and public healthcare sectors. Slides were reviewed by the pathologists and directed towards specific molecular testing, depending on the morphology observed in tissue.
Results: Three cases of *Leishmania tropica*, one case of *Leishmania infantum*, two cases of *Balamuthia mandrillaris* (and a third in which the diagnosis was made on archived DNA) and the first reported human case of *Cephalobus cubaensis*, a free-living nematode, were confirmed using PCR and sequencing on DNA extracted from FFPE. These cases, along with relevant images, are described.
Conclusion: Molecular diagnostics to identify parasites from FFPE tissue is becoming more important in the setting of global travel, climate change, emerging and re-emerging infections. Definitive diagnosis and directed management are not possible in many cases based on histomorphology alone. Histopathologists are critical to the detection of infectious diseases in many instances and a multidisciplinary approach, together with clinical microbiologists and clinicians, is key in improved diagnosis and patient outcomes. Molecular diagnostics in medical parasitology has an increasingly important role to play in infectious diseases pathology and surveillance.

E-PS-15-026
Mucosal leishmaniasis masking as squamous cell carcinoma of the tongue - a case report
A. Barreto Haagsma[1], A.L. Mylla Olesko[2], A. Morais Carneiro[2], R. Antenor de Souza e Souza[2], M. Gustavo Setubal Andrade[3]
[1]John Walton Muscular Dystrophy Research Centre, Genetics Department, Newcastle upon Tyne, United Kingdom, [2]Pathological Analysis Laboratory (Laboratório de Análises Patológicas) (LABPAT), Histopathology Department, Salvador, Brazil, [3]Prohope Hospital, Head and Neck Surgery Department, Salvador, Brazil

Background & Objectives: With the potential to cause disabling sequelae, mucosal leishmaniasis is a rare clinical variant most commonly caused by *Leishmania brasiliensis* in northeast Brazil and *Leishmania infantum* and *Leishmania donovani* in Africa and the Mediterranean Europe. Albeit its severity, this condition is still

overlooked in endemic areas. Here we present a case report of fatal case of mucosal leishmaniasis.
Methods: The patient was a 76-year-old woman that presented a tumour at the base of the tongue with 3cm at its widest measure with a 1.5cm ulceration in the right glossopharyngeal pillar, which retracted and distorted the epiglottis. The vallecula was not ulcerated but superficialized by the tumour, with the laryngeal surface of the epiglottis and the glottis free. A synchronous tumour of 1.5cm was found in the right tonsillar fossa. Patient also presented with enlarged lymph node of 2cm width on the right side of the neck. The initial and clinical differential diagnosis was squamous cell carcinoma (SCC).
Results: Biopsy of the tumour at the base of the tongue was done and histological sections showed fragments of tissue lined by squamous epithelium with ulceration and neutrophil exocytosis. The lamina propria exhibited a prominent mixed granulomatous inflammatory infiltrate containing numerous histiocytes. These histiocytes displayed numerous small, round and oval basophilic structures within their cytoplasm, consistent with amastigotes, which confirmed the diagnosis of mucosal leishmaniasis. Unfortunately, the patient passed away shortly after the biopsy due to respiratory insufficiency and an autopsy was not performed.
Conclusion: Even though its severity is known, mucosal leishmaniasis is still overlooked even in endemic areas, highlighting the need to lower the threshold for suspicion when inflammatory and granulomatous mucosal lesions are present in patients from endemic regions. Biopsy should not be delayed in such cases due to their high potential of destructive and disabling outcomes.

E-PS-15-027
Review and discussion of alveolar hydatid cyst cases
I. Guvendir Bakkaloglu[1], S. Hallac Keser[1], S. Sengiz Erhan[1], S. Sensu[2], H. Ozturkcu[3], A. Ege Gul[1], N. Ozdemir Barisik[1]
[1]Kartal Dr. Lutfi Kirdar City Hospital, Pathology, Istanbul, Turkey, [2]Istinye University, Medical Faculty, Pathology, Istanbul, Turkey, [3]SBU. Van Education and Training Hospital, Pathology, Van, Turkey

Background & Objectives: Alveolar hydatid cyst is a chronic, complicated, and sometimes fatal parasitic infection caused by Echinococcus multilocularis (EM). It is seen mainly in Eastern and Southeastern Anatolia, Trakya, and Central Anatolia regions in our country. Since EM leads to exogenous proliferation, invasion, and tissue destruction, it can be difficult to differentiate it from malignant tumours. Diagnosis is often challenging, leading to late detection and poor prognosis. Given the often non-specific clinical presentation, diagnosis relies on radiologic imaging, serologic tests, and pathologic findings. We aimed to contribute to the literature by reviewing the clinicopathologic features of patients diagnosed with alveolar hydatid cyst in our clinic.
Methods: We retrospectively evaluated the demographic characteristics, histopathologic, and radiologic findings of cases diagnosed with alveolar hydatid cyst between 2010 and 2024 using archival data.
Results: The study included 10 cases. The mean age of the patients was 43.3 years, with 6 females and 4 males. Nine cases were located in the liver, and one in the brain (left frontal and left parietal regions). Radiologically, the possibility of malignancy could not be excluded in 6 cases due to heterogeneous contrast enhancement and irregular contours. In one case, suspicion of cholangiocarcinoma was indicated. In the resection specimen, large and small cysts surrounded by a cuticular membrane on a necrotic background, along with histiocytic giant cells and chronic inflammatory cells, were observed, and the cases were reported as alveolar hydatid cysts.
Conclusion: The mean age, gender distribution, and localization of our cases are consistent with the existing literature. The radiologic suspicion of malignancy in most cases suggests that alveolar hydatid cyst should be considered in the differential diagnosis of lesions that are clinically and radiologically suggestive of malignancy, especially in the liver.

E-PS-15-028
Tularemia orchitis following pneumonic tularemia: a histopathologically confirmed case in a patient under TNF(tumour necrosis factor)-α inhibition
A. Pryalukhin[1], R. Westhofen[2], M. Kozak[3], T.-M. Scherzer[2], L. Daxecker[2], W. Hulla[1]
[1]University Hospital Wiener Neustadt / Danube Private University, Department of Pathology and Molecular Pathology Thermenregion, Wiener Neustadt, Austria, [2]University Hospital Wiener Neustadt / Danube Private University, Department for Gastroenterology and Hepatology, Wiener Neustadt, Austria, [3]University Hospital Wiener Neustadt, Department of Pathology and Molecular Pathology Thermenregion, Wiener Neustadt, Austria

Background & Objectives: Tularemia is a rare zoonotic infection caused by Francisella tularensis, with highly variable clinical presentations. Orchitis is an extremely uncommon manifestation, particularly in immunosuppressed patients. This case report highlights a rare recurrence of tularemia presenting as orchitis, emphasizing the pathological findings and diagnostic challenges in a patient under TNF-α inhibitor therapy.
Methods: A 71-year-old male with psoriatic arthritis on adalimumab was diagnosed with pneumonic tularemia, confirmed by blood cultures. Following initial remission under doxycycline, the patient presented three months later with unilateral orchitis. After orchiectomy, the testicular specimen underwent histological examination. Routine haematoxylin and eosin (H&E), PAS/alcian blue, Gram stains, and immunohistochemistry (OCT4, SALL4, CD3, CD20, CD45, CD68, CD163) were performed. PCR for F. tularensis was conducted on native tissue.
Results: Gross examination revealed an irregular, enlarged testis with an inhomogeneous mass. Histologically, a pronounced orchitis with only minimal epididymal involvement was observed. The seminiferous tubules were filled with predominantly histiocytes (partly epithelioid), neutrophilic granulocytes, and CD3-positive T-lymphocytes. In less affected areas, interstitial oedema and Sertoli-cell-only-like changes were noted, with focal spermatogenesis. Spermatogonia were detected focally using the SALL4 stain. The testicular stroma exhibited mild inflammatory infiltration, composed primarily of histiocytes, neutrophils, and CD3-positive T-cells. Scattered small purulent foci were present. No granulomatous reaction or caseous necrosis was identified at this stage. Focal lymphadenitis was also observed. Notably, no bacteria were seen microscopically, and germ cell neoplasia in situ was excluded via OCT4 staining. This represents a relapse likely due to the blood-testis barrier and limited doxycycline penetration.
Conclusion: This is the second histopathologically confirmed case of tularemia orchitis worldwide. In immunosuppressed patients, especially those under TNF-α inhibition, F. tularensis should be considered in atypical inflammatory presentations. Orchiectomy combined with extended antibiotic treatment (doxycycline and ciprofloxacin) resulted in remission. Pathologists should be sensitized to the possibility of rare relapse forms of tularemia.

E-PS-15-029
Spatial profiling of the intratumoral microbiome with RNAscope and QuPath
R. Barna[1,2], M. Zacharias[3], S. Schauer[3], A. Vigdorovits[4], M. Plass[3], G. Höfler[3], G. Gorkiewicz[3]
[1]Victor Babes University of Medicine and Pharmacy, Anapatmol Research Centre, Timisoara, Romania, [2]Dr. Victor Babes Infectious Diseases and Pneumophysiology Clinical Hospital, Pathology Department, Timisoara, Romania, [3]Medical University of Graz, Diagnostic

and Research Institute of Pathology, Graz, Austria, [4]University of Oradea, Department of Morphological Disciplines, Oradea, Romania

Background & Objectives: The intratumoral microbiome recently gained significant attention, offering a new perspective on cancer research. The spatial distribution of microbes within tumours could provide more details regarding the interaction with tumour cells (TC). We sought to define the spatial representation of tumour microbes in tissues by utilizing RNAscope and QuPath.
Methods: We selected 7 primary colorectal carcinomas (CRC), 11 lung metastases originating from CRC (mCRC), and 6 primary lung adenocarcinomas (PLA). For each case, one section of formalin-fixed paraffin-embedded tissue was analysed with RNAscope assay (16S rRNA Eubacteria; Advanced Cell Diagnostics). Slides were scanned using the Pannoramic 1000 Scanner (3DHISTECH) at 40x resolution, and image analysis was performed with QuPath.
Results: Out of 24 slides, 10 were successfully evaluated. The remaining slides were excluded due to artifacts or scanning issues. The 10 cases were represented by 6 CRC, 3 mCRC, and 1 PLA.
For CRC, the mean tumour bed area (TBA) was 202 mm², containing an average of 435,434 TC. In mCRC, the mean TBA measured 92 mm², with an average of 43,005 TC, and the single case of PLA had a TBA of 113 mm², with an average of 334,410 TC.
Comparing the number of detected signals, CRC showed the highest mean with 7,401 signals, followed by the case of PLA with 2,145 signals, and mCRC with a mean of 139 signals, further supporting the idea of increased microbial load in CRC compared with other tumours. Regarding subcellular distribution, the majority of signals in all tumour types were localized in the cytoplasm; specifically, CRC showed 65% of signals in the cytoplasm, PLA 85%, and mCRC 69%.
Conclusion: QuPath proved to be a valuable tool for analysing large amounts of data from histological slides; however, it requires high-quality slides. Future studies should aim to include larger cohorts and a more standardized approach to analysis.

Pitfalls in the interpretation of DNA mismatch repair protein expression by immunohistochemistry: experience with unusual expression patterns from the University Hospitals Birmingham

S. Nugteren[1,2], A. Iqbal[1], L. Robertson[1], B. O'Sullivan[1], M. Evans[1], P. Taniere[1]
[1]Queen Elizabeth Hospital Birmingham, University Hospitals Birmingham NHS Foundation Trust, Molecular Pathology Diagnostic Service, Birmingham, United Kingdom, [2]Erasmus Medical Centre, Pathology, Rotterdam, The Netherlands

Background & Objectives: Testing for mismatch repair (MMR) defects is routine care for patients with advanced cancer across a broad spectrum of tumour types. Commonly, the first step is immuno-histochemistry for MLH1, PMS2, MSH2 and MSH6. The interpretation of MMR protein immunohistochemistry is usually straightforward, but a minority of cases is challenging. Our objective was to aid histopathologists in the interpretation of these rare patterns and further testing based on our experience.
Methods: We collected all cases with unusual MMR protein expression patterns on immunohistochemistry performed between the 1st of July 2018 and the 1st of March 2025 at the Molecular Pathology Diagnostic Service in Birmingham. An unusual staining pattern was defined as different from a classical pattern (no loss of expression, loss of MLH1/PMS2 expression, isolated loss of PMS2 expression, loss of MSH2/MSH6 expression or isolated loss of MSH6 expression). Further testing was performed by immunohistochemistry for BRAF V600E or PCR for BRAF codon 600 and/or MLH1 methylation profiling by Pyrosequencing.
Results: We found 70 cases with unusual patterns out of a total number of 21561 specimens (0.3%) for which MMR immunohistochemistry was performed. The most frequently observed unusual pattern was the additional (complete or clonal) loss or reduced expression of MSH6 in the presence of loss of MLH1 and PMS2 expression (45/70 patients). In the majority of these cases (42/45 patients) we found a BRAF V600E mutation or methylation of the MLH1 promoter, strongly favouring sporadic nature.
Conclusion: Rare cases with unusual MMR protein expression patterns showed clonal loss of expression, reduced loss of expression or rare combinations of loss of expression, in particular concurrent loss of MSH6 and/or MSH2 in the presence of MLH1 loss. By testing for BRAF mutations and MLH1 methylation profiling we were able to prevent unnecessary referral to a clinical genetics service in most of these patients.

Impact of oxidative stress and hypoxia status on glioblastoma development

S. Lamrabet[1], A. Squalli Houssaini[1], N. Senhaji[2], M. Sekal[3], M. Karkouri[4], R. Ameziane El Hassani[5], S. Bennis[1]
[1]Faculty of Medicine, Pharmacy and Dentistry, Sidi Mohamed Ben Abdellah University, Biomedical and Translational Research Laboratory, Fez, Morocco, [2]Faculty of Science of Meknes, Moulay Ismail University, Biology, Meknes, Morocco, [3]Faculty of Medicine, Pharmacy and Dentistry, Sidi Mohamed Ben Abdellah University, Laboratory of Epidemiology and Research in Medical Sciences, Fez, Morocco, [4]Faculty of Medicine and Pharmacy , HASSAN II University, University Medical Centre of Casablanca, Anatomical Pathology Ibn Rochd, Casablanca, Morocco, [5]Faculty of Science of Rabat, Mohammed V University, Laboratory of Biology of Human Pathologies, Rabat, Morocco

Background & Objectives: Gliomas represent 30% of all brain tumours and 80% of malignant tumours. Glioblastoma is the extremely aggressive type of these tumours and accounts for half of them, as it expresses the worst prognosis, limited to 14 months. The WHO 2021 classification of brain tumours identified certain classification criteria based on molecular confirmation involving several signalling pathways adding to histological features such as necrosis, endothelial-capillary proliferation, multiple mitoses. Furthermore, the resistance against radiotherapy and chemotherapy has been related to oxidative stress and hypoxia a predominant feature in gliomas and their microenvironment and is associated with tumour growth, progression, and resistance to conventional therapy.
This study aims to highlight the main biomarkers identified in glioblastomas and establish a correlation based on the overall survival of patients. It is a retrospective study conducted over a period of 3 years, involving 90 cases of GBM collected at the Ibn Rochd University Medical Centre in Casablanca.
Methods: Our study cohort included 35 women and 55 men, with a median age of 54 and ages ranging from 13 to 79. An immunohistochemical study was conducted using anti-IDH R132H, anti-NOX4, and anti-HIF-1α antibodies.
Results: Immunostaining with the anti-IDH R132H antibody yielded negative results in 7% of the cases (3 cases), consistent with findings reported in the literature. Additionally, immunostaining with the anti-NOX4 antibody was positive in 4% of cases, while the anti-HIF-1α antibody was expressed in 32% of cases.
Conclusion: Glioblastomas are rare and highly heterogeneous tumours. Their prognosis is closely linked to the molecular profile, making it essential to tailor therapeutic strategies to the individual characteristics of each case.

E-PS-16-003

Screening of Lynch syndrome in CRC: a monocentric consecutive case series

G. Martinelli[1], R. Bruno[2], F. Marmorino[3], C. Cremolini[3], C. Ugolini[1]
[1]University of Pisa, Department of Surgical, Medical, Molecular Pathology, and Critical Area, Pisa, Italy, [2]University Hospital of Pisa, Unit of Pathological Anatomy, Pisa, Italy, [3]University of Pisa, Department of Translational Research and New Technologies in Medicine, Pisa, Italy

Background & Objectives: Lynch syndrome (LS) accounts for 1-3% of all colorectal cancers (CRC). LS screening starts evaluating mismatch-repair (MMR) proteins expression. In case of MSH2, MSH6 and PMS2 isolated deficiency (d) a genetic counselling is mandatory. Whereas, in presence of MLH1 loss, often due to somatic alterations, the analysis of *BRAF*-V600E mutation and *MLH1* promoter methylation is recommended to identify likely sporadic cases.
This study assessed LS screening efficacy in a CRC monocentric and consecutive series.
Methods: From 2022 to 2024, 1,368 CRC were evaluated for MMR proteins expression by immunohistochemistry (IHC). In dMLH1 cases *BRAF*-V600E was analysed by IHC, then only negative *BRAF*-V600E cases underwent *MLH1* methylation test by pyrosequencing. Cases negative or indeterminate for both *BRAF*-V600E and *MLH1* promoter methylation were considered LS high-risk, requiring genetic counselling.
Here, we evaluated the prevalence of LS high-risk dMLH1 cases and their clinical-pathological characteristics.
Results: Overall, 162 CRC (12%) were dMMR, 121 (73%) were dMLH1. Forty-nine dMLH1 cases were *BRAF*-V600E negative: 24 showed *MLH1* methylation, 16 were non-methylated and 9 were indeterminate. Twenty-five (non-methylated/indeterminate) dMLH1 cases were LS high-risk (diagnosis median age: 61 years *versus* 76 for low-risk group). Genetic test was performed in 22 high-risk cases: 2 were LS positive and 20 negative. Seventy-one dMLH1 cases had a special histological subtype (42 with mucinous features, 17 mucinous, 5 medullary, 4 poorly differentiated and 3 signet-ring cells), with a higher prevalence in *BRAF-V600E* positive group.
Conclusion: In CRC, the dMMR phenotype can be sporadic (75%) or constitutively present within LS (25%). LS screening, mainly based on clinical criteria, can be improved by molecular tests. Our results supported the cost-effectiveness of the sequential analysis of MMR proteins, *BRAF*-V600E mutation and *MLH1* promoter methylation in the definition of high-risk patients, reducing unnecessary genetic counselling. Indeed, here only a small proportion of dMLH1 cases (25/121) was identified as high-risk.

E-PS-16-004

Combined positive score to evaluate PD-L1 expression in gastric and gastroesophageal junction adenocarcinomas

M. Öz[1], A. Saruhan[1], Ö. Ekinci[1], N. Akyürek[1]
[1]Gazi University Faculty of Medicine, Department of Pathology, Ankara, Turkey

Background & Objectives: PD-L1 expression has been investigated as a predictive biomarker of response to immunotherapy in several tumours, and is reported to be elevated in up to 40% to 65% of gastric or gastroesophageal junction adenocarcinoma (G/GEJ). There is a need to provide reliable, standardised training for pathologists to improve their accuracy of interpretation and scoring, as the results are used directly to inform clinical decisions. We present findings regarding reproducibility and improvement for scoring PD-L1 expression for GC using online training tool.
Methods: This study included 102 cases of G/GEJ adenocarcinoma. PD-L1 expression is scored using the combined positive score (CPS), which is calculated as the number of PD-L1–stained cells (tumour cells, lymphocytes, and macrophages) divided by the total number of viable tumour cells multiplied by 100.
The CPS was categorized into a four-step score (0–3) based on clinical relevant thresholds: 0 (CPS < 1), 1 (CPS 1–4), 2 (CPS 5–9), 3 (CPS ≥ 10). Online training was led by qualified and trained pathologists from Targos Molecular Pathology.
Results: The positive rates of CPS with a cutoff value of 1 and 5 were 38,2% (39/102) and 20,5% (21/102), respectively. More than half of the cases was PD-L1 negative (CPS < 1; 61,8%), 17,6% showed low PD-L1 expression (CPS ≥ 1, < 5), 2,9% moderate (CPS ≥ 5 to < 10) and 17,6% strong expression (CPS ≥ 10). Positivity rate after online training according to 1> and 5> cutoff value were 53,3% (24/45) and 35.6% (16/45), increased in line with the literature.
Conclusion: Consistent, accurate, and reproducible scoring of PD-L1 expression, regardless of scoring method, remains a concern.The online training tool offers a means of standardised training for practising pathologists in a clinical setting and can help pathologists successfully learn techniques to confidently score PD-L1 CPS across histologic subtypes and cutoffs.

E-PS-16-005

Assessment of morphological quality and nucleic acid yield and purity from FFPE tissue samples across various clinical tissue processors

H. Breed[1], B. Kuhlman[2]
[1]Epredia, Chicago, Illinois, USA, [2]Wake Forest Institute of Regenerative Medicine, Winston-Salem, North Carolina, USA

Background & Objectives: The ability to successfully isolate adequate and pure DNA for Next-Generation Sequencing (NGS) from Formalin-Fixed Paraffin-Embedded (FFPE) tissue is critical to molecular diagnostic tests known as NGS, which are gaining popularity. These diagnostic methods empower clinicians to provide personalized treatment and care to patients. The study's objective was to demonstrate that FFPE tissue processed on the Revos tissue processor yields sufficient amounts of nucleic acids required for downstream NGS testing and is of better quality for NGS than other tissue processors.
Methods: Fresh specimens from normal (n=15) and tumour (n=8) tissues were harvested via surgical resection and immediately fixed according to standard clinical laboratory practices using 10% Neutral Buffered Formalin (NBF). Each tissue was divided into three equal parts and processed according to each manufacturer's indicated routine program; three separate tissue processors were used to assess morphological integrity across each system, and isolated DNA was evaluated for quantity and quality to be used for NGS.
Results: The Epredia Revos tissue processor resulted in excellent tissue processing with no unprocessed tissues or tissue damage from all tissues (normal and tumour) observed macroscopically and microscopically. Using the routine surgical protocol setting, we obtained excellent morphology on all tissues (normal and tumour), as observed microscopically by H&E stained slides processed on the Epredia Revos tissue processor. Importantly, we could isolate DNA and RNA from the FFPE samples with enough material (> 0.5 micrograms of total DNA) for Next-Gen sequencing or molecular testing. The 260/280 ratio of the purified DNA was greater than two units, suggesting excellent purity
Conclusion: We observed that tissue processed on the Epredia Revos Tissue Processor demonstrated the isolated DNA samples should have enough starting material to perform next-generation sequencing; sample data suggests high purity and shows excellent overall morphological features compared to the other tissue processors in the study.

E-PS-16-007

AXL: an emerging biomarker and putative tyrosine kinase inhibitor target

R. Seeböck[1,2], F. Eibensteiner[2], H. Hundsberger[2], C. Klein[2], M. Kitzwögerer[1]

[1]University Hospital St.Pölten, Institute of Clinical Pathology and Molecular Pathology, St.Pölten, Austria, [2]IMC Krems University of Applied Sciences, Institute Biotechnology, Krems, Austria

Background & Objectives: AXL, a receptor tyrosine kinase (RTK), has gained significant attention in cancer therapy due to its role in mediating resistance to Tyrosine Kinase Inhibitors (TKIs). AXL is involved in key signalling pathways that regulate cell survival, migration, and immune evasion, contributing to resistance in cancers such as non-small cell lung cancer (NSCLC), glioblastoma, and others. While AXL's role as a driver of TKI resistance is well-documented, the underlying mechanisms remain an area of ongoing research. Several AXL inhibitors, including BGB324 and R428, are currently undergoing clinical trials to evaluate their efficacy in overcoming TKI resistance or as potential novel stand-alone therapies across various malignancies. As new inhibitors targeting AXL approach clinical application, it is crucial to better understand the mechanisms through which AXL facilitates escape from TKI therapy. Furthermore, identifying potential escape mechanisms, particularly mutations, that may arise when AXL is directly inhibited is critical for improving therapeutic strategies.
Methods: In this study, we investigated AXL's mutational potential at both the DNA and RNA levels, focusing on known DNA mutations, methylation patterns, and RNA fusions. This is done by a comprehensive in silico analysis of clinical data repositores and samples analysed with our clinical partners. A key hypothesis in AXL-mediated TKI resistance is its ability to form heterodimers with other RTKs. To examine this, we employed AlphaFold 3 and subsequent PyMOL analysis to predict potential protein interactions, identifying the specific amino acids and corresponding DNA sequences relevant to successful heterodimerization
Results: Our findings aim to enhance the understanding of AXL-mediated resistance mechanisms and provide critical insights into optimizing AXL inhibition in clinical settings, with the potential to improve the effectiveness of both established and emerging TKI therapies.
Conclusion: Our primary findings highlight the importance of closely examining the molecular mechanisms underlying AXL signalling and AXL-mediated therapy resistance.

E-PS-16-008

Studying on EBER in situ hybridization with automated high-frequency ultrasonic cavitation-assisted rapid tissue processing method: an institutional experience

Y. Chen[1], Y. Yang[1]

[1]Fujian Medical University Union Hospital, Pathology Department, Fuzhou, China

Background & Objectives: Detection of EBER by in situ hybridization (ISH) has been established as the most sensitive and practical method for detecting EBV infection. However,tissue processing is still time consuming in most of pathology department. Finding a quick method of tissue processing can help reduce the detection time of EBER.
Methods: A total of 132 cases of nasopharyngeal carcinoma biopsy were collected. They were randomly divided into two groups. The control group used the traditional method which needs overnight, the experimental group used automated high-frequency ultrasonic cavitation-assisted rapid tissue processing method which needs only several hours. Compare the result of EBER ISH with two different dehydration procedures.
Results: There's no statistically significant difference between two methods, but there's statistically significant difference between the treatment time.
Conclusion: Rapid tissue processing with an ultrasonic cavitation-assisted device has no negative effect on EBER in situ hybridization in nasopharyngeal carcinoma(NPC) biopsies. It reduces the turnaround time for histopathology reports. Staining was with diaminobenzidine(DAB) may diminish heavy background compared to NBT.

E-PS-16-009

Real-world circulating tumour DNA (ctDNA) burden and androgen receptor ligand binding domain mutations (AR LBDm) in US prostate cancer patients

P. Du[1], J. Liao[2], A. Watkins[2], A. Knight[3], S. Srinivasan[1], N. Barkley[1], C. Pena[1]

[1]Merck & Co., Inc., Rahway, USA, [2]Guardant Health, Palo Alto, USA, [3]Merck Sharp & Dohme LLC, Zurich, Switzerland

Background & Objectives: ctDNA from blood-based liquid biopsies has emerged as a potential prognostic biomarker for managing prostate cancer (PC) and identifying actionable gene mutations for therapeutic targets. Recent evidence suggests that AR LBDm may play an important role in treatment resistance in PC, resulting in poor outcomes. This study utilized a large real-world database to better understand ctDNA burden and AR LBDm in US PC patients.
Methods: PC patients were identified between 06/2014 and 06/2023 from the Guardant Health INFORM™ clinical-genomic database, which links ctDNA results from the Guardant360® next-generation sequencing assay (G360) to de-identified medical claims. ctDNA burden was defined as the maximum variant allele frequency (MVAF) of all detected somatic variants. The prevalence of 12 AR LBDm detected by G360 and its association with real world overall survival (rwOS) was assessed.
Results: Among 16,757 PC patients, 87% had detectable ctDNA (median MVAF=1.9%; range: 0.01%-96.4% among ctDNA positive patients). Patients with metastatic PC had higher ctDNA positivity and burden: metastatic castration-resistant PC (mCRPC): N=6,712, ctDNA positivity 89%, median MVAF=2.4%; metastatic hormone-sensitive PC (mHSPC): N=1,348, ctDNA positivity 87%, median MVAF=1.7%; non-metastatic CRPC (nmCRPC): N=220, ctDNA positivity 81%, median MVAF=0.9%; nmHSPC: N=262, ctDNA positivity 84%, median MVAF=1.0%; p-value<0.0001). The overall prevalence of 12 AR LBDm was 15% in all patients and was higher in patients with mCRPC, with bone only metastasis, or who had received multiple lines of treatment (19% in each subgroup). PC patients with AR LBDm (N=2,482) had significantly higher median MVAF (8.7% vs. 1.3 %) and shorter median rwOS (16.2 vs. 27.4 months) than patients without AR LBDm (N=12,064).
Conclusion: Higher ctDNA burden and AR LBDm detection were observed in patients with advanced PC and associated with worse rwOS. The study suggests that ctDNA detection and presence of AR LBDm may be prognostic biomarkers that identify high-risk PC patients in clinical care.

E-PS-16-012

Relationships between genetic changes, tumour location, morphological patterns, and protein expression in pancreatic ductal adenocarcinoma

H. Nishida[1], T. Daa[1]

[1]Faculty of Medicine, Oita University, Diagnostic Pathology, Yufu, Japan

Background & Objectives: Pancreatic ductal adenocarcinoma (PDA) shows different morphological profiles and genetic alterations between the head (hPDA) and body/tail (btPDA). Differences in histological type and protein expression, rather than tumour location, can influence the frequency of lymph node metastasis and prognosis. Therefore, in this study, we investigated genetic alterations in 30 hPDA and 30 btPDA mutants. We also analysed the results, along with the findings from a previous study on characteristic morphological features and protein expression.
Methods: We evaluated the histological patterns based on haematoxylin and eosin stains. Histological patterns were evaluated using PDA-L and PDA-S. Regarding immunohistochemistry (IHC), reactivity was scored as three grades of colorimetric intensity (0, 1+, and 2+) and four grades of positive cell populations (0, 1+, 2+, and 3+). For the genetic analysis, sequencing libraries for iSeq100 were constructed using AmpliSeq PLUS for Illumina and AmpliSeq for Illumina Cancer Hotspot Panel V2 to search for 50 genes.
Results: *ERBB4*, *KDR*, and *NPM1* were frequently identified in the hPDA among the detected mutations. No significant association was observed between the investigated genetic alterations and PDA-L/PDA-S classification. IHC showed significant associations between HNF1β and *KDR*. Lymph node metastasis was significantly associated with *PIK3CA* expression. Regarding overall survival (OS), significant mutations were observed in *ERBB4* and *FLT3*. In addition, a positive correlation was observed between *ERBB4* and *FLT3*. Although *ATM* and C11ORF65 levels were not significantly correlated with OS, a positive correlation was observed.
Conclusion: Tumour prognosis may depend more on genetic alterations than on tumour location, morphological changes, or protein expression. However, treatment of PDA cases with *FLT3* mutations may be especially effective when using FLT inhibitors.

E-PS-16-013
Consensus molecular subtypes of colorectal cancer in various regions of Oman
S. Rehman[1], S. Al Busaifi[2], M.F. Chan[1], A. Shalaby[3], A. Al Zaabi[4], M. Al Masqari[5], M. Al Hinai[1], M. Al-Azri[1]
[1]Sultan Qaboos University, Family Medicine and Public Health, Muscat, Oman, [2]Sultan Qaboos University, Gastroenterology, Muscat, Oman, [3]Sultan Qaboos University, Pathology, Muscat, Oman, [4]Sultan Qaboos University, Human and Clinical Anatomy, Muscat, Oman, [5]Royal Hospital, Pathology, Muscat, Oman

Background & Objectives: Colorectal cancer (CRC) is a major health concern and a leading cause of cancer-related deaths. Recent data indicate that CRC is among the most prevalent cancers in Oman, particularly in adult males. Advances in molecular biology have identified four consensus molecular subtypes (CMS) of CRC: CMS1, CMS2, CMS3, and CMS4, classified by the Colorectal Cancer Subtyping Consortium. To assess the prevalence of molecular characteristics/genetic pathways of CRC in various regions of Oman.
Methods: One hundred fifty colorectal cancer patients were recruited from Sultan Qaboos University Hospital and Royal Hospital, Muscat, Oman, from January 2023 to December 2024. These patients underwent colonoscopic biopsy or resection. Histological examination confirmed colorectal adenocarcinoma. Paraffin-embedded tissue samples were analysed at the pathology department for mismatch repair (MMR) proteins, including PMS2, MLH1, MSH2, and MSH6. Later, they underwent further testing to categorise them into four CMS subtypes. Also, region codes were allotted to patients from all geographical regions of Oman.
Results: MMR testing via immunohistochemistry (IHC) categorised cases into two groups: MMR deficient (19 cases) and MMR proficient (131 cases). All MMR-deficient cases tested negative for BRAF mutation. MMR-proficient cases underwent further testing for p53, KRAS, beta-catenin, and TGF-beta. The findings were CMS1: 19 cases (12.6%), CMS2: 62 cases (41.3%), CMS3: 16 cases (10.6%), and the remaining 53 cases were categorised as CMS4 (35.3%).
Conclusion: CMS2 is the most common molecular subtype of CRC in Oman, followed by the CMS4 subtype. Regionally, Muscat, the largest city, bears the most significant burden of cancer cases. Understanding CRC subtypes and their regional distribution will help clinicians tailor therapy, modify healthcare policies, and enhance targeted therapeutic strategies for the Omani population. Introducing molecular testing for CMS subtyping as part of routine diagnostic protocols will help guide personalised treatment.

E-PS-16-014
Comparative analysis of molecular testing and immunohistochemistry for KRAS mutation detection in colorectal carcinoma
S. Rehman[1], S. Al Khabouri[2], S. Al Sinawi[3], A. Al Shauibi[3], A. Shalaby[3], A. Qureshi[3]
[1]Sultan Qaboos University, Family Medicine and Public Health, Muscat, Oman, [2]Sultan Qaboos University, Biochemistry, Muscat, Oman, [3]Sultan Qaboos University, Pathology, Muscat, Oman

Background & Objectives: KRAS testing is crucial for diagnosing, prognosticating, and selecting targeted therapies in various cancers, particularly colorectal carcinoma (CRC). Two primary methods for detecting KRAS mutations are molecular testing, such as PCR or NGS, and immunohistochemistry (IHC). Molecular testing provides high sensitivity and specificity by directly identifying genetic mutations at the DNA level, such as wild-type or mutant KRAS. In contrast, IHC is a cost-effective and rapid screening tool that detects mutant KRAS protein expression but may sometimes lack precision.
Objective: This study compares the diagnostic accuracy, sensitivity, specificity, and clinical utility of molecular testing for KRAS mutations with immunohistochemistry (IHC) in detecting KRAS alterations in colonic adenocarcinoma, assessing their advantages and limitations in guiding targeted therapy decisions.
Methods: The cases were selected from January 2023 to December 2024. We performed simultaneous Molecular testing for KRAS and IHC on the same paraffin-embedded tissue from 100 CRC patients. IHC was scored as 0 = negative, 1+ = weakly positive, 2+ = moderately positive, and 3+ = strongly positive. KRAS mutation was noted as positive or negative.
Results: In the molecular lab, Molecular testing was done using PCR after DNA extraction from the paraffin-embedded tissue, whereas IHC was done using routine tissue sections in the immunohistochemistry lab. Fifty-nine cases were scored as 2+ or 3+ by IHC , whereas KRAS mutation was detected in 54 cases of the 100 cases. The numbers corresponded to those detected on molecular testing; however, false positivity was seen in 5 cases, mostly 2+.
Conclusion: There is a fair concordance of KRAS detection by PCR-based molecular tests and IHC tests in routine pathology labs. However, the false negatives can be minimised by reviewing the criteria for scoring 2 + cases. While IHC can be an initial screening method, molecular testing remains the gold standard for confirming mutations and guiding targeted therapies.

E-PS-16-015
Rapid simultaneous detection of 15 pathogenic *BRAF* mutations in advanced colorectal cancer specimens
S. Ullrich[1], I. Michalk[2,3], A. Kuhls[2,3], C. Winkler[2,3], D. Aust[2,3], F. Baenke[4,5], J. Weitz[4,5], D. Stange[4,5], N. Dressel[1]

[1]Biotype GmbH, Dresden, Germany, [2]University Hospital Carl Gustav Carus Technische Universität Dresden, Institute of Pathlogy, Dresden, Germany, [3]University Hospital Carl Gustav Carus, Tumour- and Normal Tissue Bank of the University Cancer Centre (UCC), Dresden, Germany, [4]Medical Faculty and University Hospital Carl Gustav Carus, Department of Visceral, Thoracic and Vascular Surgery, Dresden, Germany, [5]National Centre for Tumour Diseases (NCT) - a partnership between DKFZ, Faculty of Medicine and University Hospital Carl Gustav Carus, TUD Dresden University of Technology, and Helmholtz-Zentrum Dresden-Rossendorf (HZDR), Dresden, Germany

Background & Objectives: *BRAF* mutations are associated with poor prognosis and high therapeutic resistance, particularly in colorectal cancer (CRC). Thus, accurate and rapid detection of *BRAF* mutations is essential for guiding further treatment decisions. The present study aimed at demonstrating the concordance between NGS-based tumour characterization and multiplex PCR-based characterization on the MODAPLEX platform. The MODAPLEX BRAF Mutation Kit was designed to detect 15 key mutations covering *BRAF* class 1 (including V600E/K), class 2 (including K601E & G469R/A/E) and class 3 (including D594G/N & N581S) alterations.
Methods: A total of 100 characterized CRC samples (EK59032007), selected and provided by the TNTB Dresden, were analysed using the MODAPLEX BRAF Mutation Kit and subsequently evaluated for concordance to NGS. NGS was conducted as part of a routine molecular diagnostic workflow via panel sequencing at the UKD Dresden. A subset of samples was analysed via whole-exome sequencing by a commercial provider.
Results: The MODAPLEX BRAF Mutation Kit accurately detected *BRAF* mutations in FFPE-derived CRC samples using 10 ng DNA input demonstrating high level of concordance to NGS. Amending preliminary analyses showed the assay's limit of detection of at least 5 % tumour content and the assay's capability to assess the *BRAF* mutation status in other entities such as melanoma and endometrial cancer. Up to 46 DNA samples were successfully analysed within 4 h underlining the rapid workflow of the MODAPLEX BRAF Mutation Kit.
Conclusion: Our study highlights the potential of a PCR-based assay on the MODAPLEX platform as a robust and time efficient alternative for the *BRAF* mutation screening in clinical settings, particularly for CRC. Its ability to rapidly and accurately identify class 1–3 *BRAF* mutations demonstrates its potential, providing tools to shape the future of personalized medicine.

E-PS-16-018

Detecting progression with liquid biopsy in a patient with three synchronous primary tumours

I. Adamik[1], L. Báthory-Fülöp[1], H. Engi[1], V. Pozonec[2], G. Rubovszky[2], B. Székely[2], E. Tóth[1]
[1]National Institute of Oncology, Department of Surgical and Molecular Pathology, Budapest, Hungary, [2]National Institute of Oncology, Department of Oncological Internal Medicine and Clinical Pharmacology "B" and the National Tumour Biology Laboratory, Budapest, Hungary

Background & Objectives: Liquid biopsy is transforming molecular pathology, yet its full integration into routine diagnostics remains under investigation. In our case, liquid biopsy was the only feasible method to detect tumour progression in a 63-year-old man with three synchronous primary tumours. He underwent left pneumonectomy after neoadjuvant chemotherapy for lung adenocarcinoma in 2021. In 2022, malignant melanoma was excised from his left arm, and at the same time, colorectal adenocarcinoma was diagnosed during a staging PET-CT examination for which he received adjuvant chemotherapy. Two years later, follow up imaging revealed multiple pulmonary metastases. Surgical or core biopsy was not feasible due to the location of the lesions and previous interventions.
Methods: Circulating free nucleic acid (cfNA (cfDNA and RNA)) were extracted from the patient's plasma via liquid biopsy, and the Oncomine Precision Assay NGS panel test was performed. Molecular analysis was also conducted on all primary tumours. Tumour DNA was extracted from formalin-fixed paraffin-embedded tissue blocks. KRAS, NRAS, and BRAF mutations were assessed using the COBAS test, while EGFR mutations were analysed with AmoyDx test.
Results: Liquid biopsy detected a BRAF V600K mutation in the cfDNA, indicating that the mutation originated from the metastasis, confirming the presence of circulating tumour DNA (ctDNA). The clonal hematopoietic origin of the mutation was excluded by examining lymphocytes from the blood sample. No actionable mutations were identified in the lung adenocarcinoma, whereas the driver mutation in the colorectal adenocarcinoma was KRAS G12X. The malignant melanoma harboured the same BRAF V600K mutation found in the cfDNA.
Conclusion: The identical mutation in both ctDNA and the primary melanoma highly suggested that the pulmonary nodules were metastatic lesions from the melanoma. Liquid biopsy not only provided a minimally invasive solution to the sampling challenge but also revealed a potential therapeutic target, highlighting its clinical utility.

E-PS-16-019

Molecular cancer profiling in microsatellite instability context: study of current pathology practice trends

T. Navickis[1], M. Kuprytė[1], M. Masevičienė[1], A. Čižauskas[1], L. Poškienė[1]
[1]Lithuanian University of Health Sciences, Kaunas, Lithuania

Background & Objectives: Molecular cancer profiling, including widely applied immunohistochemical and genetic testing on microsatellite instability (MSI), progresses in optimizing early detection, monitoring, and treatment of cancer by integrating more methods of advanced molecular technologies into clinical pathology practice. Study objective is to determine current trends of molecular cancer profiling testing in MSI context.
Methods: 502 cases of various neoplasia tested for MSI in local pathology centre in 2018-2025 (February) were selected for the study. Considering molecular profiling guidelines for a particular cancer group, application of additional molecular testing of RAS, BRAF (V600E), POLE, PD-L1, p53, HER2, and receptors of oestrogens, progesteron was also monitored. Descriptive statistics, Mann-Whitney U, $\chi 2$ tests were applied ($p<0.05$).
Results: 46.6% (n=234; 66 (15) years old (y.o)) male and 53.4% (n=268; 67.5 (18) y.o.; p=0.619) female cases were tested for MSI which was detected in 20.3% (n=102) cases. KRAS and NRAS mutation testing was performed in 4% (n=20) and 2.4% (n=12) cases, correspondingly. BRAF (V600E) testing was performed in 14.8% (n=72) cases, while p53 and POLE was checked in 6% (n=30) and 3.4% (n=17) cases, correspondingly. Molecular testing of PD-L1, receptors of oestrogens and progesteron (1.2% (n=6) of each marker), HER2 (1%, (n=5)) was rare among selected cases. 2 markers for molecular cancer profiling was performed in 21.9% (n=110), whereas ≥4 of molecular cancer profiling was performed in 1% (n=5) of cases. Molecular cancer profiling of at least 3 markers, including MSI, became a trend starting from 2023 ($p<0.001$). Female cancer patients were more likely to receive molecular profiling of 3 markers ($p<0.001$).
Conclusion: Trends of current pathology practice of molecular cancer profiling in MSI context were characterised. Accurate data on increasing count of markers in molecular profiling can serve as an ancillary tool for more complex molecular information on oncogenesis, also optimizing guidelines of molecular cancer testing in clinical practice.

E-PS-16-020

Germline structural variants in Russian patients with solid tumours: whole genome sequence results

M. Byakhova[1], M. Makarova[2], A. Semenova[1], M. Shatalova[1], M. Nemtsova[2], O. Sagaydak[2], M. Belenikin[2], N. Bodunova[3], A. Danishevich[3], I. Khathov[3], D. Kanner[4], A. Shabunin[5], D. Protsenko[6], V. Galkin[1], S. Gadzhieva[7]

[1]Moscow State Budgetary Healthcare Institution "Moscow City Hospital named after S.S. Yudin, Moscow Healthcare Department", Moscow Healthcare Department, Moscow, Russia, [2]Evogen LLC, Moscow, Russia, [3]SBHI "Moscow Clinical Scientific Centre Named after A.S. Loginov of the Moscow Department of Health", Moscow Healthcare Department, Moscow, Russia, [4]SBHI "Moscow city oncological hospital №62 Moscow of the Moscow Department of Health", Moscow Healthcare Department, Moscow, Russia, [5]SBHI "Moscow City Hospital named after S.P. Botkin of the Moscow Department of Health", Moscow, Russia, [6]SBHI "Moscow Multidisciplinary Clinical Centre "Kommunarka" of the Moscow Department of Health", Moscow Healthcare Department, Moscow, Russia, [7]Moscow Department of Health, Moscow Healthcare Department, Moscow, Russia

Background & Objectives: To analyse the significant (pathogenic/likely pathogenic – PV/LP) structural variants (SVs/CNV) in cancer patients with suspected hereditary cancer syndromes (HCS).

Methods: During the period from January 2023 to March 2025 2788 patients >18 y.o. with solid tumours and suspected HCS whole genome sequencing (WGS) were performed.

WGS: 30x, DNBseq-T7, EVOGEN LLC; bioinformatics analysis accelerators: EVA Pro, EVOGEN, Russia; MegaBOLT, MGI, China.

Results: 563 significant variants (PV/LP) in cancer-associated genes were identified (20,2%) including 40 SVs. We show some previously undescribed structural variants identified:

Male, 59 y.o., colorectal cancer, polyposis - *SMAD4,* chr18:51047298-51054779; deletion; 7481 b.p., exons 3-4, introns 2-4;

Male, 25 y.o., colorectal cancer, polyposis - *SMAD4,* chr18:50778738-53834227; deletion; ~3Mb;

Male, 38 y.o., colorectal cancer - *MSH6,* chr2:47796532-47803196; deletion; 6664 b.p., exons 4, introns 3-4;

Female, 39 y.o., breast cancer - *BRCA2,* chr13:32370570-32380320; deletion; 9750 b.p., exons 20-24, introns 19-23;

Female, 42 y.o., breast cancer - *BRCA1,* chr17:43068355-43070981; deletion; 627 b.p., exon, intron 15;

Female, 58 y.o., breast cancer - *BRCA1,* chr17:43138933-43140891; deletion; 1958 b.p.;

Female, 45 y.o., endometrial cancer - *MSH2,* chr2:47439298-47450442; deletion; 11 145 b.p., exon 8, introns 7-8;

Female, 58 y.o., breast cancer - *RAD51D,* chr17:35100447-35101208; deletion; 762 b.p.,
exons 9-10, intron 9;

Male, 48 y.o., colorectal cancer - *MLH1,* chr3:g.36600000-38800000; deletion; 2Mb, 49 genes;

Male, 27 y.o., colorectal cancer, polyposis – *APC,* chr5:112392108-112716492; inversion; 324 385 b.p., intron 1;

Female, 42 y.o., breast cancer - *NF1,* chr17:31222988-31244937; deletion; 21 950 b.p.,
exons 16-29, introns 15-29.

Conclusion: The prevalence of germline SVs in cancer patients cohorts is poorly understood due to technical limitations of NGS panels and exome sequencing. WGS makes it possible to identify SVs, including large gene deletions and copy number variations, which is a significant contribution to understanding the HCS aetiology.

Funding: Moscow City Health Department financial support

E-PS-16-021

Results of a pilot external quality assessment of ESR1 testing in cfDNA for breast cancer

E. Clough[1], J. Fairley[1], Z. Deans[1]

[1]GenQA, Edinburgh, United Kingdom

Background & Objectives: In ER+/HER2- metastatic breast cancer, *ESR1* variants drive acquired resistance to endocrine therapy and have demonstrated response to targeted therapy. Therefore, there is clinical need for testing circulating tumour DNA (ctDNA) in cell free DNA (cfDNA) for *ESR1* actionable variants at recurrence. However, testing of cfDNA is challenging due to the low fraction of ctDNA, so analytical methods require high sensitivity. This external quality assessment (EQA) was designed to assess the genotyping accuracy and reporting of *ESR1* variants in cfDNA.

Methods: GenQA delivered a pilot international EQA to thirty laboratories. Three samples were supplied to participating laboratories containing commercially available artificial plasma to mimic patient samples. Two samples contained actionable *ESR1* hotspot variants and one sample contained no actionable *ESR1* variants. Participants performed testing according to their local protocols and submitted results in the form of clinical reports. Laboratories were assessed on their genotyping accuracy and interpretation of the result.

Results: The genotyping accuracy of *ESR1* testing by participating laboratories was of a high standard. There was one false positive and one incorrect variant reported, classed as critical errors. Several laboratories did not discuss known resistance to therapies and potential therapeutic strategies associated with the *ESR1* variants reported. There was a lack of consideration for the reduced sensitivity for detecting variants in a plasma sample containing no actionable variants.

Conclusion: This EQA has demonstrated an overall high genotyping accuracy in the challenging sample type. Improvements could be made in the interpretation of the result, both in terms of therapeutics and consideration of the sample type tested. This assessment has highlighted the need for EQA participation to educate and promote standardisation of reporting.

E-PS-16-023

ESR1 hotspot mutations in metastatic breast cancer: a Tunisian series

Y. Dhouibi[1,2], M. Ben Rekaya[1,2], A. Aloui[2], A. Blel[1,2], W. Ajouli[1,2], Y. Ben Taher[2], B. Miladi[1,2], L. Bel Haj Kacem[1,2], M. Ksentini[1,2], S. Rammeh[1,2]

[1]Charles Nicolle Hospital, Department of Pathology, Tunis, Tunisia, [2]Faculty of Medicine of Tunis, University Tunis EL Manar, Theranostic Biomarkers Research Laboratory, LR23ES02, Tunis, Tunisia

Background & Objectives: Breast cancer (BC) is a major public health issue, with over 70% of cases being oestrogen receptor-positive (ER+), making hormone therapy the primary treatment. However, resistance to hormone therapy is a critical challenge. Often associated with mutations in the ESR1 gene, which encodes the oestrogen receptor alpha (ERα). This study aims to analyse the ESR1 hotspot mutations in metastatic breast cancer, assess their frequency in a Tunisian patient cohort and compare the sensitivity of real-time PCR to Sanger sequencing in detecting the D538G mutation.

Methods: A total of 43 formalin-fixed, paraffin-embedded (FFPE) tissue samples from metastatic BC patients diagnosed at Charles Nicolle Hospital, Tunisia, were analysed. DNA was extracted and ESR1 hot spot region (exon 8) was screened using Sanger sequencing and real-time PCR for the D538G mutation.

Results: The median patient age was 54 years (range: 31–82). The most common metastatic sites were pleura (86%, n=37 /43), followed by bone (9%, n=4/43) and mediastinum (5%, n=2/43). Six samples

were excluded due to insufficient quality, leading to PCR amplification failure. ESR1 mutations were detected in 10/37 cases (27%) . Sanger sequencing identified 12 genetic variations, including 11 mutations and one polymorphism. Eight mutations (D538G, Y537S, R548H, V533M, A546T, R548R, S578Y, and M528V) have been previously described, with Y537S and D538G being the most common. Four variations (A546S, G572D, S578T, S518S) were novel and unreported in databases. Real-time PCR targeting D538G showed superior sensitivity (37% vs. 5% for Sanger sequencing) in detecting rare mutations, underlining the importance of selecting appropriate and optimized molecular testing techniques.
Conclusion: This study highlights the clinical significance of ESR1 mutations in hormone therapy resistance and emphasizes the need for high-sensitive molecular diagnostic techniques. Further investigations in a larger patient cohort will provide deeper insights into the clinical relevance of these mutations.

E-PS-16-024
Molecular differences between atypical Spitz tumour and Spitz melanoma: an in-silico analysis
M.C. Sevindik[1], Y. Cakir[1], B. Lebe[1]
[1]Dokuz Eylül University Faculty of Medicine, Department of Pathology, Izmir, Turkey

Background & Objectives: Atypical Spitz tumour and Spitz melanoma are melanocytic lesions that pose histopathologic diagnostic challenges. The lack of clear distinguishing features and the high rate of interobserver discordance are the main reasons for this difficulty. In this study, we aimed to identify molecular alterations that may aid in the differential diagnosis of these two groups.
Methods: The search for Spitzoid melanoma was performed on the GEO Datasets website (https://www.ncbi.nlm.nih.gov/gds/) and, the datasets GSE142441 and GSE139314 were selected for evaluation. The determination of differentially expressed genes (DEGs) between Spitz tumour and Spitz melanoma in the first dataset, and between Atypical Spitz tumour and Malignant Spitzoid tumour groups in the second dataset, was performed using the GEO2R program. Subsequently, gene set enrichment analysis (GSEA) was conducted with the WebGestalt bioinformatics service (www.webgestalt.org) for the common genes in both comparisons. $P<0.05$ and $FDR<0.05$ were considered statistically significant.
Results: In the analysis performed for both data sets, 94 DEGs were identified. The genes with the highest level of significance included COL6A6, FGF19, DNMT3A, IRAK3, and PIK3CD ($p<0.05$). Subsequent Gene Set Enrichment Analysis (GSEA) revealed that these genes were implicated in integrin-related signalling pathways, as well as pathways associated with cell adhesion, extracellular matrix binding, extracellular receptor interaction, and protein digestion and absorption ($FDR<0.05$).
Conclusion: In the present in-silico analysis, the aim was to ascertain the distinguishing molecular features of atypical Spitz tumours and Spitz melanomas, two lesion groups that pose a challenge in the context of histopathological differential diagnosis in dermatopathology practice. Through a comprehensive gene expression profile analysis, statistically significant differences were identified. Subsequent pathway analysis revealed that DEGs were associated with cell adhesion, extracellular matrix proteins, and interactions. This finding suggests that these pathways play an important role in the progression of these lesion groups.

E-PS-16-025
Tissue acidity as a preanalytical factor affecting molecular testing: a case of lung adenocarcinoma with *EML4::ALK* fusion
K. Chatzopoulos[1], G. Christofi[1], G. Kalliopitsas[1], S. Balaska[1], A. Syrnioti[1], V. Kotoula[1]
[1]Aristotle University of Thessaloniki, Department of Pathology, Thessaloniki, Greece

Background & Objectives: Molecular profiling by next generation sequencing (NGS) performed on tissue sections from formalin fixed paraffin embedded (FFPE) tissues has been incorporated into the routine management of patients with non-small cell lung cancer. Approximately 5% of lung adenocarcinomas harbour a targetable *ALK* rearrangement, detectable even on the limited tissue of biopsy specimens. Since testing failure can lead to detrimental delays in clinical decision making, herein we aim to highlight the importance of tissue acidity as a preanalytical factor affecting the feasibility of molecular testing.
Methods: A 56-year-old woman diagnosed with a right upper lobe lung mass underwent bronchoscopic biopsy. Haematoxylin-eosin stained FFPE tissue sections were examined, followed by histochemistry, automated immunohistochemistry and targeted NGS, the latter employing the Oncomine Precision Assay in a Genexus Integrated Sequencer (CE-IVD).
Results: Microscopy showed an invasive, poorly differentiated, mucinous adenocarcinoma, with signet ring cells. Alcian blue-PAS confirmed the presence of acidic nature of neoplastic mucin. Immunostaining showed expression of keratin 7 and TTF1, notably without ALK (clone ALK1) expression by tumour cells. The first NGS attempt failed, because of inadequate performance of the molecular template. Nucleic acid extraction was performed anew by alkalinizing the lysis buffer. This template was successfully analysed in the repeated NGS run. An *EML4::ALK* fusion was detected between *EML4* exon 13 and *ALK* exon 20. Subsequently, the patient was treated with crizotinib and achieved a complete clinical, radiological and pathological response, as confirmed after examination of the lung lobectomy surgical specimen. The patient remained free of disease during a 15-month follow-up interval from the initial diagnosis.
Conclusion: This case highlights the importance of tissue acidity as a modifiable preanalytical factor that may lead to NGS failure. Validation in further studies may allow for the development of a standard operating procedure for optimal handling of inherently acidic FFPE tissues.

E-PS-16-026
ESR1 testing in circulating tumour DNA in patients with endocrine-resistant metastatic breast cancer
S. Nugteren[1,2], F. Hughes[1], T. Mullis[1], R. Dessi[1], B. O'Sullivan[1], P. Taniere[1]
[1]Queen Elizabeth Hospital Birmingham, University Hospitals Birmingham NHS Foundation Trust, Molecular Pathology Diagnostic Service, Birmingham, United Kingdom, [2]Erasmus Medical Centre, Pathology, Rotterdam, The Netherlands

Background & Objectives: The introduction of selective oestrogen receptor degraders (SERDs) for patients with ESR1-mutated metastatic breast cancer requires ESR1 mutation testing. ESR1 encodes for the ER alpha protein and ESR1 mutations are the main mechanism of acquired resistance to endocrine therapy, occurring in 20-40% of patients who receive aromatase inhibition. In patients with ESR1 mutations, treatment with SERDs improves progression-free survival. Our objective was to establish whether we could test for ESR1 mutations in circulating tumour DNA (ctDNA) in routine clinical practice.
Methods: 42 patients with hormone-positive HER2-negative metastatic breast cancer who received first line endocrine therapy with an aromatase inhibitor and had early recurrence were included in January 2025 prior to decision for treatment with Elacestrant. Per patient 20ml of blood was collected in Streck or Paxgene tubes. The APIS ESR1 Mutations Kit was used on a QuantStudio Real-Time PCR (RT PCR) system to detect 11 common ESR1 mutations.
Results: For 38/42 patients we were able to test for ESR1 mutations, as for 4 patients we received less than 20ml of blood. In the ctDNA of

12/38 cases (32%) we detected a mutation in ESR1. The average turn-around-time for all 38 cases tested was 7 calendar days.
Conclusion: We share our experience with implementing ESR1 ctDNA mutation testing in our routine practice using a validated RT PCR assay. Our department receives 5 new samples every week; we will therefore show data on a larger cohort of patients at the time of the meeting; we also recently implemented a NGS panel and will share preliminary comparative data between NGS and RT PCR.

E-PS-16-028
Pole mutations using modaplex technology (Biotype) in high-grade endometrial carcinomas
S.A. Galeano Reyes[1], M. Andújar-Sánchez[1], M.E. Fraile-Bethencourt[1], S. Lacerenza[1], I. Domazetovski[1], M. Santana-Verano[1], C. Camacho García[1], E. Dorca-Duch[2], A. Velasco-Sánchez[3], X. Matias-Guiu Guia[3]
[1]Complejo Hospitalario Universitario Insular Materno-Infantil, Pathology, Las Palmas de Gran Canaria, Spain, [2]Hospital Universitario de Bellvitge, Pathology, Barcelona, Spain, [3]Hospital Universitario Arnau de Vilanova, Pathology, Lleida, Spain

Background & Objectives: The TCGA study clearly differentiated four molecular types of endometrial carcinoma: POLE-mutated, P53-mutated, microsatellite instability, and no specific alterations. The implementation of this classification in clinical guidelines and the recent FIGO 2023 classification emphasizes the prognostic value of POLE-mutated tumours, which have a better prognosis compared to the other groups. The technical approach to detecting POLE mutations can be performed using Sanger sequencing of pathogenic exons (exons 9, 11, 13, and 14) or through massive sequencing. In this study, we used a technology that combines PCR and fragment analysis by capillary electrophoresis (Modaplex TM, BIOTYPE GmbH, Dresden, Germany).
Methods: Samples from 120 patients with high-grade endometrial carcinoma, aged between 43 and 86 years, were studied. The tumour types included 33 serous, 32 mixed with a high-grade component, 23 endometrioid G3, 19 carcinosarcomas, 8 clear cells, 4 dedifferentiated, and 1 undifferentiated, all collected between 2015 and 2025. Paraffin-embedded tumour samples were used, and after DNA extraction, the Modaplex POLE/POLD1 Mutation Analysis Kit (BIOTYPE GmbH, Dresden, Germany) was employed. This kit identifies nine (P286R, V411L, S297A, S459F, A456P, F367S, L424V, P436R, M444K) of the eleven pathogenic POLE mutations. As a confirmatory test, Sanger sequencing was performed targeting the identified mutation using the same extracted DNA.
Results: Seven samples with POLE mutations were detected, representing 5.83% of the cases. Four of these were positive for P286R in exon 9 (two endometrioid G3, one dedifferentiated, and one mixed high-grade) and three were positive for V411L in exon 13 (two serous and one mixed high-grade). The two serous cases positive for V411L were also p53-positive, classifying them as "multiple-classifiers." No mutations were detected in exons 11 and 14. All identified mutations were confirmed by Sanger sequencing.
Conclusion: These findings reinforce the role of *POLE* as a biomarker and highlight the importance of molecular profiling for accurate classification.

E-PS-16-029
Learnings from a pilot External Quality Assessment (EQA) for cfDNA extraction from plasma
M. Hellio[1], M.H. Cheetham[1], V. Williams[1], S.J. Patton[1]
[1]EMQN CIC, Manchester, United Kingdom

Background & Objectives: Efficient extraction is critical to enable sensitive and accurate detection of variants in cfDNA. EMQN has established a global pre-analytical EQA for extraction of artificial cfDNA from plasma. The objective was to evaluate the quantity and quality of eluted cfDNA and provide an external benchmark of participants' extraction processes.
Methods: Each laboratory was provided with three 4mL plasma samples containing a defined amount of cfDNA, shipped at room temperature. Participants were instructed to extract the cfDNA using their routine methodology, return all eluted cfDNA and complete a form with details of the method used. The volume of each returned sample was recorded and the cfDNA was analysed using a custom qPCR assay, the Agilent TapeStation Cell-free DNA ScreenTape assay and the Qubit™ High-Sensitivity (HS) assay.
Results: A range of different extraction methodologies were used by the participants, and a broad range of cfDNA yields were obtained for each sample.
Sample concentrations were notably higher when measured with the Qubit HS Assay compared to qPCR and the TapeStation cfDNA Screentape assay, especially for the lower-concentration sample.
The peak cfDNA fragment sizes were highly consistent across all participants and across the samples. The average size for the nucleosomal peak was 148bp (SD = 7). Only one laboratory provided samples outside the mean ± 2 standard deviation, with peaks falling below 130bp across all three samples.
Conclusion: The majority of laboratories extracted sufficient cfDNA for downstream applications such as Next Generation Sequencing (NGS) and cfDNA was mostly of a high quality. However, the broad range of cfDNA yields achieved for these standarised reference materials indicates that it may be possible for some laboratories to increase the efficiency of their cfDNA extraction. Many laboratories indicated that Qubit was used for cfDNA quantification which may not be suitable for extraction methods using carrier RNA.

E-PS-16-030
Streamlined analysis of DNA methylation and its functional consequences from FFPE tumour samples
J. Feenstra[1], S. Jackson[1], K. Sollweck[1]
[1]Thermo Fisher Scientific, South San Francisco, USA

Background & Objectives: Methylation of DNA sequences is an important mechanism for regulating gene expression, in normal cell physiology and in diseases. To detect and analyse the effects of methylation, multiple assays must be performed; however, in clinical research sample amounts are often limiting. The multifactorial analysis of consequences of methylation depends on efficient utilization of precious samples. We show efficient methods for characterizing links between methylation, mismatch repair gene expression, and microsatellite instability from small amounts of colon tumour samples.
Methods: DNA and RNA were isolated from ten 5µm FFPE preserved colon tumour samples using an automated sequential DNA/RNA extraction method. Microsatellite instability was analysed using fragment analysis by capillary electrophoresis. Mismatch repair enzyme gene expression was measured using a 5-plex panel of qPCR assays that queried *MLH1, MSH2, MSH6 and PSM2*, with *PPIA* as an internal control, and confirmed by droplet-free dPCR. Twelve potentially methylated CpGs in *MLH1* promoter were analysed by Sanger sequencing, and the fraction methylated was determined by droplet-free dPCR.
Results: From the extracted genomic DNA, two samples (CT11 and CT15) were found to have high microsatellite instability. Using the extracted RNA, *MLH1* was found to be significantly decreased in the two samples that demonstrated MSI instability. This was confirmed using dPCR with the same MMR multiplex panel. Samples with MSI had significant methylation in all CpGs in the *MLH1* promoter region. The fraction of genomic DNA methylated was determined by droplet-free PCR; both samples with high MSI had greater than 50% of the *MLH1* promoter DNA methylated.

Conclusion: Together, these results show how DNA methylation and its impact on the MMR pathway can be analysed from precious samples using fast, simple, and cost-effective laboratory assays.

E-PS-16-031

Assessment of ALK, ROS1, RET and MET exon 14 alterations using the Biocartis Idylla GeneFusion Assay and Platform; single laboratory experience on over 11000 lung cancer samples

S. Nugteren[1,2], L. Robertson[1], B. O'Sullivan[1], P. Taniere[1]
[1]Queen Elizabeth Hospital Birmingham, University Hospitals Birmingham NHS Foundation Trust, Molecular Pathology Diagnostic Service, Birmingham, United Kingdom, [2]Erasmus Medical Centre, Pathology, Rotterdam, The Netherlands

Background & Objectives: At the University Hospitals Birmingham NHS Foundation Trust, as in most of the English trusts, any newly diagnosed lung non small cell carcinoma is submitted to reflex testing for the following alterations, prior to first line treatment: EGFR, KRAS, BRAF, ALK, ROS1, RET, MET E14, HER2 amplification and PD-L1 expression. We report on our experience of testing ALK, ROS1, RET and MET exon 14 alterations for rapid assessment of FFPE samples using the Idylla GeneFusion assay on the Biocartis Idylla real time PCR platform.
Methods: One to three paraffin sections (5 micrometer thick) were loaded in Genefusion cartridges; testing incorporates RNA extraction and analysis, which is completed within 3 hours following 3 minutes handling. Testing offers flexibility for urgent cases. The analysis of raw data in equivocal cases, including the use of expression imbalance for the detection of novel fusions, was supported by Idylla Explore.
Results: 11473 FFPE lung cancer samples, referred from over 100 NHST trusts, were tested between January 2021 and January 2025. 845 cases (7%) were invalid due to insufficient material or poorly preserved tissue; by repeating the testing with more tissue, the rate of failure went down to less than 5%. 10648 samples were successfully tested and showed the following results: ALK fusions: 1.3%; ROS1 fusions: 0.4%; RET fusions: 0.5%; MET exon 14 skipping: 2.3%.
Conclusion: We report on a cost-effective method for rapid gene fusion assessment of 4 targetable alterations in lung tumour specimens. The detected rate of the respective alterations was as expected from widely published data on comparative platforms and gene fusion data correlated well with ALK and ROS1 immunohistochemistry data.

E-PS-16-033

BRCA mutations in ovarian and prostate cancer

L. de León[1], M.J. Carrillo Pohl[1], M.Á. Mármol Fábrega[1], M.C. Fula Cobos[1], E.L. Hernández Suárez[1], C. Diego Hernández[1], M.Á. Múñoz Fernández[1], P. Gómez Iglesias[1], M. Boiza Sánchez[1], C. Villanueva Sánchez[1], T. Meizoso Latova[1]
[1]Hospital Universitario de Móstoles, Anatomía Patológica, Móstoles, Spain

Background & Objectives: High-grade serous carcinoma of the ovary (HGSC) has defects in the DNA damage response (DDR) pathways. Mutations in the DDR genes, such as BRCA1 and BRCA2, are also common in prostate cancer. A better understanding of DDR pathways is essential to optimizing therapeutic options.
Methods: At the request of our hospital's Oncology Department, we analysed paraffin-fixed ovarian and prostate tissue samples from 58 patients diagnosed with HGSC or metastatic acinar adenocarcinoma of the prostate using Next-Generation Sequencing (NGS) (NextSeq/Panel HRR-IMEGEN or MiSeq).
Results: Of the 58 cases analysed, 56 (96.5%) were completed, although 5 cases (8.9%) were not evaluable. Alterations in DDR pathways were detected in 11 cases (19.6%) of HGSC and in 5 cases (8.9%) of metastatic acinar adenocarcinoma of the prostate. Among the HGSC, 6 cases (54.5%) exhibited homologous DNA recombination deficiency, 3 cases (27.2%) had a pathogenic BRCA1 variant, and 2 cases (18.1%) had a BRCA1 variant of undetermined significance. Regarding metastatic acinar adenocarcinoma of the prostate, 2 cases (40%) harboured pathogenic variants in CDK12 and ATM. Additionally, variants of undetermined significance were detected in ATM (40%) and in CHEK2 (20%).
Conclusion: Unlike literature, the most frequent alteration observed in our study in HGSC was homologous recombination deficiency with somatic BRCA mutations. However, it has been reported that germline BRCA1 and BRCA2 mutations are more common, occurring in approximately 15% of cases. Regarding metastatic acinar adenocarcinoma of the prostate, no BRCA2 alterations were identified, despite it being the most frequently mutated gene. However, according to the literature, mutations in CDK12 and ATM were detected. Currently, detecting these alterations is crucial, as treatment with PARP inhibitors is indicated for patients with HGSC and those with metastatic adenocarcinoma of the prostate.

E-PS-16-034

Assessing ChatGPT's capability against oncologists in molecular pathology report analysis

J. Garratt[1], J. Won[1], B. Sheffield[2,1], K. Bisson[1,2]
[1]Canadian Pathology Quality Assurance, Vancouver, Canada, [2]William Osler Health System, Pathology, Brampton, Canada

Background & Objectives: Molecular pathology test reports play a vital role in guiding personalized oncology care, but their quality and interpretative consistency can vary significantly. As part of the Canadian Pathology Quality Assurance (CPQA) External Quality Assessment (EQA) molecular scheme (Run M1), seven laboratories conducted colorectal cancer biomarker testing and submitted molecular pathology reports for quality assessment. This study explores the potential of ChatGPT, an artificial intelligence (AI) tool, to analyse these reports.
Methods: Reports generated during CPQA Run M1 EQA scheme for colorectal cancer biomarkers were analysed by ChatGPT and a panel of oncologists and pathologists. Evaluations covered eight key domains: patient/specimen information, diagnostic findings, molecular analysis, result interpretation, therapeutic recommendations, technical details, report formatting, and authentication. Reports were graded on their completeness and clinical relevance, with the panel's assessments serving as the gold standard.
Results: ChatGPT excelled in identifying structural deficiencies and accurately evaluated technical details and patient/specimen information. AI effectively highlighted actionable findings such as mismatch repair deficiency (dMMR) and *KRAS* mutations, however, its ability to evaluate clinical interpretations and therapeutic recommendations in the reports was less comprehensive than the expert panel. , particularly when integrating molecular findings within patient context was required. The AI tool's ability to standardize the evaluation of a report was recognized, but areas requiring nuanced clinical judgment were identified for improvement.
Conclusion: ChatGPT demonstrates promise as an adjunct for analysing molecular pathology reports in quality assurance settings, excelling in standardization and technical critique. While it effectively supports quality assurance initiatives, human oversight remains essential for clinical correlation and therapeutic planning. The integration of AI tools into quality assurance workflows could enhance report consistency and educational value for participating laboratories. This study highlights the potential for AI in pathology quality assurance programs and its role in improving report analysis across laboratories.

E-PS-16-035

Modulation of the immune microenvironment during chemoimmunotherapy in gastric cancer patients

L. Tashireva[1], E. Tsarenkova[1], A. Kalinchuk[1], S. Vtorushin[1]
[1]Cancer Research Institute, Tomsk NRMC, Tomsk, Russia

Background & Objectives: Gastric cancer (GC) ranks as the fifth most common malignancy globally. Neoadjuvant chemoimmunotherapy not only reduces tumour size preoperatively but also improves long-term outcomes. However, treatment efficacy depends on tumour molecular profiling, underscoring the need for predictive biomarkers and patient stratification. Given that immunotherapy modulates local immune responses, analysing changes in the tumour microenvironment (TME) under PD-1 blockade is critical. Study aim was to compare the immune cell composition of the TME in primary gastric tumours before and after anti-PD-1-based chemoimmunotherapy.
Methods: The study included 9 patients with gastric cancer who received neoadjuvant chemotherapy in combination with pembrolizumab. Biopsy material was collected from each of them before therapy, and tumour material (surgical) was obtained after therapy. Formalin-fixed tumour sections were stained with multiplex immunofluorescence (TSA) using CD8, CD20, CD163, PD-1, and FoxP3 antibodies and Opal 7-colour Fluorophore Kit. All staining steps were performed using the automated immunohistochemistry stainer BOND RXm. Visualization of the stained samples was carried out using the automated scanning system Vectra 3.0.
Results: Immunotherapy led to a significant two-fold increase in the number of CD8+ T-lymphocytes ($p=0.038$). The observed changes in CD8+ cytotoxic lymphocyte counts during anti-PD-1 immunotherapy were most pronounced in the PD-1-expressing subpopulation. A 10-fold increase in CD8+PD-1+ cytotoxic T-lymphocytes was detected ($p=0.0156$). The numbers of CD20+ B-lymphocytes, CD163+ macrophages, and FoxP3+ lymphocytes remained unchanged ($p>0.05$). Additionally, a significant five-fold increase in the CD8+ cytotoxic lymphocytes to FoxP3+ lymphocytes ratio was observed during anti-PD-1 immunotherapy ($p=0.0039$).
Conclusion: Combined chemoimmunotherapy for gastric cancer induces remodelling of the tumour microenvironment in patients. The obtained results may play a significant role in further research aimed at identifying predictive factors for the efficacy of immunotherapy in gastric cancer. The study was supported by the Russian Science Foundation (grant # 20-75-10033-P).

Funding: Russian Science Foundation (grant # 20-75-10033-P)

E-PS-16-036

A molecular classification to supplement the World Health Organisation classification of tumours

H. Wijesinghe[1], A. Machado[1], P. Puspanathan[1], R. Cierco Jimenez[1], C. Giesen[1], I. Indave Ruiz[1], D. Lokuhetty[1], I. Cree[1]
[1]International Agency for Research on Cancer/World Health Organization, Lyon, France

Background & Objectives: The current WHO classification of tumours (WCT) is a differentiation-rooted hierarchical classification, based on anatomical site, histopathology, and well-established relevant molecular information. Advances in personalised treatment have resulted in an increasing need for a molecular classification of tumours, based on the established and potential therapeutic targets present within tumours, irrespective of tumour type. Our objective was to provide a molecular classification tool for oncological and research use based on the WCT.
Methods: The framework used in the WCT - Genetic Tumour syndromes 5th edition (GTS-5) was expanded to map molecular targets. Each target (affected gene) was categorised according to the molecular pathway to which it belongs. Information on the type of molecular abnormality (e.g. mutation, amplification, fusion etc), associated with individual tumour types and therapeutic class of drugs available for each target were included in the map. The information was cross referenced to the relevant sections in the WCT books.
Results: Mapping molecular targets based on the molecular pathways identified in GTS-5 provides an effective structure to classify the molecular information available in the WCT. Its pathway-based approach could help personalise treatment for patients and provide cancer researchers with a framework to identify potential targets for treatment. At present over 40 molecular targets (genes) have been mapped according to this framework alongside the relevant tumours and therapeutic drug class.
Conclusion: The final version of this molecular classification of tumours will be made available on the WCT website as an online molecular classification tool with links to the relevant WCT volumes online. Having the molecular classification as an online live tool will allow it to evolve as new evidence is incorporated into the WCT.

E-PS-16-037

The impact of bile acids on the antiinvasive potential of a selective COX-2 inhibitor in malignant cells

V. Sekeruš[1], A. Lovrenski[2], N. Gardić[2], N. Pavlović[3], B. Stanimirov[4], K. Stankov[4]
[1]Department of Biochemistry, Faculty of Medicine, University of Novi Sad; Institute for Pulmonary Diseases of Vojvodina, Novi Sad, Serbia, [2]Department of Pathology, Faculty of Medicine, University of Novi Sad; Institute for Pulmonary Diseases of Vojvodina, Novi Sad, Serbia, [3]Department of Pharmacy, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia, [4]Department of Biochemistry, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia

Background & Objectives: Chronic inflammatory response and increased expression of isoenzyme cyclooxygenase-2 (COX-2) are recognized as important factors in the etiopathogenesis of colorectal cancer. Therefore, selective COX-2 inhibitors represent potential agents in the prevention and therapy of this malignant disease.
The aim of this study was *in vitro* investigation of the cytotoxic effect of celecoxib, a selective COX-2 inhibitor, and bile acids on human colorectal adenocarcinoma cells (HT-29 cell line), and to analyse the expression of genes involved in the inflammatory response, invasion and metastasis of cells.
Methods: The cytotoxic effect of celecoxib and bile acids against the HT-29 cell line was determined using the dye exclusion test (DET) and the MTT assay. Gene expression experiments were performed using the real-time reverse transcription polymerase chain reaction (qRT-PCR). The expression i.e. the amount of mRNA of the following genes was investigated: *PTGS2* (encodes the inducible isoenzyme COX-2), *CDH1* (encodes E-cadherin), *MMP2* and *MMP9* (encode matrix metalloproteinases-2 and -9).
Results: After treating the HT-29 cell line with increasing concentrations of celecoxib (10-200 μM) for 48 hours, a concentration-dependent cytotoxic effect of celecoxib was demonstrated. Compared to the untreated control group of cells, celecoxib caused a decrease in *PTGS2* and *MMP2* ($p<0.01$) and *MMP9* gene expression ($p<0.05$), and increased *CDH1* gene expression ($p<0.01$). The addition of chenodeoxycholic acid (CDCA) completely antagonized the aforementioned effects of celecoxib. Ursodeoxycholic acid (UDCA) showed a synergistic effect with celecoxib in reducing *PTGS2* and *MMP2* gene expression (without statistical significance) and *MMP9* gene ($p<0.01$ *vs.* C), while contributing to a further increase in *CDH1* expression levels ($p<0.05$ *vs.* C).
Conclusion: The results of cytotoxicity tests indicate the importance of COX-2 isoenzyme in the proliferation and survival of malignant cells. UDCA in combination with celecoxib shows favourable antiinflammatory, antiinvasive and antimetastatic potential in colorectal cancer cells.

E-PS-16-038

Mutations that matter: a case series on molecular insights into lung adenocarcinoma

S. Umare[1], M. Bharambe[1], A. Chaudhary[1], P. Doshi[1], R. Bharadwaj[1]
[1]Bharati Vidyapeeth Deemed to be University, Pathology, Pune, India

Background & Objectives: Lung adenocarcinoma, most frequently diagnosed non-small cell lung cancer, exhibits notable histological heterogeneity. While immunohistochemistry (IHC) aids in identification of poorly differentiated carcinomas, conservation of tissue for subsequent molecular analyses is paramount. Detection of specific molecular aberrations is crucial for determining patient eligibility for targeted and immune-based therapies, which often present superior outcomes compared to traditional chemotherapeutic regimens. This case series aims to elucidate critical role of accurate molecular profiling in optimizing treatment strategies and prognostic outcomes for patients with lung adenocarcinoma.
Methods: A retrospective and observational study performed at a tertiary care centre and teaching institute, Bharati Vidyapeeth (Deemed to be University) Medical College, Pune, Western Maharashtra, India. Twenty cases of histologically confirmed lung adenocarcinoma were analysed. Patient demographic data and comprehensive histopathological assessments, performed by two independent pathologists, were collected. IHC was performed, followed by detailed molecular testing. Cases exhibiting pure adenocarcinoma histology were included, while other carcinoma subtypes were excluded to maintain focus.
Results: Mean age of our study was 62.8 years. Molecular profiling revealed EGFR exon 21 mutations in 50% (n=10) of cases, while 40% (n=8) demonstrated PD-L1 expression. Less frequent alterations were observed in ERBB2 and KRAS. Targeted therapies were administered to patients based on their specific molecular profiles, aligning with personalized medicine principles.
Conclusion: This case series emphasizes the significant impact of thorough molecular profiling in guiding therapeutic decisions for lung adenocarcinoma. Identifying key genetic alterations, such as EGFR mutations and PD-L1 expression, enables the implementation of tailored treatment regimens, potentially leading to improved patient outcomes. Integration of molecular profiling into routine clinical practice is essential for optimizing patient care in lung adenocarcinoma.

E-PS-16-039

Overlapping evaluation of TNFa expression in fresh and paraffin embedded Inflammatory Bowel Disease (IBD) mucosal biopsies

W.G. Giordano[1], A. Viola[2], R. Goll[3], E. Germanà[1], V. Fiorentino[4], C. Pizzimenti[4], A. Ieni[4], G. Fadda[4], G. Giuffrè[4], G. Tuccari[4], W. Fries[2], M. Martini[4]
[1]University of Messina, Biomedical, Dental and Morphological and Functional Imaging Sciences, Messina, Italy, [2]University of Messina, Clinical and Experimental Medicine, Messina, Italy, [3]University Hospital of North Norway, Internal Medicine, Division of Gastroenterology, Tromsø, Norway, [4]University of Messina, Human Pathology of the Adulthood and Developing Age "Gaetano Barresi", Section of Pathology, Messina, Italy

Background & Objectives: The anti-TNFa drugs represent one of the most important efficacious biological drugs available for IBD patients. These drugs reduce symptoms, hospitalizations, surgeries, heal mucosal ulcers and limit the use of corticosteroid but, 30-40% of patients with IBD do not respond to these drugs, and 30-50% of patients who initially benefit from the drug, no longer respond over time. For this reason, there is the need to identify specific biomarkers to predict treatment response and monitor IBD patients. The aim of this study is to compare TNF-α levels obtained from fresh biopsies with TNF-α expression levels obtained through real-time PCR using paraffin-embedded tissues in patients with IBD, to show which of the two approaches is more accurate and cost-effective.
Methods: Tissue samples from IBD patients treated with biological or conventional treatment were included. RNA was extracted both from fresh biopsies that paraffine-embedded tissue and subsequently it was evaluated the relative expression of TNF-α/β-actin through Real-Time PCR. We used healthy colon biopsies as a control. We compared results with those previous obtained from fresh biopsies.
Results: We included 30 UC patients (25 on biological treatment and 5 on conventional treatment) who were previously tested with fresh biopsies, along with 15 normal controls. We found a very strong correlation between TNF-α expression levels evaluated with the two different methods ($r=0.89$; $p<0.0001$) confirming the higher levels in patients with active disease and the overlapping of the two different analysis.
Conclusion: We showed the potential utility of real-time PCR for quantifying TNF-α levels in paraffin-embedded tissues. This approach is more cost-effective than that involving fresh samples and offers the advantage of utilizing biopsy samples already collected for diagnostic purposes, removing the need for other samples.

E-PS-16-040

Uncommon EGFR compound mutations in NSCLC: case insights

G. Ricciardi[1,2], E. Germanà[1], W.G. Giordano[1], M. Ballato[1], R. Scarfì[3], M. Santarpia[3], V. Fiorentino[3], G. Giuffrè[3]
[1]University of Messina, Department of Biomedical, Dental, Morphological and Functional Imaging Sciences, Messina, Italy, [2]Istituto Clinico Polispecialistico C.O.T. Cure Ortopediche Traumatologiche s.p.a, Messina, Italy, [3]University of Messina, Department of Human Pathology in Adult and Developmental Age "Gaetano Barresi", Messina, Italy

Background & Objectives: *EGFR* mutations occur in approximately 14% of non-small cell lung cancer (NSCLC) cases and are crucial for identifying patients who may benefit from tyrosine kinase inhibitors (TKIs). Exon 19 deletions and exon 21 p.L858R point mutations are the most frequent, accounting for 80-90% of all *EGFR* mutations. The remaining 10-20%, known as uncommon mutations, include p.G719X, p.L861Q, and p.S768I. Compound mutations, defined as the presence of more than one *EGFR* mutation within the same tumour, are reported with a heterogeneous incidence (4-26%).
Methods: A 76-year-old female patient underwent lobectomy for NSCLC after diagnostic bronchoscopy. Histology revealed a papillary-acinar adenocarcinoma without lymph node involvement. The patient was staged as stage I and therefore did not receive adjuvant chemotherapy. Molecular analyses were performed on DNA extracted from FFPE tissue using real-time PCR. Subsequent NGS analysis was performed to further validate the real-time PCR results.
Results: Real-time PCR analysis detected two uncommon *EGFR* mutations: exon 18 p.G719X and exon 21 p.L861Q. To confirm these findings, a new DNA extraction was performed, and the same compound mutations were identified by real-time PCR. Subsequent NGS analysis confirmed the presence of the *EGFR* pathogenic variants c.2156G>C p.G719A and c.2582T>A p.L861Q, with allelic frequencies of 25.78% and 25.61%, respectively.
Conclusion: The equivalent allelic frequencies suggest that these compound mutations are likely in cis, indicating the presence of a molecularly homogeneous neoplastic cell population. The clinical efficacy of *EGFR*-TKIs in patients with uncommon *EGFR* compound mutations remains uncertain. While p.G719X + p.L861Q mutations respond well to first-generation TKIs, second-generation TKIs demonstrate a stronger inhibitory profile. Moreover, preclinical and clinical data have shown that osimertinib has activity against these complex mutations. Further research is needed to define the optimal therapeutic strategy for this patient group.

E-PS-16-041

Unusual *BRAF* mutations in melanoma patients: discordance between molecular testing methods

W.G. Giordano[1], G. Ricciardi[1,2], E. Germanà[1], M. Ballato[1], R. Scarfì[3], M. Santarpia[4], M. Lentini[3], G. Giuffrè[3]
[1]University of Messina, Department of Biomedical, Dental and Morphological and Functional Imaging Sciences, Messina, Italy, [2]Istituto Clinico Polispecialistico C.O.T. Cure Ortopediche Traumatologiche s.p.a., Messina, Italy, [3]University of Messina, Department of Human Pathology of the Adulthood and Developing Age "Gaetano Barresi", Section of Pathology, Messina, Italy, [4]University of Messina, Department of Human Pathology of the Adulthood and Developing Age "Gaetano Barresi", Section of Oncology, Messina, Italy

Background & Objectives: *BRAF* mutations occur in 40-50% of cutaneous melanomas and the majority of the mutations results in codon 600. *BRAF* p.V600E is the most frequent mutation and is present in approximately 70-88% of cases. Less common mutations have been also described in the codon 600, including p.V600K (10-20%), p.V600R (2-5%), p.V600D (1-4%), p.V600M (<1%) or p.V600G (<1%); furthermore, others unusual mutations concern codons 599 and 601 (<5%). We report two cases of unusual *BRAF* mutations detected in melanoma patients that presented discordance between molecular testing methods utilized.
Methods: A 52-year-old male patient with ulcerated nodular melanoma and an 81-year-old male patient with acromic melanoma underwent to molecular characterization after surgical excision. For both patients, DNA was extracted from FFPE skin samples and the *BRAF* status was assessed by real-time PCR utilizing *BRAF* Codon 600 Mutation Analysis Kit II (EntroGen), intended for the detection of *BRAF* mutations p.V600E/E complex (GTG>GAG/GTG>GAA), p.V600K (GTG>AAG), p.V600R (GTG>AGG), p.V600D (GTG>GAT), p.V600M (GTG>ATG) and p.V600G (GTG>GGG).
Results: *BRAF* mutations were detected in both patients by real-time PCR: variant p.V600M (c.1798G>A) in 52-year-old patient and p.V600R (c.1798-1799GT>AG) in 81-year-old patient. The same unusual *BRAF* mutations were found in two patients repeating twice the analysis. Successively, an orthogonal test was performed utilizing next generation sequencing (NGS) approach with the Myriapod NGS Cancer panel DNA (Diatech Pharmacogenetics). *BRAF* mutations in codons 599 and 601 were respectively detected in two patients. In particular, variant p.T599dup (c.1795-1797dupACA) VAF 43.76% was found in 52-year-old patient, while the variant p.K601E (c.1801A>G) VAF 84,3% was found in 81-year-old patient.
Conclusion: The presence of gene variants different from reference genes of test utilized may determine not only a false negative result but also the detection of a mismatched variant. Therefore, in molecular testing NGS should be preferred to predefined target methodologies.

E-PS-16-042

Contribution of molecular profiling in melanomas diagnosed in cutaneous and extracutaneous sites

C. Topalidis[1], K. Boulogeorgou[1], K. Chatzopoulos[1], S. Balaska[1], T. Koletsa[1], P. Hytiroglou[1], A. Cheva[1], V. Kotoula[1]
[1]AHEPA University Hospital, Aristotle University of Thessaloniki, Department of Pathology, Thessaloniki, Greece

Background & Objectives: Molecular genotyping has been incorporated into the routine clinical management of patients with melanoma. Cutaneous and uveal melanomas are characterized by *BRAF/RAS* and *GNAQ* mutations, respectively, while in some patients the primary site remains unknown. In the herein presented mini case series of cutaneous and non-cutaneous melanomas, we highlight the role of molecular profiling in patient management, including diagnostic workup and therapeutic decision making.
Methods: We present routinely diagnosed melanoma cases that were referred to our department for molecular profiling in 2022-2024. Tissue examination was performed on haematoxylin-eosin and immunohistochemical stained sections. Molecular profiling was assessed by targeted next generation sequencing (NGS) with the Oncomine™ Precision Assay GX.
Results: This series includes nine patients, five females and four males (median age: 78 years). Three patients (3/9, 33,3%) had cutaneous lesions, while the remaining six (6/9, 66,6%) had non-cutaneous tumours in the eye, nasal cavity, small intestine, axillary lymph nodes, lung and liver. In the latter group, no cutaneous primary was clinically identified, apart from the patient with the liver mass, who had a primary lesion in the eyelid conjunctiva. The following mutations were detected in lesions from respective sites: *BRAF* p.V600E (skin, nasal cavity), *BRAF* p.G469R (small intestine), *GNAQ* p.Q209P (eye, liver), *NRAS* p.Q61K (skin, lymph nodes), *HRAS* p.Q61L (skin) and *CDKN2A* loss (lung). Molecular analysis identified patients that could benefit from treatment with BRAF/MEK or tyrosine kinase inhibitors. Furthermore, in cases of unknown primary site, a cutaneous (*BRAF*, *RAS* mutations) or uveal (*GNAQ* mutations) origin might be suggested.
Conclusion: Molecular profiling by targeted NGS is feasible in the pathology laboratory and can be informative not only for identifying candidates for targeted treatment, but also for indicating a potential primary site in patients diagnosed with non-cutaneous melanoma.

E-PS-16-043

Multiplex digital PCR as a tool for detection of *BRAF* and *KRAS* mutations in liquid biopsy specimens

J. Feenstra[1], E. Kyger[1], J. Wong[1], E. Wei[1], M. Kim[1], D. Joun[1], R. Feigelman[1], A. Gupta[1], M. Schumaker[1]
[1]Thermo Fisher Scientific, South San Francisco, USA

Background & Objectives: Testing *KRAS* and *BRAF* mutations in liquid biopsy is crucial for detection of different cancers. While liquid biopsy samples can be sequenced for mutation detection, digital PCR can offer a quicker and cheaper alternative for detection of known pathogenic mutations. We designed and assessed the performance of 2 digital PCR multiplexes for detection of *BRAF* V600 mutations and *KRAS* G12 mutations for liquid biopsy testing.
Methods: Research use only assays were designed to detect and differentiate *BRAF* V600K/E/R mutations in a single reaction. A separate multiplex was designed to detect and differentiate *KRAS* G12C and G12D and undifferentiated G12A/R/S/V in one reaction. Performance of each multiplex was assessed for analytical specificity, analytical sensitivity, limit of blank and assay linearity. In addition, testing was performed on contrived liquid biopsy specimens using EDTA plasma with synthetic DNA targets. Cell free DNA was isolated using the MagMAX™ Cell-Free DNA Isolation Kit (Thermo Fisher Scientific). Digital PCR was performed on Absolute Q™ instrument (Thermo Fisher Scientific).
Results: Mutations in both genes could be accurately detected down to allelic frequency of 0.1% with 1000 copies/µl of wild type. Analytical specificity of the assays was determined to be >99.0% in reference material at 8000 copies/µl. Limit of blank was determined to be in the range of 0.0-0.05 copies/µl and linearity for all channels at $R^2 \approx 1$ across all multiplexes. *BRAF/KRAS* were detectable to 200-300 copies of wild type per ng of cfDNA from EDTA plasma.
Conclusion: *BRAF* V600 and *KRAS* G12 mutations can be detected with high accuracy down to the allelic frequency of 0.1% using the newly developed digital PCR multiplex assays on Absolute Q instrument. This rapid method for *BRAF* and *KRAS* mutation detection can be a valuable tool for analysing liquid biopsy specimens for cancer research.

E-PS-16-045

Detection of CD28 T-lymphocyte subpopulations in elderly patients with rheumatoid arthritis at the onset of the disease

N. Nizyaeva[1], A. Aleksankin[2], A. Avdeeva[3], A. Aboleshina[4], E. Zotkin[4], A. Movsesyan[5], K. Molova[6], M. Makoeva[6], L. Mikhaleva[7]
[1]Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Reproduction Pathology, Moscow, Russia, [2]Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Moscow, Russia, [3]Nasonova Research Institute of Rheumatology, Laboratory of Immunology and Molecular Biology of Rheumatic Diseases, Moscow, Russia, [4]Nasonova Research Institute of Rheumatology, Laboratory of the Evolution of Rheumatoid Arthritis, Moscow, Russia, [5]V.A. Nasonova Research Institute of Rheumatology, Laboratory of Cardiovascular Pathology in Rheumatic Diseases, Moscow, Russia, [6]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, [7]Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Director, Moscow, Russia

Background & Objectives: Studying CD28 and T-cells is essential for understanding age-related changes in T-cells and for developing potential intervention strategies to improve immune functions in the elderly. The aim of this study is to investigate the subpopulations of CD28 T-lymphocytes in the peripheral blood of patients with rheumatoid arthritis at the onset of the disease using flow cytometry.
Methods: The study included 100 patients with a confirmed diagnosis of rheumatoid arthritis (RA) according to the ACR/EULAR 2010 criteria. The mean age of the participants was 60 years (Me [25th; 75th percentile] = 60 [38.0; 68.0] years). The patients were divided into two groups: 50 patients with disease onset over the age of 60, with an average age of 68 years [64; 73], a disease duration of 2 years [1; 2], and a DAS28 score of 4.9 [4.3; 5.6] points; and 50 patients with disease onset before the age of 60, with an average age of 38 years [27; 45], a disease duration of 1.3 years [1; 2], and a DAS28 score of 4.8 [3.4; 5.4] points.
Results: The study comparing donors and patients with RA over 60 years old revealed significant differences in the percentage and absolute counts of CD8+CD28- cells. In donors, the percentage was 29.8% and the absolute count was 0.1 x 10^9/L, while in patients with RA, these values were 60.1% and 0.2 x 10^9/L, respectively ($p < 0.05$). Additionally, the percentage and absolute counts of CD8+CD28+ cells were higher in healthy donors compared to patients with RA over 60 years old, with values of 70.2% and 0.3 x 10^9/L in donors compared to 39.9% and 0.2 x 10^9/L in patients ($p < 0.05$).
Conclusion: A direct correlation was identified between patient age and the quantity of CD8+CD28- T lymphocytes, indicating that rheumatoid arthritis potentially leads to accelerated immune aging.

E-PS-16-046

Analytical validation of a highly multiplexed Droplet Digital PCR (ddPCR) assay for simultaneous detection of up to 37 variants in the EGFR, KRAS and BRAF genes

S. Jain[1], P. Pal[1], N. Mehmet[1], A. Melendez-Molina[1], C. Li[1], M. Rostamza[1], T. Newsum[1], L. Jackson[2], B. D'Alessio[2], G. Pestano[2], G. Johnson[2], R. van Haastert[3], M. Crans[3]
[1]Bio-Rad Laboratories, Pleasanton, USA, [2]Biodesix, Louisville, USA, [3]St. Antonius Ziekenhuis, Nieuwegein, The Netherlands

Background & Objectives: Lung cancer is the second most common cancer globally, of which 80-85% are Non-Small Cell Lung Cancer (NSCLC). Even with advanced screening methods, about 53% of lung cancers are still diagnosed at an advanced stage with a 5-year survival rate of 9%. Biomarker testing for actionable oncogenic driver mutations is recommended in national and international guidelines based on the improved outcomes observed with use of targeted therapies in eligible patients with metastatic NSCLC. Here, we demonstrate the performance of the ddPLEX EGFR/KRAS/BRAF Mutation Detection Assay Kit, a research use only kit developed for the QX600™ ddPCR™ System.
Methods: This kit is designed for the detection, discrimination and quantification of 37 actionable variants in the *EGFR*, *KRAS*, and *BRAF* genes in a single ddPCR well. It also has a companion total quantification well that allows for variant allele frequency (VAF) calculation. It can provide same day results with a streamlined workflow, includes positive and internal controls and is compatible with plasma and formalin-fixed paraffin-embedded (FFPE) samples. We tested analytical sensitivity, specificity, reproducibility and linearity using contrived samples. Accuracy of the assays in the kit was further validated with cfDNA samples using an orthogonal NGS method.
Results: The results demonstrated an analytical sensitivity of 0.025%-0.1% in a background of 40,000 copies of human genomic DNA for all targeted variants and an analytical specificity of 100%. The assay was linear from 20% to 0.1% VAF with a $R2 > 0.95$. With previously extracted and archived cell-free DNA from plasma, the assay showed high concordance.
Conclusion: Results indicate that the ddPLEX EGFR/KRAS/BRAF Mutation Detection Assay Kit is sensitive, accurate, and time- and cost-efficient for detecting clinically relevant NSCLC variants. Multiplexing maximizes information and reduces sampling bias from specimens with low nucleic acid quantities such as FFPE and plasma.

E-PS-16-047

Usefulness of molecular characterization in diagnostic orientation: a case report

M. Ballato[1], A. Russo[2], E. Germanà[1], G. Ricciardi[1,3], W.G. Giordano[1], R. Scarfì[4], C. Pizzimenti[5], G. Giuffrè[4]
[1]University of Messina, Department of Biomedical, Dental, Morphological and Functional Imaging Sciences, Messina, Italy, [2]Humanitas Istituto Clinico Catanese, Medical Oncology, Catania, Italy, [3]Istituto Clinico Polispecialistico C.O.T. Cure Ortopediche Traumatologiche s.p.a, Messina, Italy, [4]University of Messina, Department of Human Pathology of Adults and Developmental Age "Gaetano Barresi," Division of Pathology, Messina, Italy, [5]Pathology Unit, Papardo Hospital, Messina, Italy

Background & Objectives: In the era of precision oncology, molecular characterization of tumours has emerged as an important tool, primarily for predictive purposes. However, sometimes, molecular tests can also play a crucial role in diagnostic orientation.
Methods: In January 2024, an 81-year-old male patient was diagnosed with lung adenocarcinoma, and subsequently enrolled in a prospective study evaluating the impact of liquid biopsy in advanced tumours. Molecular characterization was performed on both a blood sample (FoundationOne®Liquid CDx) and FFPE lung tumour tissue (Myriapod NGS Cancer Panel DNA). In April 2024, after episodes of rectal bleeding, a colonoscopy revealed rectal carcinoma, later confirmed by histology. To determine whether the lung lesion represented secondary progression from the rectal carcinoma or a primary lung lesion, synchronous with the rectal carcinoma metastatic to the liver, molecular analyses were also performed on both the rectal biopsy and a re-biopsy of the lung tumour.
Results: The patient was initially staged as stage IVA, and first-line treatment with vinorelbine therapy was started. Molecular characterization revealed *KRAS* p.G12V mutation (VAF 12.5%) in liquid biopsy, while KRAS p.G12C variant was found in FFPE lung tumour tissue (VAF 59.85%). Subsequent molecular profiling of the rectal biopsy and the re-biopsy of the lung tumour showed *KRAS* p.G12V variant in the rectal tumour and *KRAS* p.G12C mutation in the lung tumour. Given the clinical, instrumental and biomolecular findings, a new diagnostic orientation was formulated: hepatic secondary

lesions from inoperable rectal adenocarcinoma, with an early-stage synchronous lung adenocarcinoma. Based on this revised differential diagnosis, therapy with capecitabine plus bevacizumab was initiated in July 2024, as recommended for patients with unresectable metastatic colorectal cancer.
Conclusion: In some pathological contexts, such as the one just described, formulating a correct diagnosis can be challenging. In these cases, molecular characterization should also be used to prevent inappropriate assessments and ensure correct patient management.

E-PS-16-048
Unusual signal patterns of FISH probes in synovial sarcoma: immunohistochemical and clinicopathological examination of 2 cases
F. Unsal Oguz[1], S. Ozsener Ozekinci[2]
[1]Dicle University, Pathology, Diyarbakir, Turkey, [2]Goztepe Prof. Dr. Suleyman Yalcin City Hospital, Pathology, Istanbul, Turkey

Background & Objectives: Fluorescence in situ hybridization (FISH) is one of the methods applied in daily clinical practice for the molecular pathological diagnosis of Synovial Sarcoma (SS). The most commonly used probe in FISH analysis is the SS18 break dual-colour signal probe designed to label sequences adjacent to SS18 on chromosome 18, and the recommended criterion for positive evaluation in FISH testing is the presence of unpaired (isolated) red and green signals. However, very few cases with an atypical pattern where the green signal is missing have been reported in the literature. We investigated the clinicopathological and immunohistochemical features of two cases with atypical patterns diagnosed with SS at our institution using the FISH method.
Methods: Two pathologists re-examined all Haematoxylin Eosin (H&E) and IHC stained slides. Cases using ZytoLight ® SPEC SS18 Dual Color Break Apart Probe in FISH testing were re-evaluated in Argenit Brand easyFISH Model software program. Clinicopathological data were analysed and followed up retrospectively.
Results: The cases were a 24-year-old male with a tumour located in the paraspinal region and a 28-year-old female with a tumour located in the lung, respectively. TLE-1 and VIMENTIN were stained diffusely and strongly positive in IHC studies. SS18 FISH tests showed an atypical pattern with isolated 5' signals in most cells. Clinically, the first case died approximately two years after diagnosis. The second case developed breast metastasis and still carries the disease.
Conclusion: SS is an aggressive tumour and SS18 rearrangement with FISH testing is important in the differential diagnosis of soft tissue tumours. Although one of these two cases with an atypical pattern showed unusual localization and high rates of poor differentiation, whether this variant is related to this pattern type can be understood with a larger case series.

E-PS-16-049
Prevalence of BRAF and RAS mutations and their association with clinicopathological factors in colorectal cancer: experience from our insitution
S. Moussa[1,2], Z. Eleuch[1,2], K. Khlifi[3], I. Belaid[3], L. Benfatma[3], S. Sakly[1,2], R. Badr[1,2], S. Mestiri[1,2], A. Bdioui[1,2], S. Hmissa[1,2]
[1]Sahloul University Hospital, Pathology Department, Sousse, Tunisia, [2]Faculty of Medicine of Sousse, Research Laboratory LR21 ES03, Sousse, Tunisia, [3]Farhat Hached Hospital, Medical oncology department, Sousse, Tunisia

Background & Objectives: Colorectal cancer (CRC) is a multifactorial disease caused by a combination of environmental and genetic factors, such as chromosomal abnormalities, epigenetic changes, and mutations. Epidermal growth factor receptor (EGFR)-signalling pathway is crucial to CRC development by activating RAS-RAF-MEK-ERK and PI3K-PTEN-AKT. RAS and BRAF are key genes in these pathways, present in 40–50% and 8–12% of CRCs, respectively. Both mutations are associated with poor prognosis in advanced disease.
We aim to determine BRAF and RAS mutation rates in CRC and their association with clinicopathological characteristics.
Methods: KRAS, NRAS, BRAF mutations was determined using PCR in total of 50patients with CCR over a period of 4years. Statistics were performed using SPSS software version20. Correlation between RAS and BRAF mutational profile and clinicopathological features were analysed by Chi-square or Fisher's exact test. *P*-value $\leq$0.05 considered statistically significant.
Results: Mean age was 54.49years, and sex-ratio was 1.9:1. Left/sigmoid localization (46.2%) and NOS subtype (84.6%) were the most frequent, with 82.7% being low-grade. Stage III/IV was reported in 86%. KRAS, NRAS, and BRAF were mutated in 27cases, 4cases (two with KRASmutated), and 2cases, respectively. KRAS and BRAF mutated were more frequent in men, unlike NRAS mutated. Left/sigmoid localization was most reported in KRAS/NRAS mutated. BRAF mutated cases exhibited balanced distribution between right and left colon. NOS subtype, low-grade and stage III/IV were most common in cases with all 3mutated genes. KRAS and NRAS mutations tended to be significantly associated with lymphatic emboli (p=0.055, p=0.075, respectively). KRAS mutated tended to be associated with perineural invasion (p=0.052) and budding (p=0.09). NRAS mutated tended to be associated with tumour grade (p=0.089) and tumour stage (p=0.089). No association was noted with BRAF mutated.
Conclusion: Our results are partly consistent with literature findings, though they are limited by sample size, lack of clinico-histological data, and by the retrospective methodology.

E-PS-16-050
Impact of TP53 and RB1 mutations on gene expression and biological pathways in extrapulmonary small cell neuroendocrine carcinomas
J. Hojný[1], N. Hájková[1], J. Dvořák[1], I. Stružinská[1], E. Krkavcová[1], E. Radová[1], P. Dundr[1], K. Pavlíčková[2], R. Matěj[2,1,3]
[1]First Faculty of Medicine, Charles University and General University Hospital in Prague, Department of Pathology, Prague, Czech Republic, [2]Thomayer University Hospital, 3rd Faculty of Medicine, Charles University, Department of Pathology and Molecular Medicine, Prague, Czech Republic, [3]University Hospital Kralovske Vinohrady, 3rd Faculty of Medicine, Charles University, Department of Pathology, Prague, Czech Republic

Background & Objectives: Extrapulmonary small cell neuroendocrine carcinomas (EP-SCNCs) are rare, highly aggressive neuroendocrine malignancies that arise in various anatomical sites. These tumours share histopathological and molecular features with pulmonary small cell carcinoma, particularly frequent TP53 and RB1 alterations, which drive genomic instability and tumour progression. However, their impact on the transcriptomic landscape of EP-SCNCs remains insufficiently characterized. This study explores the molecular consequences of TP53 and RB1 alterations, providing insights into tumour biology and potential classification refinements.
Methods: We performed rRNA-depleted whole RNA sequencing (RNA-Seq) on 109 EP-SCNC samples, stratified into four groups based on mutational profiles: TP53+RB1 co-altered (n=43), RB1-only altered (n=11), TP53-only altered (n=29), and tumours without TP53 and/or RB1 alterations (n=26). Differentially expressed genes were analysed using the Gene set Ordinal Association Test (GOAT) to identify biological processes associated with each subgroup.
Results: Tumours without TP53 and RB1 alterations exhibited upregulation of translation-related pathways, including cytoplasmic translation, ribosome biogenesis, and RNA metabolism, suggesting enhanced biosynthetic activity. TP53+RB1 co-altered tumours showed a significant downregulation of immune-related processes, indicating potential

immune evasion. TP53-only altered tumours had fewer deregulated pathways, primarily involving downregulation of nervous system processes, possibly reflecting neural de-differentiation. RB1-only altered tumours exhibited downregulation of epithelial development, cell differentiation, and tissue development pathways, suggesting a role for RB1 loss in altering cell fate determination.
Conclusion: Our findings reveal distinct transcriptional signatures associated with different TP53 and RB1 mutational profiles in EP-SCNCs. The upregulation of ribosomal and translational processes in tumours without these mutations, the suppression of immune pathways in TP53+RB1 co-mutants, and the distinct de-differentiation processes in RB1-only and TP53-only subtypes underscore the complex molecular landscape of these tumours. These transcriptomic insights provide a foundation for further multi-omics characterization of EP-SCNCs. This work was supported by the Ministry of Health, Czech Republic (MH CZ AZV NU22-03-00130 and DRO-VFN 64165).

External Quality Assessment (EQA) for Homologous Recombination Deficiency (HRD) testing in ovarian cancer: findings of a new IQN Path pilot scheme
A. Maqsood[1], V. Williams[1], F. Fenizia[2], N. Normanno[3], J. Fairley[4], T. Stockley[5], S. Chai[6], E. Rouleau[7], S. Patton[11]EMQN CIC, Manchester, United Kingdom, [2]IQN Path, Luxembourg, Luxembourg, [3]Associazione Italiana di Oncologia Medica (AIOM), Milan, Italy, [4]Genomics Quality Assessment (GenQA), Edinburgh, United Kingdom, [5]Canadian Biomarker Quality Assurance (CBQA), Toronto, Canada, [6]The Royal College of Pathologists of Australasia Quality Assurance Programs (RCPAQAP), St Leonards, Australia, [7]Gen&Tiss, Strasbourg, France

Background & Objectives: HRD is a genomic signature where cells lose their ability to repair double-stranded DNA breaks via the homologous recombination repair (HRR) pathway. HRD has been reported in approximately 50% of ovarian cancers and is a predictive marker for PARP inhibitor treatment.
A range of assays with different HRD scoring systems are used to identify HRD, and new diagnostic tests can have a high error rate when introduced into clinical practice presents. Five EQA providers collaborated under the umbrella of IQN Path to establish an international model for provision of EQA, to help assure quality of HRD testing for patients.
Methods: Fifty laboratories from 15 countries were selected to participate and sent three FFPE samples for HRD testing using their routine methodology. Clinical reports were returned for assessment of genotyping accuracy, result interpretation and clerical accuracy.
Results: Forty-four laboratories submitted results. Accuracy was high with only four instances where incorrect HRD status was reported (3.0%, 4/132). Clinical interpretation was also generally of a high standard with 88% of reports interpreting the result in relation to PARP inhibitor therapy.
However, the EQA did identify areas where improvements could be made and harmonisation is required. The main observations were as follows;

- There was variability in the terminology used to describe HRD status and score.
- The cut-off for the genomic instability score (GIS) was not stated in many cases and may be relevant for results close to the threshold.
- Laboratories using a method that included HRR panel analysis did not consistently report variants in HRR genes other than *BRCA1/BRCA2*.

Conclusion: This pilot EQA identified need for improvement and harmonisation in HRD reporting. The ongoing provision of EQA based on the model developed by IQN Path will promote high quality HRD testing through harmonisation of practice and publication of EQA results.

E-PS-16-053
The unreliability of neoplastic cell percentage visual estimation for molecular testing
J. Pimentel[1,2], J. Amaral[1], J. Maldonado[1], A.L. Alves[1], G. Fontinha[1,2], J. Gama[1], J. Madeira[1], V. Almeida[1,2], V. Sousa[1,2], R. Pina[1], A. Lai[1], R. Almeida[1], S. Petronilho[1]
[1]Unidade Local de Saúde de Coimbra, Pathology Department, Coimbra, Portugal, [2]University of Coimbra, Faculty of Medicine, Coimbra, Portugal

Background & Objectives: Molecular testing plays a crucial role in routine diagnostic pathology. Accurate determination of the neoplastic cell percentage (NCP) is essential to assess sample adequacy and for the correct interpretation of the results. This is routinely done by pathologists by visual estimation on H&E-stained slides, a highly subjective method.
Methods: We aimed to assess interobserver agreement in NCP estimation among pathologists in our centre. NCP, defined as the proportion of tumour cells relative to the total number of nucleated cells, was estimated on previously delineated tumour areas of 36 H&E-stained slides, corresponding to all cases which underwent molecular analysis from January/2024 to February/2024. These included 19 colon adenocarcinomas, 7 endometrial carcinomas, 5 melanomas, 2 ovarian carcinomas, and 3 prostate adenocarcinomas. All cases were independently evaluated by 8 specialists and 5 residents.
Results: The median difference between the highest and lowest estimated NCP per sample for all 36 cases was 50 (range 35–80). Accounting only for specialists' evaluations, median difference was 40 (range 20–80). When categorizing NCP at a 20% threshold (frequently used as the recommended minimum for NGS studies) we found that in 19/36 samples at least one pathologist (range: 1-6) estimated the NCP below 20%.
Conclusion: Our study corroborates previous findings that interobserver variation in NCP estimation is high, leading to potential misinterpretation of results and inadequate patient management. An important source of error lies in the difference between tumour area *versus* percentage of tumour cells. Indeed, upon revision of our four cases with higher discrepancies, 3 corresponded to colon adenocarcinomas with abundant mucin and/or dense lymphoplasmacytic infiltrate, and to a melanoma with extensive necrosis. Thus, careful macrodissection privileging tumour-rich areas, development of standardized methods of evaluation and, crucially, implementation of pathologists' training programs is vital. Furthermore, the development of digital automated analysis algorithms may improve the consistency of this assessment.

E-PS-16-054
An audit of non-small cell lung cancer molecular testing in Galway University Hospital
A. Nolan[1], A.M. Quinn[1]
[1]Galway University Hospital, Histopathology Department, Galway, Ireland

Background & Objectives: Testing for somatic mutations which drive lung cancer proliferation has allowed for significant advances in the treatment of the disease, in addition to PD-L1 testing for immune checkpoint therapy. We audited the reported non small cell lung cancers (NSCLC) of University Hospital Galway for 2024.
Aims: To audit the reported histology classification, molecular and PD-L1 status of samples, including cases classified as inadequate.

Methods: A list of all specimens diagnosed with NSCLC in 2024 was obtained from the laboratory information system. Information on specimen type, diagnosis and predictive marker testing was obtained from reports and molecular audit trails.
Results: 215 cases were reviewed. 51.7% (n=109) were male, and 49.3% (n=106) were female. 68.4% (n=147) were sampled from the primary tumour, 19.5% (n=42) from lymph nodes, and 12.1% (n=26) were metastatic deposits from other organs.
67.9% (n=146) were adenocarcinoma, and 26.5% (n=57) were squamous cell carcinoma. 86% (n=14) of adenocarcinoma specimens had molecular testing completed. Of the 21 specimens that did not, 24% (n=5) had insufficient material, 38% (n=8) had molecular testing done on a previous sample, and 38% (n=8) had no identifiable reason.
83.7% (n=180) of NSCLC had PD-L1 testing done. 16.2% (n=35) did not have PD-L1 testing, of these, 3.3% (n=7) had insufficient material, 7% (n=15) had testing done on previous specimens, and 6% (n=13) had no identifiable reason for not testing.
148 specimens had molecular testing in total. Of these, 52.7% (n=78) had a molecular alteration.
Conclusion: The majority of NSCLC undergo testing as per recommendations. 5.5% of adenocarcinoma specimens had no molecular testing without an identifiable reason.
6% of specimens had no PD-L1 done without identifiable reason.
This will be further investigated to assess if testing should have been completed for these specimens.

E-PS-16-056
Analysis of genomic alterations in metastatic and non-metastatic pleural mesotheliomas
A. Tan[1], S. Yurtsever Inan[1], Z. Sagnak Yilmaz[2]
[1]Manisa Celal Bayar University, Department of Pathology, Manisa, Turkey, [2]Karadeniz Technical University, Department of Pathology, Trabzon, Turkey

Background & Objectives: Molecular alterations are important in terms of both diagnosis, treatment and prediction of prognosis in cancer. Genomic changes in the pathogenesis of mesothelioma are copy number loss, gain and rarely mutations. In this study, we aimed to determine the differences between the genetic profiles of metastatic and non-metastatic mesotheliomas with the cohort in the ciobioportal dataset.
Methods: Since it was aimed to investigate genomic changes with more up-to-date data, three datasets consisting of a total of 60919 cases from 2021 and later were selected. 244 cases diagnosed with mesothelioma were included in the study. The most frequently mutated genes and the genes showing the most frequent copy number changes and structural changes were analysed in the series. Clinicopathological parameters and molecular changes were compared between the 195 metastatic and 49 non-metastatic case groups.
Results: The first five genes with the most frequent mutations in 244 cases were BAP1 (36.5%), NF2 (23%), TP53 (11.1%), SETD2 (10.7%) and LATS2 (7.8%); the first five genes with copy number changes were CDKN2A (32.4%), CKDN2B (31.1%), BAP1 (14.8%), TEK (4.5%) and NF2 (4.5%); and the first three genes with structural changes were BAP1 (4.1%), PBRM1 (1.6%) and NF2 (1.2%). The fourth and fifth most frequently mutated genes were LATS2 and TERT in non-metastatic group. The most frequent copy number alterations in the non-metastatic group showed some differences. Of the 195 cases, 99 had lung, 38 had bone, 32 had liver and 8 had brain metastases. In cases with bone and brain metastases, biphasic and sarcomatoid type was more common. NF2 mutation was significantly higher in cases with bone metastases. Microsatellite instability was seen at a higher rate in cases with liver metastases ($p<0.05$ $q<0.05$).
Conclusion: In this study, statistically significant and remarkable features were highlighted in whole genome analysis data in mesotheliomas, which are quite rare.

E-PS-16-058
A novel *SOX5::NTRK3* fusion in a patient with neuroendocrine tumour of the lungs: a case report
V. Koudelakova[1], G. Korinkova[1], H. Drimalova[1], D. Hrabos[1], O. Fischer[2], D. Skanderova[1]
[1]University Hospital Olomouc, Department of Clinical and Molecular Pathology, Olomouc, Czech Republic, [2]University Hospital Olomouc, Department of Pulmonary Diseases and Tuberculosis, Olomouc, Czech Republic

Background & Objectives: Low- and intermediate-grade neuroendocrine tumours of the lungs, commonly referred to as typical and atypical carcinoids, represent a rare but clinically significant subset of lung neoplasms. Neurotrophic tyrosine receptor kinase (NTRK) gene fusions are well-established oncogenic drivers found in various solid tumours. However, NTRK fusions are reported in only 0.5% of non-small cell lung cancers and are even rarer in pulmonary carcinoids.
Methods: We present the case of a 48-year-old female patient diagnosed with bilateral typical carcinoid tumours. Tumour biopsy samples underwent targeted next-generation sequencing (NGS) using both DNA- and RNA-based approaches. NGS was performed with the QIAseq Targeted DNA IO Panel TMB and QIAseq RNA Fusion XP - Solid Tumour Panel (Qiagen), with sequencing carried out on the SURFseq 5000 platform (GeneMind).
Results: RNA analysis identified a novel *NTRK3* fusion involving the *SOX5* (SRY-Box Transcription Factor 5) gene as the fusion partner. This oncogenic rearrangement fuses the 5′ region of *SOX5* with the 3′ region of *NTRK3*, preserving the entire tyrosine kinase domain of NTRK3. No additional clinically relevant mutations were detected. The patient is currently undergoing treatment with somatostatin analogue (Sandostatin).
Conclusion: This case report describes a novel SOX5::NTRK3 fusion in a pulmonary neuroendocrine tumour, expanding the known spectrum of *NTRK3* rearrangements. Its identification underscores the value of molecular profiling and may inform personalized treatment decisions. If standard therapy fails, NTRK inhibitors could offer a targeted alternative.

E-PS-16-059
Using next-generation sequencing (NGS) to further understand vascular anomalies: insights from the initial tests conducted at a Portuguese university hospital centre
N.J. Lamas[1,2], C. Vilasboas[1], C. Costa[1], F.E. Costa[1], L. Loureiro[3], J.R. Vizcaíno[1]
[1]Unidade Local de Saúde de Santo António (ULSSA), Anatomic Pathology Service, Genetics and Pathology Clinic, Porto, Portugal, [2]University of Minho, School of Medicine, Braga, Portugal, [3]Unidade Local de Saúde de Santo António (ULSSA), Vascular Surgery Service, Porto, Portugal

Background & Objectives: Next-generation Sequencing (NGS) has emerged as a powerful tool in the genetic analysis of malignant neoplasms, allowing a better understanding of the genetic landscape of the tumours and contributing to the diagnosis, prognostication and treatment planning. Similarly, NGS has also emerged as a powerful tool to further unravel vascular anomalies, which are developmental defects of the vasculature, encompassing a heterogeneous group of disorders. Vascular anomalies, which harbour considerable phenotypic and genetic heterogeneity, are more frequently sporadic and are associated with somatic mutations and/or double-hit mechanisms.
Methods: To share our initial experience with NGS testing for vascular anomalies we retrospectively collected cases from January 2022 until

now, which underwent routine NGS testing using the Oncomine Precision Assay (OPA) in the Genexus (Thermo-Fisher Scientific) platform or a 38-gene custom-made panel in the MiSeq (Illumina) platform.
Results: In this pilot study we were able to include 25 patients, with a slight preponderance of female patients and age ranging from 1 to 55 years old. The great majority of the cases were arteriovenous malformations (AVMs). Genetic abnormalities could not be identified in the majority of the cases. However, several cases harboured pathogenic variants of the PIK3CA gene. GNAQ pathogenic variants were also rarely identified.
Conclusion: Our experience highlights the utility of NGS in the holistic evaluation of the complex vascular malformations, paving the way for improved diagnostic accuracy and offering potential targets for personalized treatment strategies. Moreover, our findings emphasize the need for comprehensive NGS panels covering all potentially relevant genes in the context of vascular anomalies, allowing us to expand our understanding of the molecular mechanisms driving these complex disorders.

E-PS-16-060
Next-Generation Sequencing (NGS) in precision oncology: decoding the puzzle of primary vs. metastatic tumours
N.J. Lamas[1,2], C. Vilasboas[1], C. Costa[1], T. Santos[1], F.E. Costa[1], J.R. Vizcaíno[1]
[1]Unidade Local de Saúde de Santo António (ULSSA), Anatomic Pathology Service, Genetics and Pathology Clinic, Porto, Portugal, [2]University of Minho, School of Medicine, Braga, Portugal

Background & Objectives: The integration of advanced molecular techniques into Anatomical Pathology has revolutionized patient care by enabling personalized treatment strategies, prognostic predictions, and improved diagnostic accuracy. Next-generation sequencing (NGS) allows for the identification of unique genetic alterations and variants that may serve as distinguishing markers for primary versus metastatic cancers.
Methods: We present two cases where NGS played a pivotal role in diagnosing two synchronous lung adenocarcinomas and in distinguishing between primary lung versus metastatic colon adenocarcinoma.
Results: **Case 1:** A 64-year-old female smoker underwent a left lower lobectomy for two nodular lesions (3.5 cm and 1.5 cm). The histopathological analysis revealed two moderately differentiated adenocarcinomas harbouring architectural patterns with both similar and distinct features. NGS revealed an EGFR p.E746_A750del mutation in the 3.5 cm tumour and a KRAS p.G12C mutation in the 1.5 cm tumour, favoring two synchronous lung adenocarcinomas.
Case 2: A 77-year-old woman with a history of colorectal adenocarcinoma presented with a 6 cm nodule in the lung left upper lobe. The histopathological analysis showed an intestinal-type, TTF-1 negative adenocarcinoma. The medical team was initially uncertain about the metastatic nature of the lung lesion. Therefore, NGS analysis was performed on both the colon surgical specimen and lung tumour biopsy. The NGS study demonstrated that the same genomic variants of the *TP53*, *PIK3CA* and *NRAS* genes were present in both the colon and lung tumours. This finding strongly suggested that the lung tumour originated from the colon, supporting a diagnosis of metastatic colon cancer rather than a primary lung adenocarcinoma.
Conclusion: Both cases highlight the critical role of NGS in solving histopathological dilemmas. By identifying shared genomic alterations or showing distinct genetic profiles, NGS not only helped to clarify the tumour origin, but also helped to define therapeutic decisions, underscoring its potential in improving diagnostic accuracy and in defining patient-specific treatments.

E-PS-17 E-Posters Nephropathology

E-PS-17-001
Microscopic manifestation of kidney damage in the catastrophe of the century
D. Melemezoglu[1], K. Turgutalp[2], Y. Karabulut[1]
[1]Mersin University Faculty of Medicine, Pathology, Mersin, Turkey, [2]Mersin University Faculty of Medicine, Ephrology, Nefrology, Turkey

Background & Objectives: Turkey is located in an earthquake-prone region. On February 6, 2023, a devastating earthquake struck Kahramanmaraş, affecting approximately 14 million people. While extensive studies have been conducted on patient follow-up in basic and advanced life support, nephrology, and intensive care units, there is a lack of research on the renal histopathology of earthquake victims. This study aims to fill this gap in the literature by examining renal biopsy findings in affected patients.
Methods: Between February 6, 2023, and May 15, 2024, kidney needle biopsies from 40 earthquake victims aged 0-85, who presented to our clinic from 11 affected provinces, were retrospectively analysed. Demographic data such as age and gender, along with laboratory findings, were collected from the hospital information system.
Results: The mean age of the cases was 35.05 years, with 25 males and 15 females. The majority (24 cases) were from Hatay. A history of being trapped under rubble was present in 20% of cases. Histopathological examination revealed common findings such as tubulitis, tubular epithelial cell shedding, inflammatory cell infiltration, tubular casts, interstitial fibrosis, tubular atrophy, and glomerulosclerosis. Diagnoses included Proliferative Glomerulonephritis (10 cases), Focal Segmental Glomerulosclerosis (7), Necrotizing Crescentic Glomerulonephritis (6), Minimal Change Disease (3), Membranous Nephropathy (2), AA Amyloidosis (2), Membranoproliferative Glomerulonephritis (2), and Lupus Nephritis (2). Additionally, single cases of Hypertensive Nephropathy, Nephrocalcinosis, Pyelonephritis, Diabetic Nephropathy, and Cryoglobulinemic Glomerulonephritis were identified. Vascular changes, tubulointerstitial nephritis, and vasculitis secondary to hypertension were also observed.
Conclusion: Earthquakes are significant natural disasters that contribute to morbidity and mortality not only through direct trauma but also by disrupting the management of chronic conditions such as diabetes, hypertension, chronic obstructive pulmonary disease, and end-stage renal disease. This study highlights the renal complications resulting from various etiological factors, particularly crush syndrome, in earthquake victims.

E-PS-17-002
Thrombotic microangiopathy with extensive mesangiolysis as a first clinical presentation of plasmacytoma
Ž. Ledinek[1,2], N. Kojc[3], D. Šekoranja[3], Ž. Večerić-Haler[4,5]
[1]University Medical Centre Maribor, Department of Pathology, Maribor, Slovenia, [2]Faculty of Medicine, University of Maribor, Maribor, Slovenia, [3]Institute of Pathology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, [4]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia, [5]University Medical Centre Ljubljana, Department of Nephrology, Ljubljana, Slovenia

Background & Objectives: Thrombotic microangiopathy (TMA) is a rare condition characterized by systemic microthrombi causing end-organ ischemia. It can be primary, resulting from complement abnormalities, or secondary, associated with infections, malignancies, or connective tissue diseases. While renal impairment is common in multiple myeloma, TMA as its initial presentation is rare. We present a unique case where TMA was the first indication of plasmacytoma.

Methods: A 37-year-old male, who had recently recovered from infective myocarditis, underwent kidney biopsy due to a three-month history of nephrotic-range proteinuria and arterial hypertension. His kidney function was normal and urinary sediment was unremarkable. Immunoserological tests were within reference ranges. The complete blood count was normal, with no signs of systemic haemolysis. However, serum electrophoresis revealed a monoclonal IgG lambda. Kidney histopathology showed glomerular TMA with chronic mesangiolysis, while extraglomerular vessels remained unaffected. Immunofluorescence findings were minimal and nonspecific, and electron microscopy confirmed mesangiolysis with minimal podocyte effacement. The initial presumed aetiology was infection-triggered (myocarditis-related) TMA.
Results: Despite treatment with corticosteroids, complement inhibitors, and rituximab, proteinuria persisted, and kidney function deteriorated. A repeat biopsy revealed features of chronic TMA. Further imaging, including PET-CT and MRI, identified a metabolically active lesion in the right clavicle and surrounding soft tissue. Biopsy confirmed plasma cell proliferation with lambda light chain restriction, leading to a revised diagnosis of plasmacytoma. The patient was treated with daratumumab, bortezomib, and lenalidomide. At the last follow-up, two years after diagnosis, he remained clinically stable without progression of plasmacytoma.
Conclusion: This case highlights the diagnostic challenge of TMA as a rare initial manifestation of plasmacytoma. The absence of classical symptoms delayed the diagnosis, underscoring the importance of thorough follow-up and repeated investigations when renal dysfunction persisted despite initial treatment. Early recognition and appropriate management of underlying haematological malignancies in TMA cases can significantly improve patient outcomes.

E-PS-17-003
Clinicopathological analysis of 23 renal amyloidosis cases: a single-centre experience
H. Kandemir[1], D. Solakoglu Kahraman[1], D. Ayaz[1]
[1]Health Sciences University, Izmir Faculty of Medicine, Tepecik Training and Research Hospital, Medical Pathology, Izmir, Turkey

Background & Objectives: Renal involvement is a major cause of mortality in systemic amyloidosis. In renal amyloidosis, the glomeruli are the most common site of amyloid deposition, and nephrotic syndrome is the typical clinical presentation. Differentiation between AA and AL amyloidosis is performed using immunofluorescence (IF) and immunohistochemistry (IHC) techniques. Kidney biopsy plays a critical role in diagnosis and, by applying scoring and grading to biopsy findings, helps in predicting the clinical course of the disease.
Methods: This study includes all cases of biopsy-proven renal amyloidosis diagnosed between January 2018 and December 2023. The analyses involved light microscopy, Congo red staining under polarized light, IF, IHC for amyloid A, kappa, and lambda, and bone marrow examination. The classification, scoring, and grading of glomerular amyloid deposition were conducted according to the guidelines of Sen S et al
Results: A total of 23 cases of renal amyloidosis confirmed by biopsy were identified, of which 18 were primary and 3 were secondary. In two cases, the distinction between primary and secondary amyloidosis could not be established. The average age at diagnosis was 52.2 years. Edema was the most common presenting symptom. Secondary amyloidosis was predominant, accounting for 78.26% of cases. Among the secondary causes, tuberculosis, rheumatoid arthritis, and familial Mediterranean fever (FMF) were each found in five cases. Plasma cell neoplasia was detected in only one of the three primary amyloidosis cases. In two cases, differentiation between primary and secondary amyloidosis was inconclusive. The grading of renal biopsy findings correlated well with the class of glomerular involvement.
Conclusion: The combination of clinical history, IF, and IHC is essential for accurate amyloid typing. Grading of biopsy findings provides a detailed guide for assessing disease severity based on a broad range of morphological features and biochemical values. Correct amyloid typing is also crucial for selecting appropriate treatment strategies.

E-PS-17-004
Histopathological scoring and staging in renal aa amyloidosis: correlation with clinical parameters and prognostic implications
B.B. Senay[1], G. Gumrukcu[1], B. Boynuegri[2], M. Dogan[1]
[1]University of Health Sciences, Haydarpasa Numune Training and Research Hospital, Pathology, Istanbul, Turkey, [2]University of Health Sciences, Haydarpasa Numune Training and Research Hospital, Nephrology, Istanbul, Turkey

Background & Objectives: AA amyloidosis is the predominant subtype of systemic amyloidosis in developing countries and frequently involves the kidneys, resulting in proteinuria and progressive renal dysfunction. However, the prognostic utility of standardized histopathological scoring systems remains understudied. The aim of this study is to evaluate renal AA amyloidosis cases using a structured histologic scoring and staging system and to correlate pathologic findings with clinical parameters and renal outcomes.
Methods: This retrospective cohort included 74 renal biopsies diagnosed as AA amyloidosis between 2011 and 2025. Biopsies were assessed via light microscopy, immunofluorescence, and immunohistochemistry. Histopathological staging was performed using the Renal Amyloid Prognostic Score (RAPS), as described by Sen and Sarsık, incorporating glomerular, vascular, and interstitial amyloid deposition, as well as inflammation, fibrosis, and glomerulosclerosis. The cohort included five biopsies from transplant kidneys, and four biopsies were second procedures performed on previously diagnosed patients (including one transplant case). Clinical data were available for 69 patients; five were assessed solely based on pathological parameters. Renal survival was defined as the time from biopsy to initiation of renal replacement therapy (RRT).
Results: Of the 74 patients, 68% were male. The most common underlying disease was Familial Mediterranean Fever (41%). RAPS staging revealed: Stage 1 (1%), Stage 2 (38%), and Stage 3 (57%). End-stage renal disease developed in 25 patients (36%), who had higher RAPS stages and more severe baseline renal impairment. Glomerular amyloid load correlated with proteinuria, while interstitial fibrosis, inflammation, and vascular/interstitial amyloid deposition were associated with lower eGFR values.
Conclusion: Structured histopathological staging in renal AA amyloidosis reflects the extent of renal damage and correlates with clinical severity at diagnosis. This approach may support risk stratification and guide clinical management, particularly in regions where AA amyloidosis is prevalent.

E-PS-17-005
Clinicopathological characteristics of IgA nephropathy and their and correlation with MEST C scores: a single centre cohort study from Sri Lanka
C. Wijegunarathna[1], H.D. Wijesinghe[2], C. de Silva[2]
[1]National Hospital of Sri Lanka, Colombo, Sri Lanka, [2]Faculty of Medicine, University of Colombo, Colombo, Sri Lanka

Background & Objectives: IgA nephropathy (IgAN) is a poorly studied disease in a Sri Lankan setting and the value of MEST-C score in the Sri Lankan population has not been elucidated. The objective was to characterize clinical presentations and morphological patterns of

IgAN in a cohort of patients in Sri Lanka and correlate the clinical parameters with MEST-C scores.
Methods: 106 cases of IgAN diagnosed at a tertiary care centre from 2019 to 2024 were studied. Clinical data was retrieved from requested forms. Renal biopsies were reviewed by two pathologists for assessment of morphological patterns and MEST-C score. Correlation between clinical parameters and MEST-C score were assessed with multivariate regression analysis.
Results: Majority were male (n=63;59.4%); mean age 36.3 years (SD 12.7, range 14-69 years). Most had proteinuria (n=104,98.1%); sub-nephrotic (n=55;53.8%), nephrotic (n=49;45.7%) and haematuria (n=90;84.9%) microscopic (n=70;77.7%, macroscopic (n=20;22.3%) at presentation. Ten (9.8%) presented with rapidly progressive glomerulonephritis. Majority (n=58;54.8%) were CKD stage 3 or above. MEST-C scores were M1(n=97;91.5%), E1 (n=42;39.6%), S1 (n=37;34.9%), C1(17;16%) C2 (09;8.5%), T1 (32;30.2%) T2 (26;24.5%).
MEST-C sum score ≥3 correlated with eGFR(p=0.024) and serum creatinine (S.Cr)(p=0.034)
T score correlated with eGFR(p=0.012), C (p=0.027) and T (0.019) score with S.Cr, M(p=0.031) and E (p=0.029) scores with serum C3 level, serum albumin level with S (p=0.020). C3 staining intensity correlated with T(p=0.017) and eGFR(p=0.025).
Conclusion: Clinical presentations and the pattern of injury in IgAN matched other countries. However, majority were CKD stage ≥3 at presentation. The most important predictor of eGFR was T score. Glomerular C3 deposition appears to play a prognostic role.

E-PS-17-006
Beyond what we know: the role of glomerular C4d staining in transplant glomerulopathy
P.D. Adolewska[1], S. Quinones[1], M. Abad Vintimilla[1], M.M. Petrino[1], L. Yébenes Gregorio[1], J. García Aguilar[2], E. González García[2], C. Jiménez Martín[2], M. López Oliva[2], E. García Fernández[1]
[1]La Paz University Hospital, Pathology, Madrid, Spain, [2]La Paz University Hospital, Nephrology, Madrid, Spain

Background & Objectives: Late antibody-mediated rejection (AMR) diagnosis is an ensemble of criteria based on the presence of peritubular C4d (C4dptc), histological findings and donor-specific antibodies (DSA). However, the significance of C4d expression in glomerular capillaries (C4dgcap) and the mesangium (C4dgmes) remains undefined. The aim of this study is to review the transplant glomerulopathy (TG), highlighting AMR cases, and the association between C4dgcap expression and DSA.
Methods: We reviewed the TG biopsies from May 2023 to December 2024, finding 70 cases. Cellular rejection, membranous nephropathy and lupus nephritis were excluded, a total of five cases.
Results: Among 65 TG biopsies, 24.6% (16/65) were diagnosed with AMR. In non-AMR cases (46/65, 70.7%), 60.9% (28/46) showed an absolute lack of C4d staining in the glomerular compartment. C4d positivity at the glomerular compartment (18/46, 39.1%) was subcategorized into C4dgcap in 15 cases (15/46, 32.6%), with a range of expression between 2 to 35% and a weak-moderate intensity and C4dgmes in six cases (6/46, 13%), between 5 to 50% with a moderate intensity. Regarding the positive DSA (30/65, 46.1%), 40% presented a positive C4d staining (12/30), all of which were C4dcap, with a range of expression between 5 to 100% and predominantly moderate intensity. Only one case exhibited C4dgmes staining (25%, weak intensity). Among DSA-negative cases (30/65, 46.1%), 15 exhibited glomerular C4d staining (15/30, 50%), C4dgcap was predominantly weak (between 2 to 25%) except for two cases which were AMR with stronger staining (~80%). Additionally, six cases displayed mesangial staining (between 5 to 50%, moderate intensity).
Conclusion: C4dgcap staining was more prevalent and intense in DSA-positive cases, whereas DSA-negative and AMR-negative cases showed lower expression staining in both intensity and percentage of involvement. In contrast, C4dgmes was observed in a significant proportion (mean 40%) of DSA-negative cases with moderate intensity, though its significance remains unclear.

E-PS-17-007
The kidney and substance abuse – a toxic relationship
M.C. Nackenhorst[1], M. Koeller[1], J. Klaeger[1], N. Kozakowski[1], E. Mueller-Moré[2], H. Regele[1]
[1]Medical University of Vienna, Department of Pathology, Vienna, Austria, [2]Landeskrankenhaus Salzburg, University Clinic for Internal Medicine I, Salzburg, Austria

Background & Objectives: A 37-year-old female patient with a history of multi-drug abuse, and chronic hepatitis C presented to the department of nephrology with proteinuria and chronic kidney disease (CKD G3A2). The patient was under methadone substitution therapy (Substitol) for her multi-drug abuse. Blood pressure at time of presentation was 165/100 mmHg. Her baseline creatinine was within normal range until 2022 and then slowly increased over the course of two years to 1.83 mg/dl (eGFR was 37 ml/min/1,73m^2 (CKD EPI)) at current presentation. Proteinuria rose to 0.7 mgProtein/mgCreatinine during the same timeframe.
Methods: A renal biopsy was performed for investigation of progressive renal dysfunction.
Results: Histology revealed a glomerulopathy with membranoproliferative pattern of injury with conspicuous vacuolization of mesangial matrix and endocapillary cells. There were no immune deposits detected by immunohistochemistry. Electron microscopy confirmed mesangial, endothelial and also podocytic vacuoles that sometimes contained amorphic or lamellar electron dense material. This pattern was suggestive of Polyvinylpyrrolidone (PVP)-associated glomerulopathy.
Conclusion: PVP is a hydrophilic polymer widely employed as a carrier in pharmaceutical and biomedical preparations and has been previously described as a cause of CKD in patients after intravenous misuse of methadone syrup. The source of PVP in our case, however, was enigmatic as EU regulations banned PVP from methadone preparations in 2014. Upon further inquiry, the patient eventually admitted to having dissolved Oxazepam (Anxiolit forte) and Flunitrazepam (Rohypnol) tablets for intravenous injection. The manufacturer confirmed that both drugs contain PVP, thus making these the likely source of PVP. Renal function in our patient remained stable at an eGFR around 35 ml/min/1,73m^2 under supportive therapy with RAS and SGLT2 inhibitors.
To our knowledge this is the first described case of an intravenous injection of dissolved Oxazepam and Flunitrazepam tablets as a source of PVP causing CKD.

E-PS-17-009
Membranous glomerulonephritis superimposed on diabetes mellitus: description of 3 cases
J. Alvarez Figueroa[1], L. Espinosa[1], A. Florez[1], R. Andrade[1], P. Castro-Quiroga[1], S. Hernandez[2]
[1]Hospital Universitario Fundación Santa fe de Bogotá, Pathology, Bogotá, Colombia, [2]Universidad de Los Andes, Bogotá, Colombia

Background & Objectives: Membranous glomerulonephritis (MGN) is a disease characterized by subepithelial immune deposits with thickening of the glomerular capillary walls. We present 3 cases of MGN in patients with type 2 diabetes mellitus who presented with nephrotic proteinuria, where renal biopsy enabled a precise diagnosis.

Methods: The medical records of three patients with type 2 diabetes mellitus and progressive renal insufficiency with nephrotic proteinuria were retrospectively analysed. Renal biopsy was performed to assess suspected diabetic nephropathy and evaluate the possible coexistence of another glomerulopathy. Light microscopy (haematoxylin-eosin, PAS stain, Masson's trichrome, silver methenamine), immunofluorescence, and electron microscopy studies were conducted for a conclusive diagnosis.
Results: Case #1: A 42-year-old male with insulin-requiring type 2 diabetes mellitus and subnephrotic proteinuria progressing to nephrotic range, with generalized oedema. Biopsy showed findings consistent with MGN and class IV diabetic nephropathy.
Case #2: A 64-year-old male with type 2 diabetes mellitus, hypertension, dyslipidemia, and nephrotic-range proteinuria with renal deterioration. Biopsy confirmed MGN and class IIb diabetic nephropathy.
Case #3: A 69-year-old male with type 2 diabetes mellitus, hyperuricemia, and benign prostatic hyperplasia. Persistent subnephrotic proteinuria without evidence of diabetic retinopathy. Biopsy identified MGN and class I diabetic nephropathy.
Conclusion: These cases emphasize the importance of renal biopsy in diabetic patients with significant proteinuria and atypical features. The coexistence of MGN and diabetic nephropathy highlights the complexity of differential diagnosis. The identification of other glomerulopathies in diabetic patients allows for more targeted and specific treatments. It is crucial to evaluate nephrotic proteinuria in patients without diabetic retinopathy and with unusual clinical findings, avoiding the assumption that diabetic nephropathy is the sole cause of renal impairment.

E-PS-17-011
Relationship between clinico-biological parameters, histological semi-quantitative scores and T lymphocyte subsets in lupus nephritis
I.D. Caruntu[1], T. Azoicai[2], S.E. Giusca[1], E.R. Avadanei[1]
[1]University of Medicine and Pharmacy "Grigore T. Popa", Department of Morphofunctional Sciences I, Iasi, Romania, [2]CHU Helora, Service de Rheumatology, Mons, Belgium

Background & Objectives: Renal biopsy, the gold standard for lupus nephritis (LN) diagnosis, allows classification and assessment of disease activity and chronicity status. Our study focuses on the relationship between clinico-biological and histological characteristics in LN, aiming for better disease course prediction.
Methods: We analysed 53 LN cases confirmed by renal biopsy, classified as class II (2 cases), III (4 cases), IV (19 cases), V (22 cases), and VI (6 cases). Clinico-biological parameters were collected and rSLEDAI was calculated. Histological assessment used semi-quantitative scores for renal corpuscle (RC_S) and tubulo-interstitial component (TI_S). T lymphocyte subsets were immunohistochemically marked and counted. Data were statistically analysed.
Results: Among LN classes, statistical analysis showed significant differences in clinico-biological parameters (serum creatinine, eGFR [CKD-EPI], serum C3 complement, triglycerides) and semi-quantitative scores (RC_S, TI_S) (ANOVA test). We found: a significant, positive, moderate correlation between RC_S and rSLEDAI, but no significant correlation between TI_S and rSLEDAI (Pearson's correlation); no significant relationships between RC_S and TI_S, respectively, and CD4+ T lymphocyte counts (global, intraglomerular, periglomerular, and interstitial) (Spearman's correlation); a significant, positive, strong correlation between RC_S and total and interstitial CD8+ T lymphocytes, and a moderate correlation with periglomerular and intraglomerular ones (Spearman's correlation); a significant, positive, moderate correlation between TI_S and CD8+ lymphocytes in all considered areas (total, intraglomerular, periglomerular, and interstitial) (Spearman's correlation).
Conclusion: The correlative analysis of clinico-biological parameters, paraclinical and morphological indexes of activity and chronicity and T lymphocyte subsets supports the variability among LN classes. The intensity of glomerular and interstitial changes is influenced by CD4+ and CD8+ T lymphocytes, which act in the pathogenic mechanism of LN. Disease course is directly related to the severity of histological lesions. Refining clinico-pathological criteria for disease staging allows for better prognostic assessment and optimal treatment decisions.

E-PS-17-012
Role of endocapillary, extracapillary and interstitial inflammatory cells in development of IgA nephropathy
Y. Ananiev[1], N. Terzieva[1], M. Nikolova[2], I. Erkanyan[3], E. Tilkiyan[3]
[1]Medical Faculty, Trakia University, Department of General and Clinical Pathology, Forensic Medicine, Deontology and Dermatovenerology, Stara Zagora, Bulgaria, [2]University Hospital St. Iv. Rilski, Medical University, Clinic of Nehrology, Sofia, Bulgaria, [3]Second Department of Internal Diseases, Medical Faculty, Medical University of Plovdiv, Clinic of Nephrology, University Hospital "Kaspela", Plovdiv, Bulgaria

Background & Objectives: IgA nephropathy (IgAN) is the most common glomerulonephritis worldwide and there are a lot of mechanisms that drive progression. The aim of our study is to investigate endocapillary, extracapillary and interstitial inflammatory cells in development of IgAN.
Methods: We investigated 39 patients with IgAN and compared the composition of inflammatory cells in the crescents, endocapillary loops and interstitium using immunohistochemistry markers against T-lymphocytes, macrophages and dendritic cells. The correlation between the number of different cells and location and patient clinicopathological data were evaluated.
Results: Immunohistochemistry analyses demonstrated that predominant cellular type in three locations were CD68+macrophages, followed by CD8+ and CD4+T-lymphocytes (18.4+/-4.2 vs. 6.8+/-3.8 vs. 4.1+/-2.1 cells/mm^2, respectively). Cases with high endocapillary infiltration with CD68+macrophages had higher infiltration with CD68+ and CD83+cells in the crescents (χ^2=7.63, p=0.044). In addition, the infiltration with CD68+macrophages and CD83+dendritic cells were higher in patients with class IV compared to class III and V (by Haas classification) (χ^2=1.29, p=0.002). Finally, CD8+T-lymphocytes in interstitium were correlated with the level of erythrocyturia and proteinuria.
Conclusion: Our results suggest the relationships between different inflammatory cells and their localizations are "key factor" involved in development of IgAN and could be strong predictor of disease progression.

E-PS-17-014
Analysis of Serum Amyloid P component (SAP) and Apolipoprotein E (ApoE) expression in renal AL amyloidosis
S. Khutanthong[1,2], P. Paueksakon[1]
[1]Vanderbilt University Medical Centre, Pathology, Microbiology and Immunology, Nashville, USA, [2]Naresuan University, Pathology, Phitsanulok, Thailand

Background & Objectives: Our previous study has identified that AL-kappa (AL-κ) presents with higher serum creatinine and includes

a higher subset of cases with PAS-positive amyloid deposits (1). The serum amyloid P component (SAP) and Apolipoprotein E (ApoE) are signature proteins in all types of amyloidosis. This study aims to evaluate differences in the immunohistochemical expression of amyloid-associated proteins (SAP and ApoE) between AL-κ and AL-lambda (AL-λ).
Methods: Kidney biopsies previously diagnosed as AL-κ or AL-λ amyloidosis were retrospectively reviewed. Cases were selected from a prior study and included only those with at least four open glomeruli and adequate tissue for immunohistochemical staining. PAS staining status was recorded, and immunostaining for ApoE and SAP was performed. Glomerular staining was evaluated using a semiquantitative scale from 0 to 3+.
Results: A total of 85 cases were analysed: 16 AL-κ and 69 AL-λ. PAS-positive amyloid was identified in 50.0% of AL-κ cases and 18.8% of AL-λ cases. ApoE positivity was observed in 81.3% of AL-κ and 98.6% of AL-λ cases, with a statistically significant difference ($p = 0.022$). SAP positivity was noted in 75.0% of AL-κ and 79.7% of AL-λ cases ($p = 0.94$). When comparing PAS-positive and PAS-negative groups across both types, no significant differences were found in ApoE ($p = 0.45$) or SAP ($p = 1.00$) expression.
Conclusion: ApoE and SAP are frequently expressed in glomerular deposits of both AL-κ and AL-λ amyloidosis. While ApoE staining is significantly more frequent in AL-λ, PAS staining status does not correlate with differential expression of ApoE or SAP. We speculate that peptide ApoE interact more with λ than κ light chain. However, further studies including mass spectrometry are needed to better understand the underlying mechanisms contributing to the differences in ApoE and SAP expression between AL-κ and AL-λ amyloidosis.

E-PS-17-015
Histopathological evaluation in *post-mortem* renal biopsies of patients with COVID-19 and comorbidities: a case-control study
E. Morais de Castro[1], S. Hamad Mehanna[2], M. Pezzini Arantes[2], J. Wolff Barretto[3], S. Ossamu Ioshii[2], H. Machado de Sousa Proença[4], L. Noronha[2]
[1]Universidade Federal do Paraná, Curitiba, Brazil, [2]Pontifícia Universidade Católica do Paraná, Curitiba, Brazil, [3]Faculdades Pequeno Príncipe, Curitiba, Brazil, [4]Hospital do Rim, São Paulo, Brazil

Background & Objectives: Among the main systemic complications of severe cases of COVID-19, there is acute kidney injury. The objective of this study is to describe the histopathological changes in *post-mortem* kidney biopsies from patients who died as a result of the disease caused by SARS-CoV-2. These changes were evaluated through a case-control study conducted in a tertiary hospital in Brazil.
Methods: The study group, called 'COVID', consisted of kidney biopsy samples obtained from deceased patients with COVID-19, with a "Control" group included for comparison. The samples were selected based on sex, age and similar comorbidities, with emphasis on diabetes mellitus (DM) and systemic arterial hypertension (SAH). The morphological evaluation was carried out by pathologists using pre-established criteria, with glomerular, tubulointerstitial and vascular characteristics among the parameters.
Results: Tubular atrophy and interstitial fibrosis, markers of chronic kidney injury, were observed with equal frequency in both groups, probably due to the initial pairing of the samples. Regarding DM, the findings mentioned are in line with what would be expected from chronic exposure to hyperglicemia. In relation to SAH, the main identification was vascular damage, particularly arteriolosclerosis/arteriosclerosis. Acute tubular injury was the most observed feature in patients in the COVID group, probably related to ischemic damage.
Conclusion: The research demonstrated that the main change identified in the renal parenchyma of patients with COVID-19 is acute tubular injury, a fact expected considering the context of severe systemic ischemia to which these patients are subjected, with the other findings being consequences of chronic damage, mainly due to systemic diseases such as DM and SAH.

E-PS-17-016
SARS-CoV-2 infection could act as a trigger for TMA in patients with an underlying complement defect. Case report
M.T. González-Serrano[1], I. Burgos Borrego[2], I. Sánchez Ramírez[1], R. Sánchez Sánchez[1], F. Leiva-Cepas[3]
[1]University Hospital Reina Sofía, Pathology, Córdoba, Spain, [2]University Hospital Reina Sofía, Nephrology, Córdoba, Spain, [3]University of Córdoba/University Hospital Reina Sofía, Pathology, Córdoba, Spain

Background & Objectives: TMA is an endothelial lesion present in a wide range of serious diseases with very different aetiologies, manifested by microangiopathic haemolytic anaemia, thrombocytopenia and renal and neurological symptoms.
A 25-year-old woman was admitted with TMA and acute kidney injury (AKI), suggestive of atypical haemolytic uremic syndrome (aHUS). Early treatment with ravulizumab was initiated.
Methods: During follow-up, the patient's renal function persisted, with urinary abnormalities (Alb/CrCl ratio 536 mg/g, microhematuria), C3 consumption, and undetectable haptoglobin levels despite continuing ravulizumab therapy.
Results: Renal biopsy (RB) was performed. 29 glomeruli were found, 3 of which were sclerosed without crescents and frequent membrane ruptures. Presented a very mild proliferative component at the mesangial level, global and fairly diffuse endotheliosis with areas of mesangiolysis and microaneurysms, and occasional microthrombi. Immunofluorescence was negative for all antiserums. Ultrastructurally, exhibited intense endothelial degeneration without deposits. Diagnosis was glomerular and arteriolar thrombotic microangiopathy with acute and chronic findings in a well-preserved renal parenchyma. Genetic study was performed, revealing a pathogenic variant of complement factor H (CFH), preventing the expression of factor H (FH) proteins, in addition to risk polymorphisms for aHUS in the monocyte chemoattractant protein (MCP) gene.
Conclusion: Hypotheses have been developed that propose that "two triggers" are required for the development of aHUS, such as the combination of genetic background and a triggering factor. In our case, the patient meets both criteria since she presents a genetic factor, such as the presence of a genetic mutation that inactivates the gene encoding CFH, preventing the expression of FH proteins, and risk polymorphisms for aHUS in the MCP gene; and a triggering factor, such as COVID infection. There is data in the literature that supports the theory that SARS-CoV-2 infection could act as a trigger for TMA in patients with an underlying complement defect, although the mechanism that causes it is unknown.

E-PS-17-017
Subpopulations of T cells in acute cellular rejection of kidney transplant - pilot study
P. Dolonga[1], P. Senjug[2], A. Dunatov Huljev[1], L. Zibar[3], D. Galesic Ljubanovic[4], M. Glavina Durdov[5]
[1]University Hospital of Split, Pathology, Split, Croatia, [2]University Hospital of Zagreb, Pathology, Zagreb, Croatia, [3]University of Zagreb School of Medicine, Nephrology, Zagreb, Croatia, [4]University of Zagreb School of Medicine, Pathology, Zagreb, Croatia, [5]University of Split School of Medicine, Pathology, Split, Croatia

Background & Objectives: The interstitium of a healthy kidney contains scattered mononuclear cells. In acute T-cell mediated rejection

(ATCMR) following kidney transplantation, the interstitium becomes oedematous and infiltrated with lymphocytes, creating a site of intense cellular immune activity. Regulatory FoxP3+ T lymphocytes may play a role in moderating the inflammatory response, potentially exerting an anti-inflammatory effect. We aimed to investigate if the immune response in ATCMR depends on CD4/CD8 ratio and the presence of the FoxP3 regulatory lymphocytes, and if there was influence on graft survival.

Methods: Kidney transplant biopsies were analysed from 25 patients, with a median time from transplantation to biopsy of 3 months. The biopsies were immunohistochemically stained for CD4, CD8, and FoxP3. T cell counts were quantified relative to the cortex area.

Results: The median age of patients was 55 years, with creatinine levels of 147.0 µmol/L at biopsy and 125.5 µmol/L one year later. Graft function was maintained in 91.3% of patients, while 2 patients (8.7%) died. The median CD4/mm² was 81.11, CD8/mm² was 49.34, and the CD4/CD8 ratio was 1.86. FoxP3+ cells were found in 2 patients (8%). Patients with graft dysfunction were 20 years older and had higher creatinine levels at biopsy compared to those with normal graft function (p=0.049). Those with graft loss had nearly double the number of CD4 cells. FoxP3-positive patients had higher creatinine levels one year later (p=0.044). A positive correlation was found between age and the CD4/CD8 ratio (ρ=0.560, p=0.004), and between CD4 and CD8/mm² (ρ=0.608, p=0.001).

Conclusion: Our findings suggest that CD4-mediated immunity is more prevalent in older patients, potentially increasing their risk of graft dysfunction. The findings regarding FoxP3 cells differ from the limited literature, which suggests better outcomes in FoxP3 infiltrated samples, emphasizing the need for further, more comprehensive investigations.

E-PS-17-018

C3-dominant glomerulonephritis with membranoproliferative pattern secondary to chronic Q

C. Padrão[1], M. Moreira[1], J. Tinoco[1], R. Theias[1]
[1]Hospital Prof. Dr. Fernando Fonseca - ULSASI, Anatomia Patológica, Amadora, Portugal

Background & Objectives: Membranoproliferative glomerulonephritis is a pattern of glomerular injury on light microscopy characterized by proliferative endocapillary lesions in glomerulos tuft and double contour of the glomerular basement membrane. The classification of MPGN is pathophysiology-based and dependent on immunofluorescence staining.

Methods: We present a case of a 62-year-old man with progressive kidney dysfunction, haematuria, and proteinuria. His medical history consist of chronic kidney disease, hypertension, and a biological aortic prosthesis complicated by infectious endocarditis due to Cardiobacterium hominis, diagnosed and treated with antibiotics 2.5 years previously. Additionally, he was diagnosed with chronic Q fever one month before referral to Nephrology department, and he started doxycycline therapy at that time.

Results: A renal biopsy revealed hypersegmented glomeruli with mild to moderate expansion of the mesangial matrix, slight mesangial cellularity increase, and marked endocapillary hypercellularity, mainly from mononuclear cells. Silver staining showed double segmental contours in the basement membrane, interspersed with oedema and rare mononuclear cells. Two glomeruli exhibited capillary wall lysis, fibrinoid necrosis, and cellular crescents. Tubules and interstitium showed mild degenerative and reactive changes. Arterioles and arteries demonstrated mild hyalinosis and fibroplasia, without vasculitis.

Immunofluorescence revealed dominant granular and pseudolinear deposits in the capillary wall and mesangium for C3 (++++),with some deposits of IgM, C1q, and light chains kappa and lambda. Immunohistochemical testing for C4d was positive. It was assumed a C3-dominant glomerulonephritis with a membranoproliferative pattern, secondary to chronic Q fever.

The patient started immunosuppressive therapy while continuing antibiotics. His renal function stabilized, and immunosuppressive treatment was gradually reduced.

Conclusion: Q fever, caused by Coxiella burnetii, can rarely progress to chronicity specially in patients with cardiac anomalies or prosthetic devices. There are only a few reported cases of Q fever in which patients developed glomerulonephritis and even rarer cases a membranoproliferative glomerulonephritis.

E-PS-17-019

The intensity of glomerular C3 deposition predicts IgA nephropathy progression

V. Sousa[1,2,3], J. Venda[4], B. Ferreira[4], A. Henriques[4], P. Castro[4], R. Leal[4], A. Galvão[4], R. Alves[4], L. Rodrigues[4]
[1]Institute of Anatomical and Molecular Pathology, Faculty of Medicine of the University of Coimbra, Coimbra, Portugal, [2]Pathology Service, ULS Coimbra, Coimbra, Portugal, [3]CIMAGO – Research Centre for Environment, Genetics and Oncobiology, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, [4]Nephrology Department, ULS Coimbra, Coimbra, Portugal

Background & Objectives: IgA nephropathy (IgAN) is the most common primary glomerulonephritis, with a variable course, leading to end-stage renal disease in 20-40% of patients within 20 years.

KDIGO emphasizes the role of complement activation in IgAN progression. Despite well-documented histological deposition, clinical correlations remain limited. We assessed the prognostic value of C3 deposit intensity in initial IgAN biopsies at our centre.

Methods: We retrospectively analysed biopsy-proven IgAN cases (1998–2018) with at least 5 years of follow-up. A Pathologist and Nephrologist reviewed biopsies per Oxford criteria. C3 deposition was semi-quantitatively scored (1+, 2+, 3+) by a blinded Pathologist using immunofluorescence.

Results: Of 108 patients, 103 (95%) had C3 deposition and were categorized by intensity: mild (1+, n=46), moderate (2+, n=34), and high (3+, n=23). No significant differences were found in eGFR, proteinuria, or MEST-C score. However, renal survival was significantly shorter in the high-intensity group (10 years) than in the moderate (16 years) and mild (23 years) groups (Log-Rank test, p=0.029).

In a multivariate logistic regression model adjusted for clinical (age, eGFR, 24h proteinuria) and histological variables (C3 groups, MEST-C components E, S, T, and C), predictors of RRT included lower eGFR at T0 (p<0.001), high-intensity C3 deposition (p=0.006), and MEST component E (p=0.034). Cox regression showed a higher risk of RRT in patients with high-intensity deposits vs. mild (HR 2.93, 95% CI: 1.075–4.808, p=0.028). Lower eGFR at T0 (HR=0.971, 95% CI: 0.957–0.978, p<0.001) and endocapillary hypercellularity (HR=2.909, 95% CI: 1.068–6.384, p=0.012) were also independent predictors of earlier RRT initiation.

Conclusion: Our study highlights the prognostic importance of C3 deposition intensity in IgAN. High-intensity deposits were significantly associated with an increased risk of progression to RRT, which could serve as a biomarker for risk stratification and targeted therapies.

E-PS-17-020

Unmasking the unexpected: incidental discovery of renal cell carcinoma in a transplant biopsy for rejection

A.D. Timofte[1], S.E. Giusca[1], A. Covic[2], A. Covic[2], I.D. Caruntu[1]
[1]"Grigore T. Popa" University of Medicine and Pharmacy, Department of Morphofunctional Sciences I, Iași, Romania, [2]"Grigore T. Popa" University of Medicine and Pharmacy, Department of Medicine II, Iași, Romania

Background & Objectives: Renal transplant-associated malignancies are rare; their development is most often a consequence of immunosuppression, and they pose a diagnostic challenge by overlapping with allograft pathology. We present a 46-year-old female transplant recipient whose renal biopsy, performed for clinical allograft dysfunction, revealed an incidental malignancy.
Methods: A renal biopsy was performed due to allograft dysfunction. The specimen was processed for light microscopy using routine and special staining (H&E, PAS, trichrome, methenamine silver) and immunofluorescence (anti-Cd4). Microscopic examination for allograft dysfunction focused on glomerular, tubular, interstitial, and vascular changes according to Banff 2022 criteria. Immunohistochemical markers (CK7, CD10, CD117, vimentin and AMACR) were employed for accurately diagnose origin and histological tumour type.
Results: Histopathological examination showed: chronic active T-cell mediated rejection grade 1B, based on the following Banff lesion scores: 3 for total inflammation (ti), 2 for inflammation in area of interstitial fibrosis and tubular atrophy (i-IFTA), and 3 for tubulitis (t), associated to I-IFTA, based on Banff lesion score 3 for tubular atrophy (ct). Additionally, a small patch (less than half of the width of biopsy) of epithelial tumour proliferation was incidentally discovered, exhibiting a histological pattern suggestive of clear cell renal cell carcinoma. The unexpected neoplastic component was further evaluated by immunohistochemistry, revealing intense CK7 and vimentin positivity; CD10, CD117 and AMACR negativity. This atypical profile supported the diagnosis of clear cell papillary renal cell tumour (ICD-O: 8323/1), considered as borderline malignancy.
Conclusion: This case is unique due to incidental discovery of a rare tumour type in a check-up renal allograft biopsy. Tumour size was extremely small, and imaging indicated the absence of any proliferative changes of renal parenchyma. Knowledge on tumour indolent behaviour influenced the patient's decision to keep the functional allograft. In the last 6 months, she underwent regular clinical and imaging monitoring, associated with immunosuppression adjustment – maintaining stable general condition.

E-PS-17-021
LECT2 amyloidosis: a diagnostic challenge – a four-case series with bone marrow involvement in one patient
B. Öğüt[1], M. Öz[1], S. Yildirim[2], G. Güz[2], I. Işik Gönül[1]
[1]Gazi University, Pathology, Ankara, Turkey, [2]Gazi University, Nephrology, Ankara, Turkey

Background & Objectives: LECT2 (leukocyte cell-derived chemotaxine-2) amyloidosis is a rare and often underdiagnosed subtype of amyloidosis that usually presents with renal-limited disease. This case series highlights four renal biopsy-confirmed cases of LECT2 amyloidosis, including one with extrarenal involvement and accompanying monoclonal gammopathy.
Methods: Four renal biopsies diagnosed as LECT2 amyloidosis between 2022 and 2024 were retrospectively reviewed. Immunohistochemical and immunofluorescence studies were performed to characterize amyloid deposits. Clinical and laboratory data were retrieved when available.
Results: Three male patients (aged 70, 54, and 48) were referred from external centres with no available clinical information. All showed amyloid deposition in the glomerular mesangium, arteriolar walls, and interstitium, with exclusive LECT2 positivity on immunohistochemistry. No staining was observed for AA, kappa, lambda, transthyretin, gelsolin, or β2-microglobulin.
The fourth case was a 65-year-old woman with no known comorbidities, presenting with nephrotic-range proteinuria (4471 mg/day). Her renal function tests were normal. Kidney biopsy revealed diffuse amyloid deposition in the kidney parenchyma which was positive for LECT2 by immunohistochemistry. However, immunofluorescence showed a lambda monotypic light chain restriction. Subsequent bone marrow biopsy was also characterized by lambda-restricted monotypic plasma cell proliferation and, notably, diffuse LECT2 deposition in the vascular walls. Bone marrow remission was achieved with six cycles of Daratumumab plus CyBorD therapy, however, proteinuria persisted at 2340 mg/day.
Conclusion: Although often considered renal-limited, LECT2 amyloidosis may involve other organs, as demonstrated by vascular LECT2 deposition in the bone marrow of one of our patients. The presence of monoclonal gammopathy may lead to misclassification of the disease as AL amyloidosis and interferes with the correct diagnosis. Accurate subtyping through detailed immunophenotyping is essential to ensure appropriate management and avoid unnecessary treatment.

E-PS-17-022
A case of Monoclonal immunoglobulin disease (MIDD) versus proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) with overlapping features on renal biopsy
H. Tennekoon[1], N. Macrae[1]
[1]Portsmouth Hospitals University NHS Trust, Histopathology, Portsmouth, United Kingdom

Background & Objectives: Monoclonal immunoglobulin disease (MIDD) and proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) are uncommon diseases with deposition of monoclonal immunoglobulins in the glomeruli.
Methods: We describe a 55-year-old female who presented with nephrotic syndrome and microscopic haematuria and impaired renal function.
Results: On presentation; urine PCR was 1052mg/mmol with serum albumin of 20g/L. Serum Creatinine was 137umol/L. There was no paraprotein or elevation of serum free light chains. Anti-PLA2R, ANA, anti-GBM, ANCA, FR, cryoglobulins, HBS antigen, HbC antibody, HIV were negative. Kidney biopsy showed a membranoproliferative pattern of glomerulonephritis on light microscopy. Immunoperoxidase staining showed mesangial and capillary wall IgG, C3 and C1q without IgA and IgM. Kappa and Lambda were not interpretable due to background staining. Immunofluorescence of paraffin sections after protease digestion showed strong capillary wall and mesangial IgG, C3, C1q and kappa with weak segmental capillary wall IgA, IgM and Lambda. electron microscopy showed subendothelial linear as well as conventional deposits and mesangial deposits. No substructure was noted. No extra-glomerular deposits were seen. An immune complex mediated membranoproliferative pattern of glomerulonephritis with IgG kappa restriction was diagnosed with the differential diagnosis of PGNMID and MIDD. Haematological investigations did not identify a paraprotein or a plasma cell clone. The patient is responding well to high dose steroids.
Conclusion: There is clinical and morphologic overlap between PGNMID and MIDD. The presentation with nephrotic syndrome is common to both. This case had powdery electron dense deposits characteristic of MIDD along with conventional deposits more often seen in PGNMID. Extraglomerular deposits which are more common in MIDD were not seen. The absence of a identifiable clone is more common in PGNMID. Thorough evaluation of renal biopsy with light, immunofluorescence and electron microscopy is essential for diagnosis. Immunofluorescence of paraffin sections after protease digestion is an invaluable salvage technique to demonstrate clonality of deposits.

The experience of the Mohammed VI University Hospital of Marrakech in the detection of the methylation status of the O6-methylguanine-DNA methyltransferase gene in IDH wild-type glioblastomas by methylation-specific qPCR: about twenty-two cases
H. Elkhadraoui[1], A. Oukhdouch[2], B. Zinbi[2], S. Sellami[3], H. Rais[1]
[1]Morphoscience Research Laboratory, Faculty of Medicine and Pharmacy, Cadi Ayyad University, University Hospital Mohammed VI,

Pathology, Marrakech, Morocco, [2]Morphoscience Research Laboratory, Faculty of Medicine and Pharmacy, Cadi Ayyad University, University Hospital Mohammed VI, Anatomic Pathology Department, Biopathology Unit, Marrakech, Morocco, [3]University Hospital Mohammed VI, Pathology, Marrakech, Morocco

Background & Objectives: Gliomas are classified according to the fifth edition of the World Health Classification in 4 grades (1 to 4). Now, they are classified by site as well as by histological and molecular characteristics. IDH wild-type glioblastoma was considered the most aggressive glioma and is classified as grade 4 according to WHO 2021. The objective of this work is to report the experience of the Mohammed VI University Hospital in Marrakech in detecting the methylation status of the O6-methylguanine-DNA methyltransferase (MGMT) gene promoter in IDH-wild-type glioblastomas with observation of the expression of IDH1, ATRX and P53 by immunohistochemistry.
Methods: Our study involved twenty-two formalin-fixed, paraffin-embedded (FFPE) tissue blocks, the immunohistochemical study of which led to the diagnosis of glioblastoma. We examined the methylation status of the MGMT gene promoter using a specific real-time methylation PCR technique (MS-qPCR).
Results: All studied cases presented wild-type form of IDH1, loss of ATRX expression was recorded in eleven samples. In ten cases, the mutated form of p53 was expressed. The level of p53 expression varied from intense (>80% of tumour cells) to weak (<10% of tumour cells), and a staining less than 10% was considered non-mutated.
In our study, when analysing the methylation profiles of the MGMT gene promoter, we found that nine cases, presented positive methylation with a methylation rate that varies between 0.184% and 27% with a hypermethylation threshold is greater than 0.1%.
Conclusion: This study identifies MGMT promoter methylation in nine cases with positive result out of twenty-two cases of wild-type IDH glioblastomas, with the observation of the expression profile of three proteins (IDH1, ATRX and p53) by immunohistochemistry. Our study is the first in Morocco, but it should be extended to large prospective studies to confirm the results and draw definitive conclusions to suggest potential targets and appropriate therapeutic strategies.

E-PS-18-002
Diagnostic trap - primary mesenchymal intracranial chondrosarcoma
M.A. Publik[1], A.V. Dumitru[2], R.-A. Covache-Busuioc[3], C. Toader[3], M.P. Radoi[3], M.C. Ceausu[1]
[1]"C.I. Parhon" National Institute of Endocrinology, Pathology, Bucharest, Romania, [2]University Emergency Hospital, Pathology, Bucharest, Romania, [3]National Institute of Neurology and Neurovascular Diseases, Vascular Neurosurgery, Bucharest, Romania

Background & Objectives: Primary intracranial mesenchymal chondrosarcoma (PIMC) is an exceedingly rare tumour, accounting for 0.1-0.15% of all intracranial tumours. Due to its clinical behaviour, imaging appearance, localisation, and even histopathological features, it can closely resemble the much more common meningioma.
Methods: We present the case of a 35-year-old male patient who presented with cephalalgia, right hemianopsia, and seizures, progressively worsening over several months. Seven months earlier, the patient underwent surgery for a right posterior fossa (RPF) compressive mass, which was diagnosed as an atypical meningioma by a secondary centre. On current presentation, CT imaging revealed an expansive lesion in the RPF with bilateral extension and significant contrast enhancement, raising suspicion of recurrence. Emergency surgery was performed.
Results: Macroscopic examination revealed multiple pink, fleshy fragments with a soft consistency. Microscopic analysis showed an intensely vascularized mesenchymal proliferation composed of large and medium-sized, primitive-appearing, uninucleated, monomorphous cells arranged in sheets. Frequent typical mitoses, calcifications, and vascular spaces were noted within the tumour. Foci of chondroid transition were observed, with cells separated by an amorphous basophilic substance. Immunohistochemistry showed positivity for Ki67 (60%), OLIG2, S100 (in chondroid foci), CD99, NKX2.2, and SOX9. Tumour cells were negative for GFAP, Synaptophysin, IDH1, and ERG. These features support a diagnosis of primary mesenchymal intracranial chondrosarcoma.
Conclusion: PIMC is a rare and aggressive tumour that mimics the characteristics of meningioma, presenting a significant diagnostic challenge. Close attention and immunohistochemistry are essential in distinguishing this entity from more common diagnoses in order to avoid significant diagnostic pitfalls.

E-PS-18-003
Rare anatomical locations of Pleomorphic Xanthoastrocytoma: a report of two cases
E.-D. Creta[1], T. Corina[2], A. Kovecsi[2]
[1]University of Medicine, Pharmacy Science and Technology George Emil Palade, Pathology, Targu-Mures, Romania, [2]George Emil Palade University of Medicine, Pharmacy, Science and Technology, Pathology, Targu-Mures, Romania

Background & Objectives: Pleomorphic xanthoastrocytoma (PXA) is a rare tumour of the central nervous with glial origin. It commonly occurs in young patients and it is most frequently located supratentorially, particularly in the temporal lobe.
Methods: We report two cases of PXA with unusual tumour locations, affecting a paediatric and an adult pacient.
Results: Case 1: A 4-year-old girl presented with right-sided hemiparesis as the initial symptom. Brain magnetic resonance imaging (MRI) revealed a tumour in the left parieto-occipital region, measuring 77 mm, with hyperintensity on T2-weighted images and hypointensity on T 1. Imaging showed that the tumour exerted a compressive effect on the ipsilateral lateral ventricle (LV), causing compensatory dilation of the right LV and a 7 mm midline shift to the right.
Case 2: A 59-year-old man presented with motor deficits in the lower limb as the initial symptom. MRI described an intradural, intramedullary lesion spanning a cranio-caudal segment of 33 mm, corresponding to the vertebral bodies C4-C6, with an teroposterior diameter of 11.5 mm at the C5 level, showing hyperintensity on T2.
In both cases, complete surgical resection was performed. Histopathologic examination revealed characteristics of World Health Organisation (WHO) grade pleomorphic xanthoastrocytoma, No necrosis or mitotic activity were detected. Immunohistochemical findings supported the diagnosis.
Conclusion: These cases illustrate PXA with parieto-occipital and cervical spinal cord locations, which are rare, with very few cases reported in the literature. The severe clinical presentation in both cases highlights the atypical nature of these tumour locations and the significant neurological impact they can have, despite their WHO grade 2 histological characteristics.

E-PS-18-004
Mature teratoma of the conus medullaris: a rare entity in an uncommon location
Z. El euch[1,2], Z. Lajmi[1,2], R. Bader[1,2], S. Sakly[1,2], A. Bdioui[1,2], S. Hmissa[1,2]
[1]Sahloul University Hospital Centre, Department of Anatomy and Pathological Cytology, Sousse, Tunisia, [2]Faculty of Medicine of Sousse, Research Laboratory LR21 ES03, Sousse, Tunisia

Background & Objectives: Teratomas are tumours of germ cell or dysembryogenic origin, arising from aberrant tissue that includes elements from the ectoderm, mesoderm, and endoderm. They most

commonly occur in gonadal regions, as well as in the sacrococcygeal and mediastinal areas. Spinal teratomas are extremely rare, and those affecting the conus medullaris are particularly uncommon, usually seen in children. Sporadic cases in adults require heightened clinical vigilance due to their potential for neurological impairment and impact on quality of life.
Methods: A 37-year-old patient with no significant medical history presented with vesicosphincter disturbances, characterized by urinary retention, but without motor or sensory deficits. Magnetic resonance imaging (MRI) revealed an intramedullary lesion at the T12-L1 level, appearing hyperintense on both T1- and T2-weighted sequences. Based on these findings, surgical resection was performed. Intraoperatively, the lesion was observed to be adherent to the conus medullaris and an adjacent nerve root.
Results: Gross examination revealed a cystic mass containing a viscous, yellowish fluid. Histologically, the tumour demonstrated a heterogeneous composition of mature tissues, including adipose tissue, respiratory epithelium, acinar structures, squamous epithelium, and glial tissue with reactive gliosis, along with focal calcifications. No immature or malignant components were identified. The diagnosis of mature teratoma was confirmed.
Postoperatively, the patient experienced significant improvement in lumbosciatica; however, sphincter dysfunction persisted, requiring ongoing rehabilitative therapy.
Conclusion: Although rare, conus medullaris teratomas can affect patients across various age groups and lead to progressive neurological symptoms. Histopathological examination confirms the diagnosis. The benign nature of these lesions generally confers a good prognosis following complete surgical excision with tumour-free margins. Nonetheless, long-term follow-up is essential to monitor for potential recurrence, particularly in cases where immature or malignant components may be present.

E-PS-18-005
The unexpected evolution of an unusual polyphenotypic cerebral tumour
R. Khazen[1], C. Kesrouani[1]
[1]Hotel Dieu de France, Pathology, Beirut, Lebanon

Background & Objectives: The fifth edition of the WHO Classification of Tumours of the CNS introduces major changes that emphasize the importance of integrated molecular studies into definitive diagnosis. However, some cases fail to be classified even when proper and extensive testing is performed.
Methods: We present the case of a 52 y.o. patient, who presented with a five-month history of dizziness. Imaging revealed a fronto-temporal nodular mass which was initially resected and diagnosed. After recurrence one year later, it was also resected and submitted to the pathology laboratory for histological examination, immunohistochemisty and molecular studies.
Results: Histological examination of the first lesion revealed a well-circumscribed, non-infiltrating tumour composed of a mixture of spindled and epithelioid cells with gland-like structures and necrosis. Immunohistochemistry reveals a polyphenotypic pattern, with positivity for glial markers (GFAP and Olig2) and epithelial markers (Cytokeratin AE1/AE3, CK7 and CK20). The overall histologic and molecular findings did not differentiate between poorly differentiated well-circumscribed, high grade glial tumour and metastatic carcinoma of unknown origin. The recurrent lesion showed an infiltrating hypercellular proliferation composed of moderately-to-severely atypical cells, with positivity for GFAP and Olig2. Some well-demarcated foci of epithelioid and monster cells were also present and showed focal loss of GFAP and Olig2. Cytokeratin AE1/AE3 was negative. The overall findings were consistent with a glioblastoma with an epithelioid component, and we concluded that the prior lesion was in fact a high-grade glial tumour with unexpected immunohistochemical findings.
Conclusion: Despite adequate pathological workup, the tumour could not be initially classified within a standard WHO diagnosis. Even though the sharp demarcation, the presence of atypical epithelioid cells and the aberrant expression of specific epithelial markers such as CK7 and CK20 suggest at first a metastasis, the diagnosis of a glial tumour should be retained.

E-PS-18-006
Diagnostic challenges in pseudotumoral infections of the central nervous system
O. El Mnif[1], A. Zehani[1], A. Khadhar[1], I. Chelly[1], H. Azouz[1], K. Bellil[1], S. Haouet[1]
[1]La Rabta University Hospital, Pathology, Tunis, Tunisia

Background & Objectives: Some central nervous system (CNS) infections pose significant diagnostic challenges due to their diverse clinical presentations and radiological mimics. Many cases are incidentally diagnosed following surgical intervention for presumed neoplastic lesions. This study aims to present the clinicopathological characteristics of various infectious CNS lesions diagnosed in our pathology department.
Methods: We conducted a retrospective study of 27 cases of infectious CNS lesions diagnosed between 2005 and 2024.
All cases underwent surgical resection or biopsy, followed by histopathological examination using H&E staining.
Special stains such as PAS, and Grocott were applied when necessary.
Results: Patients ranged in age from 3 to 75 years, with a mean age of 34,8 years and with a male-to-female sex ratio of 1.25.
Fifteen patients were from rural area.
The most common presenting symptoms included headaches, focal neurological deficits, visual disturbances, and signs of intracranial hypertension. Radiological imaging frequently suggested tumoral processes, with lesions mimicking gliomas, meningiomas, or other expansive intracranial masses. Cystic lesions (n=8) were predominantly seen in hydatidosis cases, whereas abscess-like (n=4) formations were more characteristic of amebiasis and other fungal infections.
Histopathological examination confirmed the diagnosis in all cases. Tuberculosis cases (n=9) exhibited epithelioid granulomas with central caseous necrosis. Hydatidosis cases (n=10) demonstrated characteristic laminated eosinophilic membranes with daughter cysts containing protoscolices. Amebiasis cases (n=4) showed necrotizing inflammation with trophozoites in tissue sections. Fungal infections, including aspergillosis (n=1), mucormycosis (n=1), and phaeohyphomycosis (n=1), displayed angioinvasion and tissue necrosis.
The single case of actinomycosis showed suppuration and granulomatous inflammation surrounding actinomycotic granules.
Conclusion: CNS infectious lesions remain a formidable diagnostic challenge, often mimicking neoplasms and leading to delayed diagnosis. This case series underscores the importance of integrating histological, special stain, and molecular findings to ensure accurate diagnosis. Recognizing these infections, particularly in endemic regions, is crucial for appropriate management.

E-PS-18-008
Cystic glioblastoma multiforme mimicking neurocysticercosis: a rare presentation in Indian subcontinents
S. Babu[1]
[1]King George Medical University, Pathology, Lucknow, UP, India

Background & Objectives: Cystic glioblastoma multiforme (GBM) is a rare disease. Cystic GBM may mimic Neurocysticercosis (NCC) & other cystic benign lesions of CNS thereby causing diagnostic dilemma. Differential diagnosis of cystic brain lesion includes parasitic

lesions (e.g. NCC, echinococcosis), benign CNS neoplasms and less likely GBM, tuberculosis, fungal infections, and benign cystic lesions (epidermoid cyst, simple cyst). Cystic GBM have better prognosis.
Methods: 38 yrs. male with history of headache and intermittent fever for 13 days. CT scan revealed two peripherally enhancing lesion in right fronto-partial region and left frontal region with features and mass effect suggesting the possibility of parasitic lesion Neurocysticercosis (NCC). CSF & serological tests were negative for NCC. Bilateral frontal craniotomy with excision of SOL was done dueto mass effect. Preoperatively thin membranous cystic SOL filled with yellowish black fluid was found. Cyst wall was adherent and cleavage plane was present cyst and brain parenchyma, confirming the diagnosis of Neurocysticercosis. Total excision of both cysts was done &sent for HPE.
Results: Histopathology showed large cyst &lining of the cyst wall showed inflammation and oedema. Glial tissue bordering cyst lining showed anaplastic astrocytic tumour cellular pleomorphism, multinucleated giant cells, angectatic blood vessels, focal necrosis with cellular palisading thereby confirming the diagnosis of cystic glioblastoma multiforme.The patient was then put on radiotherapy and has received 2 cycles of radiotherapy since then.
Conclusion: Neurocysticercosis is a common parasitosis of CNS in endemic areas. In our case cystic multiple lesions without any solid component suggested the possibility of Neurocysticercosis however serological tests and CSF were negative for NCC. Histopathology played an important role in confirming the diagnosis of cystic GBM. To conclude, Cystic GBM should be kept as differential while evaluating cystic lesions of brain as it may mimic some common benign lesions. Cystic GBM have better prognosis and survival as compared to classical GBM.

E-PS-18-009
Cauda equina's neuroendocrine tumour: a series of 3 cases
O.O. Kizilkaya[1], C.S. Sucubulak[1], O.G. Celik[1], C. Turker Saricoban[1], A.M. Onenerk Men[1], S.C. Cetintas[2], S. Arslan[3], N. Comunoglu[1]
[1]Cerrahpasa Faculty of Medicine, Department of Pathology, Istanbul, Turkey, [2]Cerrahpasa Faculty of Medicine, Department of Neurosurgery, Istanbul, Turkey, [3]Cerrahpasa Faculty of Medicine, Department of Neuroradiology, Istanbul, Turkey

Background & Objectives: Cauda Equina Neuroendocrine Tumour (CENET) is a rare, low-grade intradural spinal tumour typically attached to the filum terminale. It presents with non-specific symptoms like back pain and radiculopathy and MRI can help in diagnosis. In this study, we included present three cases of this rare entity from our institution.
Methods: Available blocks and glass slides were retrieved from the archives for reevaluation and additional immunohistochemical applications.
Results: Patient 1 is a 37 year old woman who presented with lower back pain, right foot weakness, and numbness. Patient 2 is a 45 year old man who presented with a 1.5-month history of radiating pain from the right hip to the calf with no other neurological deficits. Patient 3 is a 71 year old man who had a five-year history of arm pain and radiating pain from the left hip to the lateral thigh and knee. All lesions appeared hypointense on both T1- and T2-weighted imaging. Histopathological examination revealed tumoral cells forming a nest pattern within a prominent vascular framework, surrounded by spindle-shaped sustentacular cells. The tumour cells were characterized by abundant eosinophilic cytoplasm, well-defined nuclear contours, and salt-and-pepper chromatin typical of chief cells. No cellular atypia or necrosis was observed. The tumour cells exhibited a low proliferative index, with mitotic counts of 1, 0, and 4 per 10 HPF, respectively. The tumour exhibited patchy PanCK positivity, with paranuclear dot-like staining observed in Patient 1. EMA, GFAP, GATA3 and PHOX2B were negative. S100 was positive in sustentacular cells, and both chromogranin and synaptophysin showed positivity in chief cells.
All three cases underwent resection and the prognosis was favourable with no recurrence.
Conclusion: Despite its favourable prognosis, CENET is often clinically indistinguishable from other spinal tumours and requires careful histopathological evaluation for accurate diagnosis.

E-PS-18-010
Neuropathology on AI models: how reliable can it be in generating differential diagnoses from stroke histopathology slides
A. Alotaibi[1], L. Abualloush[1], A. Hanbali[1]
[1]Jordan University of Science and Technology, Pathology, Irbid, Jordan

Background & Objectives: Accurate diagnosis of stroke-related neuropathological changes, particularly hypoxic-ischemic injury, remains a cornerstone of neuropathology. With the emergence of artificial intelligence (AI) language models, there is increasing interest in evaluating their potential to assist in neuropathological assessments. This study investigates the reliability of various ChatGPT models in generating differential diagnoses based on a histopathology slide of acute neuronal injury from stroke.
Methods: A histopathology slide demonstrating hypoxic-ischemic injury with characteristic "red neurons" in the hippocampus was selected from the University of Utah WebPath database (https://webpath.med.utah.edu/CNSHTML/CNS048.html). Five different ChatGPT models (GPT-4, GPT-4o, GPT-4o mini, GPT-3 mini, GPT-3 mini-High) were presented with the same prompt: "Based on what you see on this pathology slide, give three possible differential diagnoses and point to the most likely one." The AI-generated responses were analysed for diagnostic accuracy, reasoning, and alignment with the known pathology.
Results: The ground truth diagnosis was hypoxic-ischemic injury, an early-stage neuropathological hallmark of stroke. However, only GPT-4o included hypoxic-ischemic encephalopathy as a differential diagnosis, while the majority of models—particularly GPT-3 mini and GPT-3 mini-High—prioritized Creutzfeldt-Jakob Disease (CJD) due to their interpretation of spongiform changes. GPT-4 suggested reactive gliosis and neoplastic processes (astrocytoma, meningioma) as possible diagnoses, demonstrating variability in diagnostic reasoning across models. None of the AI models definitively identified stroke-related hypoxic injury as the most likely diagnosis.
Conclusion: OpenAI specifies that its different model variants excel in distinct task domains (e.g., reasoning, summarization), yet their performance in neuropathological differential diagnosis of stroke pathology remains inconsistent. This study highlights both the potential and current limitations of AI models in assisting neuropathological evaluations, particularly for cerebrovascular events. Further refinement and domain-specific training are essential to enhance AI reliability in neuropathology.

E-PS-18-011
Meningiomas: analysis of a series of 78 cases at the pathological anatomy department of the Mohammed VI University Hospital of Marrakech
H. Elkhadraoui[1], A. Ouaaziz[1], H. Rais[1], A. Fakhri[1]
[1]Morphoscience Research Laboratory, Faculty of Medicine and Pharmacy, Cadi Ayyad University, University Hospital Mohammed VI, Pathologie, Marrakech, Morocco

Background & Objectives: Meningiomas are the most common primary tumour of the central nervous system, arising from the arachnoid cap cells associated with the dura mater or choroid plexus , a ccounting for37,6%% of all CNS tumours. The aim of this work is to report the

experience of the Mohammed VI University Hospital in meningeal tumours.
Methods: We report a retrospective study of a series of 78 cases of meningioma diagnosed in oure stablishment between January 2014 and December2024
Results: There were 32men and 37women, one of who was diagnosed on an autopsy. The age of our patients varied between 44 and 91years. Most patients reported non-specific clinical signs such as headaches and seizures. All patients underwent brain imaging, the appearance of which was in favour of a meningioma located at the level of the cerebral convexity in 60 cases,at the level of the base of the skull in17cases and one case at the level of the optic nerve. The histolopathological and immunohistochemical study showed 75 cases of grade 1 meningioma according to WHO 2021 and distributed as follows: meningothelial in 45cases, transitional 16 cases,fibrous subtype in 11cases, psamomatous in 3 cases and 3 case of atypical grade2meningioma.
Conclusion: Meningioma are among the most common adult brain tumours whose prognosis depends on the extent of resection and histopathological grade. They must be classified according to the WHO 2021 recommendations taking into account histopathological criteria in grade1,2,3

Background & Objectives: Astrocytoma, IDH-mutant is the most common primary brain tumour in young adults, with peak incidence between the ages of 30 and 40. This genetically defined tumour is morphologically characterized by diffuse infiltration with fibrillary astrocytic, gemistocytic, or oligodendroglial differentiation. Only rarely does it exhibit a primitive neuronal component (PNET), which we aim to describe.
Methods: Our cohort was established through a nationwide search of pathology archives for diffuse gliomas with PNET differentiation. Only cases (n=18) with confirmed IDH mutation by immunohistochemistry or sequencing were included in the study. Formalin-fixed, paraffin-embedded tumour tissue samples were macrodissected, and each PNET and glial component was analysed using immunohistochemistry, next-generation sequencing, and methylation profiling.
Results: The cases in our study predominantly exhibited dual glial and embryonal morphology, while only a few demonstrated pure PNET differentiation. The PNET component showed reduced GFAP expression and expressed at least one neuronal marker, typically synaptophysin. A subset of cases displayed true large-cell/anaplastic features and cell wrapping. Furthermore, the PNET component exhibited a distinct epigenetic signature from the glial component and selectively harboured MYCN amplification and RB1 alterations.
Conclusion: All studied cases were high-grade tumours, characterized by a high total number of copy number variations, with MYCN amplification and RB1 loss being common features. These findings highlight the distinct molecular and epigenetic characteristics of the PNET component compared to the glial counterpart.

Molecular study of macrophage activity in wall of intracranial aneurysms: results of a pilot study
M. Koblizek[1], M. Hundza-Stratilova[2], M. Sandova[1], L. Krskova[3], A. Hejcl[4], A. Steklacova[5], V. Benes[5], J. Zamecnik[1]
[1]2nd Medical Faculty and Motol University Hospital, Department of Pathology and Molecular Medicine, Prague, Czech Republic, [2]2nd Medical Faculty and Motol University Hospital, Department of Rehabilitation and Sports Medicine, Prague, Czech Republic, [3]2nd Medical Faculty and Motol University Hospital, Department of Paediatric Haematology and Oncology, Prague, Czech Republic, [4]J. E. Purkyne University and Masaryk Hospital, Department of Neurosurgery, Usti nad Labem, Czech Republic, [5]1st Medical Faculty and Military University Hospital, Department of Neurosurgery and Neurooncology, Prague, Czech Republic

Background & Objectives: Our team previously identified changes in quantity and subtype ratio of macrophages in walls of ruptured and unruptured intracranial aneurysms (IA), however, their role in process of aneurysm formation and rupture remains unclear. Therefore, we studied RNA expression of genes involved in the process of extracellular matrix remodelling.
Methods: Walls of neurosurgically resected IAs (both ruptured and unruptured) were formalin-fixed and paraffin embedded. We used circle of Willis arteries from cadavers as control samples and processed them with formalin-fixation and paraffin embedding. RNA was isolated from paraffin blocks. Gene expression of *CD163, MMP2,* and *TIMP1* was measured by quantitative real-time PCR and relative gene expression was calculated using *B2M* housekeeping gene expression as a reference. Statistical significance was calculated using t-test.
Results: A total of 16 IA samples (unruptured $n = 10$, ruptured $n = 6$) and 7 control samples were included in the study. Relative expression of *CD163*, *MMP2,* and *TIMP1* genes was significantly higher in aneurysm walls compared to control samples ($p < 0.001$). Relative expression of *CD163* was significantly higher ($p = 0.029$) in ruptured IAs compared to unruptured ones. Relative expression of *MMP2* was significantly lower ($p = 0.008$) in ruptured IAs compared to unruptured ones. The difference in *TIMP1* expression between ruptured and unruptured IAs was not statistically significant ($p = 0.232$).
Conclusion: The presented pilot study confirms that macrophage count and matrix metalloproteinase expression in aneurysm walls are higher than in normal vessel walls. We found that expression of matrix metalloproteinase *MMP2* was higher in unruptured aneurysms compared to ruptured ones, which is in contradiction to our expectations of its role in aneurysm rupture.

Background & Objectives: Progressive Multifocal Leukoencephalopathy (PML) is a deadly demyelinating disease of CNS commonly related to immunosurpression. This study presents the histopathological findings of four patients with distinct clinical backgrounds.
Methods: Slides were reevaluated and additional IHC was performed.
Results: Patient-1, 61-year-old female with a history of goiter and Sjögren, presented with numbness in her arm that progressed to paralysis. Imaging revealed a mass in the right frontal lobe
Patient-2, a 60-year-old male with no previous complaints, presented with disorientation to time and place. Imaging revealed a contrast-enhancing lesion at the left temporo-occipital junction, extending into lateral ventricle.
Patient-3**,** 36-year-old female, presented with dizziness. Twenty days later, she developed speech delay and impaired balance. Imaging revealed multiple subcortical hyperintense lesions in the left part of pons, left temporal, right parietal, and left frontal regions.
Patient-4, a 40-year-old woman, developed speech difficulties and tremor. Lesions were identified in the right frontal and parietal regions. She has been under follow-up for Neuro-Behcet. JC-virus reactivation was attributed to adalimumab therapy.
For all four patients, the CSF analyses were inconclusive
All histopathological examinations revealed a brain parenchyme severely damaged by infiltration rich in macrophages, lymphoplasmacytic cells and few Creutzfeldt cells. Background neuropil damage and scattered large atypical glial cells with prominent nucleoli were present. Intranuclear viral inclusions with darker nuclear contours with central, ground-glass type amphophilic pattern were seen in both the infiltrated areas and surrounding cells resembling oligodendroglia. SV40 was diffusely positive**.** CD68 was positive in macrophages. IDH-1 mutation and ATRX loss was not observed. P53 expression was increased in the atypical nuclei and inclusions. The Ki-67 was high, reflecting increased lymphoid activity and proliferation. Diagnosis of PML was established in all patients.
Conclusion: Variable aetiology and clinical presentation of PML along with possible inconclusive CSF analyses, suggest that the diagnostic yield of biopsy can outweigh its invasiveness.

E-PS-18-016

Assessment of primary tumour and metastatic focus in gynaecological tumours that spread to the central nervous system

O.F. Mülkem[1], E. Yilmaz[1], D. Arik[1], F. Canaz[1], E. Özkara[2], E. Telli[3]

[1]Eskişehir Osmangazi University, Pathology, Eskişehir, Turkey, [2]Eskişehir Osmangazi University, Neurosurgery, Eskişehir, Turkey, [3]Eskişehir Osmangazi University, Gynaecologic Oncology, Eskişehir, Turkey

Background & Objectives: Nearly half of female mortality are caused by gynaecological tumours, particularly cervical cancer, in conjunction with breast cancer. Brain metastases are quite uncommon in women, despite the fact that gynaecological tumours are rather common. The development of metastases always results in death. Although many metastatic foci respond well to treatment, brain metastases do not.
Methods: Ten patients who had surgery for gynaecological tumours at our centre between 2010 and 2023 had samples taken of the central nervous system in the years that followed. A review that included histopathological data and other prognostic factors was carried out in addition to demographic data.
Results: The average age of our patients was 52.6±6.7 years. The most prevalent primary tumour diagnosis was ovarian(n=6, 60%), and the most frequent ovarian tumour was serous carcinoma(n=4, 66. 7%). Primary tumours of the endometrium, cervix, and vagina were also identified. The average size of the primary tumours was 51.5±44.7 mm. In terms of tumour necrosis rates for primary tumours, the lowest value was 0%, while the highest was 80%. The average duration of metastasis for primary tumours was 52±53.6 months. While the majority of metastasis localisation occurred on the right side(n=6, 60%), half of the cases were found in the frontal lobe. The largest recorded size of the metastatic deposit was 39.8±14.7 mm, and most of them were unifocal(n=7, 70%). The rate of necrosis in metastatic foci was comparable and slightly elevated. The predominant pattern of metastasis was infiltrative (n=8, 80%). The mean overall survival was 68.7±66 months.
Conclusion: In the realm of brain metastases, median survival is generally short, often lasting only months. This study assessed the distinction between primary tumours and brain metastases. In future studies, our goal is to improve our understanding of the differences between the primary tumour and the metastatic site.

E-PS-18-018

Detection of genetic alterations via molecular cytogenetic analyses in a case series of paediatric glioma patients: a pilot study

M.F. Guerrero Criollo[1], D.M. Mendoza-Urbano[2], J.S. Martínez-Rico[1], E.M. Quintero[3], E.F. Patiño[3], E. Cabrera-Bernal[4], L.A. Moreno-Gómez[5,6], P. Aux[6], N. Aponte[4], N. Olaya[2]

[1]Universidad Nacional de Colombia, Morfología, Bogotá, Colombia, [2]Universidad Nacional de Colombia, Patología, Bogotá, Colombia, [3]Fundación Hospital de la Misericordia, Patología, Bogotá, Colombia, [4]Fundación Hospital de la Misericordia, Oncología, Bogotá, Colombia, [5]Fundación Hospital de la Misericordia, Radiología, Bogotá, Colombia, [6]Universidad Nacional de Colombia, Radiología, Bogotá, Colombia

Background & Objectives: Gliomas represent the most common central nervous system tumours in children, presenting diagnostic and therapeutic challenges due to their molecular heterogeneity. The identification of molecular biomarkers is crucial to improve diagnosis, predict treatment responses, and develop new therapeutic strategies, especially in low- and middle-income countries. This study evaluated the most frequent molecular alterations in a cohort of paediatric patients diagnosed between 2016 and 2020 at a referral hospital.
Methods: Tissue samples from 50 children who were diagnosed with glioma between 2016 and 2020 and treated at HOMI-Fundación Hospital Pediátrico La Misericordia, Bogotá, Colombia were analysed via tissue microarrays and fluorescence in situ hybridization (FISH). We evaluated tumours for the presence of *KIAA1549::BRAF* fusion, *CDKN2A* deletion, *EGFR* and *N-MYC* amplification, and 1p/19q codeletion. The expression of H3K27me3 was evaluated via immunohistochemistry.
Results: The mean patient age at diagnosis was 8.05 years; 54% were females, 44% had high-grade gliomas, and 56% had low-grade gliomas. Genetic alterations were detected in 18% of the tumours, the most frequent being the *KIAA1549::BRAF* fusion (12%), of which 80% were diagnosed with pilocytic astrocytoma. A significant relationship was observed between infratentorial location and fusion, although no significant correlation was found between survival and the presence of fusion, a trend towards decreased mortality was observed in this group. Alterations in the expression of H3K27me3 (8%), alterations in *EGFR* (4%), homozygous deletion of *CDKN2A*

(2%) and heterozygous loss of 1p (2%) were detected. There was no amplification of N-MYC in any tumour.
Conclusion: Despite the relatively small sample size, the findings are consistent with the literature; despite the economic limitations to apply the WHO 2021 criteria, the methodology employed offers an affordable and accurate approach. These results highlight the need for comprehensive biomarker analysis to improve diagnostics, personalized treatments, and develop new therapies.

E-PS-18-019
Diagnostic value of the immunohistochemical marker H3K27Me in identifying midline low-grade gliomas with unfavourable prognosis
M. Senchenko[1,2], V. Degtyarev[3], D. Konovalov[2,4], L. Papusha[3], A. Tarakanova[2], D. Korobova[1], A. Druy[5]
[1]N.N. Blokhin National Medical Research Centre of Oncology, Pathology, Moscow, Russia, [2]Dmitry Rogachev National Medical Research Centre of Paediatric Haematology, Oncology and Immunology, Pathology, Moscow, Russia, [3]Dmitry Rogachev National Medical Research Centre of Paediatric Haematology, Oncology and Immunology, Neurooncology, Moscow, Russia, [4]Russian Medical Academy of Continuous Professional Education, Pathology, Moscow, Russia, [5]Dmitry Rogachev National Medical Research Centre of Paediatric Haematology, Oncology and Immunology, Molecular Oncology, Moscow, Russia

Background & Objectives: The H3K27M mutation is a crucial pathogenetic event in the development of diffuse midline glioma (DMG), which is classified as high-grade glioma (HGG). Rarely DMG may have morphology consistent with low-grade glioma (LGG). However, the H3K27M mutation has also been described in rare cases of midline pilocytic astrocytoma (PA) and ganglioglioma, leading to their unfavourable behaviour. Therefore, extremely important to identify patients with midline LGG with a potential unfavourable prognosis before molecular study.
Methods: Allele-specific PCR identified the H3F3A p.Lys28Met mutation in five cases of LGG with midline localization. In three cases, the following diagnoses were initially established: PA (n=2), LGG (n=1), diffuse LGG (n=1). In one case the diagnosis of DMG was suspected based on the loss of H3K27Me expression by immunohistochemistry (IHC). Retrospective IHC analysis for H3K27Me was subsequently performed in the other four cases.
Results: The study included 4 girls and 1 boy (aged 3.11 to 15.2y., median 12.1y.). In all cases there were midline tumour localization: medulla oblongata/pons (n=2), thalamus, basal nuclei (n=3). Histology revealed hypo- (n=3) or moderately (n=2) cellular neoplasm, with monomorphic ovoid cells with finely dispersed nuclear chromatin and scant eosinophilic cytoplasm among eosinophilic fibrillary matrix. There were no mitosis, necrosis and endothelial proliferation. In three cases, tumour was well-circumscribed. In two cases, it had diffuse growth, which was confirmed by NF-staining. The Ki-67 proliferation index varied from 1 to 5%. IHC with H3K27Me showed total loss of expression in two cases and mosaic expression in three cases. The median follow-up was 2.1 y. (range: 1.2 – 4.6y.). One patient died (follow-up 4.6y), four - alive, three of which receive palliative treatment.
Conclusion: IHC staining with H3K27Me is highly recommended for all patients with low-grade midline glioma to identify unfavourable LGG which biologically correspond to DMG.

E-PS-18-020
Atypical meningiomas: a clinicopathological study of 30 cases
M. Zghal[1], O. Boudawara[1], M. Mellouli[1], M. Triki[1], C. Chaari[1], S. Charfi[1], T. Boudawara[1], M. Bouhamed[1]
[1]Habib Bourguiba University Hospital, Pathology Department, Sfax, Tunisia

Background & Objectives: Atypical meningiomas (AM) represent 25 % of all meningiomas and correspond to grade 2 meningiomas in the 2021 WHO classification of central nervous system tumours. We aimed to investigate the clinical and pathological features of AM.
Methods: This is a retrospective study of 30 cases of AM recorded at the department of pathology of the university hospital of Sfax in Tunisia during a period of 16 years (2009-2024).
Results: The mean age was 51.7 years (30-73 years). Men were mostly affected (sex ratio = 1.3). Symptomatology was dominated by headaches and intracranial hypertension syndrome. Only one case was the result of progression of grade 1 meningioma; all other cases were de novo. The most frequent localization was the frontal lobe (53.3%), followed by the parietal, temporal and occipital lobes (16.6%, 13.6% and 12.2% of cases respectively). One case involved the olfactory nerve. Histologically, cellularity was often high (73% of cases). High mitotic index (>4 mitoses/10CFG) and necrosis were observed in 57.6% and 53.8% respectively. Cerebral invasion was present in 30%. Ki67 index (achieved in 8 cases) was greater than 10% in 3 cases. Partial removal was observed in 20% of cases. The course was marked by recurrence in 30% of cases. No transformation to grade 3 was observed.
Conclusion: AM occur de novo or as a result of the progression of grade 1 meningiomas (30% of cases). They are distinguished by a high recurrence rate (30% to 50%) and a more aggressive progression compared to grade 1 meningiomas. The main prognostic factor for recurrence remains the quality of surgical resection; the recurrence rate is lower in case of complete resection than partial resection. The other histoprognostic factors correlated with high relapse are the high mitotic index, high Ki67 index (>10%), and cerebral invasion, which stratifies patients who are candidates for adjuvant therapy.

E-PS-18-021
IDH-mutant gliomas: Is 1p/19q Co-deletion essential in canonical oligodendroglial phenotype?
A. Waghmare[1], A. Shah[1], A. Sahay[1], O. Shetty[2], M.G. Gurav[2], P. Gogte[2], A. Moiyadi[3], P. Shetty[3], V. Singh[3], T. Gupta[4], A. Chatterjee[4], A. Dasgupta[4], K. Bhattacharya[5], A. Sahu[5], A. Choudhari[5], N. Menon[5], E. Sridhar[1]
[1]Tata Memorial Hospital, Pathology, Mumbai, India, [2]Tata Memorial Hospital, Molecular Pathology, Mumbai, India, [3]Tata Memorial Hospital, Neurosurgical Division of Surgical Oncology, Mumbai, India, [4]Tata Memorial Hospital, Radiation Oncology, Mumbai, India, [5]Tata Memorial Hospital, Radiology, Mumbai, India

Background & Objectives: Oligodendrogliomas are molecularly characterized by combined *Isocitrate Dehydrogenase* (*IDH*) mutation and co-deletion of chromosome arms 1p and 19q (1p/19q codeletion). This study aims to determine the frequency and utility of 1p/19q co-deletion in IDH-mutant gliomas with classical oligodendroglial morphology.
Methods: This is a retrospective observational study of IDH-mutant gliomas Data was retrieved from the Electronic medical record and molecular pathology database over six years (2017-2022).
Results: Of the total 1276 *IDH*-mutant gliomas, 502 were of classical oligodendroglial morphology (IDH1R132H, IDH2R172K, IDH2R172W and IDH2172M), 591 were of astrocytic morphology and 183 were of admixed morphology. 331(65.94%) oligodendroglial tumours were evaluated for 1p/19q FISH, 13.6% (n=45) were uninterpretable. 278 (83.99%) cases showed 1p/19q co-deletion, molecular results while 2.4% (n=8) did not show co-deleted status. 46(25.1%) cases with admixed morphology were evaluated for 1p19q co-deletion, 20 (43.5%) were codeletion (none of which showed ATRX protein loss of expression). Of total astrocytic (n=591) cases, 11(1.8%) cases showed ATRX protein expression and were evaluated for 1p/19q FISH, one (9.1%) showed 1p/19q codeletion.
IDH-mutant, 1p/19q codeleted oligodendrogliomas were more common in older patients (41-65 years). A male predominance and

supratentorial involvement were noted. IDH1 mutation was more common (95.22%) than IDH2(4.78%). None showed p53 protein immunoexpression like TP53 mutant phenotype. None of the non-oligodendroglial tumours showed IDH2 mutations.
Conclusion: IDH-mutant diffuse glioma with classical oligodendroglial morphology and retained ATRX protein expression are invariably 1p19q co-deleted; while the astrocytic morphology and retained ATRX expression rarely show 1p19q co-deletion. However, cases with admixed morphology with IDH-mutation and retained ATRX expression do not show any consistent pattern. These findings shows a little incremental utility of additional FISH evaluation for1p19q co-deletion in IDH-mutant gliomas with classical oligodendroglioma, especially in real world scenario.

E-PS-18-022
Histopathological spectrum of neurenteric cysts: a report of two cases
S. Quinones[1], M.M. Petrino[1], P.D. Adolewska[1], J. Andrade-Restrepo[1], J.J. Pozo-Kreilinger[1], I. Esteban-Rodríguez[1], R.M. Regojo[1]
[1]La Paz University Hospital, Pathology, Madrid, Spain

Background & Objectives: Neurenteric cysts (NC) are rare, non-neoplastic developmental lesions caused by incomplete resorption of the neurenteric canal, a temporary connection between the yolk sac and amniotic cavity during early embryogenesis. These lesions commonly present during late childhood or early adulthood, with the spinal canal being their most common location. This study aims to analyse cases from our centre, focusing on imaging characteristics, histopathological features, and clinical follow-up.
Methods: After diagnosing the latest case in our centre, records from 2015 to 2024 were reviewed, resulting in two cases of NC. Clinical data and follow-up information were retrieved from the patients' electronic medical records.
Results: We report two cases of symptomatic NC, both belonging to male patients. The first case involves an 8-year-old child with a 25 millimeters cystic expansive lesion in the medulla oblongata. Histologically, the cyst was lined by a single simple columnar and cubical epithelium, rich in mucin-producing cells with some goblet cells, without atypia. The second case involves a 47-year-old adult with progressive paresthesias and a well-circumscribed intramedullary cystic lesion with a solid component in C4-C5 of 16 millimeters. Histologically, the cyst exhibited a lining of a non-atypical pseudostratified, ciliated columnar epithelium, poor in mucin-producing cells. Cyst fluid composition analysis was not performed.
Conclusion: Our observation reveals the histological variability of NC, ranging from simple columnar to pseudostratified ciliated epithelium, with varying mucin production. This spectrum highlights the critical importance of meticulous histopathological examination in differentiating NC from other cystic spinal lesions.

E-PS-18-023
The implications of the updated WHO classification of CNS tumours on paediatric brain tumours diagnosis. A South African perspective
M. Khaba[1], T. Guada[1], T. Sadiki[2]
[1]Sefako Makgatho Health Sciences University, Anatomical Pathology, Pretoria, South Africa, [2]Sefako Makgatho Health Sciences University, South Africa, Neurosurgery, Pretoria, South Africa

Background & Objectives: Primary Central Nervous System (CNS) tumours are the most common solid tumours in children. Their prognosis mostly relies on the age at presentation, histological classification and molecular characteristics.
The objective of this study was to present the prevalence and histological subtypes of paediatric brain tumours and address the implications of the latest WHO classification of CNS tumours.
Methods: A retrospective and descriptive study of cases diagnosed with CNS paediatric tumours between 2012 and 2021. The laboratory information system provided the clinicopathological characteristic data. Histological diagnoses were reviewed using the 2021 WHO Classification of tumours of the CNS.
Results: A total of 73 cases were recorded, with a mean age of 7 years, and a male predominance. Supratentorial tumours were prevalent (n=35, 48%) compared to infratentorial tumours (n=27, 37%), while the rest were unclassified. As per the WHO classification, gliomas, glioneuronal tumours, and neuronal tumours were the predominant category (n=25, 32.4%), followed by embryonal tumours (n=17, 23.3%), while choroid plexus tumours and other CNS embryonal tumours were the least prevalent (n=3, 4.1% each). The predominant tumour type was medulloblastoma (n=17, 23.3%), which was also the most prevalent malignant tumour. The most prevalent benign tumour was pilocytic astrocytoma (n= 12, 16.7%).
Conclusion: The study established baseline data for paediatric CNS tumours in our centre and Pretoria, crucial for developing guidelines for effective treatment. It will also accelerate the implementation of molecular studies in South Africa, enabling best practices in management according to the latest WHO classification of CNS tumours.

E-PS-18-024
Abnormal vimentin and histone H3 p.K27me3 immunohistochemical expression patterns as potential surrogate markers for 1p/19q-codeletion in adult-type diffuse gliomas
J. Bedekovics[1], R. Ninan[1], A. Mokanszki[1], G. Mehes[1]
[1]University of Debrecen, Department of Pathology, Debrecen, Hungary

Background & Objectives: Oligodendrogliomas and astrocytomas are diffuse-type gliomas of adulthood with overlapping molecular and histological features. The presence of *IDH* mutation is an essential diagnostic criterion for both. 1p/19q-codeletion is used to differentiate between these tumours. Molecular tests are generally less accessible and more expensive with a longer turn-around time compared to immunohistochemical tests. The aim was to determine if vimentin and histone H3 p.K27me3 (H3me3) immunohistochemical stains can be used as surrogate markers instead of 1p/19q-codeletion to differentiate between oligodendrogliomas and astrocytomas and to examine the correlation between these markers and different histological parameters.
Methods: Totally, 43 tissue blocks from adult patients with *IDH*-mutant diffuse gliomas from the Department of Pathology, University of Debrecen were analysed in this study. Cases were categorized into two cohorts based on 1p/19q-codeletion status: oligodendrogliomas (25 cases) and astrocytomas (18 cases). Vimentin (clone: V9) and histone H3 p.K27me3 (clone: EPR18607) immunohistochemical stains were performed according to the manufacturing instructions. The percentage of positive tumour cells for H3me3 and percentage of positive tumour area for vimentin were then estimated. Vimentin and H3me3 expression were correlated with 1p/19q status and conventional histological parameters including plexiform vessels, perinuclear halo, calcification, microcystic area, gemistocytic and minigemistocytic appearance, mitosis index, grade and p53 expression.
Results: The percentage of H3me3 positive tumour cells was significantly higher in astrocytomas comparing with oligodendrogliomas (mean 77.78% *vs* 13.75%, $p<0.0001$, Mann-Whitney test). The percentage of vimentin positive area was significantly larger in astrocytomas comparing with oligodendrogliomas (mean 80% *vs* 13%, $p<0.0001$, Mann-Whitney test). Loss of vimentin and H3me3 expression showed significant correlation with 1p/19q-codeletion ($p<0.0001$ for both, Fisher's exact test). Perinuclear halo, plexiform

vessels and gemistocytic morphology showed significant positive or negative correlation with both vimentin and H3me3 expression.
Conclusion: Vimentin and H3me3 immunohistochemical stains serve as potential surrogate markers for the differential diagnosis of oligodendrogliomas and astrocytomas.

E-PS-18-025
A rare *cauda equina / filum terminale* tumour: once diagnosed, expect at least 2 in a row (it can happen to you too)
D.-C. Lazureanu[1,2], A. Dema[1,2], D. Herman[2], M. Iacob[2]
[1]University of Medicine and Pharmacy, ANAPATMOL Research Centre - Anatomical Pathology, Timişoara, Romania, [2]County Clinical Hospital, Pathology, Timişoara, Romania

Background & Objectives: The last WHO Classification of Tumours involving CNS (2021, 5th Edition) mentions "nearly 300 cases have been reported since their initial description in 1970" for neuroendocrine tumours of the cauda equina region, formerly known as paragangliomas. We experienced and signed out this type of tumour twice in one month, November, last year.
Methods: Tissue fragments from two middle-age patients (male, 46 y-o and female, 44 y-o) with intradural extramedullar lumbar (L1-L3) mass were formaline fixed, paraffin-embedded and routinely stain. Additionaly, automated immunohistochemistry, using polymer detection system and DAB visualisation was performed.
Results: For both cases there were similar histopathological aspects: apparently encapsulated tumour proliferation, composed of trabeculae, rosettes, nests and (pseudo)papillae of relatively cohesive medium-sized, polygonal or discretely elongated neoplastic cells, showing rich, eosinophilic cytoplasm and pleomorphic nuclei: some rounded vesicular, other elongated hyperchromic, and still other with fine "salt and pepper" chromatin; mitotic activity was unidentified in the usual staining. Vascularization was rich with a network of capillaries either with "chicken-wire" or hemangiopericytic pattern, but also telangiectatic spaces filled with red blood cells. Associated: interstitial oedema, stromal hyalinization emerging from the meningeal / dural insertion.
The same similarity was found for the immune profil of the neoplastic cells: positive for panCK(AE1/AE3) as paranuclear granules and synaptophysin (diffuse and intense), negative for: GFAP, EMA, GATA3 and S100 (except for a few flattened cells at the periphery of neoplastic nests - sustentacular cells). The proliferation marker Ki67 was low: 1%, respectively 3%.
Conclusion: By fulfilling the WHO's criteria for diagnosis, we signed out the cases as cauda equina-filum terminale neuroendocrine tumour, G1 (well-differentiated). Being aware of its differences (histogenetically and molecularly) from paraganglioma outside the CNS, we informed our colleagues (neurosurgeons and oncologists) that total excision was curable, so there is no need for adjuvant therapy.

E-PS-18-026
Clinical and imaging mimic of posterior fossa' meningioma: medulloblastoma in young-to-middle of adulthood patients
D.-C. Lazureanu[1,2], D. Herman[2], A. Vaduva[1,2], A. Jurescu[1], R. Cornea[1,2], O. Vita[1], R. Barna[1], B. Nataras[1], M. Cornianu[1,2], A. Dema[1,2]
[1]University of Medicine and Pharmacy, ANAPATMOL Research Centre - Anatomical Pathology, Timişoara, Romania, [2]County Clinical Hospital, Pathology, Timişoara, Romania

Background & Objectives: When a neurosurgeon receives a cranian MRI interpretation of a 30 - 40 years old patient, as posterior fossa mass, apparently extraaxial, with tentorium insertion, the first thought can be: meningioma. Then, the intra-operative aspects not as expected, plus the frozen-section' diagnosis signed as: "malignant, high grade, small, blue cells" definetively changed, that first thought.
Methods: Tissue fragments from 3 middle-age patients (one male, 38 y-o and two females, 32 y-o, respectively, 45 y-o) with cranian posterior fossa mass were formaline fixed, paraffin-embedded and routinely stain. Silver impregnation for reticulin and automated immunohistochemistry (with polymer detection system, DAB visualisation) were made. Further, we have submitted representative paraffin-embedded tissue for each case to second opinion (in a reference centre for CNS tumours).
Results: H&E stain suggested a malignant tumour proliferation with the histopathological characteristics of a primitive / embryonal tumour, invading the meningeal sheath and cerebellar cortex in all 3 cases. The neoplastic cells (small, blue, round-oval, relatively monotonous, discohesive) were arranged in trabeculae and nodules relatively well delimited by a desmoplastic stroma. Silver staining highlights the rich reticulin network with complete surrounding of the neoplastic nodules. Immunohistochemically, neoplastic cells in the cellular nodules are positive for synaptophysin; GFAP variable and only in the internodular / trabecular cells; proliferation marker Ki67 was positive exclusively in internodular cells ranging from 15% to 35%. All 3 cases were confirmed in the reference centre as medulloblastoma, with the expansion of immunohistochemical testing as surrogates for molecular classification (p53, YAP1, beta-catenin), more precisely: SHH-activated medulloblastoma, TP53 wild-type, G4.
Conclusion: Even is known that medulloblastomas can arise at all ages, we had to face such diagnosis involving patients in their 4th and 5th decade of life, with a misleading imaging / preoperative aspect as meningiomas. The shift of their prognosis towards sever one was accordingly.

E-PS-18-027
Mycobacterial spindle cell pseudotumor (MSP) of the spinal cord: a case report and literature review
C.-M. Vieru[1], F. Arias Lotto[2], J.J. Domínguez Cañete[1], V.R. Baena Romero[1], C.C. Ferrara Coppola[1], V. Yuste Del Pozo[1], F. Rueda Correa[1], C. Padilla Ansala[1], L.I. Rollán López[1], C. López Galán[1], M.Á. Sáez García[1]
[1]Hospital Central de la Defensa Gómez Ulla, Surgical Pathology, Madrid, Spain, [2]Hospital General Universitario Gregorio Marañón, Surgical Pathology, Madrid, Spain

Background & Objectives: MSP is a rare, benign and diagnostically challenging manifestation caused by various species within the genus Mycobacterium, but most commonly by non-tuberculous mycobacteria (NTM) and affect primarily immunocompromised individuals. It causes tumour-like growths, affecting different parts of the body, but exceptionally the spinal cord, with only one case previously described in the literature.
Methods: We are reporting the only case of MSP of the spinal cord diagnosed in our hospital and describe clinical, radiological, histopathological, immunophenotypic and microbiologic features. This is a 79 year-old male from Guinea-Conakry with recently diagnosed active tuberculosis (M. tuberculosis positive tested by polymerase chain reactions (PCR) method) under treatment and history of chronic lymphocytic leukaemia diagnosed 2 years before and prostatic adenocarcinoma operated 12 years ago, with sudden legs hypoesthesia and weakness.
Results: The 7 mm D11 spinal cord mass observed in magnetic resonance imaging was resected and macroscopically showed a 1,3x0,7x0,5 cm whitish lesion with fibrous consistency. Histologic examination revealed a bland spindled and epithelioid histiocytic proliferation focally arranged in a fascicular and storiform architectural pattern, that effaced the background architecture and associated with mixed inflammatory infiltrate including lymphocytes and occasional neutrophils. Granulomas, multinucleated giant cells and caseous necrosis were absent. Immunohistochemical stains were positive for CD68 and negative for neural, epithelial, muscular and vascular markers. Acid-fast

staining shows acid-fast bacilli and the case was positive for NTM by PCR method. At the time of this work, the patient continues with the antimicrobial therapy and started a rehabilitation programme.
Conclusion: MSP is a rare benign lesion and to our knowledge, this is the second case described in the spinal cord. Its morphological pattern could mimic neoplastic lesions and represent a diagnostic challenge for pathologists unfamiliar with this lesion. Although immunostaining could be helpful, its morphology awareness will avoid confusion and will allow an accurate diagnosis and management.

E-PS-18-028
Pineal parenchymal tumours: a tunisian bicentric retrospective study
R. Yaakoubi[1], M. Mellouli[1], F. Kolsi[2], S. Makni[1], N. Gouiaa[1], I. Bahri[1], T. Boudaouara[1], M. Bouhamed[1,1]
[1]Habib Bourguiba University Hospital, Pathology, Sfax, Tunisia, [2]Habib Bourguiba University Hospital, Neurosurgery, Sfax, Tunisia

Background & Objectives: Pineal parenchymal tumours (PPT) are a rare group of tumours originating from the pineal gland's parenchyma. These tumours pose significant diagnostic and therapeutic challenges. This study aimed to analyse the clinical, radiological, and histological features of PPT treated surgically over a 26-year period, focusing on cases from the Neurosurgery Departments of the National Institut of Neurology in Tunis and Habib Bourguiba Hospital in Sfax.
Methods: A retrospective, bicentric study was conducted, reviewing 75 cases of pineal region tumours between 1998 and 2023. Of these, 13 cases were identified as PPT. Clinical records, radiological findings (CT and MRI scans), and histological diagnoses were analysed. Histological subtypes were classified according to the World Health Organization (WHO) grading system.
Results: The study identified 13 cases of PPT, accounting for 18% of all pineal region tumours. Radiologically, CT and MRI scans showed homogeneous lesions with intense contrast enhancement, particularly in pineocytomas and intermediate-grade pineal parenchymal tumours. Histological analysis revealed four cases of pineocytoma (Grade 1), one intermediate-grade pineal parenchymal tumour (Grade 3), and eight cases of pineoblastoma (Grade 4). No cases of papillary pineal tumour or SMARCB1-mutated myxoid desmoplastic pineal tumour were found. Notably, no pleomorphic component was observed in the pineocytomas. Adjuvant treatments, including radiotherapy (38.5%) and chemotherapy (23%), were applied, with varying outcomes. Recurrence was noted in one patient with pineoblastoma.
Conclusion: This study emphasizes the clinical and histological diversity of PPT and the importance of a multidisciplinary approach to diagnosis and treatment. The findings highlight the need for personalized treatment strategies, including adjuvant therapies, to optimize patient outcomes. Further research into the molecular characteristics of PPT could offer deeper insights into their pathogenesis and management.

E-PS-18-029
Diffuse Midline Glioma, H3 K27-altered, of the pineal gland
D. Efthymiou[1], A. Therapontos[1], S. Avgousti[1], K. Koniari[1], T. Argyrakos[1]
[1]Evaggelismos Hospital, Athens, Greece

Background & Objectives: Diffuse midline glioma (DMG), H3 K27-altered, represents an aggressive subtype of diffuse gliomas affecting midline brain structures, developed most commonly in the brainstem, thalamus, and spinal cord. Although primarily a paediatric tumour, occurrences in adults are increasingly recognised. Its incidence is estimated to be 0.54 cases per 1 million person-years overall. High-grade features such as brisk mitotic activity, necrosis, and microvascular proliferation may be present but are not required for diagnosis, as the WHO 2021 classification assigns a grade 4 to this entity by default due to the detection of H3 K27M mutations. In this report, we present a case of DMG, H3 K27-altered, originating uncommonly from the pineal gland in a 40-year-old male.
Methods: Histopathological examination assessed the morphology of the neoplasm while immunohistochemical analyses evaluated the status of IDH 1 or 2, Histone H3.3, ATRX, Olig-2, FOXG1, Ki-67 and BRAFV600E.
Results: Microscopy revealed high-grade features. Immunohistochemistry showed GFAP and Olig2 positivity with loss of FOXG1 and ATRX expression. The H3.3 K27M mutation-specific antibody demonstrated strong nuclear positivity while the H3 K27me3 trimethylated protein was retained. Staining for H3.3 G34R, H3.3 G34V, and BRAFV600E was negative. IDH1R132H and IDH1/2 mutations were absent while Ki-67 reached up to 40%.
Conclusion: This case offers additional insight into the rare presentation of pineal-region DMG, H3 K27-altered, arising in an adult patient, expanding the limited literature beyond the paediatric population. Midline tumours represent a diverse spectrum, ranging from indolent, low-grade neoplasms to aggressive, high-grade malignancies, like DMGs which carry a poor prognosis of a 2-year survival rate of <10% independently of the anatomical area. Clear distinction from other circumscribed or diffuse midline gliomas through the detection of the H3 K27M mutation is essential. This heterogeneity highlights the critical role of biopsy and molecular profiling balancing diagnostic accuracy against the significant risks of intervening in midline structures.

E-PS-18-030
Role of IL-22 and CD163+ cells in the inflammatory microenvironment of Glioblastoma multiformae
E. Aleksandrova[1], J. Ananiev[2], S. Valkanov[3], T. Vlaykova[1]

[1]Trakia University, Medical Chemistry and Biochemistry, Stara Zagora, Bulgaria, [2]Trakia University, General and Clinical Pathology, Stara Zagora, Bulgaria, [3]Trakia University, Department of Surgery, Neurosurgery, Urology and Anaesthesiology, Stara Zagora, Bulgaria
Background & Objectives: Glioblastoma multiformae (GBM) is one of the most aggressive tumours of the central nervous system. Current therapeutic approaches have reached low efficiency in preventing its progression and poor prognosis. The subpopulations of macrophages expressing the surface marker CD163 are pivotal cells in the inflammatory microenvironment of GBM. Additionally, IL-22 produced by several subsets of lymphocytes, has been reported as a promising new immune target in the complex molecular network of GBM and might be involved in the differention of $CD163^+$ macrophages.
Methods: A group of 41 patients diagnosed with GBM and 41 control individuals from the Bulgarian population were studied. Serum IL-22 concentration was assessed via the ELISA method. Immunohistochemistry was performed for assessing the density of $CD163^+$ cells in biopsy tissue of patients.
Results: We found that IL-22 concentration was significantly higher in patients compared to the controls with mean levels of 321.93±37.07 pg/mL and 222.74±25.65, respectively (p=0.006). In males (298.41±36.16 pg/mL) the serum levels of IL-22 were higher compared to females (244.88±28.26), p=0.131. The density of CD163+ cells in the tumour was also significantly higher in male patients compared to females (p=0.022). Regarding the clinical characteristics of GBM cases we observed increased IL-22 levels in patients with low neutrophil-to-lymphocyte ratio (NLR) (362.04±57.51) compared to patients with high NLR (275.49±43.59), p=0.040. The tumour tissue, both nest (21.11±5.97) and border (49.23±12.97), was also significantly enriched in $CD163^+$ cells in patients with low NLR, p=0.036 and p=0.012, respectively.
Conclusion: The preliminary results of our study indicate that serum IL-22 might be involved in modulating the inflammatory tumour microenvironment and could be associated with the recruitment and stimulation of CD163+ macrophages in the progression of GBM.

Funding: This research was funded by the Bulgarian Ministry of Education and Science (MES) in the frames of the Bulgarian National Recovery and Resilience Plan, Component "Innovative Bulgaria", Project No. BG-RRP-2.004-0006-C02, "Development of research and innovation at Trakia University in service of health and sustainable well-being", and by the Medical Faculty, Trakia University-Stara Zagora, Bulgaria, under Project No. 9/2023

E-PS-18-031

The association between TPT1 and paediatric astrocytomas: a study based on SNPs and immunohistochemistry evaluation

E. Morais de Castro[1], L.V. Barbosa[2], L. Noronha[3], C. Machado-Souza[2]

[1]Faculdades Pequeno Príncipe, Curitiba, Brazil, [2]Instituto de Pesquisa Pelé Pequeno Príncipe, Curitiba, Brazil, [3]Universidade Federal do Paraná, Curitiba, Brazil

Background & Objectives: Central nervous system tumours, including astrocytomas, are solid neoplasms with high rates of incidence and mortality in childhood. Diagnostic tools include morphological characteristics, but molecular methods have been increasingly used. Translationally controlled tumour protein (TCTP), encoded by *TPT1* gene, is a multifunctional protein which plays an important physiological role in the cell cycle. This protein has been associated with several neoplasms, including astrocytomas in adults. However, its role in paediatric astrocytomas is still unknown.

Methods: We aim to evaluate in 75 cases of paediatric astrocytomas, grades 1 (n=56) and 4 (n=19), according to the WHO classification, the frequency of three single nucleotide polymorphisms (SNP) in *TPT1* (rs1062420 [C/T], rs2234222 [T/C] and rs9595305 [T/C]), correlating it with TCTP expression, through genotyping and immunohistochemistry analyses, as well as with clinical variables.

Results: The most revealing result refers to an anatomic association. Most grade 1 astrocytomas were infratentorial whereas most grade 4 were supratentorial (p=0,006). Regarding the SNPs, results were also interesting, though not statistically relevant. As for rs1062420 [C/T], all the cases showed homozygosis or heterozygosis for T polymorphic allele, regardless of grade. Another interesting finding was that rs2234222 [G/C] showed a low incidence of C polymorphic allele (only 12% of cases, n=9). TCTP expression assessed by morphometry showed no statistic difference; grade 1 (Mean±SD 13720,24±7084,549) and grade 4 (Mean±SD 15664,03±6418,956).

Conclusion: This study sought an association between TCTP pathway and the tumorigenesis of paediatric astrocytomas. Our results reinforce the biological difference between low and high grade astrocytomas in the paediatric population. And regarding the three SNPs evaluated in this study, they do not seem to be involved in grade 1 or grade 4 astrocytomas. Further studies should be conducted for different SNPs as well as correlations with outcome, since they could still act as prognostic markers.

E-PS-18-032

P53 expression and its correlation with Ki-67 and clinical parameters in paediatric medulloblastomas from Southern Brazil

E. Morais de Castro[1], J. Ernandes Cardoso[1], N. Aparecida Lourenco[1], C. Eloisa Kulik[1], S. Hamad Mehanna[1], J. Costa Linhares[1], C. Machado-Souza[2], L. Noronha[3]

[1]Faculdades Pequeno Príncipe, Curitiba, Brazil, [2]Instituto de Pesquisa Pelé Pequeno Príncipe, Curitiba, Brazil, [3]Universidade Federal do Paraná, Curitiba, Brazil

Background & Objectives: Central nervous system tumours, including medulloblastomas, are solid neoplasms with the highest incidence and mortality rates in childhood. Medulloblastomas are aggressive WHO grade 4 tumours, diagnosed based on histopathological and molecular characteristics. Mutations in *TP53* gene are diverse, with missense mutations of single nucleotide polymorphism (SNP) being common. In southern Brazil, about two decades ago, the R337H variant was described, present in germline mutations. Establishing an association between medulloblastomas and *TP53*-R337H could provide novel insights on this neoplasm in the population of southern Brazil.

Methods: We evaluated in 48 cases of paediatric medulloblastomas, the expression of p53 through immunohistochemistry, as a potential sign of an underlying mutation, correlating it to ki67 and clinical variables.

Results: We found that regardless of histology, most cases presented normal p53 protein expression, indicating wild *TP53* (p=0,033). The lack of abnormal p53 expression indicates wild-type *TP53*, but it does not exclude underlying mutations, especially SNPs such as R337H. Regarding ki67, most classic medulloblastomas had ki67≤50%, whereas all anaplastic medulloblastomas had ki67≥75% (p=0,044). We also found a correlation between necrosis and ki67. Most cases with necrosis had ki67≥50% and most cases without necrosis had ki67≤50% (p=0,049). Seven deaths were recorded among the patients and most of them had the classic morphology. This finding was not statistically relevant. Nonetheless, it is noteworthy that most deaths had classical morphology but probably did not belong to the WNT-activated molecular group since this group usually has an excellent prognosis. Correlations with clinical parameters showed no significant results.

Conclusion: This study sought the expression of p53 through immunohistochemistry as a potential sign of *TP53* mutation. Results were negative, but associations statistically relevant between medulloblastomas, ki67 and necrosis have been made. Further studies should be conducted on the role of *TP53*-R337H mutation in medulloblastomas in the southern Brazilian population.

E-PS-18-033

Factors associated with overall survival in breast cancer patients with leptomeningeal carcinomatosis: a single institutional retrospective study

O. Boudaouara[1], W. Ghribi[1], M. Triki[1], S. Khmiri[2], M. Bouhamed[1], T. Sellami-Boudawara[1]

[1]Habib Bourguiba Hospital, Pathology Department, Sfax, Tunisia, [2]Habib Bourguiba Hospital, Carcinology Department, Sfax, Tunisia

Background & Objectives: Despite significant improvements in breast cancer (BC) treatment, the prognosis of patients with a leptomeningeal spread of tumour cells, termed as leptomeningeal carcinomatosis (LC), remains extremely poor.

This study aimed to investigate factors affecting overall survival (OS) in patients with LC related to BC.

Methods: Data analysis of our cerebral-spinal-fluid (CSF) cytology database was performed in the period between 2005 and 2021, identifying 34 patients who have undergone at least one CSF-cytology-sampling in the context of suspicion of BC-LC. Amongst them, 20 patients met diagnostic criteria for LC diagnosis (positive CSF cytology and/or neuroimaging in the presence of suggestive neurological symptoms). We used log-rank test and multivariate Cox-regression-analysis to compare patients' OS.

Results: The median age at diagnosis of LC was 49 years. Half of patients had a high-performance-status (PS) and prior or concurrent brain metastases (BM). The median OS was 5 months. In terms of management of LC, the majority of patients received a systemic treatment (ST) and a combination of at least 2 treatment modalities namely_ intrathecal treatment, ST and radiotherapy (70% and 75%, respectively).

On univariate analysis, 4 factors were associated with prolonged OS: high-PS (p=0,05), absence of BM (p=0,002), administration of ST (p=0,003), and the use of multimodal treatment (p=0,003). After multivariate analysis, we identified only 2 independent good prognostic

factors i.e. the absence of brain metastases, and the use of multimodal therapeutic approach.
Conclusion: LC represents a dreadful complication of BC, causing a drastic decline in BC patients survival rates. At this stage, median OS usually does not outreach 6 months. The results of our study confirmed that high-PS, absence of BM, use of ST, and of combined modality therapy are factors associated with prolonged OS. Only 2 factors (BM and number of treatment modalities) proved to be still prognostic after cox-regression-analysis.

E-PS-18-034
Prognostic significance of genetic biomarkers in glioblastoma IDH wild-type: a retrospective survival analysis
I. Campazas Herrera[1], I. Espadaler Fabregó[1], L. Catasús Cols[1], M. Cabamas Lladó[1], A. Gonzalez Vidal[1], L. Ferrazza Martín[1], Í. Espinosa Mariscal[1], S.M. Restrepo Arango[1], S.C. Scevola Metrallé[1], A. Gallardo Alcañiz[1]
[1]Hospital de la Santa Creu i Sant Pau, Anatomia Patológica, Barcelona, Spain

Background & Objectives: Glioblastoma, IDH wild-type, is the most aggressive primary brain tumour, characterized by a poor prognosis despite standard treatments. Genetic and molecular alterations play a critical role in tumour progression and patient survival. This study investigates the association between key biomarkers (EGFR, MGMT, mTERT, CDKN2A, p53, and PTEN) and survival outcomes.
Methods: A retrospective analysis was conducted on 92 patients diagnosed with glioblastoma, IDH wild-type. Descriptive statistics and cross-tabulations were used to assess the distribution of genetic markers and their correlation with survival. Pearson's Chi-Square and Fisher's Exact Test were applied to determine statistical significance. Kaplan-Meier survival analysis was performed to evaluate overall survival.
Results: EGFR alterations were present in 31.8% of cases, while MGMT promoter methylation was detected in 61.3%. The mTERT mutation had the highest prevalence (77.3%). No statistically significant associations were found between CDKN2A loss and p53 ($p = 0.159$), MGMT ($p = 0.926$), or mTERT ($p = 0.523$). However, a significant correlation was observed between CDKN2A loss and EGFR alterations ($p = 0.039$). Survival analysis revealed that 60.9% of patients were deceased at the time of data collection, while 32.6% remained alive with disease (AWD). Poor overall survival was significantly associated with MGMT promoter methylation ($p = 0.046$, Kaplan-Meier analysis), and a trend toward worse survival was noted in patients with CDKN2A loss ($p = 0.191$).
Conclusion: Molecular alterations are highly prevalent in glioblastoma, IDH wild-type, though their impact on survival remains complex. The observed association between CDKN2A loss and EGFR alterations suggests a potential prognostic role, warranting further investigation in larger cohorts to refine therapeutic strategies.

E-PS-18-035
Epithelioid angiosarcoma of the CNS with regional loss of INI1 expression
V. Sinatkas[1], M. Madentzoglou[1], M. Perdiki-Grigoriadi[1]
[1]Linkoping University Hospital, Clinical Pathology, Linköping, Sweden

Background & Objectives: Epithelioid angiosarcoma can be a diagnostic challenge especially in small biopsies. We describe a case of epitheliod angiosarcoma of the central nervous system (CNS) in a patient with cerebrospinal fluid leakage and clinical history of prolonged media otitis. The tumour showed regional loss of INI1 expression, with retained INI1 positivity in other tumour areas. This has profound implications in the differential diagnosis with neoplasms with loss of SMARCB1/INI1 expression at presentation or recurrence. Furthermore as shown in this report epitheliod angiosarcoma can be included in the group of neoplasms with variable, mosaic or regional expression of SMARCB1/INI1 protein.
Methods: Mayer Haematoxylin-Eosin sections of CNS open biopsy material were stained on Ventana HE 600 platform.
Immunohistochemistry was carried out on Bond III and Ventana platforms with the following antibodies: AE1/AE3, CAM5.2, MNF116, Desmin, EMA,GFAP, HMB45, mIDH1, INI1, CD3, CD79a, CD31, Ki67, Melan A, MyoD1, Myogenin, p53, S100, SMA, SOM-R2, SOX10, VImentin, WT-1, CD34, CD45, CD99,C D117,CD68, CD138, CDK4, Chromogranin A,DOG1, ERG, MDM2, MPO, NF, OCT3/4, PAX8, SALL4, Synaptofysin, STAT6 and TLE1.
Results: The tumour cells showed positivity for CD31, ERG and Vimentin, showing only faint cytoplasmatic positivity for p53 and CD99. Ki67 index was 75% in tumour cells. Regional loss of SMARCB1/INI1 expression was observed.
Conclusion: Partial loss of INI1 protein's expression can be seen in epithelioid angiosarcoma, and further perplex the already difficult diagnostic process in small biopsies from the CNS.

E-PS-18-036
Improving glioma diagnosis in Morocco: evaluation of a competency-based neuropathology masterclass
S. El attar[1], F.E. Ghlalou[1], K. Jebhi[1], M. El Ouazzani[1], H. Rachidi[1], N. Cherradi[2], H. Rais[1]
[1]Faculty of Medicine and Pharmacy, Cadi Ayyad University, Arrazi Hospital, Mohammed VI University Hospital Centre, Pathological Anatomy, Marrakech, Morocco, [2]Specialty Hospital, University Hospital Centre, Pathological Anatomy, Rabat, Morocco

Background & Objectives: Adult gliomas, the most common primary tumours of the central nervous system, pose a complex diagnostic challenge, accentuated by the 2021 WHO classification integrating morphological and molecular criteria.
To evaluate the effectiveness of a competency-based neuropathology masterclass in improving the diagnostic accuracy of gliomas among Moroccan residents and pathologists.
Methods: A quasi-experimental study was conducted with 26 participants, including a pre-test, a structured masterclass (theoretical course and practical workshop with virtual slide simulation), and a post-test. Statistical analysis used the Wilcoxon signed-rank test to compare scores before and after the intervention. A satisfaction survey was also conducted.
Results: A significant improvement in diagnostic skills was observed, with mean scores increasing from 61.54% to 81.92% (gain of 20.38 points, $p = 0.0002$). The proportion of participants achieving high scores (80-100%) increased from 11% to 73%. Comparison with a control group confirmed that the improvement was attributable to the intervention. The satisfaction survey revealed a high engagement rate, with 76.9% of participants expressing strong agreement on the relevance and clarity of the training.
Conclusion: This study demonstrates the effectiveness of a neuropathology masterclass in improving the diagnostic accuracy of gliomas in Morocco. These results highlight the importance of such initiatives in harmonizing diagnostic practices and potentially improving patient care for glioma patients.
Perspectives: Extending this approach to other training modules and diversifying case studies are recommended to strengthen national neuropathological expertise.

E-PS-18-037
A case of Gerstmann-Sträussler-Scheinker disease associated with a rare mutation
J.P. Olano[1], C. O'Connor[1], S. Chan Sanchez[1], G. Campbell[1], M. Felicella[1]
[1]University of Texas Medical Branch, Pathology, Galveston, USA

Background & Objectives: Gerstmann-Sträussler-Scheinker (GSS) disease is a rare, autosomal dominant inherited prion disorder characterized by progressive cerebellar ataxia and/or cognitive decline/dementia. Its incidence is estimated at 1-10/10^8 population. It was reported in families by Dimitz in 1913, Gerstman in 1928, and by Gerstman, Sträussler and Scheinker in 1936. The most common mutation is p.P102L. This report highlights a less common clinical presentation and a rare mutation in GSS disease.
Methods: The patient was a 54-year-old man who died after a 12-month course of rapidly progressive dementia, difficulty ambulating, and bowel and urinary incontinence. Neurological evaluation favoured corticobasal degeneration, frontotemporal dementia, and Creutzfeldt-Jakob Disease (CJD). After further workup, which included brain imaging, electroencephalography, positive 14-3-3 protein and negative RT-QuIC (Real-Time Quaking-Induced Conversion) on cerebrospinal fluid, CJD could not be definitively confirmed or excluded.
Results: A brain-only autopsy was performed due to concern for CJD. Neuropathologic evaluation showed spongiform change in many areas of gray matter and numerous large amyloid-type plaques with dense central cores. Immunohistochemistry performed by the National Prion Disease Pathology Surveillance Centre showed positivity for prion protein (PrPSc) in the plaques. Genetic testing revealed a pathogenic variant in the *PRNP* gene c.350C>T (p.A117V); the polymorphism at codon 129 in the *PRNP* gene was methionine/valine (129MV).
Conclusion: This case highlights the variability of GSS disease, particularly in presentations involving less common *PRNP* mutations such as p.A117V. While the hallmark symptoms of progressive cerebellar ataxia and cognitive decline were present, the rapid progression and prominent dementia observed underscore the influence of genetic variations on disease phenotype. The clinical overlap between GSS and CJD presents a diagnostic challenge and emphasizes the importance of neuropathologic evaluation and genetic testing in cases of dementia. Further study on rare *PRNP* mutations is needed to elucidate the impact of genetic variation on disease progression and to advance diagnostic and therapeutic approaches.

E-PS-18-038

Unravelling sarcoglycanopathies: correlations between muscle histopathology and disease severity

A. Barreto Haagsma[1], G. Selen Kocak[1], J. Michel-Sodhi[1], C. Marini-Bettolo[1], D. Moat[1], M. Guglieri[1], E. Robinson[1], M. Schiava[1], C. Bolaño Diaz[1], K. Wong[1], E. Grover[1], M. James[1], S. Segovia[1], M. Elseed[1], D. Salman[1], E. Harris[1], A. Topf[1], L. Luce[1], J. Hudson[2], M. Henderson[3], Y. Parkhurst[3], E. Graham[2], V. Straub[1], G. Tasca[1], R. Muni Lofra[1], J. Diaz-Manera[1]
[1]John Walton Muscular Dystrophy Research Centre, Genetics Department, Newcastle upon Tyne, United Kingdom, [2]Newcastle upon Tyne Hospitals NHS Foundation Trust, Genetics Department, Newcastle upon Tyne, United Kingdom, [3]Newcastle upon Tyne Hospitals NHS Foundation Trust, Muscle Immunoanalysis Unit, Newcastle upon Tyne, United Kingdom

Background & Objectives: Sarcoglycans are transmembrane proteins critical for muscle cell integrity. Their loss causes sarcoglynopathies, a subset of limb-girdle muscular dystrophies (LGMD) with variable phenotypes. This study describes the histopathological findings of a large cohort of sarcoglynopathies and studies the association of these findings with disease severity.
Methods: Muscle biopsy data was collected, including the sampled muscle, disease duration at biopsy (time from symptom of onset to the date of biopsy), key findings from haematoxylin-eosin (H&E) staining, and results from immunohistochemistry (IHC). Kaplan-Meier analysis was used to estimate the time to loss of ambulation. To further stratify disease severity, we calculated the 25th and 75th percentiles of ambulation loss timing.
Results: Data on 25 muscle biopsies was collected (8 LGMDR3, 8 LGMDR4, 8 LGMDR5, and 1 LGMDR6). Mean age at biopsy was 17.52 ± 11.89 years. All biopsies underwent H&E staining, while 21 patients had additional analysis using IHC. Histopathological analysis revealed varying degrees of myopathic changes, including rounded fiber atrophy, fiber size variability, increased internal nuclei, endomysial fibrosis, and fatty infiltration. Patients with severe disease who lost ambulation within eight years of disease onset exhibited moderate to severe fatty replacement, with a Spearman's correlation coefficient between severity and H&E staining of 0.51 ($p = 0.029$). In alpha patients, there was a significant reduction of IHC staining for α-sarcoglycan in severe cases ($r = 0.91$, $p = 0.03$). No significant correlation was found between β-sarcoglycan or γ-sarcoglycan IHC staining and disease severity ($p = 0.35$ and $p = 0.29$ respectively).
Conclusion: Histopathological and protein expression analyses largely mirrored clinical severity, with more pronounced fatty replacement in patients experiencing rapid loss of ambulation. Among the sarcoglycans, α-sarcoglycan reduction correlated most clearly with disease severity on immunohistochemistry, suggesting that α-sarcoglycan quantitation may serve as a relatively robust marker for disease progression.

E-PS-19-001

Clinicopathological features and prognostic factors in uveal melanoma: a retrospective analysis of 69 cases

V.S. Recalde[1], F.S. Mendoza[1], C.M. Gentile[2], A. Irarrázaval[3], J. Valenzuela[3], P.X. De la Iglesia Niveyro[1]
[1]Hospital Italiano de Buenos Aires, Anatomía Patológica, Ciudad Autónoma de Buenos Aires, Argentina, [2]Hospital Italiano de Buenos Aires, Oncología Ocular, Ciudad Autónoma de Buenos Aires, Argentina, [3]Consultores Oftalmológicos, Ciudad Autónoma de Buenos Aires, Argentina

Background & Objectives: Uveal melanoma (UM) is the most frequent primary intraocular malignancy in adults, with histopathological features playing a crucial role in determining prognosis. This study aims to assess the clinicopathological characteristics, tumour staging, and clinical outcomes in a cohort of 69 UM cases diagnosed over 13 years.
Methods: We conducted a retrospective analysis on 69 enucleation specimens diagnosed with UM between 2012 and 2025 at the Hospital Italiano de Buenos Aires. Tumours were categorized by histological subtype, growth pattern, T stage, extrascleral invasion, lymphovascular invasion, and vascular loops. Clinical records were reviewed to assess patient outcome, including metastatic progression and survival, with follow-up data available for 55% of cases.
Results: The cohort's mean age was 58 (14–90 years), with 38 males and 31 females. Thirteen patients had glaucoma, and 11 had undergone prior brachytherapy. The most common histological subtype was mixed (61%), followed by spindle cell (17%) and epithelioid (17%). Three cases were completely necrotic, so the histological subtype could not be determined. The growth patterns included dome-shaped (48%), mushroom-shaped (32%), diffuse (3%), and others (17%). Lymphovascular invasion and vascular loops were observed in 25% and 13% of cases, respectively, and were significantly associated with poor overall survival ($p<0.05$). T stage also correlated strongly with survival ($p<<0,01$).
Among patients with available follow-up data (median 34 months), 39% developed distant metastases, with the liver being the most frequent site, followed by lungs and bones.

Conclusion: This study provides valuable insights into the clinicopathological features of UM, emphasizing the prognostic significance of T stage, lymphovascular invasion, and vascular loops. These factors were strongly associated with overall survival. Although the study is limited by the challenges of long-term follow-up in referral-based populations, the findings contribute to the understanding of UM and may help guide future risk stratification and treatment strategies.

E-PS-19-002

Recurrent adenoid cystic carcinoma of the left orbit: a case report

S. Sakly[1], S. Moussa[1], A. Bdioui[1], Z. El Euch[1], R. Badr[1], S. Mestiri[1], S. Hmissa[1]
[1]Sahloul University Hospital, Pathology, Sousse, Tunisia

Background & Objectives: Adenoid cystic carcinoma (ACC) is a rare malignant neoplasm that primarily originates in the salivary glands but also manifests in other regions, including the orbit. Orbital ACC accounts for 1% and usually originates from the lacrimal gland. Few cases have been reported without lacrimal gland involvement. ACC is known for slow growth and often poses a challenge in diagnosis due to its ability to mimic other conditions. There are many differential diagnoses for orbital masses, and distinguishing ACC from similar lesions is often difficult.
This case report aims to highlight the clinical and histopathological features of recurrent ACC of the left orbit.
Methods: We report the case of a recurrent CAK diagnosed at our department. Clinical, radiological, and histopathological data were analysed from pathology reports and the patient's medical records. The patient presented with recurrent exophthalmos a period of 4 years following the initial diagnosis and treatment.
Results: A 74-year-old male patient, with history of diabetes and hypertension, presented with left exophthalmos. An initial biopsy confirmed ACC. A subsequent resection of the tumour with clear margins was performed. Four years later, he returned with similar symptoms. An MRI revealed a 36x22mm tumour in the left extra-conal space. The patient underwent left orbital exenteration with lymph node dissection. Pathological examination revealed a tumour infiltrating the upper eyelid, iris, irido-corneal angle, posterior chamber of the left orbit, and the sclera, with numerous perineural invasions and vascular emboli. Lymph node dissection revealed the presence of a metastatic lymph node. The tumour was classified as pT3N1.
Conclusion: This case emphasizes the importance of considering ACC in the differential diagnosis of orbital masses. Recurrent exophthalmos should raise suspicion for ACC, and accurate histopathological evaluation is crucial for definitive diagnosis. Early detection and treatment of recurrence are key to managing this aggressive tumour.

E-PS-19-003

Beneath the surface: the silent rise of conjunctival melanoma from a nevus

E.-I. Marinescu[1], A. Dumitru[1], A. Marin[1], A.-V. Tudorache[1]
[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background & Objectives: Conjunctival melanoma is a rare and aggressive ocular malignancy that arises from melanocytes in the conjunctival epithelium. Its incidence is rising globally, attributed to genetic, environmental, and precursor lesion-related factors. This case highlights the pathological and clinical features of a 47-year-old Caucasian male diagnosed with melanoma involving the palpebral conjunctiva, originating from a pre-existing nevus.
Methods: The patient presented to the clinic with a mass on his left lower eyelid, near the lash line, which had gradually increased in size over the past three months. The lesion had mainly caused mild irritation and a foreign body sensation in his eye. No history of eye surgeries, trauma, infections, or family background of melanoma.
Results: Upon examination, the patient displayed a pigmented lesion with irregular borders, ranging in colour from brown to black, with visible blood vessels on the surface, giving it an ulcerative appearance. Microscopically, the examined tissue revealed a malignant melanocytic tumour composed of medium to large polygonal cells with hyperchromatic, pleomorphic nuclei, some displaying prominent acidophilic nucleoli. Areas of distinctive brown pigment have been noted. These nevoid neoplastic cells, organized into nests, extended from the conjunctival epithelium into the underlying stroma, exhibiting pagetoid spread. Signs of mitotic activity and numerous apoptotic bodies further complicate the picture. Encouragingly, no lymphovascular or perineural invasion was present, indicating a less invasive case.
The presumptive diagnosis of melanoma was later confirmed through immunohistochemical analysis, which revealed strong positivity for PRAME (Preferentially expressed Antigen in Melanoma, >75%), HMB45, SOX10, Ki67 (>30%), and p16.
Conclusion: Although conjunctival melanomas are rarer than their cutaneous counterparts, it is crucial to remain vigilant for any unusual nevi in the ocular region. While this case has progressed favorably, it should not be seen as the norm, but rather as an exception to this potentially alarming condition.

E-PS-19-004

Case report: orbital myeloid sarcoma as initial presentation of Acute Myeloid Leukemia in a 13-year old patient

B. Abbasov[1], J. Musayev[2], M. Bagirzade[2], S. Qasimova[1], M. Mustafayev[1], M.A. Ciftcioglu[1]
[1]National Oncological Centre, Pathomorphological Laboratory, Baku, Azerbaijan, [2]Baku Pathological Centre, Baku, Azerbaijan

Background & Objectives: Myeloid sarcoma is a rare extramedullary manifestation of acute myeloid leukaemia (AML) that can present in various anatomical locations, including the orbit. We report a case of a 13-year-old patient who initially presented with an orbital mass, which was later diagnosed as myeloid sarcoma with underlying AML.
Methods: A 13-year-old previously healthy child presented with a rapidly enlarging, painless orbital mass causing mild proptosis and swelling. There were no systemic symptoms such as fever, weight loss, or night sweats. Orbital imaging (MRI) revealed a well-defined, enhancing soft tissue mass measured 2.9x4.0x4.5 cm, involving upper and postero-lateral wall of right orbit with extension to the retrobulbar adipose tissue.
The tumour excision consists of the diffuse infiltration of medium- to large-sized atypical cells with a high nuclear-to-cytoplasmic ratio and prominent nucleoli. The tumour cells was positively stained with Myeloperoxidase, TdT, CD34, CD31. The negative stains were CD3, CD4, CD7, CD8, CD20, CD23, CD30, BCL6, CD7, LCA, PAX5, CyclinD, Langerin, Vimentin, Actin, Desmin, MioD1, Myogenin, CD1a, S100. These findings were consistent with a diagnosis of myeloid sarcoma. A bone marrow examination was not performed initially.
Results: Myeloid sarcoma is a rare and often misdiagnosed entity, particularly in paediatric patients with no prior history of leukaemia. Early recognition is crucial, as isolated myeloid sarcoma often progresses to overt AML. Standard treatment typically involves systemic AML-directed chemotherapy rather than localized therapy alone. Cytogenetic and molecular studies are essential for risk stratification and prognosis, but they were not performed in this case.
Conclusion: This case emphasizes the importance of including myeloid sarcoma in the differential diagnosis of paediatric orbital tumours. Immunohistochemical markers play a key role in distinguishing MS from other small round blue cell tumours. Early systemic workup and initiation of chemotherapy are essential to improve outcomes.

E-PS-19-005

Microcystic adnexal carcinoma of eyelid and orbit: an update and management

A.V. Pagliari[1]
[1]U.O. ORL ASST Crema, Dipartimento di Chirurgia ASST Crema, Crema, Italy

Background & Objectives: Primary skin cancers include melanocytic and the vast non-melanoma skin cancer group. The former group is dominated by melanoma the latter by basal and squamous cell carcinoma. A small fraction comprises appendageal tumours also know as adenexal tumours. Malignant adnexal tumours are frequently located in the head and neck. Skin appendageal tumours do not form a single form. Microcystic adnexal carcinoma, of the overarching group of apocrine and eccrine differentiation, is very rare low-grade malignant skin tumour with a high rate of misdiagnosis and a preponderance for local recurrence but seldom nodal or distant metastasis first described by Goldstein in 1982.
Methods: A 66 year old man presented with a slow-growing asymptomatic nodule of left inferior medial eyelid and submitted to radical excision extended to bone of orbit floor and reconstructed with cadaver bone fixed by micro-crews and micro-plates. The tumour recurred three years after in lateral part of inferior eyelid. The tumour was widely excised, lateral canthus anchored to reverse temporal flap and cheek rotation/advancement flap was employed for soft tissue reconstruction.
Results: Histopathological examination showed a dermal neoplasm with infiltrative growth pattern and deep invasion of subcutaneous adipose tissue and skeletal muscle. The tumour lacked any connection to the epidermis and consisted of horn cysts. Ductal structures, nests and strand of neoplastic cells embedded in a fibrosclerotic stroma. Epithelial membrane antigen (EMA) , cytocheratin (CK), CK 15, and carcinoembryonic antigen, Ber-EP4, are helpful in histologic differentiation diagnosis.
Conclusion: Microcystic adnexal carcinoma is a rare but commonly misdiagnosed frequently recurrent malignancy which poses a significant diagnostic and treatment challenge to clinicians. Microcystic adnexal carcinoma of the eyelid and orbit requires multidisciplinary approach to diagnosis and management.

E-PS-19-006

Conjunctival squamous cell carcinoma in situ: a rare entity not to be missed

R. Yaakoubi[1], M. Mellouli[1], M. Triki[1], M. Bouhamed[1], C. Chaari[1], R. Kallel[1], L. Ayedi[1], T. Boudaouara[1], M. Zghal[1]
[1]Habib Bourguiba University Hospital, Pathology, Sfax, Tunisia

Background & Objectives: Conjunctival squamous cell carcinoma in situ (SCC in situ) is a rare but significant pre-invasive neoplasm of the conjunctiva. It is often associated with risk factors such as excessive UV exposure and can occur in the presence of pre-existing lesions, such as pterygium. The histological diagnosis of SCC in situ can be challenging due to subtle cytological and architectural atypia, without invasion of the basement membrane.
This case highlights the diagnostic difficulties of SCC in situ in the context of an advanced pterygium and illustrates the histopathological features that are critical for accurate identification.
Methods: A 50-year-old female, followed for advanced right eye pterygium, underwent surgical resection of the affected tissue. The excised fragment was submitted for histopathological examination. The histological features were analysed using standard staining techniques.
Results: Histologically, the conjunctival epithelium was acanthotic, with architectural disorganization affecting the full height of the epithelium in some areas. Moderate cytological atypia with upper-layer mitoses were observed, but there was no invasion of the basement membrane. The underlying stroma was inflammatory. These findings were consistent with a diagnosis of SCC in situ, without evidence of stromal invasion or basement membrane breach.
Conclusion: Conjunctival SCC in situ presents a diagnostic challenge, particularly in the setting of advanced pterygium. While the absence of basement membrane invasion is a key feature, the identification of architectural and cytological abnormalities is critical for diagnosis. A precise diagnosis is essential to prevent progression to invasive carcinoma. Close correlation between histological examination and clinical presentation is crucial for proper management of such lesions.

E-PS-19-007

Histopathological findings of corneal amyloidosis

C. Gomez Gonzalez[1], B. Yaman[1], B. Sarsik Kumbaraci[1], T. Akalin[1], M. Palamar Onay[2], S. Sen[1]
[1]Ege University Faculty of Medicine, Department of Pathology, Izmir, Turkey, [2]Ege University Faculty of Medicine, Department of Ophthalmology, Izmir, Turkey

Background & Objectives: The eye is a target organ for amyloidosis, with partial or broad compromising. Stromal corneal dystrophies (CD) are the leading group of diseases that are the source of amyloid, which can be either primary-localized or secondary corneal amyloidosis. Chronic ocular irritation, inflammation, or infection can lead to secondary localized corneal amyloidosis. The aim of the present study is to provide a histopathologic description of corneal amyloidosis in the context of the clinical diagnosis of CD in a single tertiary centre in Türkiye.
Methods: A total of 27 corneal buttons, obtained through penetrating keratoplasty from 20 adult patients diagnosed with CD between 2000 and 2025, were analysed. Congo-red stain positivity served as the primary inclusion criterion. The parameters assessed in each corneal button included epithelial and stromal characteristics, corneal thickness, and the localization, distribution, and thickness of amyloid deposits.
Results: The male-to-female ratio was 12:8, with a median age of 53±15.6 years (range: 21-83). Among the samples, 22 were naïve corneal buttons, and 5 were regrafts. The median corneal thickness was 0.6 mm (IQR: 0.39–1.90), while the median amyloid deposit thickness measured 0.1 mm (IQR: 0.01–1.10).
Linear subepithelial deposits alongside small stromal amyloid deposits were commonly observed in naïve corneal buttons. Large subepithelial amyloid deposits were prominent in regrafts. Two naïve corneal buttons exhibited keratohyalin deposits (Masson-trichrome positive), and one showed macular corneal degeneration; they all had amyloid deposits. Epithelial hyperplasia, atrophy, and stromal changes, such as cellularity, vascularization, and inflammation, varied across samples.
Conclusion: This study highlights the histopathological and clinical characteristics of corneal amyloidosis. Histopathological examination of corneal buttons from keratoplasty procedures provides valuable insights into accurate diagnosis and facilitates timely clinical management of amyloidosis.

E-PS-19-008

A rare case of primary cutaneous T-cell lymphoma mimicking eyelid carcinoma: diagnostic and therapeutic challenges

U.R. Arain[1], R. Babovic[1], S. Awotesu[1], D. Kacavenda-Babovic[2]
[1]James Paget University Hospital, Ophthalmology, Great Yarmouth, United Kingdom, [2]Norfolk and Norwich university Hospital, Pathohistology, Norwich, United Kingdom

Background & Objectives: Primary cutaneous T-cell lymphomas (CTCLs) are rare lymphoproliferative disorders, particularly when arising in the periocular region. Their clinical appearance often mimics more common eyelid malignancies such as squamous cell carcinoma

(SCC) or keratoacanthoma, making early diagnosis and management challenging.
Methods:
We present the case of a 70-year-old man with a solitary, enlarging lesion (16 mm × 16 mm) on the lower left eyelid. The initial differential diagnosis included SCC and keratoacanthoma. The lesion was surgically excised in its entirety, and the defect was reconstructed using a full-thickness skin graft.
Results: Histopathological examination unexpectedly revealed a T-cell lymphoma. Immunophenotyping confirmed a diagnosis of CD30-positive primary cutaneous T-cell lymphoproliferative disorder. Differential considerations included mycosis fungoides, primary cutaneous anaplastic large-cell lymphoma, and lymphomatoid papulosis. Staging with PET scan showed no systemic involvement or lymphadenopathy. The lesion was excised with clear margins, and no adjuvant systemic therapy was initiated. The patient remains under close surveillance in the haematology clinic, with chemotherapy reserved for any signs of recurrence.
Conclusion: This case illustrates the diagnostic complexity of rare eyelid lesions and reinforces the importance of histopathological and immunophenotypic analysis. Early recognition and multidisciplinary management are crucial for optimal outcomes in atypical CTCL presentations.

E-PS-19-009
Heterogeneity in uveal melanoma: a retrospective study about monosomy of Chromosome 3 and vascular density
S. Büsker[1], C. Cacchi[1], M. Lammert[1], N. Ortiz-Brüchle[1], D. Jonigk[1]
[1]Institute for Pathology RWTH Uniklinik, Aachen, Germany

Background & Objectives: The increasingly accurate definition of parameters of prognostic significance in melanoma of the uvea represents a topical challenge. The availability of advanced therapies (among others targeting tumour neoangiogenesis) requires detailed histological evaluation of melanomas of the uvea.
Methods: From our archive (eight evaluable cases), we wanted to evaluate not only the presence or absence of Chromosome 3 monosomy (FISH analysis) in uveal melanoma cases, but also the percentage of cells with Chromosome 3 monosomy in the areas with epithelioid and spindle-shaped morphology.
We evaluated (immunohistochemistry with CD34) the maximum density of vessels and their appearance in both melanoma components.
Results: The mean vascular density (hot spot evaluation, number of vessels per HPF) is 21/HPF in the epithelioid tumour component compared to 11/HPF in the spindle-appearing component.
The morphology of the blood vessels in the areas of epithelioid appearance appears more complex with greater variability in calibre than in the spindle-shaped areas.
Of the cases evaluated for Chromosome 3 monosomy: in one third of the cases a discrepancy, within the same melanoma, was observed between the epithelioid component (with presence of monosomy) versus the spindle-shaped component (negative for monosomy).
In the remaining two-thirds of the cases studied, although there was concordance for the result of chromosome 3 monosomy (two cases with and two cases without chromosome 3 monosomy), the percentage of cells with Monosomy 3 in the epithelioid areas compared to the spindle areas was 35% to 18%.
Conclusion: Although the limited number of cases does not allow for general considerations, these data further underline the importance of tumour heterogeneity within uveal melanoma when evaluating parameters such as chromosome 3 monosomy and blood vessel density in these cases of melanoma.

E-PS-20-001
Insights into congophilic angiopathy: three case reports
D. Krepysheva[1], S. La Rosa[1], G. Agresta[2], M. Cerati[3]
[1]University of Insubria, Unit of Pathology, Department of Medicine and Technological Innovation, Varese, Italy, [2]University of Insubria, Division of Neurosurgery, Varese, Italy, [3]University of Insubria, Unit of Pathology, Varese, Italy

Background & Objectives: Cerebral amyloid angiopathy (CAA) is a cerebrovascular disorder characterized by amyloid-β (Aβ) deposition in cortical and leptomeningeal vessels, leading to intracerebral haemorrhages (ICH) and cognitive decline. Severe cases show fibrinoid necrosis, microaneurysms, vessel rupture, and perivascular gliosis. Neuroimaging often reveals white matter hyperintensities and cerebral microbleeds as severity biomarkers.
Methods: We present three cases of CAA-related ICH, illustrating clinical and pathological variability. Histology was performed with haematoxylin-eosin and Congo red staining. The severity of CAA was assessed using Greenberg and Vonsattel histopathological grading criteria.
Results: Case 1: 79-year-old female, left frontal haemorrhage on CT, no MRI. Symptoms: acute headache, vomiting. No prior amyloid pathology or dementia. Histology: vascular thickening, fibrinoid necrosis in leptomeningeal vessels (Grade 4 CAA).
Case 2: 69-year-old female, left parieto-occipital haemorrhage on CT, no MRI. Symptoms: hemiplegia, aphasia. No amyloid pathology or dementia history; on antiplatelets. Histology: vascular thickening in leptomeningeal vessels (Grade 2 CAA).
Case 3: 73-year-old male, left parietal hematoma on CT, no MRI. Symptoms: aphasia, hemiparesis. No prior amyloid pathology or dementia. Histology: vascular thickening, fibrinoid necrosis in leptomeningeal and cortical vessels (Grade 4 CAA).
Conclusion: Histological severity correlated with clinical and radiological findings, with fibrinoid necrosis and vascular thickening linked to extensive vascular involvement and severe presentations. The vessel caliber influenced haemorrhage extent and location. These cases emphasize the importance of integrating histopathology, imaging, and clinical data to refine prognosis and guide treatment. Further studies using advanced neuroimaging are warranted to better assess vascular amyloid burden, haemorrhagic risk, and cognitive decline.

E-PS-20-002
Lafora disease: a case series of a rare entity
I. Noomen[1], S. Ben Hammouda[1], S. Mabrouk[1], A. Ben Mabrouk[1], L. Njim[1], A. Bellalah[1], M. Njima[1]
[1]Fattouma Bourguiba Hospital, Pathology, Monastir, Tunisia

Background & Objectives: Lafora disease (LD) is a rare form of progressive myoclonal epilepsy of autosomal recessive inheritance, having characteristic intracellular inclusions which are referred to as Lafora bodies. Lafora bodies present in neurons and in many other cell types cause a dysfunctional activity inside the cell. This study attempts to relate together the clinical and pathological findings in three cases of LD with the importance of their making a diagnosis of LD through axillary skin biopsy.
Methods: A retrospective study was done on the clinical information and histopathological data with three patients diagnosed as LD from the clinical records at Fattouma Bourguiba University Hospital.
Results: The mean age at diagnosis was 33.7 years. All patients were female and classified as having drug-resistant progressive myoclonic

epilepsy. One patient was also found to have cerebellar ataxia and visual hallucinations, while a strong family history of LD was noted in another patient whose sibling was diagnosed with LD at the age of 40. PAS-positive small rounded intracytoplasmic inclusions (Lafora bodies) were seen with great frequency in each axillary skin biopsy from the apical cells of the sweat ducts and in myoepithelial cells surrounding the apocrine glands.
Conclusion: Lafora disease is an extremely rare form of terrible, progressive, myoclonic epilepsy caused by mutations in either EPM2A or EPM2B encoding Laforin or Malin, respectively. Despite the absence of established family history concerning LD in these patients, and obvious onset of symptoms during adolescence, this case series stresses the importance of axillary skin biopsy in early diagnosis for the patients who suffer from Lafora disease. Primarily, early diagnosis will create opportunities for genetic counselling and supportive management, which eventually would help in the optimal management of afflicted individuals, improving outcomes in this difficult disorder.

E-PS-20-003
Diagnostic and therapeutic challenges in multiple primary malignant tumours
A.-I. Nitu[1], A. Vaduva[2,1], S. Taban[2,1], C.D. Lazureanu[2,1], A. Dema[2,1], S. Dema[3]
[1]Departament of Pthology, Pius Brinzeu County Clinical Emergency Hospital, Timisoara, Romania, [2]ANAPATMOL Research Centre, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania, [3]University Clinic of Oncology, Department of Radiotherapy, Municipal Hospital, Timisoara, Romania

Background & Objectives: Advances in the diagnosis and treatment of malignancies have led to a rise in the occurrence of multiple primary neoplasms, which develop independently throughout a patient's lifetime, each with its own distinct origin and progression. This study aims to explore the relationships between different types of cancers, the prevalence of synchronous and metachronous malignant tumours, and the diagnostic and therapeutic strategies used for managing these cases.
Methods: This retrospective study analysed medical records of patients with at least two primary cancers, admitted to the Radiotherapy Department at Timisoara Municipal Hospital between 2020 and 2024. Relevant data were collected from patient histories and medical documents.
Results: The study included 51 patients (25 women, 26 men) diagnosed with two or more primary malignant tumours. The average age at diagnosis was 69 years (range: 43–87). Of the cases, 46 involved two distinct cancers, while 5 had three malignant tumours, with metachronous tumours being more common than synchronous. The most frequently affected sites were the colorectum, prostate, breast, and endometrium. Rare cases included sarcoma, salivary gland tumours, and maxillary cancers. Histopathological analysis revealed the following types: NOS, mucinous, and adenoma-like adenocarcinomas for colorectal cancers; invasive carcinoma NOS for breast cancers; endometrioid, squamous, and serous carcinoma for uterine cancers; acinar adenocarcinoma for prostate cancers. Most tumours were moderately differentiated, with some showing poor differentiation.
Treatment involved surgery, chemotherapy, hormonal therapy (for breast and prostate cancers), and radiotherapy (both curative and palliative).
Conclusion: This study underscores the elevated risk of second primary cancers, particularly among older patients who benefit from early cancer detection and effective treatments that extend their lifespan. Women often had both breast and uterine cancers, while men commonly presented with prostate and colorectal cancers. These findings highlight the critical need for continuous surveillance in cancer survivors.

E-PS-20-004
Evaluating pathology residency training in Romania: a survey-based approach
M.M. Koteles[1], G.-E. Olteanu[2,3,4]
[1]County Emergency Hospital Bihor, Department of Pathology, Oradea, Romania, [2]British Columbia Cancer Agency, Department of Pathology, Vancouver, Canada, [3]University of British Columbia, Department of Pathology and Laboratory Medicine, Vancouver, Canada, [4]Romanian National Society of Pathology (Uniunea Patologilor - UNIPAT), Board of Directors, Bucharest, Romania

Background & Objectives: Pathology is a specialty that requires extensive hands-on training, beyond what textbooks can provide. To gain insight into the romanian residency training experience and satisfaction, we designed a survey to evaluate key aspects of residents' professional development.
Methods: We designed two questionnaires using an online platform, SurveyMonkey, ensuring the anonymity of responses. The first was a 6-item version for first-year residents, and the second was a 19-item version for residents in years 2 to 5, with a total of 22 questions across both versions. The survey began with 3 demographic questions for all participants. First-year residents answered 3 additional questions, while residents in years 2 to 5 answered 16. The survey included 12 multiple-choice questions assessing satisfaction on a 5-point scale, 4 yes/no questions, and 3 check-box questions with options and free-text suggestions. The questionnaires were distributed via email and shared through the Romanian National Society of Pathology's (UNIPAT) official WhatsApp group.
Results: 89 responses were received, with a 91% completion rate. Of 81 completed responses, 12.35% were from first-year residents, and 87.65% from residents in years 2-5. Among first-year residents, 80% cited work-life balance and personality fit as the main reasons for choosing pathology, with other reasons including remuneration and minimal patient contact. Among residents in years 2-5, 46.47% rated training quality "acceptable". Research and academic opportunity satisfaction was low, nearly 60% finding them insufficient or unsatisfying. Despite high satisfaction with workplace colleagues, personnel, and residency coordinators, more than 70% of participants stated being unable to discuss career paths and opportunities with their supervisor, while up to 75% considered working in Romania after completing their training unlikely or improbable.
Conclusion: By identifying strengths and weaknesses in Romania's pathology residency training, this study aims to foster dialogue to enhance mentorship and programs, ensuring the healthcare system benefits from skilled pathologists.

E-PS-20-005
Multiple peritoneal adenomatoid tumours mimicking peritoneal carcinomatosis during hiatus hernia repair: a case report
G. Carrola[1], M. Mexia Leitão[1], M. Zbronska[1], X. Wen[1], A. Duarte[1]
[1]Unidade Local de Saúde de Santo António, Anatomic Pathology Service, Genetics and Pathology Clinic, Porto, Portugal

Background & Objectives: Peritoneal adenomatoid tumour (PAT) is a very rare, benign neoplasm. Adenomatoid tumour more frequently involves the uterus, Fallopian tubes and paratesticular region. Despite being considered of mesothelial origin, very few cases were reported in extragenital abdominal serosa. Multiple tumours are even rarer and raise suspicion for malignancy. We present a case in which intraoperative findings suggested peritoneal carcinomatosis, but was ultimately diagnosed as multiple peritoneal adenomatoid tumours (mPATs).
Methods: A 62-year-old female with multiple comorbidities, including hypertension and congestive cardiac failure, presented with gastrointestinal reflux disease secondary to a hiatus hernia. Surgical repair was indicated after failure of conservative management. During surgery,

several peritoneal lesions with suspicion for carcinomatosis were discovered. Abdominal and pelvic organs showed no macroscopic lesions. Excision biopsies of the lesions were sent to our department for histopathological evaluation.
Results: We received two irregular omental fragments, with velvety serosal surfaces, measuring 3.5 cm and 2.5 cm in the maximum dimensions, respectively. Serial sectioning revealed multiple well circumscribed, witish and firm nodules, the largest measuring 1.0 cm in diameter. Microscopically, the nodules consist of a neoplasm composed of uniform cuboidal cells, without pleomorphism, variably arranged in tubular, glandular, and trabecular patterns within a hyalinised stroma. No necrosis or mitotic activity was observed. Immunohistochemistry showed reactivity for calretinin, CK5, and D2-40, and lack of immunoreactivity for BerEP4, GATA-3, PAX8 or ER. Immunoreactivity for BAP1 was also preserved. Proliferative index was low (<2%). These findings were consistent with the diagnosis of mPATs.
Conclusion: This case highlights the diagnostic challenge of mPATs, which can clinically mimic peritoneal carcinomatosis. While benign, awareness of this entity is crucial for accurate diagnosis and management. Multidisciplinary discussion is recommended for rare presentations and histopathological assessment coupled with clinical surveillance is fundamental for such patients.

E-PS-20-006
Incidence of cardiac tumours in a tertiary care hospital
A.J.C. van der Biezen[1], B. López-Martinez Bernal[1], M. Cebollero Presmanes[1], F.J. Menarguezz Palanca[1], F. Alijo Serrano[1], C. Agra Pujol[1], F. Arias[1], M. Garcia Martos[1], M.d.C. López Varela[1], F.J. Díaz Crespo[1]
[1]Hospital General Universitario Gregorio Marañon, Pathology, Madrid, Spain

Background & Objectives: Cardiac tumours are rare but have high morbi-mortality, requiring timely detection and treatment. They are classified as malignant or non-malignant, with primary tumours being mostly benign (90%), while secondary tumours are more common. Advances in molecular and imaging techniques have enhanced their detection and understanding.
Methods: Between 1997 and 2024, 53 cardiac tumours were diagnoed in our hospital: 47 primary and 6 secondary. The most common benign primary tumours were papillary fibroelastoma (35%), myxoma (30%), and lipoma (3%). In children, 4 rhabdomyomas and 1 hemangioma were found. Among malignant tumours, there were 4 sarcomas and 1 with uncertain metastatic potential.
Results: Papillary fibroelastoma was the most common benign primary tumour (40%), mainly affecting the aortic and mitral valves, with most cases being incidental. Myxoma was the second most frequent (34%), predominantly in women, mostly found in the left atrium. Cardiac lipoma accounted 4% of benign tumours, located in the left ventricular wall. In children, rhabdomyoma was the most common, diagnosed prenatally and removed without complications, while one haemangioma was found in a patient with hypoplastic left heart syndrome. Among malignant tumours, 4 sarcomas and 1 inflammatory myofibroblastic tumour were identified. The most common subtype was undifferentiated pleomorphic sarcoma. Secondary cardiac tumours included metastases from melanoma and squamous cell carcinoma, as well as cases of intramyocardial leiomyoma (associated with EBV), T-cell lymphoblastic leukaemia, peripheral T-cell lymphoma, and high-grade large B-cell lymphoma.
Conclusion: The incidence of primary cardiac tumours has increased, while biopsies for secondary tumours have declined due to advancements in multimodal imaging, reducing the need for invasive procedures. Secondary tumours indicate advanced metastatic disease with poor prognosis. Biopsies in high-risk cardiac areas pose significant risks, and metastatic tumours are often biopsied at safer sites outside the heart. As a result, metastatic cardiac tumours, though more common, are typically managed without confirmatory biopsy.

E-PS-20-007
***ALK* rearrangements is very rare in peritoneal mesothelioma**
A. Demirci[1], F.S. Gürevin[1], N. Akyürek[1], M.İ. Gündüz[1]
[1]Gazi University School of Medicine, Pathology, Ankara, Turkey

Background & Objectives: Peritoneal mesothelioma (PeM) is a rare malignancy with a generally poor prognosis. Anaplastic lymphoma kinase (*ALK*) alterations (activating mutations, amplifications, and fusions/rearrangements) occur in 3% of cancers, though *ALK* fusions/rearrangements are less common. There are several ongoing studies suggesting that the potential for ALK fusion as a tumour-agnostic biomarker.
Methods: In total, 46 patients with PeM were evaluated in the present study. Expression of ALK and/or rearrangement of *ALK* was evaluated by immunohistochemistry (IHC) (D5F3, Ventana) and confirmed ALK rearrangemant by fluorescence in situ hybridization (FISH) using a break-apart probe (ZytoVision)
Results: Among the 46 PeM patients, there were 25 males and 21 females, with a median age of 63,7 (range: 28–83). Histologically, 38 patients were epithelioid, 4 were biphasic and 4 were sarcomatoid subtype. Focal and weak ALK positivity was found in only one case and no ALK rearrangement was detected by FISH.
Conclusion: ALK alterations are extremely rare in PeMs and making studies in these diseases difficult.

E-PS-20-008
Well-differentiated papillary mesothelial tumour of the peritoneum in advanced age
G. Richter[1], P. Richter[1], R. Lueck[2]
[1]Institute of Pathology, Hameln, Germany, [2]MVZ Orthomotio-Med, Hameln, Germany

Background & Objectives: Benign mesothelial tumours are rarer than malignant mesotheliomas and are often found in the peritoneum as incidental findings in women. They include the adenomatoid tumour (AT), the well-differentiated mesothelial tumour (WDPMT), the mesothelioma in situ (MIS), and the solid papillary mesothelial tumour (SPMT). Well-differentiated papillary mesothelial tumour (WDPMT), formerly known as well-differentiated papillary mesothelioma, is a histologically distinctive mesothelial tumour of uncertain malignant potential found in the pleura, peritoneum, and tunica vaginalis.
Methods: We present a case of a 77-year-old Caucasian femalewith a single papillary tumour measuring 15 millimeters at the colon ascendens. The specimens were routinely stained with haematoxylin and eosin. Moreover,Periodic acid–Schiff (*PAS*) was processed. Additionally, the specimens were immunohistochemically stained with primary antibodies Pan-cytokeratin (Roche), cytokeratin 5/6 (Roche), cytokeratin 7 (Roche), cytokeratin 20 (Roche), calretinin (Roche) and KI-67 (Roche).Furthermore, immunohistochemically staining with primary antibody PAX8 (Roche) was performed.
Results: The tumour is composed of papillae with myxoid cores covered by a single layer of generally bland, flattened to cuboidal mesothelial cells. There is no evidence of invasion. Immunohistochemicalanalysis showed that the mesothelial cells expressed calretinin, Pan-cytokeratin, CK 5/6 and CK7, while no expression of CK 20 was detected.
Conclusion: Well-differentiated papillary mesothelial tumour has been included in the WHO classification of gynaecologic tumours since 2020 and in the classification ofthoracic tumours since 2021, replacing the term of well-differentiated papillary mesothelioma. We present a case of a female patient in advanced age, a 77-year-old Caucasian female with a single papillary tumour of 15 millimeters at the colon

ascendens. Due to the probable positive prognosis, no intervention is necessary, but ongoing monitoring is recommended.

E-PS-20-009

Correlation between p53 immunoexpression and *TP53* mutation status in extrapulmonary small cell neuroendocrine carcinomas and its association with patient survival

K. Pavlickova[1], P. Waldauf[2], P. Dundr[3], N. Hajkova[3], M. Svajdler[4], P. Fabian[5], I. Staniczková Zambo[6], M. Flidrova[3], J. Laco[7], H. Hornychova[7], P. Delongova[8], J. Skarda[8], J. Hrudka[9], R. Matej[9,3,1]
[1]Thomayer University Hospital, 3rd Faculty of Medicine, Charles University, Pathology and Molecular Medicine, Prague, Czech Republic, [2]3rd Faculty of Medicine, Charles University, Department of Anaesthesia and Intensive Care, Prague, Czech Republic, [3]Charles University and General University Hospital in Prague, Department of Pathology, First Faculty of Medicine, Prague, Czech Republic, [4]Charles University, Medical Faculty in Pilsen, Bioptická Laboratoř s.r.o. and Šikl's Department of Pathology, Pilsen, Czech Republic, [5]Masaryk Memorial Cancer Institute, Department of Oncological Pathology, Brno, Czech Republic, [6]Masaryk University, St. Anne's University Hospital and Faculty of Medicine, 1st Institute of Pathologic Anatomy, Brno, Czech Republic, [7]Charles University, Faculty of Medicine in Hradec Králové and University Hospital Hradec Kralove, The Fingerland Department of Pathology, Hradec Kralove, Czech Republic, [8]University Hospital Ostrava and Faculty of Medicine University of Ostrava, Department of Clinical and Molecular Pathology and Medical Genetics, Ostrava, Czech Republic, [9]3rd Faculty of Medicine, Charles University, Department of Pathology, University Hospital Kralovske Vinohrady, Prague, Czech Republic

Background & Objectives: Extrapulmonary small cell neuroendocrine carcinoma (EP-SCNC) is a rare malignancy with a poor prognosis. Despite its morphological similarity to lung small cell carcinomas, its oncogenesis remains uncertain.
Methods: One hundred and seventy-one EP-SCNC were enrolled in a multicentre study, and all tissue samples underwent an immunohistochemical p53 analysis. One hundred twenty-five samples were molecularly analysed using next-generation sequencing (NGS), comprising DNA and RNA analysis.
Results: p53 normal/wild type expression was detected in 68 cases (39.8%), whereas aberrant expression was detected in 103 cases (60.2%). Molecular *TP53* alteration was detected in 92 out of 125 tumours (73.6%). The *TP53* mutation was shown to be prognostic and associated with shorter overall survival (p=0.041). The multivariate analysis of p53 and *TP53* mutational status found that it impacted overall survival relative to distinct sites of tumour locations ($p = 0.004$ and $p = 0.001$, respectively). Age did not influenced survival in the multivariate analysis of p53 and *TP53* (p=0.002; p<0.001 resp.).
Among tumours with paired immunohistochemical and molecular results, 108 exhibited concordance between the immunohistochemical and molecular analysis, whereas 17 were discordant. Accordingly, p53 aberrant expression was tightly associated with a *TP53* mutation (p<0.001). In discordant cases, molecular analysis revealed no alteration in three tumours with p53 overexpression. In contrast, in 14 tumours with wild-type p53 expression, *TP53* genetic alteration was detected. Possible causes of discordance are discussed in this manuscript.
Furthermore, the incidence of aberrant p53 expression / *TP53* molecular alteration was noticeably lower in EP-SCNC than in small-cell lung carcinomas.
Conclusion: Therefore, in EP-SCNC, other driver mutations than *TP53* alteration should be sought since personalized therapy can improve patient prognosis.

Funding: This work was supported by the Ministry of Health of the Czech Republic and Thomayer University Hospital (FTN, 00064190), the Agency for Health Research of the Czech Republic (project NU22-03-00130), by Charles University (Cooperatio Medical Diagnostics and Basic Medical Sciences)

Developing a risk-based standard operating procedure to streamline multidisciplinary team meeting preparation

J. Brewis[1], M. Flynn[1]
[1]Salisbury District Hospital, Salisbury, United Kingdom

Background & Objectives: Increasing workload and case complexity in multidisciplinary team (MDT) meetings have outpaced resource allocation rendering the current system unsustainable. The Royal College of Pathologists (RCPath) provides best practice guidance, emphasizing the need for a proportionate, risk-based approach to case selection, tailored to local circumstances and workforce capacity.
Methods: Aim: To develop a Standard Operating Procedure (SOP) for a district general hospital to streamline MDT preparation, optimize resource allocation, and enhance reporting efficiency.
Results: Insights: The development process highlighted key challenges in implementation including stakeholder engagement, adaptation to local workflows, and balancing efficiency with clinical governance. Lessons learned are shared to inform future SOP development in similar settings.
Conclusion: The introduction of a structured SOP is expected to significantly reduce MDT preparation time, allowing for improved reporting efficiency and service sustainability. Future work will focus on embedding this model into routine practice, evaluating its long-term impact, and refining the approach based on emerging needs. Additionally, the evolving role of AI-assistance will be a critical consideration in future MDT optimization strategies.

Ethical issues concerning the use of archived human tissue samples for research in pathology

C. Dagher[1], A. Abi-Gerges[2], S. Dagher[3], R. Clément[4]
[1]Mohammed Bin Rashid University of Medicine and Health Sciences (MBRU), Basic Sciences- Pathology, Dubai, United Arab Emirates, [2]Gilbert and Rose-Marie Chagoury School of Medicine, Lebanese American University, Basic Sciences, Byblos, Lebanon, [3]School of Pharmacy, Lebanese American University, Pharmacy, Byblos, Lebanon, [4]Laboratory of Forensic Medicine, Faculty of Medicine, Nantes, France

Background & Objectives: Human tissues collected and archived in usual clinical practice by pathology departments remain a rich and essential source of information potentially available for research. The use of pathology archived tissue samples as research specimen involves a variety of ethical concerns regarding confidentiality and autonomy, especially that informed consent is practically impossible to obtain retrospectively. Our objective is to assess the knowledge and attitude towards the use of archived human tissue samples for research in pathology among the Lebanese population.
Methods: The study was conducted at the Pathology department of Sacred-Heart Hospital in Baabda, Lebanon over a period of two months. Upon consent, hundred patients who have undergone biopsy or surgery with a pathology specimen sent to the laboratory were invited to complete anonymously a validated questionnaire made of 14 questions in total.
Results: Seventy six participants would accept and consent on the use of their tissue specimens for research, with no statistical correlation regarding gender, education, religion and age. Interestingly, 71% were not aware about the fate of their tissue specimens after the diagnosis

is issued. Almost all participants (93.4%) would want to be informed if their stored tissues were to be used for research. Reasons for refusal were evaluated and attributed mostly (45.8%) to patient's fear of research results.

Conclusion: Our study shows that almost all responders wish to be informed prior to the use of their tissue for research purpose. Therefore, our results highlight the need for drafting and establishing national laws and ethical procedures in medical pathology departments in respect to obtaining a clear informed consent and regulating the use of diagnostic specimens for future research studies and education purposes.

E-PS-20-012

The changing landscape of immunohistochemical testing using pan-cytokeratin antibodies in diagnostic histopathology. A survey of results from the UK NEQAS ICC & ISH external quality assessment programme

A. Dodson[1], S. Parry[1]

[1]UK National External Quality Assessment Scheme for Immunocytochemistry and In-Situ Hybridisation, London, United Kingdom

Background & Objectives: Antibodies to cytokeratin (CK) proteins were amongst the first to be employed in diagnostic histopathology. Wide-spectrum (pan) CK-antibodies reactive to commonly expressed CK protein family members continue to be universally used to identify tumours of epithelial lineage to this day.

UK NEQAS has conducted external quality assessment (EQA) surveys to test the quality of pan-CK testing by immunohistochemistry (IHC) since the early 1990's. We examined the data accrued as a result to look for trends that may inform methodological choices and advance testing quality.

Methods: The most recent four EQA Runs were selected to maximise the applicability of results. Within each run primary antibody, antigen retrieval, detection and automated platform data were examined for associations with improved stain quality outcomes. Run-to-Run results were investigated for time-related trends.

Results: Four EQA Runs conducted in 2008, 2011, 2019 and 2021 were examined (span: 13 years). Number of submissions was 375, 360, 300 and 276 respectively (total: 1,311).

Overall, where information was submitted (1,246, 95.0%), 1,192 (95.7%) used one of three primarys; AE1/AE3 (654, 52.5%), MNF116 (348, 27.9%), AE1/AE3/PCK26 (190, 15.2%). Multiple other antibodies were represented in the remaining submissions (54, 4.3%) - not further described.

There was a marked change in proportional use of antibodies between 2008 and 2021; use of both AE1/AE3 and MNF116 declined from 52.5% to 44.9% and from 35.9% to 22.8% respectively, that of AE1/AE3/PCK26 increased from 5.5% to 29.3%.

Overall, the proportions of users of the three main antibodies that passed assessment were, AE1/AE3: 91.7%; AE1/AE3/PCK26: 93.3%; MNF116: 91.0%.

The proportions of participants passing at the latter two Runs was markedly higher compared to the two earlier Runs; overall 99.6% and 98.4% passed the latter and 91.0% and 87.6% the earlier pairs of Runs.

Conclusion: The quality of pan-CK testing by IHC is high and has improved over time.

E-PS-20-013

Flipped classroom: a successful method in pathology teaching

S. Kamoun[1], H. Maaroufi[1], F. Loued[1], Y. Loukil[1], A. Ben Amor[1], A. Goucha[1], I. Bettaieb[1], Y. Houcine[1], M. Driss[1]

[1]Salah Azaiez Institute, Pathology Department B, Tunis, Tunisia

Background & Objectives: Flipped learning is currently a focus of attention among educators worldwide. It is part of initiatives aimed at making classes less lecture-based and students more active. In Tunisia, courses at the pathology college are still taught using a passive, transmissive method. The aim of this study was to assess the impact of a flipped classroom dedicated to residents in terms of knowledge acquisition and learner satisfaction.

Methods: On June 7, 2024, a course on thyroid pathology was held, organized at the Faculty of Medicine of Tunis by the Department of Pathology B at Salah Azaiez Institute. This course utilized the flipped classroom model, along with other innovative teaching methods: group work, peer learning, mind mapping, and gamification. Three questionnaires, available online via Google Forms, were used to evaluate the learners' knowledge and satisfaction. Statistical analysis was performed using SPSS software.

Results: All the residents responded to the three questionnaires (n=30). The success rate for the nine questions after the educational intervention was 0%, 96%, 92%, 50%, 62.5%, 12.5%, 71%, 42%, and 0%, respectively. The educational intervention significantly improved the success rate of the residents on questions 2, 3, and 7 (p=0.01, 0.02, and 0.02, respectively). Ninety-five percent of the residents rated the scientific content, activities, and atmosphere as excellent. The overall rating for the course was 4.95/5.

Conclusion: In conclusion, the flipped classroom model enhances the learning experience of pathology residents by providing a framework where theoretical knowledge is reinforced through practical classroom activities, making training more effective and better suited to the demands of the field.

Thus, the future directions of this work are to expand the concept of active learning and improve the validity and reliability of assessment tests.

E-PS-20-014

Evaluation of medical students training in pathology department of Sahloul Hospital

A. Bdioui[1,2], I. Hadhri[3], S. Moussa[2], O. Bekacem[2], S. Mestiri[2], S. Hmissa[2]

[1]Sousse Medical School, Research Laboratory Oncogenesis and Tumoral Progression LR21ES03, Sousse, Tunisia, [2]Sahloul Hospital, Pathology, Sousse, Tunisia, [3]Farhat Hached Hospital of Sousse, Pathology, Sousse, Tunisia

Background & Objectives: In medicine, combining theory and practice learning, is crucial to student training. The recent reform of medical education includes practical training in pathology.

Our objective is to evaluate the supervision of medical students in our pathology department.

Methods: This study was conducted over a period of five years (2020-2024). It is destined to the fourth-year students of Sousse medical school, as part of an optional two-week course.

During the training, students take part in the various technical stages and gross. They are then supervised by a senior who teaches them short courses analysing real-life situations . At the end of the training period, the students, working in teams, have to give oral presentations . The final assessment of the course takes the form of an Objective Structured Clinical Examination. The quality of this training was assessed by 15 questions focusing on their experience in the laboratory and the impact this had on their training.

Results: Analysis of the questionnaire showed that 95% of the students had a better understanding of pathology. Prior to this experience, 90% of them had no knowledge of the macroscopic examination or the technical stages. Furthermore, 82% of the students did not understand the importance of frozen section examination in patient management.

The senior lecturers' presentations enabled the students to apply their theoretical knowledge more effectively. The flipped classroom approach improved their communication and oral presentation skills, as well as slide presentation rules.

Overall student satisfaction was estimated at 85%. However, 30% of the students wished for more microscopy sessions.
Conclusion: Training in the pathology laboratory has improved the skills of future doctors in terms of knowledge and professional attitudes. We believe that this contribution should not be limited to small groups but should be extended to all students.

E-PS-20-015
International classification of diseases for oncology – 4: bridging cancer registry data with an evolving tumour classification
H. Wijesinghe[1], G. Goldman Levy[1], A. Znaor[1], B. Rous[2], R. Watanabe[3], P. Puspanathan[1], R. Jakob[4], E. Krpelanova[4], I. Cree[1], F. Bray[1], D. Lokuhetty[1]
[1]International Agency for Research on Cancer/World Health Organization, Lyon, France, [2]Cambridge University Hospitals, NHS Foundation Trust, Cambridge, United Kingdom, [3]St. Marianna University School of Medicine, Kawasaki, Japan, [4]World Health Organisation, Geneva, Switzerland

Background & Objectives: International Classification of Diseases for Oncology(ICD-O) topography, morphology and behaviour of tumours is used by pathology registries and hospital and population-based cancer registries, for coding data critical for cancer control and research. With advances in tumour classification and definition of new entities, increasing granularity is needed in coding morphology. The fourth edition of ICD-O(ICD-O-4) aims to provide a structure of unique codes to existent and newly defined tumour entities facilitating accurate coding of data by cancer registries.
Methods: In April 2021 the IARC/WHO ICD-O Committee launched a survey questionnaire of all International Association of Cancer Registries(IACR) members to seek an opinion on updating ICD-O-3.2 by adding an extra 5th alphanumeric digit to existing four-character morphology codes, as opposed to introducing the use of International Classification of Diseases-11th(ICD-11) as a primary classification for use in cancer registries. 90%(250/276) of respondents agreed to the proposal. The beta version of ICD-O-4, including the proposed codes for tumours listed in WHO Classification of Tumours-5th edition, was developed by the IARC/WHO ICD-O Committee and published on the IARC-WCT website (https://tumourclassification.iarc.who.int/icdo4/) in 2024 for open consultation.
Results: Changes made to ICD-O-4 include, addition of a 5th alphanumeric digit in the morphology code, introduction of new morphology codes, changes in first four digits of morphology codes used in ICD-O-3.2, changes of behaviour codes(e.g. lymphangioleiomyomatosis changed from /1 to /3), introduction of a new topography code for gastroesophageal-junction(C16.7), detailed codes for extrahepatic bile ducts(C24.2 and C24.3) and cystic duct(C24.4), and change of topography code for anal skin cancer from skin(C44.5) to anus(C21.3).
Conclusion: ICD-O-4 was compiled in response to increased needs for granularity and in consultation with pathologists, epidemiologists, public health researchers and cancer registry community. The five-digit morphology codes enable hierarchical and detailed coding of tumours, while the new topography codes reflect the evidence base on tumour aetiology and staging.

E-PS-20-016
Intraoperative consultations of frozen sections diagnostic accuracies
P. Aksenova[1], L. Rudiuk[1], O. Reshetnikova[1], S. Korenev[1]
[1]Immanuel Kant Baltic Federal University, Kaliningrad, Russia

Background & Objectives: Differential diagnosis based on the intraoperative frozen sections (IFS) histological examination provide surgeon with assess the operated organ's condition. Time constraints, stressful situations and lack of skills may result in pathologist's wrong interpretations. The aim of our study was to reveal a value of IFS consultation in final diagnosis taking into account possible diagnostic errors.
Methods: The data of 972 patients with IFS examination during their surgery were enrolled in the study. Clinical features of each case, medical records, intraoperative consultations result and histopathology reports were evaluated. For a more reliable analysis of the IFS consultations' accuracy compared with final diagnosis, following point system was introduced: 1 – complete discrepancy of the conclusion, 2 – partial coincidence, 3 – complete coincidence of the conclusions. Spearman coefficient used in statistical analysis.
Results: Present study has shown that examination of IFS requires highly professional training of a pathologist to correctly assess the macroscopic picture and histological characteristics of the tissue sent from the operating room. It has been established that the frequency of intraoperative examinations at the University Clinic varies between 2.5-3 percent of the total number of surgeries with the collection of histological material annually. Both in 2022 and in 2023, the majority of IFS consultations and after routine histological examination ended in complete coincidences (respectively: 87.48% and 88.23%). Discrepancies decreased in a number of pathologies of the following organs: thyroid gland - 23.5%, breast – 13.9%, ovaries – 11.9%, lungs – 11.8%, pancreas – 9.1% and lymph nodes – 4.7%. Spearman's correlation coefficient (p) was 0.370.
Conclusion: IFS morphological diagnosis has an important value and primarily based on effectively identified suspected area by a surgeon. Diagnostic accuracies of the IFS study of malignant neoplasms tissues should be based on coordinated work of a clinician and a pathologist, which contributes to its improvement and increases the effectiveness of treatment.

E-PS-20-017
Annotation discrepancies in prostate cancer gleason grading: implications for deep learning training
R. Peyret[1], C. Radulescu[2], N. Nerrienet[1], S. Sockeel[1], S. Rorive[3], I. Salmon[3]
[1]Primaa, AI, Paris, France, [2]Hôpital Foch, Pathologie, Suresnes, France, [3]CurePath, Bruxelles, Belgium

Background & Objectives: Supervised learning is the predominant approach for training deep learning models in Gleason pattern segmentation on histopathology slides. However, precise annotations are essential, and inter-observer variability in the evaluation of Gleason score remains a major challenge, with reported kappa values as low as 0.34 and a concordance rate of 57% at the slide level (Ozkan et al., 2016). This variability raises critical questions on how to construct robust training and test datasets for deep learning applications.
Methods: We collected 200 tumoral prostate slides and had three independent pathologists annotate each slide at the gland group, gland and cellular level using six labels: Gleason 3, Gleason 4, Gleason 5, IDC, HGPIN, ASAP. Annotations were reviewed by senior prostate specialists to ensure consistency. Pathologists underwent specialized training, and both pathologists and data scientists reviewed annotations to align methodologies. A multireader test set was created to estimate local annotation variability, and a consensus ground truth was derived by merging annotations.
Results: Our analysis quantified annotation discrepancies: the concordance area ratio between two pathologists was 33% on average, while 42% of the regions were labeled by only one pathologist. Additionally, 50% of the annotated regions had conflicting labels, with the most frequent confusion occurring between Gleason 3 and Gleason 4 patterns. The derived slide-wise Gleason score yielded an inter-observer kappa of 0.2.

Conclusion: Local gland-level annotation exhibits higher variability than slide-wise Gleason scoring. This variability must be explicitly considered in model training and evaluation to ensure robustness in automated Gleason grading.

E-PS-20-018

An enhanced 10-minute method for Tissue Macroarray construction

S. Lopez-Prades[1,2], G.A. Caballero[1,2], I. Aldecoa[1,3,2], M. Cuatrecasas Freixas[1,2,4]

[1]Hospital Clinic de Barcelona, University of Barcelona, Pathology, Biomedical Diagnostic Centre (CDB), Barcelona, Spain, [2]August Pi i Sunyer Biomedical Research Institute (IDIBAPS-FCRB), Barcelona, Spain, [3]Hospital Clinic de Barcelona, University of Barcelona, Neurological Tissue Bank of the Biobank, Barcelona, Spain, [4]Carlos III Health Institute, Liver and Digestive Diseases Biomedical Research Centre Network (CIBERehd), Madrid, Spain

Background & Objectives: Tissue Microarrays (TMA) are common in pathology research for the simultaneous analysis of multiple tissue samples on a single slide. Nevertheless, its small sized cores (0.2–2mm) may limit representativeness. Tissue Macroarrays (Macro-TA), with cores from 3 to 8mm, offer an alternative for small cohorts of cases, better area selection, geographical analyses or histological heterogeneity analyses in samples, biomarker studies, or quality control. Nevertheless, Macro-TA construction has faced challenges in sample orientation, and its preparation is time consuming, often exceeding one hour per Macro-TA. We here present an optimized Macro-TA construction method that ensures precise orientation and localization of samples throughout all the process while significantly reducing construction time.
Methods: Selected samples were identified and marked on HE-stained sections and on donor paraffin blocks. A digital template was designed to detail case identification and layout. A scaffold was created using an inclusion sponge (Deltalab, Spain). Then, a punch-biopsy instrument (Kai Medical, Japan) was used to make perforations on the sponge. An extra half-core perforation notch was made on one corner for orientation control. Then, the perforated sponge was placed in a tissue embedding metal mold. Each tissue core was extracted from the donor block using the punch and retrieved with a metallic probe to minimize tissue handling. Tissue cores were then inserted into the sponge perforations following the digital template. Finally, the mold was filled with paraffin and allowed to solidify.
Results: Each Macro-TA block was constructed, containing from 9 to 48 cores and a total preparation time between 7 and 25 minutes, depending on the diameter of the punch used. The sponge did not interfere in H&E stains or any other technique performed.
Conclusion: This is an improved fast and reproducible new method for Macro-TA construction without the need of specialized instrumentation, facilitating their implementation in diagnostic and research pathology laboratories.

E-PS-20-019

Detection of neutrophil extracellular traps by flow cytometry in patients with systemic lupus erythematosus

A. Mglinets[1], N. Nizyaeva[2], A. Aleksankin[2], A. Avdeeva[3], Y. Gorbunova[3], L. Kondratyeva[3], A. Tarasenko[3], A. Aleksankin[3]

[1]Academy of Postgraduate Education of The FSCC FMBA of Russia, Resident, Moscow, Russia, [2]Avtsyn Research Institute of Human Morphology of FSBSI "Petrovsky National Research Centre of Surgery", Moscow, Russia, [3]V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia

Background & Objectives: NETosis is a process in which activated neutrophils form net-like structures in the extracellular space known as neutrophil extracellular traps (NETs), composed of decondensed chromatin, histones, and granular proteins. In rheumatic diseases, the formation of NETs leads to damage to organs and tissues, accompanied by inflammation and thrombosis. Increased production of myeloperoxidase (MPO), proteinase-3 (PR-3), and neutrophil elastase (NE) is of significant importance in the pathogenesis of systemic vasculitis, while nucleic acids and DNA molecules act as autoantigens in systemic lupus erythematosus (SLE). The aim of the study was to assess the main parameters of neutrophil extracellular trap formation and their changes in patients with systemic lupus erythematosus.
Methods: The study included 64 patients with a median (Me [25; 75 percent]) age of 38.0 [27.5; 46.5], all with confirmed diagnosis of SLE. The median duration of SLE was 9.0 [3.0; 16.0] years, and the disease activity was considered low with an SLEDAI-2K of 4 [2; 11] compared to healthy donors (n=20). The NETs were assessed using flow cytometry by detecting myeloperoxidase in neutrophils after stimulation with phorbol 12-myristate 13-acetate (PMA).
Results: In the results, the flow cytometry study showed that the MPO content in neutrophils from healthy donors in the control group, after stimulation with PMA, was 25.9 [7.7; 42.8], which was significantly lower compared to the SLE patient group, which had a level of 64.2 [38.2; 73.5] (P=0.0006).
Conclusion: In conclusion, neutrophils from SLE patients differ significantly from those of healthy donors, demonstrating impaired phagocytic clearance, increased tendency towards apoptosis, and abnormal oxidative metabolism.

E-PS-20-020

Comparative Experimental Pathology – a success story

T. Groll[1], C. Mogler[1], K. Steiger[1]

[1]Institute of Pathology, Technical University of Munich, TUM School of Medicine and Health, Munich, Germany

Background & Objectives: Comparative experimental pathology (CEP) deals with analysing and comparing animal models to their corresponding human diseases, revealing parallels, but also differences on tissue level. This is essential in biomedical research in order to use animal models reliably, responsibly, and efficiently. It is also important with respect to the "3Rs" principles. Yet, much biomedical research using animal models is published without the involvement of pathologists with specific knowledge.
Methods: At the Institute of Pathology of the Technical University of Munich, the CEP core facility has been set up and fully integrated into the human general and surgical pathology institute, which is a unique setting in Europe. Since CEP was established in 2016, diverse project requests have been constantly increasing, as has the number of affiliated veterinary and human pathologists with model-specific expertise (e.g., background lesions, species specificities).
Results: Integration of the CEP built synergies between both, human and veterinary pathology. This increased, first, methodological and technical possibilities, and second, the exchange of current scientific knowledge.
Conclusion: With this example, we aim to advocate for more frequent integration of veterinary and comparative pathology into human biomedical research and for making the best use of the resulting synergies.

E-PS-20-021

Precision nutrition: breakthrough of multi-omics precision medicine

I. Vamvakaris[1], O. Mpoulioglou[2], E. Kopana[2], A.N. Kontouli Pertesi[2], I. Gkiozos[3], K.N. Syrigos[3], A.K. Anagnostopoulos[4]

[1]Sotiria Hospital, Pathology, Athens, Greece, [2]Biomedical Research Foundation of the Academy of Athens, Biotechnology, Athens, Greece, [3]Sotiria Hospital for Diseases of the Chest, National and Kapodistrian University of Athens, Oncology Unit, 3rd Dept of Medicine, Athens,

Greece, [4]Biomedical Research Foundation of the Academy of Athens, Dep. Int. Med. Biotechnology, Athens, Greece

Background & Objectives: Precision nutrition is a pioneering field that offers multidimensional nutrition recommendations tailored to an individuals' genetic and endocrine background. Use of multi-omics platforms encompassing genomics, transcriptomics, proteomics and metabolomics allows analysis of an individual's genetic fingerprint, protein expression and metabolite presence leading to creation of customized dietary quota. The scope of the study is the modelization of a pipeline that leads from collection of biological material from an individual to production of a tailored nutrition plan.
Methods: The approach entails distinct steps towards generation of vast datasets. The first node of the pipeline involves the precise analysis of biological samples (e.g. blood, urine, saliva, feces), by exhaustive multi-omics analysis integrating technologies such as DNA-seq, RNA-seq and Mass Spectrometry. The second and focal pivot of the pipeline is the implementation of bioinformatics tools towards integrative adaptation of previously collected data.
Results: Specifically, data pre-processing, quality control and integration of multi-omics data are combined towards the construction of a model. The final model, through utilization of machine learning algorithms, is used to predict individual dietary responses, risk factors as well as create personal nutrition plans.
Conclusion: Precision nutrition, a sub-domain of personalized medicine, offers a new point of view to disease prevention and regulation. Multi-omics-derived data to are used create a predictive model for nutrition planning, the final goal being optimizing management of cancer and chronic or metabolic diseases, or offering a personalized plan to improve the individual's health status.

E-PS-20-022
Digestive cancer risk associated with quality of water in Boyacá, Colombia
B.M. Bernal Gomez[1], D. Bernal[2]
[1]Universidad Pedagógica y Tecnologica de Colombia, Medicina, Tunja, Colombia, [2]Uptc Primo Levi GIBP, Tunja, Colombia

Background & Objectives: Disinfection By-Products (DBPs) are chemical compounds formed during water treatment when disinfectants like chlorine react with organic matter, posing a cancer risk through genotoxicity, DNA repair disruptions, and chronic inflammation. Regulatory frameworks in Colombia, guided by the Water Quality Risk Index (IRCA) weigh these cancer risks against pathogen-related disease prevention, differing from European approaches. Boyaca, Colombia—an agriculturally driven region with unregulated mining activity—has significant DBP concentrations in its water supply. Such exposure may correlate with elevated rates of digestive cancers, including colorectal and gastric cancers. Aims to create a risk assessment model, based on cancer prevalence in relation to DBP exposure, integrating raw data on cancer incidence and water quality based on water quality index (IRCA) and quantitative measure of DBPs (trihalometanes, haloacetics acids and emergents DBPs) across 15 municipalities.
Methods: A cross-sectional study with a mixed design was conducted. Water consumption data and Boyacá registries on gastric and colorectal cancers were collected, with a one-year exposure adjustment, across municipalities ranging from <5,000 to >100,000 inhabitants (397,014 total; 493 cases annually). Cancer risk from ingestion and dermal exposure—calculated using Tafesse's equation for chronic daily intake—was evaluated. A cancer risk map based on DBP concentrations and digestive cancer rates was created to test the hypothesis linking increased water carcinogens to elevated cancer incidence.
Results: Model show moderate positive correlations between DBP levels and digestive cancer rates across municipalities. Linear regressions modeled gastric and colon/colorectal cancers, with incidence measured at 124.17 per 100,000 and a model risk of 804.30, clearly underscoring public health concerns.
Conclusion: Excessive chlorine use, increases DBP formation, thus the need for optimized water treatment practices and regulatory standards in Boyacá and in Colombia. Taken together, findings support the need of longitudinal designs (cohorts) to more conclusively confirm these associations with cancer incidence

Funding: Minciencias

E-PS-20-023
Optimizing the iDISCO protocol for metastasis analysis in human lymph nodes
P. Kouchakan[1], C. Capitini[1], I. Zlobec[2], L. Silvestri[1]
[1]LENS, University of Florence, Florence, Italy, [2]Tissue Medicine and Pathology, University of Bern, Bern, Switzerland

Background & Objectives: Lymph nodes serve as major hubs for metastatic cell growth, secondary dissemination, and immune modulation. Lymph node metastasis (LNM) is crucial for cancer staging, clinical management, and prognosis. Conventional histological methods rely on 2D biopsy sections, which may miss key structural details, limiting insights into micro-metastases and cellular interactions. Three-dimensional (3D) imaging using iDISCO tissue clearing provides a more comprehensive approach. This study aims to optimize the iDISCO protocol for multiplexed 3D imaging of human lymph nodes to investigate metastatic patterns, angiogenesis, and immune cell distribution.
Methods: Human lymph node samples were deparaffinized and processed using a solvent-based clearing approach. The protocol included methanol-based dehydration, bleaching with hydrogen peroxide, rehydration, permeabilization, and blocking. Immunolabeling was performed using four biomarkers—CD3, CD31, Cytokeratin, and Podoplanin. Samples were then dehydrated, delipidated using dichloromethane (DCM), and finally made transparent with dibenzyl ether (DBE). Imaging was conducted using a light-sheet fluorescence microscope equipped with four channels to capture all markers simultaneously.
Results: We successfully established a protocol for multiplexed 3D imaging of human lymph nodes. The optimized iDISCO protocol effectively rendered the samples transparent while preserving structural integrity. This facilitated detailed visualization of metastatic lesions, vascular structures, and immune cell organization. The improved protocol enhances the detection of micro-metastases and enables precise spatial analysis of tumour-immune interactions within lymph nodes.
Conclusion: Our findings demonstrate the advantages of 3D imaging over traditional histological techniques, offering a more detailed and comprehensive approach to studying lymph node metastases. The optimized iDISCO protocol provides a valuable tool for investigating tumour progression and immune response, with potential implications for refining cancer diagnostics and treatment strategies.

E-PS-20-024
Heterogeneity of reparative processes in the Achilles tendon: a comparative analysis of three anatomical zones in the early postoperative period
V. Mironov[1], A. Ivanov[2], E. Guryanova[1,3], N. Zhuravleva[3], V. Diomidova[3], N. Ukhterova[3], M. Sapozhnikov[3]
[1]Postgraduate Doctors Training Institute, Cheboksary, Russia, [2]The Republican Bureau of Forensic Medical Examination of the Ministry of Health of the Chuvash Republic, Cheboksary, Russia, [3]Chuvash State University by I.N. Ulianov, Cheboksary, Russia

Background & Objectives: The aim was to compare the morpho-functional characteristics of three anatomical zones of the Achilles

tendon on the 7th day of healing of the tendon complex after suturing an experimental tendon rupture.
Methods: 23 mature male rabbits (10±2 months, 3.2±0.5 kg) underwent dissection and X-shaped suturing of the tendons of the soleus and calf muscles of the left hind limb. After 7 days, the tendon complex was removed from the surrounding tissues. The sections were stained with haematoxylin-eosin and the Cason method. The proximal, middle and distal tendon zones, and the tendon sheath were studied. Morphometry was performed in Scope Photo 3.0 (10 measurements/field). Statistical processing was performed in jamovi using Mann-Whitney criteria, Chi-square and Spearman correlation.
Results: Heterogeneity of reparative processes was observed after surgery.: the skin and subcutaneous tissue were in the proliferative healing phase, zonal differences were revealed in the tendon complex - the proximal part showed active inflammation (hyperemia, cellular infiltration), the middle part combined exudative inflammation with initial fibroplasia (immature regeneration, decreased optical density of collagen to 0.074±0.03 cu), and the distal part showed exclusively dystrophic changes (fibrinoid swelling, ischemia).
The optical density of collagen was reduced in all zones of the main group relative to the intact one (0.97 ± 0.02 cu): the proximal part (0.089 ± 0.01 cu), the middle part (0.074 ± 0.03 cu), and the enthesis (0.081 ± 0.03 cu). The total area of the vessels of the microcirculatory bed in the proximal part increased due to large vessels (>50 microns) against the background of a decrease in capillaries, small vessels (<30 microns) prevailed in the middle part, postcapillary venules dominated in the enthesis.
Conclusion: The area of the inflammatory infiltrate was 18.9%, the regeneration zone was 34.87% of the surface of the sections, which indicates the competitiveness of the degradation and recovery processes.

E-PS-20-025
Arachnoiditis: an integrative review of cases based on structural anatomy, pathology and clinical manifestations
B.M. Bernal Gomez[1], M.A. Lopez Ulloa[1], L.D. Cardenas Casallas[1]
[1]Universidad Pedagógica y Tecnologica de Colombia, Medicina GIBP, Tunja, Colombia

Background & Objectives: The arachnoid is described as consisting of an internal layer enriched with reticular cells and collagen, and an external mesenchymal layer. The internal layer interacts with the pia mater and vascular elements, while the external layer is contiguous with the dura mater and subdural space. These structural divisions are essential for maintaining the stability and function of the arachnoid in cerebrospinal fluid dynamics and neural protection, despite its avascular nature. Defined as inflammation of the arachnoid, arachnoiditis not is an infectious meningitis; exhibits varied clinical neurological presentations, frequently mimicking nerve root disorders. With an estimated occurrence of 25,000 cases worldwide annually, its aetiology involves infections, trauma, and exposure to irritants. Aims to review case reports of patients following medical procedures, redefining the understanding of this condition.
Methods: Comparison and review of the clinical and pathological presentation of arachnoiditis in patients who have undergone medical procedures; Cases were obtained on grey literature and medical databases to identify histopathology and common symptoms and signs associated with the condition.
Results: A total of 50 cases of patients diagnosed with arachnoiditis (in pathology specimen) following medical procedures. Among these, 76% were women and 24% were men, with an average age of 41.75 years (standard deviation of 17.11). The age range of patients varied from a minimum of 11 years to a maximum of 76 years. The most frequent trigger for arachnoiditis was the administration of epidural anesthesia during labour or the use of analgesics for chronic back pain.
Conclusion: The most frequently reported signs included motor deficits and sensory disturbances as pain in the lower limbs and in the back. Mechanisms by which anesthetics can cause tissue damage are chemical detergent properties that can lead to cell lysis, and any foreign object, such as needles or catheters, can provoke secondary injuries to the nervous system.

E-PS-20-026
Enhancing laboratory quality through six sigma: a case study on process improvement
P. Doshi[1], R. Bharadwaj[1], M. Padwal[2], M. Modak[3]
[1]Bharati Vidyapeeth Deemed University Medical College, Maharashtra, Pathology, Pune, India, [2]Bharati Vidyapeeth Deemed University Medical College, Maharashtra, Biochemistry, Pune, India, [3]Bharati Vidyapeeth Deemed University Medical College, Maharashtra, Microbiology, Pune, India

Background & Objectives: Medical laboratories play a vital role in healthcare by providing accurate and timely diagnostic results. However, errors in sample processing, delays in test turnaround times, and inconsistencies in quality can affect patient outcomes. Implementing Six Sigma, a data-driven methodology for process improvement, can help laboratories minimize defects, streamline operations, and enhance overall efficiency. This study examines the impact of Six Sigma in a clinical laboratory, focusing on reducing sample rejection rates and improving turnaround time.
Methods: A retrospective analysis was done in a tertiary medical Centre, Western Maharashtra, India conducted using the Define, Measure, Analyze, Improve, Control, (DMAIC) framework to identify key problem areas. Baseline data revealed a 5% sample rejection rate due to mislabeling, improper handling, and inadequate documentation and samples. Turnaround times also exceeded the standard benchmark, leading to diagnostic delays. A series of interventions, including barcode-based sample tracking, standardized training for laboratory staff, and quality monitoring, were implemented to address these issues.
Results: Post-intervention analysis demonstrated a significant reduction in errors, with sample rejection rates dropping from 5% to 1.39%. Additionally, turnaround time improved by 29%, leading to faster clinical decision-making. The enhanced quality control measures also contributed to greater test accuracy, improved compliance with regulatory standards, and increased patient satisfaction.
Conclusion: This study highlights the effectiveness of Six Sigma in improving laboratory performance and ensuring high-quality diagnostic services. By fostering a culture of continuous improvement, medical laboratories can achieve greater operational efficiency and enhanced patient outcomes. The findings support broader adoption of Six Sigma methodologies across healthcare settings to optimize laboratory processes and drive excellence in diagnostic services. Further research should explore long-term sustainability and the integration of advanced technologies to enhance Six Sigma applications in laboratory management.

E-PS-20-027
Tissue biobanking proficiency testing – a sustainable way to assure high quality standards in biobanking
T. Pfeffer[1], C. Kaufhold-Wedel[2], F. Hinterberger[3], D. Kieslich de Hol[2], N. Nguyen[4], P. Schirmacher[5,1,3], A. Brobeil[5,2]
[1]German Centre for Infection Research (DZIF) Tissue Biobank at the partner site Heidelberg, Heidelberg University Hospital, Heidelberg, Germany, [2]Tissue Bank of the National Centre for Tumour Diseases (NCT) Heidelberg, Heidelberg University Hospital, Heidelberg, Germany, [3]BioMaterialBank Heidelberg, Heidelberg University Hospital, Heidelberg, Germany, [4]German Biobank Node, Charité, Universitätsmedizin Berlin, Berlin, Germany, [5]Institute of Pathology, Heidelberg University Hospital, Heidelberg, Germany

Background & Objectives: For tissue-biobanking and its services, e.g. histotechnological processing, tissue analyses and the whole processing chain, proficiency tests are useful tools to test and demonstrate high quality and expertise. This is necessary to avoid alterations in histopathological morphology or on molecular level caused by preanalytical processes, such as transportation, processing and storage.
Methods: For this purpose, the NCT Tissue Bank of Heidelberg University Hospital, in close cooperation with the German Biobank Node (GBN), organizes and performs tissue proficiency tests since 2017.
Results: Seventeen tissue biobanks across Germany participated in the last round robin. The aim of this successfully established nationalwide quality-assurance program for tissue-biobanks is to offer objective review and to evaluate sample quality and processing procedures and it includes the assessment of a histopathological evaluation of tissue biosamples, sampling processes and macroscopic assessment of centrally distributed fresh tissue-samples, its fresh freezing, preparation of cryosections, staining procedures, and DNA/RNA-extraction from cryo preserved tissue including the respective concentration and nucleic acids integrity measurements. The results are jointly evaluated in personal feedback sessions and considered for the design of the following proficiency test.
Conclusion: Here, we present the structured performing and results of the GBN tissue biobank proficiency test. The results are valuable resources allowing refinement and harmonization of tissue-related processes. This is important to ensure consistent high and comparable sample quality, a sustainable use of biomaterials and optimal tissue sample processing in the context of tissue biobanking.

E-PS-20-028
Clinical value of percutaneous CT-guided core biopsy for solid tumours diagnosis
G. Arismendi Morillo[1]
[1]University of Deusto, Faculty of Health Sciences, Bilbao, Spain

Background & Objectives: CT-guided percutaneous core biopsy is a highly valuable diagnostic tool al clinical setting. We aimed to evaluate the feasibility, safety, and diagnostic yield of percutaneous CT-guided core biopsy.
Methods: A total of 174 CT-guided percutaneous core biopsies in adult patients with solid tumours of liver, lung, retroperitoneum, pancreas, abdominal cavity, pelvic cavity, kidney, mediastinum and miscellaneous sites, between 2021 and 2023 were done.
Results: Pathological diagnosis was achieved in 166 cases (95.4%). Malignant tumour was diagnosed in 134 (81%) cases. Pathological diagnosis in each biopsy from liver (60), mediastinum (10), kidney (7), and miscellaneous sites (5) was accomplished. In 8 cases (lung 3 of 30, pancreas 2 of 17, retroperitoneum 1 of 23, intra-abdominal cavity 1 of 12, and pelvic cavity 1 of 10), the pathological diagnosis no was succeed. There were no major procedure-related complications.
Conclusion: Percutaneous CT-guided biopsy is an effective and safe procedure for initial diagnosis of patients with solid tumours. Affords a high diagnostic yield (95%) for pathological and immunohistochemical characterization. Anatomical obstacles, corporal movement and respiratory motion of patient are linked to the unsuccessful diagnosis.

E-PS-20-029
Clinicopathological features of the term "undifferentiated malignancy" used by the pathologists and the prevalence rate of BRG1 loss under this diagnosis
C. Chang[1], Y.-C. Kao[1]
[1]National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Pathology, Tainan, Taiwan
Background & Objectives: Most pathological reports include tumour differentiation and categorized into carcinoma, or sarcoma, etc. However, occasionally, tumour differentiation cannot be confidently told by conventional exams and a term "undifferentiated malignancy" will be used. One of the reasons may be the epithelial-mesenchymal transition (EMT) phenomenon, which obscures epithelial features while obtaining mesenchymal or sarcomatous features. In addition, sarcomas may mimic carcinoma, morphologically or even immunophenotypically. Although there is literature regarding diagnostic approaches, no study has been explored in a clinical cohort.
Methods: Retrospectively, 90 cases were enrolled with a diagnosis of "undifferentiated malignancy" or "poorly differentiated malignancy" at our institution (NCKUH) from January1st, 2000 to August 30th, 2023. The mean age was 58 years, with a male-to-female ratio of 1.7. Clinicopathological features and immunophenotypes were obtained from both electronic records and slide review. Re-classification was done based on current WHO system. BRG1 immunohistochemical stain was added additionally, for which losing expression was prevalent in undifferentiated carcinoma from various origins. Molecular studies were performed in five cases for treatment purposes.
Results: After thorough investigations, the diagnoses included carcinoma (n=71), sarcoma (n=13), melanoma (n=2), germ cell tumours (n=3), and olfactory neuroblastoma (n=1). Liver and lung were the most common origins. Prognosis was extremely poor, most patients died (~80%) with a mean follow-up of 18.2 month. Nine of 75 cases undergone BRG1 staining lost BRG1 expression, which were all carcinomas. The origins included lung (n=5), stomach (n=1), liver (n=1), sinus (n=1) and thyroid (n=1). Two cases revised the original diagnoses into SMARCA4-deficient tumour, including thoracic and sinonasal origins. Five cases had molecular studies, which revealed MET amplification, EGFR amplification, RICTOR amplification, and BRAF V600E mutation but without recurrent genetic changes.
Conclusion: In conclusion, this study helps us to know when pathologists diagnose "undifferentiated malignancy" and unraveled their nature.

Funding: This study is granted by National Cheng Kung University Hospital, Taiwan (grant No. NCKUH-11304031) and approved by IRB (No. B-ER-116-320)

E-PS-20-030
A game-changer in histology, histopathology and cytology learning: virtual microscopy platform developed in an European university consortium
C. Amalinei[1], I.D. Caruntu[1], R.A. Balan[1], A. Grigoras[1], L. Lozneanu[1], S.E. Giusca[1], A.D. Timofte[1], E.R. Avadanei[1], M.B. Chifu[1], A. Rusu[1]
[1]Grigore T. Popa University of Medicine and Pharmacy, Morphofunctional Sciences I, Iaşi, Romania

Background & Objectives: Virtual microscopy (VM) platforms may enhance medical education by providing digital access to high-quality images. By collaboration with other European partners, our team developed a virtual microscopy platform, entitled Virtual Microscopy Histology and Histopathology.
Methods: Developed by a consortium of medical universities in Iasi, Alicante, Plovdiv, and Gdansk, Virtual Microscopy Histology and Histopathology platform uses Aperio AT2 scanners (Leica Microsystems) to digitize slides at 0.25 µm resolution. Hosted on secure, cloud-based servers, it ensures scalability, reliability, and fast access to a large collection of digital slides. The user interface is intuitive and responsive, compatible across desktops, tablets, and smartphones.
Results: Virtual Microscopy Histology and Histopathology platform, launched in September 2024, provides a dynamic and engaging learning environment, allowing users to study both normal and pathological tissue specimens in high detail. Interactive features, including seamless zooming, screenshot-taking, and the ability to add annotations, enhance the learning experience, fostering active engagement. The platform's VM library is organized into 20 chapters to align with

medical curricula, offering comprehensive coverage of histology, histopathology, and cytology. The integrated quiz section, which generates randomized tests with images for recognition, helps students assess their knowledge and reinforce learning. Feedback from users, with more than 90% 5-star rating, highlights its value in promoting self-paced learning and improving diagnostic skills, particularly for students and residents, with multilingual support and easy-to-use interface. The platform continues to grow, regularly adding new content. Plans to expand the pathology section and include more complex cases further strengthen the platform's educational utility.
Conclusion: Virtual Microscopy Histology and Histopathology platform offers an interactive, digital tool for histology and pathology education. It provides a flexible and accessible approach for learners, empowering undergraduate and postgraduate medical students and pathology professionals with advanced diagnostic training through modern technology.

Funding: This study is supported by Erasmus+ project 2022-1-RO01-KA220-HED-000089017

E-PS-20-031
Is it red just dead, or something ahead? A one-centre experience with lymph node necrosis
V. Maskoliunaite[1,2], U. Mickys[2]
[1]Vilnius University, Faculty of Medicine, Institute of Biomedical Sciences, Department of Pathology and Forensic Medicine, Vilnius, Lithuania, [2]National Centre of Pathology, Affiliate of Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania

Background & Objectives: Isolated lymph node necrosis is an uncommon histopathological finding. In most cases, it is associated with underlying conditions, frequently malignancies. Immunohistochemistry (IHC) use in such cases is controversial but may provide valuable diagnostic insights. This study evaluates the diagnostic utility of IHC in cases of extensive lymph node necrosis and its role in suspicion of malignancy and subsequent diagnosis.
Methods: Over the past 15 years, we retrospectively analysed 43 cases of total or subtotal (up to 95%) necrosis in lymph node biopsies. IHC was performed to assess retained antigen expression. The retained reactions included lymphocytic markers (CD20) and epithelial markers (Pan-Cytokeratin (PanCK), CK7, CK20). Clinical, follow-up data and prior diagnoses were reviewed.
Results: Prior malignancy diagnosis was established in 41.9% of cases, with necrosis primarily linked to therapeutic effects. Follow-up data were unavailable for 14% of cases. In 11.6% of cases, a final malignancy diagnosis was confirmed in subsequent biopsies. Notably, in 32.6% of cases, initial pathological suspicion of malignancy was correctly raised based on IHC findings. These included 10 cases of B-cell lymphoproliferative disorders, predominantly diffuse large B-cell lymphomas (n=5), and carcinomas (n=4). The interval between the initial pathological diagnosis and the final malignancy confirmation ranged from two weeks to two months. One remarkable case involved a patient with a history of B-cell lymphoproliferative disorder and axillary lymph node biopsy showing complete tumour necrosis. Retained PanCK and CK7 expression led to a surprising diagnosis of breast carcinoma, which was not previously suspected clinically.
Conclusion: IHC in necrotic lymph nodes, particularly structural cytoplasmic and membranous markers, can be retained as a valuable diagnostic tool. It aids in identifying tumour cell lineage and some architectural-cytological characteristics, as well as improving patient management.

E-PS-20-032
Weekly nationwide virtual uropathology consensus meetings among Turkish pathologists: a vibrant example of multidisciplinary effort in continuous uropathology education
M. Akgul[1], D. Baycelebi[2], M. Oktay[3]
[1]Brigham and Women's Hospital, Department of Pathology, Boston, USA, [2]19 Mayis University School of Medicine, Department of Pathology, Samsun, Turkey, [3]Memorial Health Group, Department of Pathology, Istanbul, Turkey

Background & Objectives: Consensus meetings are important aspects of daily surgical pathology practice, however, organized nation-wide effort in establishing weekly case-discussion platforms is rare.
Methods: Under the supervision of Turkish Uropathology Working Group, a weekly online consensus meeting is planned. Regardless of the type of the laboratory setting (e.g. academic tertiary setting, community hospitals, private pathology labs, small rural pathology laboratories), practice type (general or subspecialty-type pathology practice), and level of experience (resident, fellow, faculty and/or staff) were invited to the consensus meetings. Zoom platform (Zoom Communications, San Jose, CA, USA) were used to established free-of-charge case discussion platform. All discussed cases were required to be completely de-identified from personal information.
Results: Between July 2024 - February 2025, 32 weekly consensus meetings were performed every Tuesday (of 35 weeks, 91%). Attendees were from 17 different Turkish cities; mean number of attendees in each weekly meeting was 29 (range 5 - 54 attendees). in 32 meetings, a total of 101 cases were discussed with an average of 3 cases per meeting (range 0 - 5). Number of cases based on organs were as follows: Kidney (62, 61.3%), urinary tract (22, 21.7%), prostate (6, 5.9%), testis (5, 4.9%), penis (1, 0.9%), and others (5, 4.9%). Moreover, starting January 2025, brief multidisciplinary (medical oncology, urology, and radiology) sessions on the management of urologic neoplasia were conducted (n = 3), and journal club-style article presentations were performed (n=4; 3 renal tumours, 1 prostatic adenocarcinoma).
Conclusion: Weekly nationwide virtual urology consensus meeting is a great tool for continuous pathology education. It is critically helpful in countries where urologic pathology fellowship training is not formally established, and it is a great tool to consult challenging cases, particularly for pathologists practicing in remote/limited resource setting.

E-PS-20-033
Applications of three-dimensional printing in surgical pathology: new perspectives
P. Kousidis[1], I. Sidiropoulos[1], S. Tsiopoulos[1], G. Panselinas[1], A. Nikolaidou[1]

[1]"Theageneio" Anticancer Hospital, Pathology, Thessaloniki, Greece
Background & Objectives: Three-dimensional (3D) printing techniques have been developing rapidly in the past decade. The emergence of affordable, easy-to-use 3D-printing equipment, and user-friendly 3D-design software, have permitted the design and creation of novel devices even by non-experts in the field of computer-aided design. We present a review of the current literature on the applications of 3D-printing in Surgical Pathology, with an analysis of future directions.
Methods: A literature search was performed on the subject, on the databases PubMed, Web of Science and Google Scholar. Several keywords were used, alone or in combination, including "3D-printing", "pathology", "instrument". The final results were summarized.
Results: Several publications on applications of 3D-printing were located, expectedly, mainly in the field of gross examination. In the

setting of prostatectomy specimens, a design of cutting guides to align the sections with magnetic resonance imaging findings exists. The potential for scanning and producing 3D-printed model replicas from excision specimens, to enhance training, has also been explored. Our team created a novel grossing instrument, to aid in metallic staple removal in pulmonary excision specimens, in order to enhance margin evaluation. Further studies exist on other subspecialties of Pathology.
Conclusion: The field of 3D-printing in Surgical Pathology is highly promising, yet currently underexplored. Mainly in surgical specialties, these techniques have been widely utilized for prostheses, instruments and in surgical training. The ease in designing and producing novel instruments and devices can evolve the practice of Pathology.

E-PS-20-034
How important is undergraduate teaching at pathology conferences?
F. Leiva-Cepas[1], M.J. Gálvez Medina[2], I. Sánchez Ramírez[2], J. Osuna Soto[2], V. Dávila Flores[2], A. Sanz Zorrilla[2]
[1]University of Cordoba/Universitary Hospital Reina Sofia, Department of Morphological and Socio-Health Sciences/Pathology Unit, Cordoba, Spain, [2]Universitary Hospital Reina Sofia, Pathology Unit, Cordoba, Spain

Background & Objectives: Pathology is a medical specialty and a fundamental subject in medical training. Medical conferences are a way to network with colleagues and learn about new advances. The objective of this study is to identify the role of undergraduate teaching at European pathology conferences.
Methods: Abstracts from the last 10 European conferences published in the journal Virchows Archiv were analysed, searching for the following identifiers: teaching, university, subject, teaching, degree, students. The types of studies were analysed, including oral presentations and posters. The data were analysed using conventional statistics. Teaching papers on medical residents were excluded.
Results: Between 2014 and 2024, a total of 45 oral communications and 12 posters related to teaching or teaching innovation were presented. They were presented by faculty from universities with affiliated university hospitals. Representativeness compared to other subjects averages 2-3%, and there is no teaching topic at the conference. Thirty percent of the papers and posters are related to microscopic visualization and training in the recognition of pathological structures.
Conclusion: European pathology conferences show little interest in teaching pathology in the medical degree program. It doesn't address a specific topic, and the ESP doesn't have a program specifically focused on teaching. The ESP must become involved in generating new teaching and academic vocations to ensure that pathologists and non-related professionals are responsible for teaching pathology to the physicians of the future.

E-PS-20-035
Could pathology laboratory improve accuracy of neuropsychological profiling in early-stage Type 2 Diabetes Mellitus cognitive decline?
B.M. Bernal Gomez[1], M.C. Jimenez Martinez[2], C.M. Baracaldo[3]
[1]Universidad Pedagógica y Tecnologica de Colombia, Medicina GIBP, Tunja, Colombia, [2]Universidad Pedagógica y Tecnologica de Colombia, Medición y Evaluación Psicológica en Contextos Básicos y Aplicados, Tunja, Colombia, [3]Universidad Pedagógica y Tecnologica de Colombia, Medicina APS DCB, Tunja, Colombia

Background & Objectives: The survey of neuropsychological profile in patients with early-stage Type 2 Diabetes Mellitus (T2DM) can mitigate the impacts of cognitive impairment due to disease and this research explores potential connections with early stages of dementia. Interdisciplinary involvement of pathology and neuropsychology, aims to combine psychological evaluations with biochemical analyses, including cytological and chemical examinations of cerebrospinal fluid (CSF), to enhance diagnostic accuracy Additionally, the measurement of biomarkers levels such as Brain-Derived Neurotrophic Factor (BDNF) in blood, influenced by the positive effects of physical exercise, offers a valuable tool to preserve synaptic function, aiding early identification of cognitive decline or confirming a healthy cognitive status.
Methods: A cross sectional study was made to compare participants divided into two groups: 25 with T2DM and 25 without the diagnosis; It was analysed the cognitive profile of patients diagnosed with Type 2 Diabetes Mellitus (T2DM) compared to non-diabetic individuals. Each one was eavaluated using neuropsychological tests such as the MMSE, Rey Auditory Verbal Learning Test, and Rey Complex Figure Test; BDNF leves, glycemic status HbA1c and CSF.
Results: Participants aged between 40 and 70 years old showed that those with T2DM exhibited cognitive deficits in visual memory, visuoconstruction, and working memory, while non-diabetic participants performed better in memory and attention-related tasks. Used biochemical and pathological parametes had some usual presentation without significative differences between groups.
Conclusion: This research contributes to understanding how T2DM influences cognitive processes, advocating for interdisciplinary approaches to improve diagnostic and therapeutic strategies. By addressing cognitive challenges early, patients with T2DM can benefit from personalized care aimed at enhancing their quality of life Insights into neuroinflammation and biochemical changes associated with T2DM are difficult to clear into bias of selection and scarce of participants as control of cases; nowadays It could reinforcing its potential role in the development of cognitive decline or incipient dementia.

E-PS-20-036
Intraoperative communications: pathologist-surgeon communication reexamined
M. Jikurashvili[1], S. Jayade[1], C.J. Monis[1], M. Gabeshia[1], S.K. Tonny[1], G. Ganesh[1]
[1]Tbilisi State Medical University, Pathology, Tbilisi, Georgia

Background & Objectives: Effective intraoperative communications between pathologists and surgeons is crucial for guiding surgical procedures, particularly during frozen section analysis. Miscommunication in this high-pressure setting can lead to delays, misinterpretations and potential errors that affect outcomes. These challenges often stem from using highly specialized terms and medical jargon, including abbreviations which different specialists can interpret differently. Our study aims to identify common communication patterns and propose strategies to enhance accuracy and efficiency.
Methods: We examined intraoperative communication patterns among surgeons in Georgia's high-impact hospitals, specifically focusing on those working in oncology settings. A mixed-methods approach was utilized, combining both qualitative and quantitative data collection techniques. The data collection process involved distributing a structured questionnaire through the Google Forms platform. The questionnaire contained multiple sections, like: epidemiologic data, case scenarios, open-ended questions and etc.
Results: Our findings suggest that the key challenges include ambiguous terminology, time constraints and lack of standardized phrasing, which contribute to miscommunication. The results also revealed that surgeons with 10+ years of practice were found to have greater misjudgments in understanding pathological terms when faced with case-based scenarios in the survey. Participants with higher scores in the case scenarios tended to consult existing literature more frequently when faced with ambiguous diagnoses, whereas those with lower scores relied more on contacting the same pathologist who issued the report. These findings highlight potential variability in

individual approaches to understanding pathology reports, suggesting that disparities may stem from differences in problem-solving strategies too.
Conclusion: Optimizing intraoperative communication requires a multidisciplinary approach, integrating standardized diagnostic phrasing, closed-loop communication techniques and digital pathology solutions. By refining communication strategies, pathologists and surgeons can enhance the accuracy and efficiency of frozen section analysis, ultimately improving patient outcomes. Future research should focus on evaluating these interventions in clinical practice to establish best practices for intraoperative diagnostics.

E-PS-20-037
A diagnostic trial centre as a key research infrastructure
S. Noh[1], A. Stenzinger[1], P. Schirmacher[1]
[1]Institute of Pathology, Heidelberg University Hospital, Heidelberg, Germany

Background & Objectives: Pathological assessment has a substantial impact on clinical trials. Trial inclusion, secondary or even primary endpoints or trial-associated research require the expertise of pathologists and thus structural integration of pathologists and histopathological and molecular pathological technology. Guiding trial requests from stakeholders such as the pharmaceutical industry or clinicians and the pathological expertise in a structured manner improves clinical trial outcome, research use and performance of the involved pathology institutions. Therefore, in 2012 we established a diagnostic trial centre in the academic setting at Heidelberg University Hospital as a key translational research infrastructure.
Methods: The diagnostic trial centre operates in a quality-controlled manner according to official standards and especially in GCP conformity.
Results: Performance and key indicators are presented. In the last years the trial centre has contributed to and supported a wide range of trials, e.g. IITs, industry-driven trials, and comparable PPP projects in multi- or single-centre settings. Services of the diagnostic trial centre encompass trial-based case-management, documentation, communication, quality management as well as related administrative issues, such as contractual management, reporting and billing. The diagnostic trial centre closely interacts with diagnostic pathology and other infrastructures, especially tissue biobanking and molecular as well as computational pathology; it is part of the tissue-based research infrastructure platform of the Institute of Pathology.
Conclusion: The demand for histo- and molecular-pathological assessments in clinical trials is increasing as biomarker-driven patient selection, therapy decision making and cooperative translational research projects with industry are increasingly implemented. These approaches result not only in a rising need for pathological expertise, but also in a substantially higher number of samples to be processed highlighting the importance of a coordinating diagnostic infrastructure that acts as a relay between all stakeholders involved. As such a diagnostic trial centre is a key part of the tissue-based research infrastructures.

E-PS-20-038
Vimentin immunohistochemistry as a diagnostic tool to differentiate oligodendrogliomas from astrocytomas in resource-limited settings
M. Al-Hussaini[1], N. Hasasneh[1], Y. Talab[1], R. Alabweh[1], O. Alayyan[2]
[1]King Hussein Cancer Centre, Department of Cell Therapy and Applied Genomics, Amman, Jordan, [2]King Hussein Cancer Centre, Office of Research and Scientific Affairs, Amman, Jordan

Background & Objectives: Astrocytomas and oligodendrogliomas are common primary brain tumours with distinct histopathological and molecular features. Accurate diagnosis relies on morphology, immunohistochemistry (IHC), and molecular testing. In settings where molecular diagnostics are not readily available, alternative methods are necessary. We aim to assess the diagnostic value of vimentin IHC in distinguishing between these two entities in resource-limited settings.
Methods: This retrospective study included cases of oligodendrogliomas and astrocytic gliomas diagnosed at King Hussein Cancer Centre (KHCC) from 2017 to 2024. The included cases underwent 1p/19q co-deletion FISH and vimentin IHC staining. Diagnostic metrics, including sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy of vimentin IHC, were calculated using FISH results as the reference standard.
Results: 116 cases were included: 65 oligodendrogliomas confirmed by 1p/19q co-deletion and 51 astrocytic gliomas (including pilocytic astrocytoma [n=1], diffuse astrocytoma [n=13], anaplastic astrocytoma [n=11], and glioblastoma [n=26]). Among oligodendrogliomas, 89.3% (n=58) were negative for vimentin, while 10.7% (n=7) were positive. In contrast, 86.3% (n=44) of astrocytic gliomas were vimentin-positive and 13.7% (n=7) were negative. The PPV of negative vimentin IHC in diagnosis of oligodendrogliomas (positive for 1p/19q co-deletion and negative vimentin IHC) is 89.2%. The NPV of positive vimentin staining in the diagnosis of oligodendrogliomas (negative for 1p/19q co-deletion and positive vimentin IHC) is 86.2%. The sensitivity (ability of vimentin IHC to correctly detect oligodendrogliomas) is 89.2%, while the specificity (ability of vimentin to correctly detect astrocytic gliomas) is 86.3%. The accuracy of vimentin IHC in differentiating between the two entities is 87.9%.
Conclusion: Vimentin IHC is a cost-effective and accessible tool for differentiating oligodendrogliomas from astrocytic gliomas in settings lacking molecular diagnostic capabilities. Negative vimentin staining is a strong indicator of oligodendroglioma, while positive staining favours astrocytoma. This approach may aid in accurate diagnosis and treatment planning in resource-limited environments.

Funding: The work was supported by the Intramural Research Grant Program at King Hussein Cancer Centre

High inter-observer agreement and determination of the training effect in the CPS assessment of PD-L1 in different indications
G. Bänfer[1], L. Freese[1], R. Diezko[1], C. Hale[2], H.-U. Schildhaus[3]
[1]Discovery Life Sciences Biomarker Services GmbH, Biomarker Academy, Kassel, Germany, [2]Discovery Life Sciences LCC, IHC Services, Newtown, USA, [3]Discovery Life Sciences Biomarker Services GmbH, Pathology, Kassel, Germany

Background & Objectives: Immunohistochemical testing for programmed cell death-ligand 1 (PD-L1) has proven to be a useful predictive marker for anti-PD-1 therapy. Tumour cells (TC) and/or tumour-associated immune cells (TAIC) are used to determine the level of PD-L1 expression often detected by using the PD-L1 IHC 22C3 pharmDx. samples are either evaluated by the Tumour Proportion Score (TPS: TC PD-L1 staining) or by the Combined Positive Score (CPS: PD-L1 TC and TAIC staining). Depending on the country CPS is used in Gastric Cancer (GC), Oesophageal Cancer (EC) Cervical Cancer (CC) and Urothelial Carcinoma (UC), Head and Neck Squamous Cell Carcinoma (HNSCC) and Triple-Negative Breast Cancer (TNBC). We present data conducted between 2017 and 2024 years for a worldwide, expert-led training in PD-L1 interpretation for the indication name above using CPS.
Methods: All pathologists assessed 20 blinded samples on day 1 and 25 samples on day 2. Latter one only if they participated in the 2-day training. The reproducibility of PD-L1 scoring at the relevant cut points between (inter) and within observer (intra) was assessed.

In 2020, a test was added to measure the training effect by collecting data from the same samples before and after training (n = 5 or 6, respectively for HNSCC).
Results: A total of 2093 participants were trained in 194 sessions. Inter-observer agreement ranged between 88.5% ± 11.8 for TNBC to 93.4 ± 9.6 for UC and intra-observer ranged from 91.3% ± 12.0 for EC to 95.1 ± 17.3 for CC. When looking at the training effect across all indications, around one third showed a higher level of agreement than before the training, and around 50% showed no differences.
Conclusion: The data not only show a high reproducibility of CPS scoring in a variety of indications including challenging cases, but also show the positive impact of standardized training for pathologists in complex biomarker.

Harnessing AI-driven emotional analysis to accelerate change management: a multi-method approach in clinical laboratory settings
F. Pereira[1,2,3], T. Osadolor[1], S. Di Palma[1], I. Sharp[2], P. Ruwona[1], D. Cook[1], N. Newman[1]
[1]Berkshire and Surrey Pathology Services, Cellular Pathology, Surrey, United Kingdom, [2]School of Engineering and Science of the Greenwich University, Biomed, London, United Kingdom, [3]School of Medicine and Biomedical Sciences, Institute for Research and Innovation in Health of the University of Porto, Portugal

Background & Objectives: Berkshire and Surrey Pathology Services (BSPS), a joint venture of five NHS Trusts, is one of the UK's largest pathology networks processing more than 50 million tests annually. In response to the rapid technological evolution in clinical laboratories, BSPS launched a pilot study to evaluate staff perspectives on organisational transformation, with a particular focus on the role of Artificial Intelligence (AI) - Large Language Models (LLMs). Inspired by AI-led workforce analysis trends in industry, including Microsoft, the study aimed to explore how AI could support staff wellbeing and engagement during change.
Methods: A GPT-o1 model was used to systematically analyse six months of internal communication data, supported by triangulation with interviews, discussions, and workflow observations. The analysis incorporated Lewin's Change Management Model, the Job Demands-Resources (JD-R) Model, and the Linguistic Inquiry and Word Count (LIWC) tool to assess emotional tone, workload balance, and organisational readiness. Insights informed change strategies using Kotter's 8-step model and cognitive-behavioural techniques, such as reframing and behavioural activation.
Results: Findings revealed a strong negative correlation between limited professional development, entrenched practices, and staff morale, driving resistance to technological innovation. High workloads and technological gaps increased frustration and led to cognitive fatigue and avoidance behaviours. LIWC confirmed a negative emotional tone in internal communications, reflecting a focus on general goals over individual recognition, contributing to disengagement.
Conclusion: The study concludes that combining AI-driven text analysis with behavioural frameworks enables the development of responsive, human-centric change strategies. Targeted interventions, such as early engagement, transparent communication, clear role definitions, and accessible training, can enhance receptiveness to change. Integrating BJ Fogg's behaviour model may further support staff motivation, communication, and professional growth. Ultimately, AI-enhanced strategies offer a scalable, evidence-based approach to improving wellbeing, reducing resistance, and fostering sustainable innovation in NHS pathology services, by identifying the drivers.

E-PS-20-042
Transforming an NHS histopathology laboratory through staff engagement and proactive leadership
F. Pereira[1,2,3], S. Di Palma[1], T. Osadolor[1], P. Ruwona[1], D. Cook[1], N. Newman[1]
[1]Berkshire and Surrey Pathology Services, Cellular Pathology, Surrey, United Kingdom, [2]School of Engineering and Science of the Greenwich University, Biomed, London, United Kingdom, [3]School of Medicine and Biomedical Sciences, Institute for Research and Innovation in Health of the University of Porto, Porto, Portugal

Background & Objectives: Berkshire and Surrey Pathology Services (BSPS), a leading pathology network serving over 3.2 million people in the South East, faces rising demand and increasing complexity in histopathology services. In response, BSPS initiated a pilot study to assess staff perspectives on organisational transformation. The objective was to explore how to transition BSPS into a leading, patient-centred care provider by addressing challenges such as low morale, high turnover, lack of training opportunities, and reduced confidence in leadership.
Methods: A structured, multi-method approach, integrating psychological and change leadership theories, was used in this study to evaluate change readiness within a histopathology laboratory setting. Baseline behavioural audits and segmentation were used to assess readiness and resistance, while a behavioural risk matrix, guided by tech adoption personas, helped develop a targeted communication strategy.
Our approach integrated the Awareness, Desire, Knowledge, Ability, and Reinforcement model, BJ Fogg's Behaviour Model, and the Theory of Planned Behaviour. The change strategies effectiveness was reinforced by cognitive-behavioural techniques, reframing, behavioural activation, and exposure.
Results: Analysis revealed three staff segments: one highly engaged and innovation-driven; a second patient-focused but hesitant about new technologies; and a third with minimal engagement and high resistance. Staff perceptions revealed a consistent pattern of disengagement stemming from preconceived notions about AI, particularly concerns around accuracy, complexity, and job relevance. AI-assisted text analysis, mapped to behavioural models, supported the development of targeted interventions. Insights emphasised the need for an open, blame-free culture to build trust. Staff visits to the clinical oncology departments shifted the focus back to the needs of patients.
Conclusion: To understand the NHS's diverse international landscape requires cultural sensitivity, strong leadership, and inclusive communication.
Technology must be integrated with human-centric care, and targeted strategies, such as peer mentoring, early engagement, and clear role structures, are key to enhancing receptiveness and driving sustainable innovation.

E-PS-20-043
The level of collagen type I and type III in connective tissue of umbilical hernia of men and women
S. Ryabtseva[1], M. Korneeva[1], D. Golovach[2]
[1]Institute of Physiology of National Academy of Sciences of Belarus, Centre of Morphological Research, Minsk, Belarus, [2]6th City Clinical Hospital, Surgery, Minsk, Belarus

Background & Objectives: The ratio and level of collagen type I and type III determine the strength of connective tissue and scar tissue. The aim of the study was to evaluate the expression level of collagen type I and type III in the connective tissue of umbilical hernia of men and women.

Methods: Seven men and six women with umbilical hernia was included in this study. During surgery a piece of anterior abdominal wall was obtained from umbilical hernia and a piece from the skin of resection edge. The immunohistochemistry antibody collagen type 1A2 (E-AB-10155, 1:400) and collagen type 3A1 (E-AB-22071,1:400) were used. The expression was analysed by the image analysis software Aperio Image Scope [v12.4.6.5003].
Results: The expression of collagen type I was 2.0 (1.0;2.0) %, type III - 5.0 (5.0;6.0) % in the skin of men from resection edge (I:III=1:2.5, p=0.0022). The expression of collagen type I was 17.5 (9.0;28.0) %, type III - 8.0 (3.0;10.0) % in the skin of men under hernia sac (I:III=2.2:1.0, p=0.0091). The expression of collagen type I was 33.5 (18.0;50.0) %, type III - 8.0 (3.0;18.0) % in tissue of hernial sac (I:III=4.2:1.0, p=0.0091). In the skin of women from resection edge the expression of collagen type I was 2.3 (2.0;3.0) %, type III - 8.6 (7.0;10.0) % (I:III=1.0:3.6, p=0.0002) and under hernia sac: the expression of collagen type I - 12.5 (9.0;14.0) %, type III - 17.0 (12.0;19.0) % (I:III=1.0:1.4, p=0.0640). The expression of collagen type I was 22.5 (17.0;34.0) %, type III - 25.5 (19.0;37.0) % in fibrous tissue of the hernial sac of women (I:III=1.0:1.01, p=0.0650).
Conclusion: This study showed a difference in collagen formation in men and women with umbilical hernias: for men was characterized the change in synthesis of collagen type I, but for women - as a type I and type III.

New approach to 3D reconstruction of the perineural invasion in prostatic cancer in laboratory mice
J. Gulczynski[1,2], D. Sigorski[3], J. Jain[4], R. Gupta[4], A. Parthasarathy[4], E. Izycka-Swieszewska[1,2]
[1]Medical University of Gdansk, Div. of Pathology and Neuropathology, Gdansk, Poland, [2]Copernicus Hospital Gdansk, Dept. of Pathology, Gdansk, Poland, [3]University of Warmia and Mazury, Department of Oncology, Olsztyn, Poland, [4]Pramana Inc, Cambridge, USA

Background & Objectives: Perineural invasion (PNI) is a commonly known process in prostatic cancer, but exact mechanisms are still to be assessed. Our research was to establish a new approach to 3D reconstruction in a lab model of prostatic cancer in mice.
Methods: We analysed tissues obtained from laboratory mice injected with PC3 ML cells to develop prostatic cancer. After scarification the full body was fixated in formalin, decalcified and paraffin embedded. Serial sections were stained with H&E with interval neurofilament staining of every 3rd section. Volumetric scanning of slides was done using Pramana Spectral scanner for 3D reconstruction using dedicated software.
Results: Preliminary results show optimal 3-D reconstruction of PNI at lower magnification with good correlation with MRI. However inter block serial sections pose the challenge with 3-D reconstruction at cellular level, as the same cells cannot be traced in serial sections from subsequent blocks owing to cell size of 10-15 um. To overcome this, we adopted the new approach based on a 5 um serial section from the same FFPE block using the information across the Z stack layers which yielded more accurate results.
Conclusion: The preliminary results let us believe that in the nearest future by such analysis we will be able to understand better processes ongoing in human tissues, like carcinogenesis, development, inflammation and others. Volumetric scanning based 3-D reconstruction may help not only in analysis of malignant invasion, including perineural, but also in non-malignant maladies.

Histopathological features of paediatric Wilson disease in liver biopsies
M. Keçik[1], E. Karakuş[1]
[1]Ankara Bilkent City Hospital, Pathology, Ankara, Turkey

Background & Objectives: Wilson Disease (WD) is an autosomal recessive disorder characterized by pathological copper accumulation, primarily affecting the liver and brain. This study aims to investigate the histopathological features of paediatric WD in liver biopsies.
Methods: Liver biopsies from 14 paediatric patients (aged 7–21 years) diagnosed with WD between 2019 and 2025 were analysed. Patients were categorized into three groups based on the mode of diagnosis: neurological, hepatic, and incidental (or family screening).
Results: Histopathological analysis revealed diverse liver pathology, including fibrosis (8 patients), portal inflammation (9 patients), interface hepatitis (7 patients), focal necrosis (5 patients), confluent necrosis (3 patients), copper accumulation (10 patients), and steatosis (6 patients). Biochemical markers showed uniformly low ceruloplasmin levels (0.092–0.195 g/L) and elevated hepatic copper levels (18.5–874 µg/g) in all patients. Urinary copper excretion was significantly increased (70.5 to >3200 µg/24h).
Clinically, hepatic involvement was the most common presentation, followed by neurological symptoms and incidental diagnosis. Among the patients, 5 had a family history of consanguinity, 2 exhibited hepatomegaly, 1 had splenomegaly, and 2 presented with abdominal ascites. Jaundice and Kayser-Fleischer rings were observed in 1 patient each. Cranial MRI findings were consistent with WD in 3 cases.
Conclusion: This study underscores the importance of integrating histopathological, biochemical, and clinical data for diagnosing paediatric WD. The variability in clinical presentation and histopathological features highlights the need for a high index of suspicion, particularly in cases with a family history of consanguinity or unexplained liver disease.

E-PS-21-002
A retrospective evaluation of congenital thoracic malformations
Z. Koca[1], E. Karakuş[1], E. Doğan[1]
[1]Ankara Bilkent City Hospital, Pathology, Ankara, Turkey

Background & Objectives: Congenital thoracic malformations (CTM) are a rare group of anomalies, including Congenital pulmonary airway malformation (CPAM), bronchopulmonary sequestrations (BPS), congenital lobar emphysema (CLE), and bronchogenic cysts (BC). Prenatal ultrasound has allowed intrauterine diagnosis of congenital thoracic malformations and managed by a paediatric surgeon from early on.
Methods: This retrospective study examines the diagnosis of CTM and was conducted on 36 patients between March 2019 and March 2025 at Ankara Bilkent City Hospital in Ankara, Türkiye. Patient characteristics, including demographic and clinical data, were gathered through a patient record system. All patients were histopathologically diagnosed with CTM, and their demographic data, including age, sex, cardiac findings, and prenatal diagnosis, were recorded.
Results: In this retrospective study, 36 patients (females and males) diagnosed with CTM were enrolled. The mean age of participants was 2.58 years (ranging from 1 month to 16 years). We reported 23 cases (63.9%) of CPAM (13 cases of CPAM type 1 [36.1%] and 12 cases of CPAM type 2 [33.3%]), 3 cases (8.3%) of bronchogenic cyst, 9 cases (25%) of sequestration (3 cases of extrapulmonary sequestration [8.3%]

and 5 cases of intrapulmonary sequestration [13.9%]), 1 case (2.8%) of lymphangioma, 1 case (2.8%) of bronchial atresia, 2 cases (5.6%) of congenital lobar emphysema, and 1 case (2.8%) of combined vascular malformation. Five cases (13.9%) had overlapping features with CPAM, referred to as hybrid lesions. There were 2 cases of mucinous adenocarcinoma arising in congenital pulmonary airway malformation type 1. Cardiac abnormalities were present in 10 cases (27.8%).
Conclusion: The predominant lung malformation in this study was congenital pulmonary airway malformation. Most of the patients underwent lobectomy. All patients were early symptomatic at the time of diagnostic workup. The most common clinical signs and symptoms were respiratory distress and recurrent pulmonary infections.

E-PS-21-003
A challenging diagnosis: paediatric multifocal Langerhans cell histiocytosis with an unusual phenotype
D.-G. Popa[1], E. Cojocaru[2,1], D. Mihăilă[2], A. Ivanov[2], T.E. Ciolan[1], A.D. Vasile[1], D.G. Ciobanu Apostol[3,1], P. Plămădeală[2]
[1]"Grigore T. Popa" University of Medicine and Pharmacy, Iași, Romania, [2]"Sf. Maria" Emergency Clinical Hospital for Children, Iași, Romania, [3]"Sf. Spiridon" Emergency Clinical Hospital, Iași, Romania

Background & Objectives: Langerhans cell histiocytosis (LCH) is a rare disorder characterized by the clonal neoplastic proliferation of Langerhans cells in various tissues. It usually manifests during childhood and it can involve any organ. Most commonly affected sites are the bone and skin.
Methods: A 7-month-old female patient was admitted to the Children's Hospital Iași in 2022 for an erythematous rash involving the face and neck. The clinical diagnosis was chronic dermatitis, with clinicians also considering psoriasis as a differential diagnosis. The patient was admitted again in 2024, with two more suspect lesions on the eyelid and left shoulder. All three lesions were biopsied.
Results: The initial microscopic assessment done in 2022 revealed the presence of histiocyte rich inflammatory infiltrate in the papillary dermis. The histiocytes were immunohistochemically (IHC) positive for CD1a and S100, thus indicating a LCH diagnosis.
The lesion located on the shoulder presented a histologically matching picture with the initial result, the remarkable difference being the addition of multiple giant cells. The histiocyte population was CD1a negative and CD68 positive in IHC, thus raising the suspicion of an independent juvenile xanthogranuloma.
The palpebral lesion presented multiple Touton-like giant cells and negative foci of histiocytes for CD1a in IHC. Examining the clinical and histological data, a synchronous Erdheim-Chester disease diagnosis can be considered.
Conclusion: Whilst the initial histopathological assessment supports the diagnosis of LCH, ruling out Rosai-Dorfman disease and verifying the association with Erdheim-Chester disease calls for additional IHC evaluation, currently being carried out in our case. This type of testing usually involves markers that are infrequent and difficult to access such as Langerin, CyclinD1 and BRAF. Our case is valuable by contributing to a better understanding of the morphological similarities and associations of these rare afflictions, that are scarcely mentioned in medical literature.

E-PS-21-004
Placental chorioangioma and associated pregnancy complications: a retrospective analysis
M. Emin[1], G. Toker[1], E. Karakuş[1]
[1]Ankara Bilkent City Hospital, Pathology, Ankara, Turkey

Background & Objectives: Placental chorioangioma is a rare pregnancy disorder associated with various maternal and foetal complications. This study retrospectively reviews maternal and foetal outcomes in pregnancies affected by placental chorioangioma and evaluates factors influencing disease prognosis. Histological changes in placentas were analysed using the standardized classification system proposed by the Amsterdam Placental Workshop Group.
Methods: This retrospective study was conducted at Ankara Bilkent City Hospital in Ankara, Türkiye. The study population included all pregnancies with ultrasound-detected chorioangiomas or histologically confirmed chorioangiomas between January 2019 and December 2024.
Results: Placental chorioangioma was diagnosed in 13 patients. Foetal vascular malperfusion was detected in all cases (100%). Maternal vascular malperfusion was observed in 6 cases (46.2%). Ascending intrauterine infection was present in 1 case (7.7%), while chronic villitis was not observed in any case. Regarding pregnancy outcomes, induced abortion or foetal loss occurred in 4 cases (30.8%), preterm birth in 11 cases (84.6%), caesarean delivery in 10 cases (76.9%), preeclampsia in 4 cases (30.8%), and polyhydramnios in 5 cases (38.5%).
Conclusion: Placental chorioangioma is associated with a high risk of adverse pregnancy outcomes, including preterm birth, foetal vascular malperfusion, and maternal complications such as preeclampsia. Early diagnosis and careful monitoring are essential for the effective management of these pregnancies.

E-PS-21-005
Retrospective evaluation of paediatric cholestatic liver diseases
H. Yavaş[1], E. Karakuş[1]
[1]Ankara Bilkent City Hospital, Pathology, Ankara, Turkey

Background & Objectives: Paediatric cholestatic liver diseases are rare conditions that can result from multiple specific underlying aetiologies, often associated with high morbidity. The aim of this study was to evaluate the etiological spectrum of paediatric cholestatic liver disease.
Methods: Patients diagnosed with cholestasis under the age of 2 years were included in the study. A total of 49 patients (27 girls, 22 boys) with cholestatic liver disease, who were followed up between 2013 and 2024, were retrospectively evaluated. Patients were categorized into intrahepatic and extrahepatic cholestasis groups. Liver biopsies were examined for cholestasis, giant cell change, inflammation, and fibrosis.
Results: The causes of cholestasis included progressive familial intrahepatic cholestasis (n=4, 8.2%), extrahepatic biliary system disorders (n=19, 38.8%), total parenteral nutrition and sepsis-associated cholestasis (n=3, 6.1%), genetic disorders (n=1, 2.0%), metabolic diseases (n=3, 6.1%), syndromic and non syndromic ductopenia (n=8, 16.3%), idiopathic neonatal hepatitis (n=9, 18.4%), and others (n=4, 8.2%). Cholestatic features were found in all cases (100%). Giant cells containing bile were observed in 22 cases (44.9%). Moderate to severe fibrosis was present in 26 cases (53.1%). Varying degrees of portal inflammation were observed in all cases, while lobular inflammation was found in 20 cases (40.8%). Interface hepatitis was identified in 26 cases (53.1%).
Conclusion: This study demonstrated that the most common causes of neonatal cholestasis were biliary atresia and idiopathic neonatal hepatitis. However, a smaller proportion of cases were attributed to genetic or metabolic liver diseases.

E-PS-21-006
Histopathological features and seasonal distribution of chronic histiocytic intervillositis
J. Dogan[1], S. Ozan[1], E. Karakuş[1]
[1]Ankara Bilkent City Hospital, Medical Pathology, Ankara, Turkey

Background & Objectives: Chronic histiocytic intervillositis (CHI) is a rare placental lesion with high recurrence rates, characterized by maternal mononuclear cell infiltration in the intervillous space, often accompanied by perivillous fibrin deposition and trophoblast damage.

This study evaluates the clinical course, histopathological findings, and seasonal prevalence of CHI. This is the first study to investigate seasonal variations in CHI.
Methods: We analysed 32 CHI cases, assessing histomorphological findings like maternal vascular malperfusion (MVM), foetal vascular malperfusion (FVM), and inflammatory lesions based on Amsterdam Placental Workshop Group criteria. Seasonal distribution was evaluated by categorizing cases into four seasons. Poisson regression and chi-square tests were used for statistical analysis.
Results: Of the 32 cases, 10 were primiparous and 22 multiparous. Nine cases involved advanced maternal age (>34 years). Intrauterine foetal demise or abortion occurred in 18 cases. Foetal vascular malperfusion was present in 46% of cases, maternal vascular malperfusion in 28%, ascending intrauterine infection in 43%, chronic deciduitis in 46%, and chronic villitis of unknown aetiology in 12%. A higher risk of CHI was observed in fall and winter, though the trend was not statistically significant ($p > 0.05$) due to the small sample size.
Conclusion: CHI is associated with high recurrence rates (70%-100%) and significant foetal morbidity and mortality. While a potential seasonal trend was noted, the small sample size limits definitive conclusions. Larger studies are needed to confirm seasonal variations in CHI.

E-PS-21-007
Trophoblastic inclusions in stillborn placentas from third-trimester pregnancies: correlations with malperfusion and inflammation
F. Çıtık[1], E. Karakuş[1]
[1]Ankara Bilkent City Hospital, Pathology, Ankara, Turkey

Background & Objectives: Placental abnormalities are among the most common causes of unexplained stillbirth. Trophoblastic inclusions, which result from abnormal infoldings of the trophoblast bilayer, have been associated with poor neurodevelopmental outcomes, including autism. This study investigates histological changes in placentas associated with stillbirth, particularly focusing on trophoblastic inclusions, using the standardized classification system proposed by the Amsterdam Placental Workshop Group.
Methods: This retrospective study analysed 76 placentas from pregnancies between 30 and 40 weeks of gestation, collected over a two-year period. The cases were categorized based on the presence (n=54) or absence (n=22) of trophoblastic inclusions. Clinical and pathological variables, including maternal age, gestational age, placental weight, maternal vascular malperfusion (MVM), foetal vascular malperfusion (FVM), villitis, intervillitis, and ascending infection, were examined. The criteria for MVM included placental hypoplasia, infarction, retroplacental haemorrhage, decidual arteriopathy, and developmental abnormalities such as distal villous hypoplasia and accelerated villous maturation. FVM findings encompassed thrombosis, segmental avascular villi, villous stromal vascular karyorrhexis, intramural fibrin deposition, stem vessel obliteration, and vascular ectasia. The pathologist reviewing the samples was blinded to demographic and clinical data. Descriptive statistics and group comparisons were employed to identify patterns associated with trophoblastic inclusions.
Results: Trophoblastic inclusions were identified in 71.1% of cases (n=54), while 28.9% (n=22) showed no inclusions. Placentas with trophoblastic inclusions had a higher mean weight (456 g) compared to those without inclusions (405 g). MVM was less frequent in the inclusion group (31.5% vs. 40.9%), while FVM was more common (57.4% vs. 31.8%). Villitis was observed in 20.4% of placentas with inclusions, compared to 40.9% in the non-inclusion group. Ascending infections were also more frequent in the inclusion group (20.3% vs. 13.6%).
Conclusion: These findings suggest a correlation between trophoblastic inclusions and specific placental pathologies, underscoring the need for further research to elucidate their clinical implications.

E-PS-21-008
A rare case of an adenomyoma found in a Meckel diverticulum
D. Baptista[1,2], M. Correia[3], S. Pedrosa[1], J. Lopes[2,1]
[1]ULS São João, Pathology, Porto, Portugal, [2]Faculdade de Medicina da Universidade do Porto (FMUP), Pathology, Porto, Portugal, [3]ULS São João, Paediatric Surgery, Porto, Portugal

Background & Objectives: Adenomyoma of the gastrointestinal tract is a tumour-like condition defined by the presence of glandular structures lined with mucus-producing columnar epithelium, interspersed with smooth muscle bundles. It is most commonly found in the pylorus of the stomach or the duodenum and is rarely observed in the small intestine. In paediatric cases, intussusception is the most frequently reported complication. Here, we present a case of adenomyoma occurring in a Meckel diverticulum.
Methods: A 12-year-old male patient was admitted to the hospital with a 48-hour history of abdominal pain, bilious-vomiting, diarrhoea, fever, and refusal to eat. Abdominal ultrasound revealed ileocolic intussusception, with approximately 10 cm of invaginated bowel loop and significant small bowel distension, indicating possible small bowel obstruction. A segmental enterectomy was performed the day after admission.
Results: A 3.5cm segment of intestine was examined. Upon opening the specimen, an invaginated diverticulum measuring 2.3×1.5×1.2cm was identified. Histological examination revealed an intestinal wall lined with enteric-type mucosa, exhibiting preserved villous architecture and confirming the diverticular lesion observed macroscopically. The lesion contained heterotopic gastric glands and dilated cystic glands surrounded by bundles of smooth muscle.
Immunohistochemical analysis demonstrated smooth muscle actin and focal desmin expression in the smooth muscle bundles, with EMA and focal MUC6 expression present in the cystic glands.
The final pathological diagnosis was adenomyoma arising within a Meckel diverticulum and gastric heterotopia.
Conclusion: We report a case of small intestinal adenomyoma arising in a Meckel's diverticulum. To date, only seven paediatric cases have been documented, with just one involving a Meckel's diverticulum. To our knowledge, this is the first case reported in Portugal. The rarity of this entity in the literature may stem from underreporting or limited recognition by both surgeons and pathologists. Greater awareness and increased vigilance in identifying this lesion may enhance detection and facilitate more frequent diagnosis.

E-PS-21-009
Meconium pseudocyst in a 2-day-old neonate: a case report of a rare congenital entity and possible association with MTHFR and CTFR gene mutations of the mother
C. Gouta[1], M. Pavlidou[2], C. Yfanti[1], T. Stathopoulou[2], E. Sakellariou[1], S. Angelidou[1]
[1]Hippokration General Hospital, Department of Histopathology, Thessaloniki, Greece, [2]Hippokration General Hospital, 1st Neonatal Clinic and NICU, Thessaloniki, Greece

Background & Objectives: Meconium pseudocyst and meconium peritonitis are two rare congenital entities that co-exist in neonates with perforation of gastrointestinal tract leading to meconium leak into the peritoneal cavity.
Methods: A 20-year-old pregnant woman, carrier of mutation in CTFR gene of cystic fibrosis and heterozygous for MTHFR polymorphism (c677t) for thrombophilia presented at our gestational department at 22 weeks of gestation for the appointment of level 2 ultrasound. Ultrasound examination revealed gastrointestinal tract atresia of the neonate and an abdominal, intraperitoneal cystic lesion of maximum diameter

of 10 cm that extended from pelvis to liver. Cesarian section was performed at 37 weeks of gestation and the female infant was admitted to the neonate intense care unit. During the second day of life the neonate was subjected to surgical removal of the cyst and side-to-side small bowel anastomosis.
Results: Microscopic examination of the cyst wall showed a bowel-like layered structure consisting of muscularis propria (circular muscle and longitudinal muscle) and serosa with inflammation. Alongside the internal cystic layer, denuded of the typical intestinal epithelium, calcified, reactive, fibrovascular tissue was observed, which contained macrophages with intracytoplasmic meconium. Consequently, the diagnosis of meconium pseudocyst was established.
Conclusion: Meconium pseudocyst is formed in cases of sterile chemical irritation of the peritoneum (meconium peritonitis) secondary to bowel atresia or ileus. Gastrointestinal tract perforation provokes a fibrous reaction that results in the formation of a fibrous cyst around the leakage. Meconium pseudocyst and meconium peritonitis are associated with cystic fibrosis of the neonate. However, to our knowledge, there is no reported correlation of those entities with mutations in MTHFR gene. Our case report contributes to the literature presenting a rare case of congenital meconium pseudocyst and posing questions regarding the association of this occurrence with CTFR and MTHFR mutations.

E-PS-21-010
Orbital undifferentiated pleomorphic sarcoma in a 4-year-old child – a case that challenged the medical teams of two hospitals
T.-E. Ciolan[1], D. Mihăilă[2], G.F. Dumitrescu[3], P. Plămădeală[2], M.F. Trandafirescu[1,2], A. Sava[3], D.G. Popa[1], D. Zamosteanu[1], E. Cojocaru[1,2]
[1]"Grigore T. Popa" University of Medicine and Pharmacy, Iași, Romania, [2]"Sf. Maria" Emergency Clinical Hospital for Children, Iași, Romania, [3]"Prof. Dr. Nicolae Oblu" Emergency Clinical Hospital, Iași, Romania

Background & Objectives: Undifferentiated pleomorphic sarcoma (UPS) is a highly rare and aggressive malignant tumour characterized by an unclear pattern of differentiation. It is most commonly reported in the long tubular bones of older adults, often presenting as a rapidly growing, destructive mass.
Methods: A 4-year-old male patient was admitted to the Neurosurgery Hospital Iași with remarkable unilateral proptosis of the right eye, decreased visual acuity and periocular pain and pressure. A head MRI identified an irregular orbital mass with intracranial extension. Following surgical intervention, tissue samples were collected for histopathological and immunohistochemical examination, conducted in collaboration with pathologists from Children's Hospital in Iași.
Results: The histopathological evaluation revealed a proliferation of atypical cells with numerous multinucleated giant cells (MGCs) and frequent mitosis (5-6/mm²). Immunohistochemical (IHC) analysis showed positivity for CD68 and Ki67 (10-20% of tumour cells) and negativity for Desmin, CD99, p63, and p53. Initially, a giant cell osteolytic and infiltrative bone tumour was suspected. Due to the patient's age, a second opinion was requested. Reevaluation in Children's Hospital identified the tumour proliferation destroying bone tissue, with numerous MGCs. Further IHC tests showed positivity for SMA (50% of tumour cells), CD68, and Ki67 (40%), while Myogenin, MyoD1, CD99, and S100 were negative. Based on these findings, the final diagnosis was orbital undifferentiated pleomorphic sarcoma.
Conclusion: Our patient was diagnosed with undifferentiated pleomorphic sarcoma of the right orbit, an unusual presentation both in terms of location and the patient's age. This case report is significant due to the complex clinical and histological features, which required collaboration between the pathology teams of two hospitals to achieve a thorough understanding and an accurate diagnosis.

E-PS-21-011
Transient abnormal myelopoiesis as a cause of intrauterine death in a foetus with Down Syndrome
J. Lages dos Santos[1], J. Pimentel[2], C. Cerdeira Manuel[2], R. Pina[2], M.A. Cipriano[2]
[1]Unidade Local de Saúde Gaia Espinho, Department of Anatomic Pathology, Porto, Portugal, [2]Unidade Local de Saúde de Coimbra, Department of Anatomic Pathology, Coimbra, Portugal

Background & Objectives: Transient abnormal myelopoiesis (TAM) is a hematologic disorder associated with trisomy 21 characterized by abnormal proliferation of cells of myeloid lineage. While TAM typically resolves in 2-3 months postnatally without treatment, some cases can lead to early death, particularly when associated with ascites, hepatomegaly and coagulopathy. TAM typically presents perinatally and is rare in the prenatal period. As such, cases of prenatal manifestation of TAM are particularly relevant as the current available data is still limited.
Methods: We report a case of intrauterine foetal demise (IUFD) of a male foetus with trisomy 21 at 32 weeks and 4 days of gestation. The mother was 45 years old and had two previous gestations resulting in two healthy children.
On prenatal screening at 11 weeks absence of nasal bones was detected leading to a diagnosis of trisomy 21 after amniocentesis, QF-PCR and karyotyping (47, XY, +21), upon which the mother refused termination.
At 32 weeks and 4 days of gestation the mother detected absence of foetal movements which prompted the visit to the ED where, upon confirmation of IUFD, delivery was induced with mifepristone.
Results: On foetal autopsy, besides minor defects associated with Trisomy 21, we detected splenomegaly and hepatomegaly which upon histological examination showed to be due to extensively increased extramedullary myelopoiesis. These findings are consistent with TAM and the cause of death was attributed to hepatic dysfunction secondary to excessive myelopoiesis and congestion.
The available literature highlights hepatosplenomegaly as one of the most common symptoms in cases of IUFD secondary to TAM.
Conclusion: Although typically perinatal, TAM can also present in utero with manifestations ranging from light and self-limiting to severe and fatal. This case is in line with the notion of TAM developing as a gradual process that begins in utero and highlights the need to recognize this diagnosis early.

E-PS-21-012
Placental mesenchymal dysplasia and foetal mesenchymal hamartoma: a case report of this extraordinary clinical presentation
M.A. Salcedo Armijos[1], D. Borreguero Gallego[1], C. Zamora del Pozo[2], C. Bravo Arribas[2], C. Martínez Payo[2], R.M. Regojo Zapata[3], E.M. Pena Burgos[1]
[1]Hospital General Universitario Gregorio Marañón, Pathology, Madrid, Spain, [2]Hospital General Universitario Gregorio Marañón, Obstetrics and Gynaecology, Madrid, Spain, [3]Hospital Universitario La Paz, Pathology, Madrid, Spain

Background & Objectives: Placental mesenchymal dysplasia (PMD) is an extremely rare entity characterized by excessive mesenchymal proliferation in the chorionic villi, resulting in placentomegaly, multicystic appearance, and vascular abnormalities of the placenta. Only 11 cases of foetal hepatic lesions and PMD are reported in the PubMed database.
Methods: We present the case of a 41-year-old patient whose pregnancy was complicated with foetal growth restriction (FGR) and oligohydramnios. Multiple and focal vascular placental cysts, and a hepatic foetal cyst were detected in ultrasound studies. Genetic analysis of the amniotic fluid was normal. Labor was induced at 30 weeks of

pregnancy due to progressive foetal deterioration. The foetal lesion was surgically removed after birth.
Results: Macroscopic examination of the placenta revealed placentomegaly, and multiple and focal cystic formations arranged in clusters, predominantly on the maternal surface. Histologically, enlarged villi with stromal overgrowth, myxoid stroma, cistern-like spaces, and poor vascularization were observed interspersed with smaller villi containing small peripheral vessels. Immunohistochemical p57 staining showed preserved expression in cytotrophoblast cells but a total loss of expression in villous mesenchymal cells. The hepatic lesion was a solid and cystic mass with primitive mesenchyme and myxoid stroma, consistent with a mesenchymal hamartoma.
Conclusion: The coexistence of a hepatic mesenchymal hamartoma and PMD has been extraordinarily reported. However, the similarities in their histopathological and pathogenetic characteristics suggest a possible common embryonic origin. This origin may be linked to genetic alterations in growth regulation, particularly androgenetic/biparental mosaicism and the genetic methylation of the 11p15.5 locus, which has been implicated in both entities. PMD is associated with FGR, stillbirth, neonatal death, structural malformations and genetic syndromes - specially the Beckwith-Wiedemann syndrome (reported in 20% of the cases). This case highlights the importance of an integrated prenatal approach, including clinical, imaging, genetic and histopathological assessments, to achieve an accurate diagnosis and guide appropriate perinatal care.

E-PS-21-013
Undifferentiated embryonal sarcoma of the liver arising from mesenchymal hamartoma in a paediatric patient: a case report
D. Zamosteanu[1], D. Mihăilă[2], T.-E. Ciolan[1], M. Trandafirescu[1,2], P. Plămădeală[2], O.I. Bărbuță[2], E. Cojocaru[1,2]
[1]"Grigore T. Popa" University of Medicine and Pharmacy, Iași, Romania, [2]"Sf. Maria" Emergency Clinical Hospital for Children, Iași, Romania

Background & Objectives: Undifferentiated embryonal sarcoma (UESL) and mesenchymal hamartoma of the liver (HMH) represent mesenchymal tumours with overlapping clinicopathological characteristics and identical chromosomal abnormalities. The diagnostic challenge arises from their similar presentations, requiring careful histopathological and immunohistochemical examination to distinguish between them.
Methods: We report a challenging UESL case in a 4-year-old male who was admitted to emergency room in critical status due to epileptic seizures. Following extensive assessments, radiological findings revealed a well-defined solitary mass in the left hepatic lobe, with no signs of metastatic disease. Tissue samples were taken and processed for extemporaneous, histopathological, and immunohistochemical examination to confirm the diagnosis.
Results: The extemporaneous examination suggested immature teratoma while haematoxylin-eosin evaluation revealed a proliferative area, displaying a nodular, heterogeneous architecture with hyperplastic and irregular biliary ducts within a myxoid or fibrous stroma. Immunohistochemical analysis showed positivity for CK7 and AE1/AE3 in ductular epithelium, along with focal positivity for S100. Subsequently, foci of spindle cell proliferation with highly pleomorphic cells, with unclear cell borders, large and hyperchromatic nuclei, prominent nucleoli, frequent atypical mitoses and eosinophilic PAS-positive globules disposed in myxoid stroma with necrotic areas were identified. The immunohistochemical profiling showed a focal positive reaction for vimentin and desmin, along with negative expression for myogenin and myoD1. Ki67 was positive in 30% of tumour cells.
Conclusion: The malignant transformation of HMH into UESL is particularly rare, with only a few reported cases in paediatric patients. Our case highlights the critical role of immunohistochemistry in distinguishing HMH from other paediatric tumours, as clinicoradiological features are nonspecific. Additionally, its unusual location and incidental presentation further complicate the diagnosis in our patient. Understanding the oncogenic mechanisms and implementing a targeted diagnostic approach are essential for accurate risk assessment and tailored treatment in such complex cases.

E-PS-21-014
Placenta with multiple chorangiomas: a case report of a rarely documented entity
M. Zbronska[1], I. Araújo[1], N. Chiote[1], D. Sá[1], A. M. G. Pereira[1]
[1]Unidade Local de Saúde de Santo António, Anatomic Pathology Service, Genetics and Pathology Clinic, Porto, Portugal

Background & Objectives: Placental chorangioma is a benign, nontrophoblastic neoplasm of uncertain aetiology. It has been suggested that hypoxia may induce the overexpression of vascular growth factors, creating a favourable environment for capillary proliferation. Chorangiomas are most often asymptomatic and of little consequence. Nonetheless, large (>4cm) or multiple tumours can affect foetal circulation. Multiple lesions are associated with serious complications, usually leading to intrauterine foetal demise or perinatal death.
Methods: We present the case of a 33-year-old pregnant patient with a long history of iron-deficiency anaemia and a well-controlled vitamin B12 deficiency, positive for anti-parietal cell antibodies. Aside from anaemia (haemoglobin: 8.9g/dL, low ferritin, normal vitamin B12) detected in the third trimester, the pregnancy was otherwise uneventful. Vaginal delivery occurred at 38 weeks, resulting in a live birth (Apgar score: 9/10/10, weight: 3330g)**.** Due to the unusual appearance of the placenta, it was sent to the Department of Pathology for further evaluation.
Results: Gross examination revealed a fragmented placenta with a total weight of 870g (>97th percentile). Focal pale areas and multiple nodular lesions were identified, the latter measuring between 0.5 and 5.5cm and comprising 40-50% of the placental volume. The cut surface of the lesions consisted of haemorrhagic, cystic, necrotic, and solid yellow areas. Histopathological analysis showed multiple chorangiomas of different morphological variants, many of which had areas of necrosis. Focal syncytiotrophoblast hyperplasia, delayed villous maturation, diffuse chorangiosis, and chorangiomatosis were also observed.
Conclusion: Multiple chorangiomas are associated with poor foetal outcomes and a high mortality rate, which contrasts with the result of this case. Our case involved not only multiple lesions but also large ones, along with a newborn delivered without complications and, to date, showing adequate psychomotor development. Maternal anaemia may have contributed to the overall presentation, although the exact aetiology remains unknown.

E-PS-21-015
Autopsy findings in a case of autosomal recessive polycystic kidney disease associated with polydactyly: a case report
M.C. Yıldız[1], H.S. Toru[1]
[1]Akdeniz University, Department of Pathology, Antalya, Turkey

Background & Objectives: Autosomal recessive polycystic kidney disease (ARPKD) is a rare hereditary disorder affecting the kidneys and hepatobiliary system, often leading to perinatal morbidity and mortality. The disease is caused by mutations in the PKHD1 gene. While ARPKD is primarily a renal and hepatobiliary disorder, it's association with limb anomalies such as polydactyly has been reported in rare cases. This report presents a foetal autopsy case diagnosed prenatally with ARPKD and polydactyly at 14 weeks of gestation.
A 24-year-old pregnant woman with a history of consanguinity underwent ultrasonography at 14 weeks and 3 days of gestation. However,

the kidneys appeared hyperechoic and polycystic. At 16 weeks, follow-up ultrasonography showed bilateral multicystic kidneys and oligohydramnios. Based on these findings and the parental decision, the pregnancy was terminated.
Methods: A foetal autopsy was conducted, including macroscopic and routine haematoxylin-eosin histopathological examination.
Results: External examination revealed maceration, low-set ears, micrognathia, and a contracted appearance of the left-hand fingers. The hands had five fingers each, while both feet had six toes. The right upper and lower extremities were contracted. Both kidneys contained multiple cystic masses, the largest measuring 0.5 cm. Histopathological examination confirmed the presence of cystically dilated collecting ducts, characteristic of ARPKD. The renal architecture was distorted, with the replacement of normal parenchyma by multiple cysts. No evidence of hepatic fibrosis was observed in this case. Additionally, the presence of polydactyly suggests a syndromic association, possibly overlapping with ciliopathies.
Conclusion: Detailed ultrasonographic evaluation in early gestation allows for timely diagnosis of ARPKD, facilitating informed decision-making for affected families. The presence of polydactyly in association with ARPKD may suggest an extended ciliopathy spectrum, warranting further genetic and syndromic evaluation. Genetic counselling is crucial, especially in cases with a history of consanguinity, to assess recurrence risks and provide reproductive guidance.

E-PS-21-016
Cornelia de Lange syndrome phenotype in perinatal period: a multi-case pathological analysis
M.A. Abad Vintimilla[1], C.R. Mena Soria[1], V. Diaz Castro[1], E. Tornay Mora[1], R.M. Regojo Zapata[1]
[1]Hospital Universitario La Paz, Pathology, Madrid, Spain

Background & Objectives: Cornelia de Lange syndrome is a rare genetic disorder characterized by developmental abnormalities, facial dysmorphism, and intellectual disability. Diagnosis is clinically suspected and can be confirmed by genetic testing (cohesin complex). There are few descriptions of foetal phenotype.
Methods: We reviewed our autopsy records from 1967 to 2023, and found five cases of Cornelia de Lange syndrome. All have complete autopsy, radiological study, and placental examination (according to the Amsterdam Consensus classification).
Genetic tests were carried out in the four most recent cases. Our results were compared with previously published studies.
Results: The age of the cases ranged from 17 weeks of gestation to 3 months. In our five cases, we observed a wide range of anatomical abnormalities. Limb deformities and skeletal anomalies were present in all cases, while typical facial features were observed in four cases. Microcephaly and synophrys were each identified in three cases, and hirsutism in two cases. Structural cardiac, renal, and digestive malformations were noted in four cases. As a significant finding, two cases presented with diaphragmatic hernia and umbilical hernia respectively, and two cases had intrauterine growth restriction.
Considering the clinical minor, major, and genetic diagnostic criteria, two cases were diagnosed based on only clinical signs, while the three more recent cases were confirmed through genetic analysis, all of them with a pathogenic variant in the NIPBL gene which belongs to the cohesin complex.
Conclusion: This research enhances our understanding of Cornelia de Lange syndrome phenotype in the foetal period, in terms of the complexity and diversity. This series illustrates that this syndrome can be diagnosed in foetus after induction and in newborns at birth as the phenotype is presents early. Sustained research efforts and a multidisciplinary approach are indispensable for accurate prenatal diagnosis and prognosis of these patients.

E-PS-21-017
Pathological analysis of lesions associated with vein of Galen aneurysm: an autopsy study (1967–2024)
V. Macarrón[1], S. Quinones[1], V. Hincapié Baena[1], V.Y.C. Díaz Castro[1], E. Tornay Mora[1], R.M. Regojo Zapata[1], M.I. Esteban Rodríguez[1]
[1]La Paz University Hospital, Pathology, Madrid, Spain

Background & Objectives: Vein of Galen aneurysmal malformations (VGAM) are congenital vascular anomalies of the cerebral venous system, classified as arteriovenous malformations (AVMs). VGAM represents the most prevalent vascular malformation in foetal and paediatric populations. The clinical-pathological impact varies depending on malformation severity and medical interventions.
This study reviews autopsy cases of VGAM, analysing their epidemiological characteristics and pathological findings.
Methods: A retrospective search of autopsy cases from 1967 to 2024 was conducted at a tertiary hospital to identify VGAM diagnoses. Pathological reports were reviewed to extract clinical-pathological variables.
Results: Nine cases were identified, with a mean gestational age of 37 weeks. One case (11.1%) involved intrauterine death, while the remaining postnatally survived for 6 hours to 21 days. Male predominance was noted (66.7%), and one case (11.1%) involved a twin pregnancy. Aneurysmal rupture with subdural haemorrhage occurred in two cases (22.2%), and thrombosis with subarachnoid haemorrhage in one (11.1%). Acute neuronal necrosis affected seven cases (77.7%), involving multiple CNS regions in three (33.3%). White matter gliosis was observed in four cases (44.4%), diffusely in two (22.2%). Additional findings included basilar AVM (11.1%) and periventricular leukomalacia (11.1%). Regarding the heart involvement, myocardial anomalies were present in five cases (55.6%). Atrial septal defect (22.2%), persistent ductus arteriosus (11.1%), and myocardial infarction (11.1%) were detected. Foetal hydrops was identified in one case (11.1%).
Conclusion: AVMs are characterized by abnormal arterial-to-venous drainage, leading to venous stasis and reduced systemic perfusion due to shunting. VGAM arise from embryological alterations involving multiple arteriovenous shunts in the prosencephalic vein of Markowski, precursor of the vein of Galen.
Cardiomegaly was the most frequent pathological finding, present in over half of the cases. Severe heart failure may lead to foetal hydrops. Neurological complications from vascular compression and shunting contribute significantly to morbidity and mortality, as evidenced by the high incidence of hypoxic-ischemic encephalopathy.

E-PS-21-018
Severe colitis and accelerated adenoma development in an adolescent with a homozygous ITGAV variant
M. Simplício[1,2], R. Portugal[1,2], J. Lopes[1,2], R. Amorim[3], I.P. Pais[3], M.C. Espinheira[3], F. Carneiro[1,2,4], E. Trindade[3]
[1]Unidade Local de Saúde de São João (ULSSJ), Department of Pathology, Porto, Portugal, [2]Faculty of Medicine of the University of Porto (FMUP), Porto, Portugal, [3]Unidade Local de Saúde de São João (ULSSJ), Department of Paediatrics, Unit of Paediatric Gastroenterology, Hepatology and Nutrition, Porto, Portugal, [4]Ipatimup (Institute of Molecular Pathology and Immunology of the University of Porto), Porto, Portugal

Background & Objectives: Integrin heterodimers containing an Integrin alpha V subunit (ITGAV) are crucial for development and play significant roles in cell adhesion and signalling. Reduced ITGAV expression/function has been associated with severe embryonic defects, neurodevelopmental disorders, vision impairment, atopy, and inflammatory bowel disease (IBD), with varying

phenotypic manifestations depending on whether the loss of function is complete or incomplete.
Methods: A 15-years-old male patient with a long-standing history of severe colitis, managed with prednisolone, azathioprine and infliximab, associated with growth problems, eye abnormalities, dermatitis, alopecia, and multiple food allergies, was identified as a carrier of a homozygous "ITGAV NM_002210.4: c.1136A>T" variant. In late 2024, he underwent a colonoscopy which revealed multiple polyps, that were not present in a prior examination two years earlier. Histological, these polyps were adenomas with both low- and high-grade dysplasia. In January 2025, a total colectomy surgery was performed.
Results: Examination of the total colectomy specimen identified 10 sessile and pedunculated polyps, with the largest measuring 4.3 cm. Several subcentimeter polyps were also noted. The adenomas predominantly exhibited tubular architecture with low-grade dysplasia; larger adenomas showed pseudo-invasion, with mucus extravasation and focal calcification. Lamina propria of both the polyps and surrounding mucosa was permeated by moderate/severe lymphoplasmacytic infiltrate with eosinophils. No invasive neoplasia was detected.
Conclusion: The described ITGAV variant is associated with severe IBD, but its role in carcinogenesis remains unclear. Although ITGAV expression has been observed in multiple cancers, its specific involvement in digestive system cancer is not well understood. This case represents the first known patient with this variant to reach adolescence, providing novel insights into its potential carcinogenesis effects. The early-onset and rapid development of adenomatous lesions highlights the need for further investigation into ITGAV's contribution to tumour progression.

E-PS-21-019
Testicular adrenal rest tumours in congenital adrenal hyperplasia
M. Emin[1], E. Güler[1], E. Karakuş[1]
[1]Ankara Bilkent City Hospital, Pathology, Ankara, Turkey

Background & Objectives: Congenital adrenal hyperplasia (CAH) is an inherited disorder that impairs adrenal steroid synthesis. In male CAH patients, testicular adrenal rest tumours (TARTs) are a significant complication, often confused with Leydig cell tumours (LCTs). This case report highlights the diagnostic challenges of TARTs and the importance of long-term monitoring in CAH patients.
Methods: A 15-year-old male with 21-hydroxylase deficiency (CYP21A2 mutation) was referred after scrotal ultrasonography detected a left testicular mass, suggestive of TART. The patient had been diagnosed with CAH during infancy following an episode of diffuse hyperpigmentation and adrenal crisis. In 2024, he underwent surgery for a right testicular mass, which was histopathologically diagnosed as a Leydig cell tumour (LCT) at another medical centre. After the surgery, the patient was treated with hydrocortisone for six months.
Results: During a routine follow-up, scrotal ultrasonography revealed a lesion in the left testicle, consistent with TART. A reevaluation of previous biopsy specimens further supported this diagnosis. The histopathological examination showed sheets, nests, and cords of polygonal cells with abundant eosinophilic cytoplasm. Some cells contained lipochrome pigments, but Reinke's crystals were absent. The cells exhibited mild nuclear pleomorphism without mitotic activity. Immunohistochemical analysis revealed positive staining for inhibin and calretinin in the lesion cells. These findings, along with the absence of Reinke crystals, confirmed the diagnosis of TART and suggested a favourable prognosis.
Conclusion: This case highlights the diagnostic challenges in differentiating between TART and LCT in patients with CAH. The absence of Reinke crystals were critical in distinguishing TART from LCT. This case also emphasizes the necessity of long-term endocrine and radiological follow-up to ensure accurate diagnosis and appropriate management of CAH patients. Early and accurate diagnosis of TART can lead to a more favourable prognosis and better patient outcomes.

E-PS-21-020
Pentalogy of Cantrell: rare and challenging cases
P. Delongová[1,2], E. Urbančíková[1], V. Skopelidou[1,2], J. Pavlíček[3,4], D. Grečmalová[1,2], J. Škarda[1,2], R. Špaček[5,6]
[1]Institute of Pathology and Molecular Genetics, University Hospital of Ostrava, Ostrava, Czech Republic, [2]Institute of Molecular and Clinical Pathology and Medical Genetics, University of Ostrava, Ostrava, Czech Republic, [3]University Hospital of Ostrava, Paediatrics and Neonatal Care, Ostrava, Czech Republic, [4]University of Ostrava, Paediatrics and Neonatal Care, Ostrava, Czech Republic, [5]University Hospital of Ostrava, Gynaecology and Obstetrics, Ostrava, Czech Republic, [6]University of Ostrava, Gynaecology and Obstetrics, Ostrava, Czech Republic

Background & Objectives: The Pentalogy of Cantrell is a sporadic congenital syndrome characterized by midline defects of the sternum, diaphragm, pericardium, anterior abdominal wall, and heart. The exact aetiology of the syndrome is unknown and has yet to be discovered.
Diagnosis of Pentalogy of Cantrell and its individual manifestations is based primarily on prenatal ultrasound screening. Early prenatal diagnosis helps families make informed decisions regarding pregnancy and, if necessary, determine the extent of the disability for planning subsequent therapeutic strategies. Treatment for Cantrell's pentalogy depends on the defects' presence and extent. This syndrome may be associated with chromosomal aberrations and genetic testing can be a valuable part of the multidisciplinary diagnostic process.
Methods: We selected relevant cases from our laboratory's archive, evaluated them in detail, and categorized them.
Results: We present two cases from the spectrum of the Pentalogy of Cantrell.
Conclusion: The diagnosis of Pentalogy of Cantrell is challenging, especially in foetuses in low gestational weeks. The advantage is a multidisciplinary approach and detailed examinations leading to an assessment of the extent of the defects, determination of the syndrome subtype and determination of possible therapy. For families, it is appropriate to supplement genetic testing, which can influence their informed decision-making about pregnancy.
In the event of termination of pregnancy, it is up to the pathologist to confirm the correctness of the diagnosis or to determine the diagnosis itself through autopsy.

E-PS-21-021
A rare presentation of neurofibromatosis coli in a paediatric patient
H. Yavaş[1], E. Karakuş[1]
[1]Ankara Bilkent City Hospital, Pathology, Ankara, Turkey

Background & Objectives: In patients with neurofibromatosis type 1 (NF1), gastrointestinal neurofibromas may present as widespread GI involvement or as isolated, sporadic lesions. NF1 is an autosomal dominant condition that affects approximately 1 in 3,000 individuals. Approximately 25% of NF1 patients develop gastrointestinal manifestations, including neurofibromas originating from the myenteric plexus. These tumours can lead to complications such as bleeding, melena, obstruction, and abdominal pain. Neurofibromas may affect various parts of the gastrointestinal tract, including the jejunum, stomach, ileum, duodenum, and colon. While typically solitary, multiple serosal and mucosal polypoid nodules can develop in patients with NF1.
Methods: A 6-year-old female patient presented with chronic diarrhoea and hyperpigmented lesions (café-au-lait spots) that had persisted for

five years. Additionally, the patient had a history of frequent respiratory tract infections.
Results: Physical examination revealed cryptitis in the left tonsil, while the abdominal examination showed no abnormalities. Due to persistent diarrhoea, a colonoscopy was performed, which revealed multiple firm, white polyps measuring 10 to 15 mm in the transverse colon, sigmoid colon, and rectum. Histopathological analysis of colonic biopsies identified neoplastic formations composed of neural cells, Schwann cells, and fibroblasts with spindle shaped morphology and polypoid structures localized within the colonic mucosa. Immunohistochemical studies showed positive staining for S100 and CD34, while DOG-1, CD117, and desmin were negative. Laboratory tests indicated a low naive B cell level (36%), and further investigations for common variable immunodeficiency disease are ongoing.
Conclusion: Histological findings, in correlation with clinical data, support a diagnosis of neurofibromatosis coli (diffuse/submucosal neurofibromatosis). Nutritional supplementation has been arranged to manage diarrhoea, and the patient will be closely monitored due to the potential for recurrent polyps.

E-PS-21-022
Lethal perinatal hypophosphatasia caused by a novel mutation in the ALPL gene
J. Dogan[1], S.P. Eren[1], E. Karakuş[1]
[1]Ankara Bilkent City Hospital, Medical Pathology, Ankara, Turkey

Background & Objectives: Perinatal hypophosphatasia is a rare genetic disorder caused by mutations in the ALPL gene, leading to decreased tissue-nonspecific alkaline phosphatase (TNAP) activity and impaired bone mineralization. The severe perinatal form is associated with intrauterine complications such as short and curved bones, lack of skeletal mineralization, and pulmonary hypoplasia. This case report presents a diagnosis of perinatal hypophosphatasia at 19 weeks of gestation.
Methods: A 23-year-old mother underwent foetal ultrasound at 19 weeks, revealing micrognathia, short ribs, micromelia, and absent nasal bone. Limb lengths were below the 1st percentile, with hypomineralization observed. The pregnancy was terminated due to severe findings. X-ray imaging and histological examination of the femur were performed. Exome sequencing was conducted on a foetal skin sample to identify ALPL gene mutations.
Results: Imaging showed diffuse osteoporotic bone structure, lack of cranial ossification, thin and deformed ribs, and shortened, bowed femurs and humeri. No ossification was observed in the tibia and fibula. External examination revealed a hypoplastic cranium, epicanthal folds, flattened ears, a thick nasal bridge, and micrognathia. Histological analysis of the femur showed hypercellularity and disorganization. Exome sequencing identified a homozygous pathogenic variant in the ALPL gene.
Conclusion: This case highlights a severe form of perinatal hypophosphatasia caused by a novel ALPL gene mutation, leading to significant bone abnormalities and mineralization defects. Early diagnosis is crucial, and further data on the clinical course of the disease are needed.

E-PS-21-023
Gross and histopathological findings of 111 triplet placentas: a descriptive analysis
E.M. Pena Burgos[1], M. De la Calle Fernández-Miranda[2], J.J. Pozo Kreilinger[3], R.M. Regojo Zapata[3]
[1]Hospital General Universitario Gregorio Marañón, Pathology, Madrid, Spain, [2]Hospital Universitario La Paz, Obstetrics and Gynaecology, Madrid, Spain, [3]Hospital Universitario La Paz, Pathology, Madrid, Spain

Background & Objectives: Triplet pregnancies have increased over the past few decades due to an increase in assisted reproductive technology (ART). They are considered high-risk pregnancies, and placental evaluation is key for understanding the pregnancy outcomes. Triple placentas pathological findings have not been thoroughly described.
Methods: This is a retrospective observational study that includes all triplet pregnancies followed up in a tertiary referral hospital for multiple pregnancies between January 2000 and December 2024 whose placentas were sent for analysis in a Pathology Department. Gross and pathological placental findings were examined.
Results: A total of 111 triplet pregnancies (333 foetuses) were analysed. Miscarriages or stillbirths occurred in 7.5% of the foetuses. Up to 70.3% of the cases were conceived by ART. The median gestational age at delivery was 32 weeks (P25=30; P75=34). Most cases (50.4%) were trichorionic triamniotic. The mean placental weight was 869±243 g and the median placental size was 22.5 cm (P25=18; P75=30). They presented up to 52.2% of abnormal umbilical cord insertion (marginal or velamentous) and a total of 43.8% of the placental discs showed both central and peripheral intraparenchymatous infarcts (from 0.4 to 3.2 cm). The most frequent histopathological findings were accelerated villous maturation (65.1%), chorangiosis (53.7%), intervillous fibrin deposits (29.4%) and villous oedema (24.3%). The most frequent finding within the inflammatory pattern was chronic villitis of unknown aetiology (9.3%).
Conclusion: Triplet placentas present high rates of gross and pathological abnormalities that may be related to the complications developed in these high-risk pregnancies. Further studies are needed to analyse whether these findings are related to factors such as chorionicity or ART.

E-PS-21-024
Exploring the rare co-occurrence of chronic histiocytic intervillositis and massive subchorionic thrombohematoma: pathological insights into placental dysfunction and foetal loss
O. Greenberg[1], C. Weizman[1], D. Hershkovitz[1]
[1]Tel Aviv Sourasky Medical Centre, Pathology, Tel Aviv, Israel

Background & Objectives: The co-occurrence of Chronic Histiocytic Intervillositis (CHI) and a Massive Subchorionic Thrombohematoma (Breus' Mole) in the same placenta is an extremely rare and complex pathological scenario. Both conditions can contribute to adverse pregnancy outcomes, and their simultaneous presence may indicate significant maternal-foetal interactions and placental dysfunction.
The aim of this study is to examine the pathological findings in a case of IUFD at 18 weeks, focusing on the presence of significant placental features including a large subchorionic hematoma, chronic histiocytic intervillositis (CHI), elevated perivillous fibrin deposition. Understanding these features will provide insight into the pathophysiology of IUFD and the role of placental pathology in foetal loss.
Methods: A placental specimen was subjected to histopathologic examination. Standard haematoxylin and eosin (H&E) staining was performed to assess general tissue structure and inflammatory changes. Immunohistochemistry was used for CD68 and CD3 to evaluate the presence and extent of macrophage infiltration (CHI) and T-cell involvement in the villous tissue (VUE). Additionally, the degree of fibrin deposition was assessed to determine placental insufficiency and its potential contribution to foetal demise.
Results: Histopathologic examination revealed a massive bubchorionic thrombohematoma , which likely contributed to uteroplacental insufficiency. Moreover the placenta also demonstrated elevated perivillous fibrin deposition, indicating compromised placental function. Immunostaining for CD68 highlighted moderately sized clusters of macrophages, indicating chronic histiocytic intervillositis (CHI).
Conclusion: This is the first report of these two pathologies co-occurring, raising the possibility of a relationship between chronic histiocytic intervillositis and Breus' Mole.
These findings highlight the complex nature of placental pathology and its crucial role in understanding the mechanisms behind early foetal

loss. Further studies on the interplay of these pathologic features are needed to refine our understanding of their clinical significance and potential impact on pregnancy outcomes.

E-PS-21-025

Underestimated cranial nerve involvement in spinal muscular atrophy type 1: the need for immunohistochemical staining

S. Quinones[1], A. Andreu-Cervera[2], V. Company[2], M. Martínez-Sempere[2], I. Esteban-Rodríguez[1], I. Voinescu[3], M. De Uribe-Viloria[4], E.P. Sánchez-López[1], R.M. Regojo[1], E. Puelles[2]
[1]La Paz University Hospital, Pathology, Madrid, Spain, [2]Institute of Neurosciences (CSIC-UMH), Campus de San Juan, Alicante, Spain, [3]Analiza Sociedad de Diagnóstico, Madrid, Spain, [4]Clínico de Valladolid University Hospital, Valladolid, Spain

Background & Objectives: Spinal muscular atrophy type 1 (SMA1), also called Werdnig-Hoffman disease, is the most severe form of spinal muscular atrophy, characterized by hypotonia from early infancy and difficulties in swallowing and breathing. The histopathological diagnosis of cranial nerve involvement is challenging due to anatomical and embryological complexities, limitations in histopathological characterization, and the availability of specific immunohistochemical markers. Furthermore, the limited experience with cranial nerve pathologies complicates their precise identification. Some authors have proposed the term "brainstem dysgenesis" to describe these abnormalities. The aim is to perform a detailed neuropathological analysis of motor neuron populations in individuals with SMA1.
Methods: We reviewed our records of clinical autopsies foetal (from week 22), perinatal, and infant from 1967 to 2019 and 10 cases of SMA1 were found. These cases were reevaluated and the tissue samples were reprocessed with haematoxylin-eosin and Cresyl violet staining, along with immunohistochemical analysis using choline acetyltransferase (ChAT) and other markers to evaluate motor neuron involvement in the brainstem and spinal cord.
Results: Cranial nerve degeneration and intense gliosis was detected in all cases. Regarding the cranial nerves involved, the hypoglossal nerve (XII) was most frequent (9/9 cases), followed by the facial (VII, 3/9), oculomotor (III, 2/9), abducens (VI, 1/9), and vagus (X, 1/9) nerves. Additionally, the spinal cord exhibited atrophy, gliosis, and/or neuronal degeneration in the anterior horn in five cases. The immunohistochemical analysis with ChAT demonstrated greater cranial nerve involvement compared to initial histopathological evaluation.
Conclusion: Haematoxylin-eosin staining alone may underestimate cranial nerve involvement in SMA1 and other disorders affecting cranial nerves. Incorporating specific immunohistochemical studies is recommended to enhance the identification of motor neurons in suspected cases. We support the term "brainstem dysgenesis" to better characterize histopathologically similar entities, suggesting that SMA1 shares features with other motor brainstem dysgenesis.

E-PS-21-026

A rare foetal case of congenital erythropoietic porphyria: Importance of prenatal and postmortem evaluation

V. Hincapié Baena[1], S. Quinones Garrido[1], V.Y.C. Diaz Castro[1], E. Tornay[1], M.I. Esteban Rodriguez[1], R. Regojo Zapata[1], M. Parrón Pajares[2]
[1]Hospital Universitario La Paz, Pathology, Madrid, Spain, [2]Hospital Universitario La Paz, Paediatric Radiology, Madrid, Spain

Background & Objectives: Congenital erythropoietic porphyria (CEP) is a severe autosomical recessive disease due to a uroporphyrinogen III synthase deficiency, leading to uroporphyrinogen I accumulation that cannot be metabolized into haemoglobin. Prenatal manifestations include anaemia, haemolysis and hydrops fetalis.
Methods: We presented a case of legal pregnancy termination diagnosed using fluorescence analysis of amniotic fluid. A complete autopsy study was performed, including postmortem radiography, placental examination and genetic analysis of foetus and parents using Sanger sequencing. Additionally, a review of autopsy records of our centre from 1967 to 2024, identified eight porhyria cases, with this being the only foetal case.
Results: A male foetus at 21 weeks of gestation with appropriate somatometry and development for gestational age was analysed. Notable findings included generalized subcutaneous oedema, pleural and pericardial effusion, severe extramedullary haematopoiesis with diffuse hepatic siderosis, and circulating nucleated red blood cells indicating anaemia. Additionally, the foetus showed facial dysmorphism with closed palpebral fissures, anteverted nares, elongated philtrum, thin upper lip, micrognathia, short nasal bridge, and low-set ears. Pulmonary hypoplasia and a renal cortical cyst with hemosiderosis were observed. Radiological findings showed mildly shortened long bones with coarse trabeculation suggestive of osteopenia. Foetal skin genetic analysis revealed NM_000375.3(UROS): c.217>C (p.Cys73Arg) mutation in homozygosity and parents in heterocygosis.
Conclusion: Our findings present a rare case of CEP, a genetic condition rarely found in autopsy literature. However, the limited cases available exhibit similar anatomical-pathological features. These results highlight the importance of fluorescence analysis in amniotic fluid as an accessible and useful tool for anteantal diagnosis in suspected cases. Furthermore, postmortem studies including placental examination, provide critical insights for planning future pregnancies and recurrence risk assessing.

E-PS-21-027

Diffuse systemic lymphangiectasia, renal cystic dysplasia, and cystic hygroma: a case report from foetal autopsy. What does this indicate to us?

H.S. Toru[1], E. Ocak[2]
[1]Akdeniz University School of Medicine, Pathology, Antalya, Turkey, [2]Van Education and Research Hospital, Pathology, Van, Turkey

Background & Objectives: Congenital/foetal generalized lymphangiectasia is a rare condition characterized by the dilation of lymphatic vessels. . Cystic hygroma is a macrocystic lymphatic malformation that typically occurs in the posterior triangle between the neck and axilla in 75% of cases. Renal dysplasia is observed in 2% of paediatric autopsies. The conditions categorized under renal dysplasia include multicystic dysplasia, renal agenesis, hypoplastic dysplasia, segmental dysplasia, and congenital hydronephrosis, both with and without dysplasia. These lesions are primarily of developmental origin, but they may also be part of a syndromic association with a genetic basis.
Methods: We present a case of a 17-week foetal termination performed at the family's request due to prenatal findings.
Results: The moher is a 26-year-old woman with no known complaints or diseases. There is no consanguinity between the parents. Prenatal-ultrasound examination revealed widespread soft tissue oedema, a large cystic hygroma in the neck, atrophic changes in the kidneys, increased echogenicity of the abdominal fluid, and anhydramnios. After termination, foetal autopsy revealed a foetus weighing 223 grams with body measurements consistent with the gestational age of 17-weeks. The autopsy findings showed 4x4 cm cystic lymphangioma in the neck, diffuse systemic lymphangiectasia, and renal cystic dysplasia in the right kidney. Based on these combined findings, a possible chromosomal anomaly was considered a primary concern. Chromosomal analysis performed on the amniotic fluid was completed following the foetal autopsy examination and was reported as consistent with classic Turner syndrome.
Conclusion: Pathological conditions from different spectrums of chromosomal anomalies may be encountered in foetal autopsy

examinations. Although the prenatal imaging and autopsy findings in our case are consistent with Turner syndrome, it is evident that the existing data can suggest a chromosomal anomaly even without the results of chromosomal analysis. We found it valuable to present our case due to the presence of different pathological findings observed together.

E-PS-21-028

Combined vascular malformation of the lung associated with extralobar pulmonary sequestration: a rare neonatal case

H.S. Toru[1], T. Kuş[1], G. Karaguzel[2], I.H. Budak[1]
[1]Akdeniz University School of Medicine, Pathology, Antalya, Turkey, [2]Akdeniz University Scholl of Medicine, Paediatric Surgery, Antalya, Turkey

Background & Objectives: Combined vascular malformations (CVMs) are congenital anomalies characterized by the coexistence of two or more types of malformed vascular channels—most commonly venous, lymphatic, capillary, or arterial—within a single lesion. According to the ISSVA classification, CVMs are structural, non-neoplastic lesions that grow proportionally with the individual and may not be clinically apparent at birth. Their recognition is essential for diagnosis, management, and distinguishing them from vascular tumours.
Methods: A term neonate (38w2d, 2907g) born at Akdeniz University Faculty of Medicine was admitted to the NICU for observation due to a prenatal diagnosis of a right-sided thoracic mass. MRI findings revealed a large cystic lesion occupying the right hemithorax, with a vascular pedicle arising from the descending aorta, suggestive of pulmonary sequestration. The patient was discharged after 1 day of non-invasive support and referred to paediatric surgery. At 1 month of age, the sequestered extralobar lung tissue was surgically excised.
Results: Histopathologic examination of the excised lung tissue revealed abnormal, dilated vascular channels located in subpleural, septal, and peribronchial areas. Immunohistochemistry showed CD34 positivity in all malformed structures, with partial CD31 positivity indicating venous features. Absence of epithelial markers Pan-CK and TTF-1 excluded neoplastic or epithelial components. Elastic staining and SMA highlighted elastic lamina and smooth muscle layers, consistent with venous vessel morphology. These findings confirmed a **combined vascular malformation with venous and lymphatic components** in association with extralobar sequestration.
Conclusion: This case highlights the importance of integrating imaging, histopathology, and immunohistochemistry for diagnosing complex vascular malformations in neonates. Combined vascular malformations involving the lung are exceptionally rare and may coexist with other congenital anomalies such as pulmonary sequestration. Awareness of this entity is critical for accurate diagnosis and tailored surgical management.

E-PS-21-029

The bacteriological and virological investigation of stillbirth: further guidance is required to improve diagnosis and standardisation of testing

C. Platt[1], H. Ellam[2], C. Moldovan[1], M. Narayanan[3]
[1]Newcastle upon Tyne Hospitals NHS Foundation Trust, Cellular Pathology, Newcastle, United Kingdom, [2]Newcastle upon Tyne Hospitals NHS Foundation Trust, Virology, Newcastle, United Kingdom, [3]Newcastle upon Tyne Hospitals NHS Foundation Trust, Microbiology, Newcastle, United Kingdom

Background & Objectives: In the UK stillbirth affects 3.9 per 1000 births[1], of which 10-25% may be caused by an infection[2]. There are no current guidelines detailing optimal specimen type and laboratory testing procedures for different pathogens, and there is variation in practice.
To determine current practices for bacteriological and virological investigation of stillbirth to facilitate development of local guidelines.
Methods: Bacteriological and virological tests performed on post-mortem stillbirth samples received at a regional UK laboratory over a 2-year period (20/4/2021 – 20/4/2023) were reviewed.
Results: Virology: 57 samples were received from 53 stillbirths: 49 liver tissue, 6 lung tissue, 1 splenic tissue, 1 heart swab.
There was considerable variation in test selection, with a selection of 9 PCRs performed: CMV, EBV, adenovirus, HSV-1, HSV-2, VZV, parvovirus, toxoplasma and enterovirus. No specimens were tested for syphilis.
All tests were negative except for 2 positive CMV PCRs (both deemed clinically significant) and 1 weak-positive adenovirus PCR (uncertain clinical significance). Negative PCR results may be useful in providing evidence for lack of infection.
Bacteriology: 72 samples were received for bacterial culture from 39/53 stillbirths. The most common sample types were heart swabs (26), lung swabs (23), and lung tissue (13).
Bacterial growth occurred in 40% of samples, with E.coli, Enterococcus faecium and Pantoea spp most frequently isolated.
Conclusion: There was variability in both specimen types and test selection. In our series the most common specimen types were liver tissue for viral PCRs and heart and lung swabs for bacterial culture. The optimal sample type for investigation of different pathogens is unclear, and interpretation of clinical significance of results can be difficult.
Maternal serological results are often not available alongside foetal samples to assist interpretation of results and guide appropriate test selection.
Development of guidelines would be helpful to improve microbiological investigation of stillbirths and reduce variation in practice.

E-PS-21-030

Immunohistochemical features of the germinal matrix in children with extremely low body weight and intraventricular haemorrhages

A. Drobintseva[1], A. Chepelev[2], M. Nazina[2], R. Nasyrov[2]
[1]Saint Petersburg State Paediatric Medical University, Histology and Embryology named after A.G. Knorre, Saint Petersburg, Russia, [2]Saint Petersburg State Paediatric Medical University, The Prof. D.D. Lohov Department of Pathological Anatomy with Course of Forensic Medicine, Saint Petersburg, Russia

Background & Objectives: The most prevalent complication in infants with extremely low birth weight is intraventricular haemorrhage (IVH). This condition affects the germinal matrix, a specialized tissue composed of numerous thin-walled blood vessels located in the region of the lateral ventricles of the brain. When exposed to a harmful stimulus, such as hypoxia, an apoptotic cascade is triggered, directly inhibiting the proliferation of neural progenitor cells, glial cells, and the intricate vascular network within the brain. The aim of the study was determination the level of CD31 and CD95 expression intensity in the germinal matrix of infants born with extremely low birth weight with IVH.
Methods: The material of the brain tissue of the lateral ventricles of 10 newborns born at 22-25 weeks of gestation with a body weight from 500 to 1000 g, who developed LVH, was studied. The life span ranged from several hours to 11 days after birth. The sections were stained with haematoxylin and eosin, immunohistochemical (IHC) staining with CD95 (inductor of apoptosis) and CD31 (marker of endotheliocytes and indicators of angiogenesis).
Results: During the IHC analysis, notable CD95 immunoreactivity was detected in ependymal cells and CD31 in endotheliocytes of

germinal matrix. The greatest expression of CD95 and CD31 was observed in the area of rupture of the vascular wall of the microcirculatory bed. A negative correlation was observed between marker expression and gestational age.
Conclusion: Increased apoptosis was observed in areas of vascular wall damage and ependymal lining destruction. This may indicate a significant role of apoptosis in the pathogenesis of IVH. The pattern of CD31 expression indicates active angiogenesis, which in turn shows the extreme importance of the morphofunctional state of the germinal matrix. Further studies of the pathogenesis of IVH in premature infants are needed to develop preventive strategies.

E-PS-21-031
A rare case with an unusual location: immature teratoma of tongue in a foetus
A. Üzümcü[1], A. Bayram[1], S. Bağbudar[1], T. Saraç Sivrikoz[2], S. Önder[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Department of Pathology, Istanbul, Turkey, [2]Istanbul University, Istanbul Faculty of Medicine, Department of Obstetrics and Gynaecology, Istanbul, Turkey

Background & Objectives: Teratomas are the most common congenital tumours. While they predominantly occur in the sacrococcygeal and gonadal regions, head and neck presentations are rare, accounting for approximately 5% of all cases. Within the head and neck, the nasopharynx and cervical regions are the most affected sites. Teratomas of the tongue are exceedingly rare. Here, we present a case of an immature teratoma arising from the tongue in a foetus.
Methods: A 31-year-old woman at 17 weeks and 6 days of gestation, conceived naturally from a consanguineous marriage, underwent prenatal ultrasonography. The examination revealed a mass in the oral cavity. Subsequently, a medical abortion was performed.
Results: Gross examination at autopsy revealed a 5.5×3×1.5 cm exophytic lesion originating from the base of the tongue and protruding from the oral cavity. The lesion had a soft consistency with focal firm areas and a surface covered with papillary projections. Microscopic examination of the tumour demonstrated a heterogeneous lesion composed of varying proportions of bone, cartilage, skin adnexa, and glandular tissue. An immature component was identified, characterized by the presence of neuroepithelial tissue. The immature neuroepithelium exhibited neural tube formation and rosettes structures. Based on these findings, a final pathological diagnosis was immature teratoma.
Conclusion: Tongue teratoma is a rare congenital tumour. In the literature, most reported cases of tongue teratomas are mature teratomas, while immature teratomas are exceedingly rare. Our aim in presenting this case is to raise awareness among pathologists regarding this rare case in an unusual location.

E-PS-21-032
Placental mesenchymal dysplasia: a rare mimicker of molar pregnancy – report of two cases
A. Canastra[1], J. Rodrigues Alves[2], C. Branco[2], D. Gomes Pinto[2,3], P. Borralho[1], R. Ilgenfritz[1,2]
[1]CUF Descobertas Hospital, Pathology Department, Lisbon, Portugal, [2]ULS Almada-Seixal - Hospital Garcia de Orta, Department of Pathology, Almada, Portugal, [3]NOVA Medical School, Lisbon, Portugal

Background & Objectives: Placental mesenchymal dysplasia (PMD) is a rare vascular and mesenchymal anomaly that mimics a partial hydatidiform mole, posing diagnostic challenges. Its aetiology remains uncertain, though dysregulation of growth and angiogenic factors have been implicated. The most consistent molecular alteration in PMD is androgenetic-biparental mosaicism. PMD has been associated with adverse pregnancy outcomes, including foetal growth restriction, intrauterine foetal demise, and Beckwith-Wiedemann Syndrome (BWS). This report describes two cases of PMD.
Methods: Case 1: A 36-year-old healthy woman with a previous normal pregnancy was referred for suspected molar placenta on ultrasound. Severe foetal growth restriction prompted an emergency caesarean at 27 weeks. The preterm newborn developed sepsis, anaemia, and thrombocytopenia, passing away at 1 month and 19 days of life.
Case 2: A 37-year-old healthy primigravida underwent amniocentesis at 16 weeks due to a suspected molar placenta. Intrauterine foetal demise occurred at 20 weeks. Karyotype analysis showed a tetraploid placenta, while the foetus had a normal karyotype. However, genetic evaluation was insufficient to rule out BWS.
Results: Both cases showed placentomegaly and grossly visible vesicles. Histopathology revealed villous stromal expansion, eccentric vascular proliferation, thick-walled foetal vessels with thrombi and chorangiosis-like features. Some areas displayed villi with normal maturation, while others showed marked oedema with cistern formation. No atypical trophoblastic proliferation was identified. p57 staining was preserved in trophoblast but was lost in villous stroma of dysmorphic villi. The first case resulted in neonatal death due to intracranial haemorrhage, secondary to a left middle cerebral artery aneurysm. In the second case, placental insufficiency was the cause of death, and the foetus presented with severe hydrops, a hepatic cyst, adrenal cytomegaly and pancreatic neuroendocrine hyperplasia.
Conclusion: PMD is a crucial differential diagnosis due to its clinical implications and potential misinterpretation as a molar pregnancy. Precise identification is essential to ensure appropriate clinical management.

E-PS-21-033
The cause of strongyloidiasis of the newborn
A. Mglinets[1], N. Gabitova[2], A. Kedrova[2], T. Belousova[3], E. Trifonova[3], Y. Gien[3], M. Makarov[3], N. Niziaeva[4], M. Zakharova[5], A. Tsygankova[3]
[1]Academy of Postgraduate Education of The FSCC FMBA of Russia, Department of Obstetrics and Gynaecology, Moscow, Russia, [2]Academy of Postgraduate Education of The FSCC FMBA of Russia, Moscow, Russia, [3]Vidnovskiy Perinatal Centre, Vidnoe, Russia, [4]Avtsyn Research Institute of Human Morphology of FSBSI "Petrovsky National Research Centre of Surgery", Moscow, Russia, Laboratory of the Reproduction Pathology, Moscow, Russia, [5]Chaika Clinics, Moscow, Russia

Background & Objectives: Strongyloidiasis is helminthiasis caused by roundworms which get into bloodstream, migrate into lungs and trachea; there larvae are coughed up, get into intestine and after two moults they lay eggs.
Data on transplacental infection are contradictory, although there are no morphological and physiological obstacles.
Placental villi are washed by maternal blood from spiral arteria, which are expended over 2mm till the end of pregnancy. With strongyloid larvae size up to 0,5-0,6mm placental barrier is passable for them.
Methods: Autopsy
Results: Prematurely baby at 26'th week of gestation was born by Caesarean-section due to premature detachment of a low-lying placenta (body weight/length were 800g/35cm), 4/6 on Apgar scale.
Due to extreme immaturity, respiratory failure, spontaneous left-side pneumothorax after resuscitation measures in operating room one received intensive care.
At the same time, clinical picture of "acute abdomen" with a formation of abdominal infiltrate and intestinal obstruction manifested itself. That is why resection of ileum, double-barreled ileostomy and excision of Meckel's diverticulum was performed. Strongyloidia were founded in operating material.

Baby's condition in postoperative period remained very serious due to multiple organ failure. At the 6th day from operation (29th day from delivery) biological death occurred.
Autopsy shows extreme immature and premature sings. The main disease was disseminating form of strongyloidiasis with of brain, lungs, spleen, small intestine and lymph nodes extensive lesion.
Death occurs due to pulmonary and cerebral oedema. Adult strongylides 2,2-2,5mm length were found subpleural in right lung lower lobe and under spleen capsule.
The abundance of larval forms in intestines allowed us to identify pathogen using light microscopy. Filariform and rhabditiform larvae were identified in the surgical and autopsy material.
Conclusion: Autopsy shows extreme immature and premature sings. The main disease was disseminating form of strongyloidiasis with of brain, lungs, spleen, small intestine and lymph nodes extensive lesion.

E-PS-21-034
Abnormal placental invasion: parental allele specific methylation of the human gene locus INS
A. Mglinets[1], M. Aksenova[2], N. Nizyaeva[2], M. Ekarerina[3], N. Gabitova[1]
[1]Academy of Postgraduate Education of The FSCC FMBA of Russia, Moscow, Russia, [2]Avtsyn Research Institute of Human Morphology of FSBSI, Petrovsky National Research Centre of Surgery, Moscow, Russia, [3]Vidnovskiy Perinatal Centre, Vidnoe, Russia

Background & Objectives: An incompetent uterine scar after caesarean sections and placenta previa are considered the main risk factors for placenta accreta spectrum disorders (PAS)/ Until recently, no significant involvement of genetic factors in the development of this pathology was assumed. About 100 placental genes are expressed selectively, depending on the parent from which they are inherited. The insulin gene INS is located next to the paternally expressed IGF2 gene and the maternally expressed H19 gene in an imprinted cluster on human chromosome 11p15.5. In an attempt to elucidate the role of methylation in parental imprinting at the INS gene locus we undertook an allele specific methylation study of the human INS gene in patients with PAS.
Methods: Fifty-four biological samples of the blood and placenta patients with PAS were analysed. TaqMan genotyping wasperformed for the locus *–23HphI* (rs689). *HpaII* and *GlaI*-mediated methylated DNA digestion was performed.
Results: For 24 patients with a heterozygous placental genotype, the parental origin of the alleles of the polymorphic region –23HphI of the INS gene was determined. The paternal "A" allele of the -23HphI SNP was associated with the number of previous caesarean sections and depth of placenta invasion. No signs of methylation of any of the parental alleles were detected in the patients' blood samples. For any of the paternal placental alleles, fluorescence intensity remained unchanged after DNA treatment with GLA1 restriction enzyme (m=447; SD=123). For paternal alleles of the "A" of the -23HphI SNP, after restriction, the number of amplification cycles was delayed by an average of 3.5 cycles (m=3.47; SD=0.82).
Conclusion: Preliminary results of partial methylation of paternal alleles in the 5-untranslated region of the INS gene in patients with PAS were obtained.

E-PS-21-035
Foetal vascular malperfusion in chronic deciduitis: an underlying association?
E. Doğan Kabadayi[1], O. Karatepe[1], E. Karakuş[1]
[1]Ankara Bilkent City Hospital, Pathology, Ankara, Turkey

Background & Objectives: Chronic deciduitis (CD), characterized by lymphocytes and plasma cells in the basal plate of the placenta, has been linked to pregnancy complications. Despite its clinical significance, the underlying mechanisms linking CD to these complications remain poorly understood. Foetal vascular malperfusion (FVM), a condition characterized by impaired blood flow in the foetal placental circulation, has also been implicated in adverse foetal outcomes, including stillbirth and neonatal morbidity. While both CD and FVM are independently recognized as contributors to placental dysfunction, their potential association has not been thoroughly investigated. This study examines the relationship between CD and FVM to determine whether an association exists.
Methods: This retrospective study analysed 176 placentas diagnosed with CD. Clinical and histopathological parameters, including advanced maternal age (40 cases), gestational age, maternal vascular malperfusion (MVM), FVM, villitis, and ascending infection, were evaluated. The study included 57 preterm births (<32 weeks). Statistical analyses included chi-square tests, Fisher's exact test, and logistic regression. Statistically, $p<0.05$ is considered statistically significant.
Results: FVM was observed in 44.3% of CD cases. Chi-square and Fisher's exact tests showed no significant relationship between FVM and MVM ($p = 0.541$), preterm birth ($p = 0.123$), or advanced maternal age ($p = 0.657$). Logistic regression confirmed that these factors were not significant predictors of FVM.
Conclusion: The high prevalence of FVM in CD cases highlights a potential link between these two conditions, although no direct statistical association was established in this study. This raises the possibility that other underlying mechanisms, such as immune dysregulation or vascular pathology, may contribute to the co-occurrence of CD and FVM. Further research with larger cohorts and prospective designs is needed to elucidate the clinical significance of this relationship and to explore the potential interplay between maternal and foetal placental pathologies in adverse pregnancy outcomes.

E-PS-21-036
Exaggerated placental site reaction following an elective interruption of pregnancy: a case report
E. Nardi[1,2], D. Mulone[3], V. Arena[2]
[1]University of Florence, Section of Anatomic Pathology, Department of Health Sciences, Florence, Italy, [2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Area of Pathology, Department of Woman and Child Health and Public Health, Rome, Italy, [3]University of Verona, Department of Diagnostics and Public Health, Verona, Italy

Background & Objectives: Gestational trophoblastic diseases are a group of rare pregnancy-related disorders.
They enclose premalignant disorders such as complete and partial hydatidiform mole, exaggerated placental site, and placental-site nodule as well as malignant disorders.
Exaggerated placental site (EPS) reaction is an abnormal process in which intermediate trophoblast cells infiltrate the endometrium and myometrium at the implantation site. Although EPS does not typically lead to adverse pregnancy outcomes, its recognition is essential in pathological evaluations to avoid unnecessary interventions or misdiagnoses.

We report herein a case of an exaggerated placental site subsequent to elective pregnancy termination.
Methods: A 35-year-old patient (G0P1) with a history of surgically treated endometriosis underwent voluntary termination of pregnancy. Approximately two weeks post-procedure, the ultrasonographic examination revealed the presence of hyperechoic, vacuolated, and intensely vascularized material (colour score 4) in the fundic region. Given the documented occurrence of arteriovenous malformation following abortions[7], the differential diagnoses under consideration for gynecologists encompassed both arteriovenous malformation and post-abortion residual effects. An embolization was performed and the neoformation was therefore removed and submitted for histological examination.
Results: Microscopic analysis revealed that the fragments comprised residual placental parenchyma with fibrotic villi and involutive aspects interspersed with fibrin-blood clots. Endometrial flaps, in close proximity to muscular elements, were observed with persistent intermediate trophoblast elements exhibiting modest atypia.
These findings were consistent with those characteristics of an exaggerated placental site.
Conclusion: Gestational trophoblastic diseases are a rare group of diseases that originate from trophoblasts with an incidence ranging from 1.19/1000 to 1.66/1000 pregnancies.
The diagnosis of exaggerated placental site reaction typically occurs during curettage procedures performed to investigate post-gestational vaginal bleeding.
Clinicians should be aware of this possible reaction after an interruption of pregnancy and manage these patients carefully in order to avoid possible complications.

E-PS-21-037

Development of minimally invasive gene therapy for childhood-onset neurodegeneration with cerebellar atrophy (CONDCA) using adeno-associated virus vectors

A. Araki[1,2], H. Wada[1], N. Hama[3], K. Hasegawa[3], C. Takamoku[1], M. Yoshida[3], M. Omura[1], K.-i.K. Kuwako[3]
[1]Shimane University, School of Medicine, Department of Organ Pathology, Izumo, Japan, [2]Shimane University Hospital, Department of Pathology, Izumo, Japan, [3]Shimane University, School of Medicine, Department of Neural and Muscular Physiology, Izumo, Japan

Background & Objectives: CONDCA is an autosomal recessive paediatric disorder caused by biallelic mutations in the *ATP/GTP-binding protein 1* (*AGTPBP1*) gene, which encodes a cytosolic carboxypeptidase 1 (CCP1) with deglutamylase activity. CONDCA patients typically exhibit progressive motor and cognitive impairments, often leading to childhood mortality with no effective treatments at present. A previous study using *Agtpbp1* mutant mouse model suggests that replenishing CCP1 with normal function could represent a promising therapeutic strategy for CONDCA.
Our study demonstrates the efficacy of gene therapy using adeno-associated virus (AAV) vectors to deliver a functional mouse Ccp1 mutant in a Ccp1-deficient mouse model of CONDCA.
Methods: 1. Characterization of CONDCA-related CCP1 mutants. Mouse Ccp1 R791C and Q848* (aligns with human CCP1 R799 and Q856, respectively) were expressed in HEK293 cells. Their expression and deglutamylase activity were examined by Western blotting.
2. Generation of CONDCA model mice.Ccp1-deficient mice (*Ccp1-/-*) as a model for CONDCA were generated using the iGONAD method, then histological, behavioural, and biochemical analyses were performed.
3. Generation of an AAV vector expressing functional Ccp1 for gene therapy. A transvenous administration system with a BBB-penetrating AAV vector carrying the PHP.eB capsid and synaptin 1 promoter were employed to express functional Ccp1 in Purkinje cells.
4. Injections of CCP1-AAV (or control AAV) into the orbital venous plexus of Ccp1-deficient neonates at postnatal day 0 and performed histological and behavioural analysis to examine pathology.
Results: Expression of N-terminally truncated form of Ccp1 (Ccp1 Δ1), which retains deglutamylase activity, in neurons of Ccp1-deficient neonates via a blood-brain barrier-penetrating AAV vector strongly prevented Purkinje cell degeneration during postnatal development. Gene therapy with Ccp1Δ1 significantly improved motor function in Ccp1-deficient mice.
Conclusion: This study provides robust preclinical evidence supporting the potential of postnatal AAV gene therapy as a treatment strategy for CONDCA.

E-PS-21-038

Foetal vascular malperfusion in preterm newborns with segmental intestinal dilatation

H. Hornychová[1], A. Matějková[1], I. Musilová[2], J. Lešková[3]
[1]University Hospital and Charles University, Faculty of Medicine in Hradec Králové, Fingerlad Department of Pathology, Hradec Králové, Czech Republic, [2]University Hospital and Charles University, Faculty of Medicine in Hradec Králové, Biomedical Research Centre, Hradec Králové, Czech Republic, [3]University Hospital and Charles University, Faculty of Medicine in Hradec Králové, Department of Paediatric Surgery and Traumatology, Hradec Králové, Czech Republic

Background & Objectives: Foetal vascular malperfusion is a well-known risk factor for neurological impairment in newborns, and few studies report also its importance in necrotizing enterocolitis. Retrospective study of foetal vascular malperfusion in preterm newborns with segmental intestinal dilatation is presented.
Methods: Between years 2007 and 2023, 34 preterm newborns underwent operative treatment for segmental intestinal dilatation (defined as limited bowel dilatation with a three- to fourfold increase of diameter without intra or extraluminal obstruction) at the University hospital in Hradec Králové. Archive slides from the placenta were available for 28 cases. Foetal vascular malperfusion was assessed according to the Amsterdam criteria.
Results: Gestational age ranged from 24+0 to 33+6.
7 cases were from twin placentas (4 dichorionic diamniotic, 2 monochorionic diamniotic, and 1 monochorionic monoamniotic).
Foetal vascular malperfusion was found in 17 cases (61 %), high grade variant in 6 cases (21 %).
Among the dichorionic diamniotic placentas, foetal vascular malperfusion was observed only in the placenta of the affected twin in 3 cases.
Conclusion: The incidence of foetal vascular malperfusion in patients who developed segmental intestinal dilatation is considerably higher than the overall incidence of foetal vascular malperfusion (which, according to literature, reaches a maximum of 25% in the very preterm group). It could be hypothesized that the reparative processes following post-thrombotic changes within the intestinal wall may contribute to architectural impairment of the muscular layers typically seen in segmental intestinal dilatation.

Funding: This work was supported by the project BBMRI-CZ LM2023033

E-PS-21-039

Chorioamnionitis grade and stage and foetal / neonatal outcome - a three-year retrospective study in a tertiary centre

A. Lai[1], C. Cerdeira[1], M. Vilela[1], R. Pina[1]
[1]Unidade Local de Saúde de Coimbra - Hospitais da Universidade de Coimbra, Serviço de Anatomia Patológica, Coimbra, Portugal

Background & Objectives: Histologic acute chorioamnionitis (AC) is defined as an acute inflammation involving chorion and amnion,

associated with increased risk of preterm labour and foetal/neonatal mortality. For each case we graduate maternal (MIR) and foetal (FIR) inflammatory response, regarding location (stage) and severity (grade) of inflammation. Usually low-grade inflammation cases are related with uncomplicated deliveries.
Our objective is evaluate the relationship between AC classification in terms of stage and grade and pregnancy outcome.
Methods: We retrospectively reviewed all cases of placentas submitted to histologic evaluation in our institution, in the last 3-years, including only singleton pregnancies with AC and possibility of MIR/FIR evaluation.
Results: From 1537placentas, 218met the inclusion criteria (14.2%). The median gestational-age was 32.5weeks (range 14-41) and the median maternal-age was 32years (range 15-49).
One-hundred and sixty-one new-borns were alive when discharge from hospital. From those, 7 cases had severe MIR and FIR: all were in 3rdtrimester and underwent antibiotic therapy.
The remaining 57cases (26.1%) had an unfavourable outcome, with foetal/neonatal death occurred in relationship with AC in 41cases (71.9%); remaining cases were due to other pathologies. From those 41cases, 11 don't have a FIR despite the presence of MIR, even though, there were 3cases (27.3%) from 3rdtrimester, 2 with an identified microorganism. In the group with severe MIR and FIR we had 10cases, 6 from 2ndtrimester, and 50% showed positive microbiologic studies.
We also observed 3cases with mild MIR and severe FIR (2live newborns; 1stillbirth): none of the new-borns had an identified microorganism, while the stillborn had 2 simultaneous microorganisms.
Conclusion: Our study demonstrate that a higher percentage of high-grade AC is more commonly associated with poor outcome - in accordance with literature. But not all cases with high-grade or discordant AC results in foetal/neonatal death: advanced gestational age, associated microorganisms and early neonatal care play an important role in outcome.

Pattern of childhood cancer in Maputo, Mozambique in 10 years: data from Maputo Central Hospital Cancer Registry
F. Fernandes[1], M. Sacarlal[1], L. Matias[1], M. Marumbe[1], C. Lorenzoni[2], C. Carrilho[3]
[1]Maputo Central Hospital, Pathology, Maputo, Mozambique, [2]Maputo Central Hospital, PATHOLOGY, Maputo, Mozambique, [3]Universidade Eduardo Mondlane, PATHOLOGY, Maputo, Mozambique

Background & Objectives: Childhood cancer is a public health problem, with high mortality rates mainly in low- and middle-income countries where it is underdiagnosed and underreported. In sub-Saharan Africa, paediatric cancer is increasing and near 90% of children who are diagnosed with cancers dies. We aimed to describe the patterns of childhood cancer in a tertiary hospital of Mozambique over a 10-year period.
Methods: This was a retrospective descriptive cross-sectional study. Data were retrieved from the cancer registry of the Maputo Central Hospital (MCH) and included all cases in children from 0 to14 years old, registered between June 1, 2014, and May 31, 2024. The topography and morphology were coded according to the International Classification of Oncological Diseases and the International Classification of Childhood Cancer, 3rd edition.
Results: Out of 20842 new cases of cancer diagnosed during the study period in MCH, 1060 cases (5.5%) occurred in children aged 0 - 14 years. From these, 557 (52,5%) were seen in males. Approximately 36% of the cases (n=380) were diagnosed in children aged 0 - 4 years old. The most common cancer in all age groups was leukaemia (197; 18,5%), followed by lymphomas (165; 15,5%), kidney cancer (129; 12,2%), Kaposi Sarcoma (104; 9,8%) and rhabdomyosarcoma (71, 6,6%). Variations were found when considering 5-years age groups. The most common cancer were Nephroblastoma in the group of 0-5 years, leukaemia's in the groups from 5-9 years and lymphomas in the age group of 10-14 years, respectively.
Conclusion: This study provides the data related with childhood cancer pattern in MCH since the implementation of the Cancer registry of the MCH in 2014 and can potentially contributes to select priorities for cancer control care in children including early and adequate diagnosis and treatment in the country.

E-PS-21-041
Complex pathological approach to assessing shaken baby syndrome
O. Sudareva[1], E. Ignatyeva[1], S. Lezhenina[1], A. Grigoryeva[1], E. Guryanova[1,2]
[1]Chuvash State University by I.N. Ulianov, Cheboksary, Russia, [2]Postgraduate Doctors Training Institute, Cheboksary, Russia

Background & Objectives: Shaken baby syndrome (SBS) is underreported in autopsy literature, particularly regarding pathomorphological correlations between central nervous system (CNS) injury, anatomical vulnerabilities, and meningeal embryogenesis defects. This study analyzes two SBS autopsies to explore these relationships.
Methods: Autopsies of two infants (2 months and 11 months 17 days) included detailed CNS assessment: vertebral artery sections, brain/spinal cord with membranes, cervical spinal nerves. Histochemical staining (haematoxylin-eosin, Kason), immunohistochemistry for neuronal/endothelial markers were performed.
Results: Both children were from young parents, the first pregnancy without complications; were born full-term (Apgar 8/9). They grew and developed according to their age. When collecting additional information, it was established that the parents had used abrupt movements to calm both children down when rocking them in their arms the day before.
- Case 1 (2 months): Subdural hematoma in the cervical spinal cord connected to a vascular "tangle" in the C2-4 pia mater. Histology revealed venous malformation with deformed vessels, smooth muscle defects, and pseudo-connective tissue outgrowths. Endothelial cells showed strong VEGFR2 expression. Spinal cord necrosis and vacuolar nerve fiber degeneration were noted.
- Case 2 (11 months): Massive left hemispheric subdural hematoma, optic nerve haemorrhage, and necrosis in C2-4 spinal cord posterior horns/medulla oblongata. Vertebral artery haemorrhage and spinal cord angiomatosis with weak VEGFR2 expression in venous vessels were observed. Bridging vein abnormalities draining into the sagittal sinus suggested vascular fragility.
Conclusion: Both cases reflect severe impulsive CNS trauma distinct from concussion, exacerbated by congenital vascular malformations. Defective embryogenesis (e.g., venous wall structural abnormalities, dysregulated VEGFR2 signalling) likely predisposed infants to haemorrhage and necrosis under mechanical stress. The findings underscore the interplay of developmental anomalies and trauma in SBS mortality. Comprehensive autopsy protocols, including detailed vascular histology and molecular marker analysis, are critical for diagnosing SBS and elucidating its mechanisms, particularly in infants with embryological CNS vulnerabilities.

E-PS-21-042

Foetuses teratomas. Clustering of cases

J.A. Costas Fernandez[1], E. Mateo Álvarez[1], Y. Rey Fanjul[1], M. Poch Arenas[1], G. Meijide Santos[1], D. Rodríguez Villar[1], R. Rodríguez Aguilar[1]
[1]Hospital Universitario de Cabueñes, Anatomia Patológica, Gijón, Spain

Background & Objectives: Sacrococcygeal teratoma (SCT) is the most common foetal germ cell tumour, usually benign and highly vascularised. The incidence is 1 in 35,000-40,000 newborns.
Prenatal ultrasound currently detects up to 90% of SCTs. A rapidly growing neoplasm with a predominant solid component associated with high vascularisation is the characteristic of a tumour with poor prognosis.
Methods: We present 2 cases:
A 35-year-old, first-time pregnant woman at 21 weeks who was diagnosed with a type I SCT by prenatal ultrasound. At 22 weeks, a voluntary termination of pregnancy (VTP) was performed.
A 32-year-old woman, with a history of a previous pregnancy, who at 20 weeks was diagnosed by prenatal ultrasound as having type 2 SCT. At 22 weeks, a VTP was performed.
Results: Two 22-week foetuses were received:
The first, female, weighed 474 grams with a sacrococcygeal tumour measuring 4.5x4x3cm which was classified as SCT type 1 as ultrasonography identified a predominance of the external component over the internal component with a cul-de-sac anus without continuity with the intestine. On section, the parenchyma was heterogeneous and brownish in appearance, with a friable consistency, with a cystic area reaching the sacrum and adjacent bone structures without infiltration.
The second, male, weighed 670 grams with a sacrococcygeal tumour measuring 8x6x5.5cm, which was classified as SCT type 2. Ultrasonographically there was equality between the external and internal components.
Microscopically
We identified: Vegetative ganglia, pancreatic glandular tissue, bone marrow tissue, cartilage, immature neural tissue with rosette formation, choroid plexus, respiratory epithelium, squamous epithelium and mature glial tissue were identified in both cases.
Conclusion: Malignant teratoma belongs to the group of rare diseases and has serious consequences for the foetus and may lead to the need for abortion. Definitive diagnosis is based on the identification of multiple tissues from different germ lineages (endoderm, mesoderm and ectoderm) within the same tumour.

E-PS-21-043

Screening for gene mutations by targeted RNA-Seq in support of a malignant lymphoid diagnosis from 60 histological abnormal paediatric biopsies revealed spectra of molecular abnormalities, some, but not all are within a specific histopathological subtype

B.-Y. Ngan[1], R. Siddaway[1], A. Arnoldo[1]
[1]Hospital for Sick Children, Paediatric Laboratory Medicine, Division of Pathology, Toronto, Canada

Background & Objectives: Targeted NGS RNA-Seq molecular analysis by Tru-Sight(Illumina) was used to detect molecular alterations in paediatric biopsies which showed lymphoid abnormalities. The ability to use the findings to diagnose malignancy is discussed.
Methods: Biopsies from 60 paediatric patients (age 1.5 to 17 years) were analysed. Samples included lymph nodes (48), tonsils (3), skin (3), conjunctiva (1), spleen (1), ileum (2), appendix (1) and testicle (1). Histological diagnoses were made in accordance with the 5th ed. WHO classification of tumours, which included IHC, cytogenetic (FISH), B or T cell clonal testing. RNA was extracted from FFPE tissue shavings.
Results: The numbers of positive biopsies and the types of mutations (Mut) /gene fusions reported in the designated categories are: I. Paediatric type follicular lymphoma (2/4 Lymph Nodes Mut+: 1/4 *TNFRSF14*; 1/4 *KMT2D;* 2/2 *TET2* ;1/4 *IDH1*;1/4 *EZH2*, 1/4 *SGK1*); 1/1 conjunctiva: (*IDH1*, *MAR2K1*); 1/1 skin: (*TET2*, *KMT2D,MAP2K1*); 1/1 testicular: (*KMT2D; CREBBP, BCL2, BCL6, BCL10* and *EZH2*, *IRF8*). II. Burkitt: 4/6 Mut+: (*DDx3X, ID3; ID3, KRAS, FOXO1, CREBBP, TP53, Myc, PTEN* and *H1-4,Myc, PTEN, ARID1, ID3, DDX3X*). III. Lymphoplasmacytic: 1/1: (*CYP1B1*). IV. High grade B cell lymphoma with11q aberration: 2/2 Mut+:(*TP53,PIK3C; PTEN*). 4/4 without 11q aberration were Mut+:(*MKRN1::BRAF, TP53, BRCA2, TCF3, GNA13*; *FOXO1, GNA13, MUTYH, PTEN*; *NBN*; *Myc*). V. B cell lymphoma with IRF4 alteration: 1/1 Mut+(*TNFRSF14*). VI. DLBLC: 5/11 Mut+:(*KMT2B; KMT2B, EZH2*; *TP53*; *TP53; KMT2D, HIST1-4, NF2*; *TP53, RHOA*). VII. Mediastinal large B cell lymphoma: 2/2 Mut+:*TP53, SETD2, STAT6*; *TNFA1P*). VIII: Hodgkin's (6/6 negative for Mut). IX. ALCL: 4/8 fusions*: NPM::ALK*; 1/8 *ATIC::ALK*; 1/8 *NFKB::TYK2*). X. T-cell Lymphoblastic: 2/4 Mut+: (*FBXW* ; *NOTCH1,PTEN*); XI. Lymphoid hyperplasia of AICDA immunodeficiency: 1/1 (*TNFA1P3*). XII. Atypical reactive:1/4 Mut+:(*BCL6*). XIII. PTGC: 1/2 Mut+:(*EZH2*).
Conclusion: We observed while some lymphomas showed similar mutations, absence or heterogeneous molecular spectra were encountered. Correlations with histo-immuno-cytogenetic findings are important to make accurate diagnoses.

E-PS-21-044

Desbuquois syndrome: a rare osteochondrodysplasia

B. Lopes[1,2], L. Branquinho Ruivo[3,4], M. Ribeiro[3], J. Almeida Tavares[3]
[1]IPO Lisboa, Pathology, Lisbon, Portugal, [2]Nova Medical School, Lisbon, Portugal, [3]ULS Santa Maria, Pathology, Lisbon, Portugal, [4]Escola Superior de Tecnologias da Saúde de Lisboa, Lisbon, Portugal

Background & Objectives: Desbuquois Syndrome is a rare osteochondrodysplasia with autosomal recessive inheritance, first described in 1966, with fewer than 50 cases reported. The diagnosis relies on the correlation between physical, radiological and molecular analysis. Type 1 and type 2 are associated with mutations in the CANT1 and XYLT1 genes, respectively.
Methods: This report describes a male newborn of a 28-year-old puerpera from Bangladesh, delivered at 41 weeks and 3 days with Desbuquois Syndrome, who progressed to early neonatal death.
Results: The newborn had a birth weight of 2945g and a total length of 38.1cm. Physical and radiological examinations revealed features of intrauterine growth restriction, such as crown-to-rump length of 31cm and foot and hand lengths of 4.6cm and 4cm, respectively; severe micromelia, joint hyperlaxity, a flattened face with midface hypoplasia, and a long philtrum; narrow and short chest with increased intermamillary distance; herniation of abdominal viscera, pulmonary hypoplasia, and dilation of the right heart cavities; omphalocele; shortened long tubular bones and proximal femur with 'swedish key' appearance. The pathogenic variant *c.100delinsTT* in homozygosity in the *CANT1* gene was identified, rendering the diagnosis.
Desbuquois Syndrome affects skeletal, pulmonary, and cardiac systems. Early detection of the clinical and radiological features is crucial. The differential diagnosis includes Larsen Syndrome, which shares similar characteristics, however, the radiological and molecular findings were key factors confirming the diagnosis. The prognosis is often guarded, with complications associated with pulmonary hypoplasia and cardiac malformations.

Conclusion: Desbuquois Syndrome should be considered in newborns with skeletal dysplasia, with joint hyperlaxity and cardiac and pulmonary anomalies. Genetic confirmation is essential. This case highlights the importance of early diagnosis, clinical monitoring, and genetic counselling due to its poor prognostic.

E-PS-21-045

Kisspeptin dysregulation in early pregnancy complications: linking serum levels with placental expression patterns

A. Mollova[1], Y. Merdzhanova-Gargova[2], A. Mihaylova[3], M. Koleva-Ivanova[1], E. Uchikova[4], N. Parahuleva-Rogacheva[4]
[1]Medical University, Department of General and Clinical Pathology, Plovdiv, Bulgaria, [2]Medical University of Plovdiv, Department of Obstetrics and Gynaecology, Plovdiv, Bulgaria, [3]Medical University, Department of Healthcare Management, Plovdiv, Bulgaria, [4]Medical University, Department of Obstetrics and Gynaecology, Plovdiv, Bulgaria

Background & Objectives: Kisspeptin (KISS1) plays a crucial role in trophoblast invasion, placental development, and pregnancy maintenance. Altered kisspeptin levels have been implicated in early pregnancy loss, but the relationship between serum kisspeptin levels and placental KISS1 expression remains limitedly studied. This study aims to evaluate the correlation between serum kisspeptin concentrations and immunohistochemical (IHC) expression of KISS1 in placental tissue from early abortion cases and healthy pregnancies.
Methods: A total of 50 women with early pregnancy loss (≤12 weeks gestation) and 50 women who underwent elective abortion were included, with the latter group serving as controls. Serum kisspeptin levels were measured in all 100 participants using an enzyme-linked immunosorbent assay (ELISA). Placental tissue was collected after abortion for KISS1 immunohistochemistry (IHC).
Results: Women with early pregnancy loss had significantly lower serum kisspeptin levels compared to healthy controls. Immunohistochemistry showed reduced KISS1 expression in placental tissues from miscarriage cases, with a strong correlation between serum kisspeptin levels and placental staining intensity. Higher placental KISS1 staining was associated with higher serum kisspeptin levels, supporting the link between systemic and placental kisspeptin function.
Conclusion: This study demonstrates a direct correlation between serum kisspeptin levels and placental KISS1 expression**,** suggesting that kisspeptin could serve as a biomarker for pregnancy viability. Lower kisspeptin levels in both serum and placental tissue may indicate placental dysfunction contributing to early pregnancy loss. Further research is warranted to explore its clinical applications in predicting and managing pregnancy complications.

Funding: This study is financed by the European Union-NextGenerationEU, through the National Recovery and Resilience Plan of the Republic of Bulgaria, project № BG-RRP-2.004-0007-C03

E-PS-21-046

Angiomatosis of soft tissue: histopathological comparative analysis of three cases

K. Nimchenko[1], P. Mary[2], R. Vialle[2], M. Wassef[3], A. Durlach[4], V. Dalstein[5], H. Ducou Le Pointe[6], A. Coulomb-L'hermine[1]
[1]Armand Trousseau Hospital-Sorbonne Université, Department of Anatomical and Cytological Pathology, Paris, France, [2]Armand Trousseau Hospital-Sorbonne Université, Orthopedic and Reconstructive Surgery for Children, Paris, France, [3]Hôpital Lariboisière, AP-HP, University Paris Diderot, Department of Pathology, Paris, France, [4]University Hospital Centre of Reims, Department of Pathology, Reims, France, [5]University of Reims Champagne-Ardenne, Cellular Biology, Reims, France, [6]Armand Trousseau Hospital-Sorbonne Université, Radiology, Paris, France

Background & Objectives: Angiomatosis of soft tissue (AST) is a rare, high-flow vascular anomaly. It affects children and young adults, occurring either sporadically or in association with PTEN hamartoma tumour syndrome (PHTS). The overlap of AST on clinical, radiologic, and histopathologic features with other soft tissue lesions makes diagnosis challenging.
Methods: We retrospectively reviewed the medical records of three children diagnosed with AST in our institution between 2019 and 2025. Clinical, imaging, and histopathological features were reviewed along with sequencing data.
Results: Three children (6 to 11 years) presented with painful soft tissue masses: two 3 cm knee masses and one 15 cm thigh mass. Two children had no predisposition syndrome, and one had Gorlin syndrome. Imaging suggested a haemangioma in two cases and a vascularized soft tissue mass in one case. All underwent upfront surgical excision.
Histopathological examination revealed poorly circumscribed fibro-adipose lesions with a nodular lymphoid component containing thick-walled veins, bulbiform arteries, and honeycomb-like vascular structures composed of dilated, thin-walled, back-to-back veins.
Immunohistochemistry showed SMA-positive abnormal smooth muscle bundles and CD31 and CD34 expression by abnormal vascular endothelial cells in all cases and podoplanin-positive lymphatic channels in two cases.
Recurrence occurred in two children, 1.5 and 2 years post-surgery, emphasizing the need for long-term follow-up and better treatment strategies.
Conclusion: AST occurs in children on the lower limbs close to joints. Key features include malformed veins, bulbiform arteries, pseudoalveolar vessels, and a nodular lymphoid component within a fibro-adipose tissue, which are essential to diagnose AST. PTEN and PIK3CA mutations highlight the relevance of molecular testing for both diagnostic accuracy and treatment planning. While surgical excision remains the primary therapeutic approach, the risk of recurrence underscores the need for long-term follow-up. Incorporating genetic analysis into clinical practice may improve patient management, and further research into targeted therapies could enhance treatment outcomes for this rare condition.

E-PS-21-047

Severe propionic acidemia in newborns: case report

Z. Zhalimbetova[1], B. Ibraimov[1], Y. Mezhanskya[1]
[1]Corporate Fund "University Medical Centre", The CAD of Laboratory Medicine, Pathology and Genetics, Astana, Kazakhstan

Background & Objectives: Propionic acidemia is a rare autosomal recessive hereditary metabolic disorder associated with a deficiency of the enzyme propionyl-CoA carboxylase (PCC), whose genes are localized in the 13q22-q34 region of the chromosome. A PCC defect leads to the accumulation of toxic organic acids and the development of systemic lesions. Macro- and microscopically, the disease is manifested by degenerative changes in the liver, brain, and kidneys caused by metabolic intoxication.
Methods: In the presented clinical case, we are talking about a newborn boy who lived only 5 days.
Results: Propionic acidemia was diagnosed shortly after birth, but the child died of pneumonia due to a prolonged clinical course of the disease. A postmortem examination revealed a rare pathological change — widespread vacuolization of the gray matter of the brain, previously described in just one case. In addition, pronounced perivascular and pericellular oedema, necrobiotic changes in the neurons of the cerebral cortex, small-droplet fatty dystrophy of hepatocytes, as well as vacuolar dystrophy of the epithelium of the renal tubules with areas of necrosis were detected, which indicates acidemia. Laboratory tests performed by tandem mass spectrometry revealed an increased level of propionylcarnitine (12.093 mmol/l at a norm of 0.160–6,500), which confirmed the diagnosis.

Conclusion: Thus, the clinical and morphological data combined with the results of laboratory studies suggest that this patient had a pronounced metabolic lesion characteristic of propionic acidemia. The described case highlights the need for early diagnosis of this disease, including neonatal screening using the mass spectrometry method, which can contribute to the timely initiation of therapy and reduce the risk of adverse outcomes.

E-PS-21-048

Morphofunctional characteristics of the placenta in experimental miscarriage associated with preeclampsia

N. Nizyaeva[1], K. Artemyeva[2], E. Ponomarenko[3], I. Stepanova[3], A. Stepanov[3], M. Kondashevskaya[3], T. Patsaev[4], A. Akhmetshina[2], L. Mikhaleva[3]
[1]Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Laboratory of the Evolution of Rheumatoid Arthritis, Moscow, Russia, [2]Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Reproduction Pathology Department, Moscow, Russia, [3]Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Moscow, Russia, [4]National Research Centre "Kurchatov Institute", Moscow, Russia

Background & Objectives: Rodents are often used for in vivo studies of gestational pathology. The aim is to characterize placental changes in a model of experimental miscarriage associated with preeclampsia (PEM).
Methods: Uncomplicated pregnancy (UP) was modeled using a combination of ♀CBA×♂Balb/c mice, PEM was reproduced using a combination of ♀CBA×♂DBA/2 mice and the introduction of 25 μg of muramyl dipeptide intraperitoneally per 1 animal on the 5th and 7th days of pregnancy (DG). The placenta was isolated on GD 14 and examined using light and scanning electron microscopy (SEM); cytokine production in placenta was measured using flow cytofluorimetry.
Results: The placenta in UP consisted of several layers of giant trophoblast cells (GTC), a spongiotrophoblast zone, and a labyrinth with lacunae and vessels uniformly filled with blood. In PEM, the placenta was distinguished by a thin discontinuous GTC layer, suffusion and stagnation of blood in the labyrinth. Excessive proliferation of trophoblas embedded the maternal and foetal labyrinth components. By SEM, it was shown that in UP, the maternal surface of the placenta is smooth, with a large number of uniformly located pinopode-like formations. The trophoblast of the labyrinth was characterized by a moderately fenestrated smooth surface with wide and deep vascular passages. The placenta on PEM was with flattened and chaotic pinopode-like formations on the maternal surface. Thrombotic deposits were observed, as in the labyrinth, making it difficult to visualize fenestrae and narrowed vessels. Pathological pregnancy was accompanied by a significant increase in IL-1 concentration, as well as a decrease in the level of IL-4, -6 and-10.
Conclusion: We identified in experimental miscarriage associated with preeclampsia signs of placental insufficiency. Our results showed that this model is suitable for modelling preeclampsia.

E-PS-21-049

The uteroplacental region is an alternative system for regulating arterial pressure

N. Nizyaeva[1], M. Mahmutova[2], N. Gabitova[2], T. Belousova[3], K. Artemyeva[1], T. Fokina[1]
[1]Federal State Budgetary Scientific Institution "Petrovsky National Research Centre of Surgery", Laboratory of the Evolution of Rheumatoid Arthritis, Moscow, Russia, [2]Vidnovskiy Perinatal Centre, Moscow, Russia, [3]Vidnovskiy Perinatal Centre, Vidnoe, Russia

Background & Objectives: It is known that BNP (brain natriuretic peptide) and its precursor ProBNP are markers of cardiovascular pathology and are synthesized in the atria. It is an angiotensin antagonist, has a protective effect on the cardiovascular system. Preeclampsia is characterized by an increase in blood pressure over 140/90 mm Hg, and in severe cases over 160/110 mmHg. The aim of the study: to assess whether the placental structures and the uterine wall can be a source of BNP and ProBNP.
Methods: A total of 20 placentas from women with severe PE, aged 25-43 years(34-38 weeks of gestation), were examined. The level of BNP and ProBNP staining(Hytest, RU) in the placental and myometrium structures was assessed using hematoxilin and immunohistochemistry. Staining is measured in units of optical density by ImageM programm.
Results: Histological examination with haematoxylin and eosin staining revealed that severe PE had dissociated, randomly located fibrotic villi, the syncytiotrophoblast was significantly exfoliated, the villi were exposed, and signs of placental insufficiency were noted. In the comparison group, the villous tree corresponded to the gestational age. Weak ProBNP staining was found in the comparison group in the villous(35(24-36) and extravillous trophoblast decidual cells, and vascular endothelium. In severe PE, on the contrary, a decrease in staining espessially in damaged villi 21(4-42). Although the preserved villi were characterized by increased staining. Placental ProBNP is a resource for entering the mother's bloodstream in hypertensive disorders. ProBNP was also moderately expressed in the cytoplasm of smooth muscle cells of the inner third of the myometrium ($p<0,05$).BNP expression was represented by no staining in both groups and was not significant.
Conclusion: Decreased ProBNP expression in placental tissue in severe PE. A decrease in ProBNP, which has protective properties in hypertensive disorders, in placental structures indicates depletion of compensatory mechanisms in severe PE and a breakdown of regulatory mechanisms.

Funding: FGFZ-2025-0005

E-PS-21-050

Epidemiological and histopathological profile of renal tumours in children

M.l. Marrakchi[1], M. Atrous[2,1], K. Chaita[2,1], Z. Atrih[3], S. Bensaci[2,1]
[1]Cancer Disease Research Laboratory, Faculty of Medicine, Salah Boubnider University, Constantine, Algeria, [2]Department of Pathology EHS Daksi, Constantine, Algeria, [3]Department of Paediatric Surgery El Mansourah, Constantine, Algeria

Background & Objectives: Renal tumours comprise 7 to 8% of all tumours in children. Nephroblastoma is by far the most common (90%), followed by renal cell carcinomas RCC (4%), clear cell sarcoma of kidney CCSK (3%), and the rhabdoid tumour of the kidney (2%).
The objective of this study was to assess the histopathological spectrum of lesions in tumour nephrectomy specimens of children.
Methods: We present a retrospective study conducted in the Department of Pathology EHS DAKSI Constantine Algeria, including nephrectomy specimens of paediatric patients received over a period of three years (August 1st, 2021 to July 31, 2024). A total of 23 cases were studied.
Results: Patients were aged from 3 months to 14 years (mean 3.86 y). 60.90% of children (n=14) were males (1.6 M/1F). Tumours measured 3.3 cm to 15 cm (mean 8.5 cm). Histological analysis found a nephroblastoma in 20 patients (86.96%), a RCC in 2 patients (8.70%) and CCSK in one patient (4.34%). The SIOP classification concerned nephroblastoma and CCSK (21 patients): 71.43% were intermediate risk tumours n=15, 19.05% were low risk tumours n=4 and 9.52% were high risk tumours n=2. 82.60% of our patients had a complete surgical

resection (n=19). The COG staging was also performed for nephroblastoma and CCSK: 52.38% of our tumours were a COG I (n=11), 28.57% were of COG II (n=6) and 19.05% were of COG III (n=4). The RCCs were respectively pT1aNx and pT2a tumours.
Conclusion: Renal tumours occur in children essentially under the age of 5. Histologically, they are largely dominated by nephroblastma (90%). The treatment advocates pre-operative therapy followed by surgical resection. Prognosis is determined by histopathological type, stage at presentation (COG or TNM) and evenly response of prior therapy.

E-PS-21-051
Fatal congenital toxoplasmosis: contribution of autopsy and histopathology to diagnosis
S. Charfi[1], O. Boudawara[1], H. Dhouib[2], S. Bardaa[2], T. Sellami Boudawara[1], M. Triki[1]
[1]CHU Habib Bourguiba, Pathology, Sfax, Tunisia, [2]CHU Habib Bourguiba, Legal Medicine, Sfax, Tunisia

Background & Objectives: Congenital toxoplasmosis is a parasitic infection transmitted in utero, often asymptomatic or mild. However, severe cases can lead to neurological damage and, in rare instances, be fatal. This case highlights the crucial role of histopathological examination in confirming the diagnosis.
Methods: A forensic autopsy was conducted on a 40-day-old male infant born by caesarean section four days before term due to acute foetal distress. The newborn exhibited feeding refusal and general deterioration before being found deceased. Macroscopic examination and histopathological analysis were performed to identify the underlying cause of death, focusing on neurological and systemic findings indicative of congenital toxoplasmosis.
Results: The external examination revealed a pale, hypotrophic infant (47 cm, 2140 g, 33.5 cm head circumference) with purpuric lesions on the ankles. Autopsy findings included multivisceral congestion, pulmonary oedema, and supraventricular yellowish-tan brain lesions. Histopathological analysis identified cerebral haemorrhagic foci surrounded by inflammatory infiltration, periventricular reactive gliosis, and toxoplasmic trophozoite cysts, confirming congenital toxoplasmosis. These findings correlated with severe systemic involvement, suggesting a fulminant progression of the infection. The absence of prior diagnosis or treatment highlights the silent yet potentially fatal nature of this condition in neonates.
Conclusion: This case underscores the importance of autopsy and histopathological analysis in diagnosing congenital toxoplasmosis, particularly in fatal cases. These methods are complementary, with macroscopic findings suggesting the disease and histopathology confirming it. The study highlights the necessity of prenatal toxoplasmosis screening, serological monitoring in pregnant women, and early therapeutic intervention to improve neonatal prognosis and prevent severe outcomes.

E-PS-21-052
Paediatric sacrococcygeal ependymoma: a rare extraneural localization with diagnostic challenges - case report
K. Goncalves Villarreal[1], I. Garcia Miranda[1], D. Bravo Blanco[1], I. Orbegozo Arrizabalaga[1], L. Zaldumbide Dueñas[1], L. Mosteiro Gonzalez[1]
[1]Cruces University Hospital, Bilbao, Spain

Background & Objectives: This study presents a rare paediatric case of extracranial and extraspinal myxopapillary ependymoma with sacrococcygeal localization. While these tumours typically arise in the distal spinal cord and carry a favourable prognosis, this case demonstrated anaplastic features, that may indicate increased risk of aggressive behaviour. This case highlights the importance of considering uncommon locations.
Methods: An 8-year-old male presented with an 8 cm sacral mass initially radiologically suspected to be a pilonidal sinus. Complete surgical resection was performed, revealing a 3.5 × 3.5 cm solid, whitish mass with haemorrhagic areas on sectioning.
Results: Microscopic examination showed dermal and subcutaneous tumour infiltration with moderate-to-high cellularity displaying papillary, solid, and cord-like architectural patterns. Tumour cells featured round nuclei with granular chromatin, radially arranged around vascular structures forming papillae with numerous pseudorosettes and occasional true ependymal rosettes, embedded in Alcian blue-positive myxoid matrix. Notable absence of necrosis or microvascular proliferation was observed. Immunohistochemical profiling demonstrated strong GFAP and S-100 positivity. The proliferation index reached 30% by Ki-67 staining with mitotic activity up to 7/mm².
Conclusion: Extracranial ependymomas represent exceptionally rare neoplasms, showing slight female predominance, with presacral/sacrococcygeal localization being the most frequent extracranial site, which is hypothesized to originate from coccygeal medullary vestiges. The myxopapillary variant predominates in reported cases. The observed histological features - including high cellularity, reduced myxoid component, elevated mitotic count and proliferation index, support the anaplastic features. This case underscores: 1) the necessity for multidisciplinary management, and 2) the unresolved question regarding adjuvant therapy for sacral region presentations. Our patient remains recurrence-free during follow-up, though local radiotherapy is being considered due to metastatic potential.

E-PS-21-053
Foetal neoplasms: a study in foetal autopsy perspective
M. Özşen[1], Ü. Yalçınkaya[1]
[1]Bursa Uludag University Faculty of Medicine, Department of Pathology, Bursa, Turkey

Background & Objectives: Foetal neoplasms are neoplasms that have increased in frequency in recent years due to technological advances in foetal imaging techniques and increased awareness, but are still extremely rare. They are found in approximately 0.01% of all live births, 0.5% of all stillbirths and 1.2% of foetuses with birth defects.
The aim of this retrospective study was to review our 18-year foetal autopsy series and to examine the clinicopathologic features of the cases with neoplasia in the perspective of the literature.
Methods: Clinical records and pathology reports of foetal autopsies performed in our centre between 2007 and 2025 were reviewed and cases diagnosed with foetal neoplasia were identified. In the screening performed without differentiation between benign and malignant neoplasia, 16 cases diagnosed with foetal neoplasia were identified.
Results: Of the 16 foetal autopsies, 8 (50%) were female and 8 (50%) were male. The mean gestational week was 23.6+5.2 weeks, the minimum gestational week was 16 weeks and the maximum gestational week was 34 weeks. Maternal age ranged between 18 and 36 years with a mean of 27+6.5 years.
Histopathological evaluation revealed vascular neoplasia in 8 (50%), teratoma in 5 (31.3%), cardiac myxoma in 1 (6.3%), cardiac rhabdomyoma in 1 (6.3%) and high-grade diffuse glial tumour in 1 (6.3%) of 16 foetuses. Among the vascular neoplasms, 5 were haemangioma, 2 were lymphangioma and 1 was arteriovenous malformation. Among the 5 cases with teratoma, 1 was an immature teratoma and the others were mature teratomas.
Conclusion: The rare foetal neoplasms comprise a heterogeneous group of neoplasms. The basic steps of patient management in foetal neoplasms include evaluation of the cases by experienced physicians using the right imaging techniques, proper parental counselling,

planning of foetal surgical intervention if necessary and termination of pregnancy under mandatory conditions.

E-PS-21-054

Histopathological findings in placenta delivered from SARS-CoV-2 infected mothers. A single centre experience from South Africa

M. Khaba[1], C. Baker[2], J. Chokoe-Maluleke[3], P. Magangane[4]
[1]Sefako Makgatho Health Sciences University, Anatomical Pathology, Pretoria, South Africa, [2]Sefako Makgatho Health Sciences University, Electron Microscopy, Pretoria, South Africa, [3]University of Cape Town, Anatomical Pathology, Cape Town, South Africa, [4]Wits University, Anatomical Pathology, Johannesburg, South Africa

Background & Objectives: There is a paucity of data describing the effects of the coronavirus disease 2019 on placental pathology from South Africa. The consequences of SARS-CoV-2 on the human placenta and the newborn are still not clearly understood, yet there have been reports of stillbirth and preterm birth. Chronic histiocytic intervillositis and massive perivillous fibrin deposition have been described as the common features associated with SARS-CoV-2 infection in the placenta. The objective of this study was to describe the histopathological features of the placenta in women affected by SARS-CoV-2 in our centre.
Methods: This was a retrospective study which assessed histopathological features of placenta delivered from women infected with SARS-CoV-2 in the Department of Anatomical Pathology, Ga-Rankuwa, South Africa, from 01/03/2020 to 31/12/2023. The clinicopathological data was retrieved from the National Health Laboratory Service's laboratory information system. The placenta was assessed according to the Amsterdam consensus. Data was analysed using a statistical software package.
Results: A total of 64 placenta were delivered from SARS-CoV-2 infected mothers with an average age of 28 years old (range 14 – 42). According to Amsterdam consensus, maternal vascular perfusion (45%, n=29) was the commonest finding, followed by foetal vascular perfusion (25%, n=16), chronic villitis (22%, n=14) and acute chorioamnionitis (8%, n=5).

Conclusion: This study is the first of its kind in South Africa. These findings corroborate that the placenta that has been infected with SARS-CoV-2 primarily exhibits characteristics of maternal foetal perfusion. Although no pathognomonic features were identified, it is crucial for obstetricians to anticipate the potential adverse pregnancy outcome in these cases.

E-PS-21-056

Early infantile form of globoid cell leukodystrophy (Krabbe disease): the histopathological description of an interesting case

L. Chinezu[1,2], M. Enache[3], N. Nagy[3], H. Jung[3]
[1]G.E. Palade UMFST Targu Mures, Histology Department, Targu Mures, Romania, [2]Forensic Medicine Institute, Pathology Department, Targu Mures, Romania, [3]Forensic Medicine Institute, Forensic Department, Targu Mures, Romania

Background & Objectives: Globoid cell leukodystrophy (GCL) is a rare and severe disorder caused by a mutation in the GALC gene, leading to galactocerebroside accumulation and white matter degradation. This study aims to highlight the histopathological characteristics of GCL in a case report.
Methods: We present the case of a one-year-old boy who was diagnosed with GCL at four months of age, based on symptoms of irritability, developmental delay, and motor deterioration, confirmed by genetic testing. His sister had the same condition and passed away at one year and six months. The child died at home, and an autopsy was performed.
Results: An autopsy was carried out at the Institute of Forensic Medicine in Targu Mures. Macroscopic examination revealed moderate brain atrophy with widened sulci and weight reduction. On sectioning, the white matter showed a greyish appearance and increased consistency. The subcortical white matter appeared unaffected. Histologically, the white matter contained numerous macrophages, multinucleated globoid cells around blood vessels, and intense gliosis. Additionally, areas of dystrophic calcifications were noted. Respiratory failure due to bronchopneumonia was determined as the cause of death.
Conclusion: This case underscores the importance of considering GCL in the differential diagnosis of neurodegenerative disorders in infants. The characteristic histopathological features are vital for diagnosis and understanding the disease pathology. Early recognition is essential for both clinical management and genetic counselling, given the severe and progressive nature of the disease.

E-PS-21-057

Foetal intracranial haemorrhage, porencephaly and an occipital soft tissue malformation associated with collagen 4a1 mutation

A. Konstantinidou[1], S. Katafygiotis[2], V.E. Chouliara[1], A. Ververi[2]
[1]Medical School, National and Kapodistrian University of Athens, 1st Department of Pathology, Athens, Greece, [2]Papageorgiou General Hospital, Department of Genetics for Rare Diseases, Thessaloniki, Greece

Background & Objectives: Foetal intracranial haemorrhage complicates up to 1‰ of pregnancies and may deeply influence the perinatal course affecting neonatal morbidity and mortality. In many cases the cause may not be identifiable. Risk factors include infectious disease, alloimmune thrombocytopenia, maternal drug exposure, maternal trauma, coagulation disorders and twin-to-twin transfusion syndrome. Genetic disorders associated with an increased risk for cerebral arteriopathy, have been reported in a few foetal cases. Of those, COL4A1 gene mutations are responsible for a hereditary autosomal dominant cerebrovascular disease, characterized by a wide phenotypical spectrum, including the development of perinatal intracranial haemorrhage, as well as porencephaly / schizencephaly. Herein, we describe a case of a foetus with microvascular haemorrhagic encephalopathy, porencephaly and a COL4A1 pathogenic variant.
Methods: Termination of pregnancy at 22 weeks-gestation was carried out due to pathological prenatal ultrasonographic and MRI brain findings. Foetal autopsy was performed and followed by whole exome sequencing (WES) in foetal genomic DNA.
Results: At autopsy the foetus showed increased growth (100^{th} centile), bilobed lungs and a small atrial septal defect. There was a soft-tissue stalk connecting the scalp with the posterior fontanelle, without an underlying encephalocele. Histology of the brain showed scattered parenchymal petechial microhemorrhages, siderophages consistent with older haemorrhage, encephaloclastic lesions, porencephaly, and areas of decreased density of the white matter. In the placenta small villous vessels were seen to be dilated and haemorrhagic. WES identified a heterozygous missense variant in the COL4A1 gene: c.3104G>T (p.Gly1035Val) (rs1555302922), classified as pathogenic in the ClinVar database [ID 440782]. Maternal serology for TORCH infection and PCR testing on foetal tissues for cytomegalovirus and herpesviruses was negative, while there was no other evidence suggestive of congenital infection.
Conclusion: Foetal intracranial haemorrhage and disruptive lesions considered idiopathic may have underlying genetic causes, which should be accounted for and investigated.

Pathology in Cambodia: the past, present, and future

S. Seng[1,2], H. Kouch[2], M. Nheb[1,2], S.V. Chhut[2]
[1]Calmette Hospital, Phnom Penh, Cambodia, [2]University of Health and Sciences, Phnom Penh, Cambodia

Background & Objectives: Pathology in Cambodia has a complex history, shaped by periods of progress and setbacks. The first known pathologists, trained in France and played a key role in the field's early development before their tragic disappearance during the Khmer Rouge era. The systematic eradication of intellectuals led to the total collapse of pathology services, leaving the country without specialists for over a decade. It was not until the late 1980s that pathology was revived, demanding extreme efforts to restore diagnostic services with limited resources.
Methods: Over the next two decades, Cambodia saw only a handful of new pathologists trained abroad, and diagnostic capabilities remained basic, relying primarily on conventional histology and cytology. A significant milestone was reached in 2015 with the establishment of the country's first pathology residency program. Despite its success in training 10 pathologists to date, the program struggles with low recruitment and continues to depend on international collaborations, particularly from Asia and Europe.
Results: Currently, only 10 pathologists serve in eight laboratories across Phnom Penh, offering routine histology, and a few special stains. Among them, only the laboratory at Calmette Hospital is equipped to perform frozen sections, a broader range of more than 10 special stains, and limited immunohistochemistry. However, molecular diagnostics remain unavailable in pathology labs, limiting the ability to implement modern classification systems and precision medicine. Emerging technologies, including digital pathology and artificial intelligence, further highlight the urgent need for infrastructure development and workforce expansion.
Conclusion: Future efforts must focus on strengthening local training, increasing mentorship, and expanding laboratory capabilities. Establishing molecular diagnostics, such as FISH and PCR for targeted genetic testing, is a critical step forward. International partnerships will remain essential in bridging these gaps and ensuring sustainable progress in Cambodia's pathology services.

E-PS-22-002

Leveraging social media for professional growth: empowering pathology residents in low-resource settings

P. Pepra-Ameyaw[1], B. Adjei-Mensah[1], N.B.-D. Pepra-Ameyaw[2]
[1]Korle Bu Teaching Hospital, Pathology, Accra, Ghana, [2]Korle Bu Teaching Hospital, Haematology, Accra, Ghana

Background & Objectives: Social media's impact has extended beyond traditional domains, notably in the medical profession, including specialized fields like pathology. Social media platforms such as LinkedIn and Twitter have become essential for professional interactions, knowledge sharing, and career advancement. This study examines the role of virtual social networks in shaping the professional development of pathology residents in low-resource settings in West Africa.
Methods: A cross-sectional, multi-institutional survey was conducted in the Pathology Departments of Korle Bu Teaching Hospital and Komfo Anokye Teaching Hospital from July to August 2024. An online questionnaire was distributed via WhatsApp to pathology residents. Data analysis was performed using STATA 14 to assess the influence of virtual media on professional development and career progression.
Results: A total of 34 pathology residents participated. The majority (83%) were aged 30 and above, with 53% identifying as female. Anatomic Pathology residents made up the largest group (47%). Of the respondents, 77% regularly used social media for professional development, with YouTube being the most frequently used platform cited by 83.9% of respondents . Regarding social media's utility for learning, 56% rated it as somewhat useful, and 23% as very useful.
The majority of residents found social media beneficial for professional development. For increasing understanding of the profession, 79% found it useful. In problem-solving, 79% rated it somewhat or very useful. For critical thinking, 85% found it useful, and 94% found it helpful for clinical decision-making. In enhancing clinical expertise, 85% rated it useful.
Conclusion: Social media plays a significant role in the professional development of pathology residents in low-resource settings. The high perceived usefulness of these tools highlights their importance in advancing clinical skills and knowledge. While most residents appreciate these resources, addressing the concerns of those who find them less useful could improve engagement and optimize their impact.

Delphi's echo: interim findings on a cross-continental biobanking effort

L. Winter[1], A. Artinger[1], H. Konate[2], M. Maiga[2], C.B. Traoré[2], F. Diarra[2], P. Hofman[3], R. Baber[4], R. Kirsten[5], S. Balam[2], C. Brochhausen[1]
[1]Institute of Pathology, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany, [2]University of Science Technical and Technologies of Bamako (USTTB), Bamako, Mali, [3]University Côte d'Azur and IHU RespirERA, Biobank Côte d'Azur BB-0033-00025, Nice, France, [4]Institute for Laboratory Medicine, Clinical Chemistry and Molecular Diagnostics, University Hospital Leipzig, Leipzig, Germany, [5]Integrated Biobank Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany

Background & Objectives: Despite ongoing globalization, a profound North-South gap persists across various scientific disciplines, including medical research and biobanking. From this perspective, we developed a collaborative network between Mali and Germany to facilitate integrative research, establish the base for a robust biobank system in Mali and ultimately reduce global inequalities.
Methods: To facilitate our collaborative efforts, we conduct a Delphi process, a structured communication technique to achieve consensus among a panel of experts from diverse backgrounds. Our expert panel includes 11 members: five from Germany, five from Mali, and one neutral, mediative expert from France. This methodology emphasizes the anonymity of responses to ensure unbiased input, iterative rounds, and controlled feedback after each round. The process started with an initial round of open questions to explore broad perspectives in the collaboration regarding biobanking and precision medicine.
Results: The Delphi process focused on the central question: "How can we efficiently design future collaborative projects?" Key expectations included agreement on the need to establish common educational programs, foster international exchanges of scientific experience, and initiate collaborative projects in biobanking and precision medicine. However, several challenges have been identified. Resource and infrastructure limitations include funding, facility availability, equipment access, and connectivity between medical information systems. Research coordination faces the absence of standardized protocols and varying scientific frameworks. Geographic and systemic obstacles include differing legal frameworks, distance, language barriers, and diverse system knowledge. Effective collaboration also requires improved sharing of experiences and partnership development.
Conclusion: After a successful first round, our network will shortly continue with the second and third rounds that will feature more specific, closed questions to solidify consensus on discussed issues, such as a harmonized minimal dataset. In general, the Delphi process

provides a powerful tool in times of global uncertainties and disrupted discourse. It facilitates debates, discussions, and the development of effective joint solutions.

E-PS-23-001

Synchronous and metachronous malignancies in a heavy smoker: a case of metastatic lung carcinoma, neuroendocrine tumour and follicular thyroid carcinoma

M. Luetić[1], M. Mamić[2], M. Glavina Durdov[1], M. Ćaleta Rade[1]
[1]University Hospital Centre Split, Split, Croatia, [2]General Hospital Šibenik, Šibenik, Croatia

Background & Objectives: A 69-year-old male smoker with a 100 pack-years history presented in April 2023 with a three-month history of left hip. Scintigraphy findings raised suspicion of sarcoma; however, an iliac bone biopsy revealed metastasis of adenocarcinoma of unknown origin (CK7, CK19 positive and TTF-1, CK20, CDX2, PAX8 negative).
Methods: Colonoscopy and gastroscopy were unremarkable. Thoracic MSCT demonstrated a 1.7x1.6x1.2 cm peribronchial lesion in the right middle lobe with central necrosis. No evidence of dissemination was observed on abdominal MSCT. Cytological and pathological analysis of bronchoscopic samples confirmed a poorly differentiated carcinoma (TTF1, p40 negative) with 70% PD-L1 expression. Molecular analysis showed no mutations in EGFR, ALK, ROS1, RET or MET genes. Chemoimmunotherapy was initiated, and follow-up MSCT showed regression of the primary lung lesion.
Results: In May 2024, the patient sought medical attention for swallowing difficulties and throat pain. Fiberendoscopy and MSCT revealed a 2.9x2.1x1.3 cm epiglottic mass. Two biopsys confirmed a malignant epithelial tumour with neuroendocrine differentiation. Surgery was performed and histopathological examination established a diagnosis of grade 2 neuroendocrine tumour with bilateral lymph node metastasis. Additionally, a 1.5 cm angioinvasive follicular carcinoma was detected in the left thyroid lobe.
Adjuvant radiotherapy was recommended, but the patient declined further treatment. He remains under regular oncologic surveillance and continues to receive immunotherapy as part of his treatment regimen. Follow-up assessments indicate stable disease with no evidence of progression.
Conclusion: This case underscores the challenges of diagnosing and managing malignancies in heavy smokers, emphasizing the need for a multidisciplinary approach in oncologic care. The occurrence of synchronous and metachronous tumours suggests a potential underlying genetic and/or environmental predisposition. Although molecular testing ruled out common driver mutations, potentially broader genomic analysis could provide valuable insights to refine future treatment strategies.

E-PS-23-002

Pulmonary nodular hyperplasia presenting as tumour like mass suspected for malignancy in patient with rheumatoid arthritis and positive Quantiferon test: a case report

G. Erić[1], L. Bedeković[1]
[1]University Clinical Hospital Mostar, Department of Pathology, Cytology and Forensic Medicine, Mostar, Bosnia and Herzegovina

Background & Objectives: Pulmonary nodular lymphoid hyperplasia (PNLH) is a rare benign lymphoproliferative interstitial lung disease which is radiologicaly difficult to differentiate from malignant tumours. It is assosiated with autoimune diseases such as rheumoatoid arthritis and lung infections such as tuberculosis.
Methods: We report a case of a 59-year-old woman without pulmonary simptomatology with recently diagnosed rheumatoid arthritis (RA) who has been administred to pulmologist because of a positive Quantiferon test. A multi sliced computed tomography thorax scan showed a tumour like mass with differential diagnosis of lung infiltrat in the lower right lung lobe.
Patient medical history including evidence of rheumatoid artritis, microbiology Quantiferon test and bacterial culture tests were assesed throught hospital electronic system for medical records.
Results: Percutaneous transthoracic needle biopsy was perfomed but histopathologic findings were nonspecific and undiagnostic. Subsequently, atipical right lower lobe resection was perfomed. PNHL was confirmed throught light mycroscopy morphology and imunohistocemical examination of postoperative speciment. Histopathologic evidence of lung tuberculosis was not found.
Conclusion: PNLH is most often presenting as unilocular tumour like mass and in some cases as multilocular mass mimicing malignancy. It has been documented in various autoimmune diseases including RA but case reports searched throught pub med database which establish a definitive connection between PNLH and RA are limited and rather include assosiations with a more general group of interstitial lung diseases.

E-PS-23-003

Bronchial fibroepithelial polyp: a case report on a rarely encountered malignancy mimic

S. Neves[1], I. Araújo[1], M. Zbronska[1], A. Duarte[1]
[1]Unidade Local de Saúde de Santo António, Serviço de Anatomia Patológica, Clínica de Genética e de Patologia, Porto, Portugal

Background & Objectives: Bronchial fibroepithelial polyps are rare lesions that appear to be underreported. Since they have not been extensively studied, there is still debate over whether they are neoplastic (similar to skin tags) or hyperplastic (similar to anal tags). These polyps have male predominance and can present with haemoptysis, cough, fever or as asymptomatic lesions. Previous case reports have shown that they mostly mimic malignancy, although they can also resemble pneumonia. Recurrence may occur if incompletely resected, but the prognosis is favourable.
Methods: We report a case of a 59-year-old male who presented with right-sided chest pain that persisted for four months, without other symptoms. He had personal history of smoking, schizophrenia and dyslipidemia, as well as a family history of breast cancer. The CT scan showed an irregular nodule measuring 28 mm in the apical region of the right lung, as well as a 14 mm nodule in the superior lobe of the left lung. These findings were consistent with PET scan results. However, bronchoscopy and endobronchial ultrasound revealed a previously undiagnosed vegetative lesion with 1 cm in long axis located in the basal pyramid of the right lung, prompting a biopsy.
Results: The biopsy of the vegetative lesion revealed a lobulated lesion with a squamous and respiratory mucosa lining, and a fibrovascular stroma core with a sparse mononucleate inflammatory infiltrate. Immunohistochemistry showed epithelial immunoreactivity for CK7 and p63, as well as stromal immunoreactivity for vimentin and CD34/SMA (capillaries). Desmin was not immunorreactive. Transthoracic biopsies of the other lesions previously described in the imaging exams confirmed lung adenocarcinoma.
Conclusion: The patient underwent chemoradiotherapy and is currently receiving immunotherapy. No follow-up bronchoscopy has been performed. This case highlights a rare but underdiagnosed entity that may be encountered. Furthermore, bronchial fibroepithelial polyps may resemble malignant lesions, often leading to misinterpretation during bronchoscopy or imaging exams.

E-PS-23-004

Peritoneal mesothelioma: review of cases in a Portuguese tertiary centre

C. Leal[1,2], A. Marques[1,2]
[1]Unidade Local de Saúde de São João, Pathology Department, Porto, Portugal, [2]Faculdade de Medicina da Universidade do Porto, Pathology Department, Porto, Portugal

Background & Objectives: Mesothelioma is a malignant proliferation of mesothelial cells lining the serosal surfaces, with peritoneal mesothelioma (PM) accounting for 6-10% of cases. We retrospectively reviewed all PM cases managed at our institution, focusing on clinical, histopathologic, and immunohistochemical features, as well as treatment outcomes.
Methods: Between 1999 and 2025, we identified 11 confirmed cases of PM, based on histopathological examination and immunohistochemical profiling. Clinical data, including age, sex, occupational history, and treatment regimens, were collected from medical records.
Results: The cohort was predominantly male (9/11; 82%) with a median age of 60 years. Only two patients had known asbestos exposure (2/11; 18%). The majority were diagnosed with diffuse malignant mesothelioma (10/11; 91%), with one case of well-differentiated papillary mesothelial tumour (1/11; 9%). Most of the diffuse malignant mesotheliomas were of the epithelioid subtype (9/10; 90%), with one biphasic case (1/10; 10%). Immunohistochemistry showed positivity for mesothelial markers: calretinin (82%), WT1 (73%), podoplanin (55%), and CK5 (64%). The loss of BAP-1 was also analysed. Regarding treatment, 27% (3/11) of patients underwent hyperthermic intraperitoneal chemotherapy (HIPEC), and 64% (7/11) received adjuvant/palliative chemotherapy. The patient with a well-differentiated papillary mesothelial tumour remains recurrence-free after 63 months of follow-up. Of the patients with diffuse malignant mesothelioma, two were lost to follow-up, two are alive with disease, and six died of the disease, with a median survival of 21.6 months.
Conclusion: Our findings align with the literature, showing peritoneal mesothelioma as a rare, poor-prognosis disease. Unlike pleural mesothelioma, few patients had asbestos exposure, suggesting other etiologic factors may play a role. Histopathological and immunohistochemical analysis are critical in distinguishing PM from peritoneal carcinomatosis.

E-PS-23-005

Rare pulmonary neoplasms: a multimodal diagnostic approach

B.E. Kézdy[1], L. Fülöp-Báthory[1], E. Tóth[1], E. Csernák[1], É. Szövördi[2]
[1]National Institute of Oncology Hungary, Department of Surgical and Molecular Pathology, Budapest, Hungary, [2]B.A.Z. County Central Hospital and University Teaching Hospital, Department of Pathology, Miskolc, Hungary

Background & Objectives: Rare pulmonary neoplasms pose a significant diagnostic challenge due to their low incidence and histological diversity. Accurate classification is essential for appropriate clinical management but often requires a comprehensive diagnostic strategy integrating histopathology and molecular profiling. In this study, we present two exceptionally rare pulmonary tumours, underscoring the critical role of multimodal diagnostics.
Methods: Immunohistochemical staining was performed as part of routine laboratory protocols. Molecular profiling was conducted using the Oncomine Comprehensive Assay Plus panel, and ZytoLight SPEC KRAS/CEN 17 Dual Color FISH analysis was performed.
Results: The first case involved a 1.5-year-old child with a cystic pulmonary lesion. Histopathological analysis identified rhabdomyoblasts in small foci via desmin and myogenin staining. Molecular analysis reveal a DICER mutation at low allele frequency.
The second case concerned a 74-year-old male with a lung tumour. Detailed immunohistochemical findings raised multiple differential diagnoses, including metastatic hepatoid/yolk sac-like adenocarcinoma of the stomach, metastatic germ cell tumour, and high-grade foetal adenocarcinoma. Notably, molecular analysis identified a 12p isochromosome, strongly suggesting a germ cell tumour. Imaging and other clinical studies failed to reveal an extrathoracic primary tumour.
Conclusion: In the first case, histopathological and molecular findings confirmed a type I pleuropulmonary blastoma arising in the context of type IV congenital pulmonary adenomatoid malformation.
In the second case, given the presence of a 12p isochromosome and the clinical context, the most probable diagnosis was a primary pulmonary germ cell tumour, or an occult metastatic germ cell tumour, both extraordinarily rare entities in this age group.
These cases highlight the diagnostic complexity of rare pulmonary neoplasms and the essential role of molecular pathology in achieving diagnostic precision. Our findings contribute to the limited literature on these tumour types and may aid in refining diagnostic and therapeutic strategies.

E-PS-23-006

A rare case of granulomatous reaction to diffuse idiopathic neuroendocrine cell hyperplasia (DIPNECH) radiologically mimicking rapidly progressive malignancy

J. Mooney[1], M.B. Will[2], D.A. Dorward[1]
[1]Royal Infirmary Edinburgh, Department of Pathology, Edinburgh, United Kingdom, [2]Royal Infirmary Edinburgh, Department of Cardiothoracic Surgery, Edinburgh, United Kingdom

Background & Objectives: A 53-year-old female non-smoker presented with an 18-month history of persistent cough. Initial CT scan demonstrated an 11mm right upper lobe nodule as well as numerous small nodules throughout both upper and middle lobes. Only the larger upper lobe lesion was FDG avid on PET scan and biopsy demonstrated this was a carcinoid tumour.
Methods: Interval CT scan showed significant increase in size of the middle lobe lesions with features concerning for rapid progression of malignancy. A middle lobe wedge excision with intraoperative frozen section was performed to determine the histogenesis of the rapidly growing nodule prior to decision regarding resection/management of the upper lobe nodule. Histological examination showed a 22mm nodule of confluent, necrotising granulomatous inflammation with no evidence of malignancy. An upper lobe anterior segmentectomy was therefore undertaken to excise the carcinoid tumour.
Results: Following formalin fixation, tissue analysis confirmed necrotising granulomatous inflammation containing occasional neuroendocrine tumourlets, and foci of neuroendocrine hyperplasia that were not present in the sections used for frozen section. No mycobacteria or other pathogens were identified. The right upper lobe contained two separate carcinoid tumours, multiple carcinoid tumourlets and foci of neuroendocrine cell hyperplasia.
Conclusion: Overall, the features were those of a rarely described florid granulomatous inflammatory reaction to diffuse idiopathic pulmonary neuroendocrine hyperplasia (DIPNECH) which can mimic rapidly progressive malignancy on imaging. This case underscores the importance clinical, pathological and radiological correlation, as well as the value of intra-operative frozen sections in guiding surgical decision making particularly when dealing with complex and unusual presentations of disease.

E-PS-23-007

A case report of NTRK translocations in a patient's lesion of the left lung's lower lobe

P. Aksenova[1], L. Rudiuk[1], O. Reshetnikova[1]

[1]Immanuel Kant Baltic Federal University, Fundamental Medicine, Kaliningrad, Russia

Background & Objectives: Translocations of NTRK genes are significant oncogenic drivers in various tumours, both in children and adults. Herein we report a case of pleomorphic undifferentiated NTRK1-positive sarcoma with the lower lobe of the left lung involvement.
Methods: The medical history, laboratory and instrumental data of the clinical case were analysed. Histological slides of the lung's tissue samples were stained with haematoxylin & eosin, then studied according to a standard protocol. Immunohistochemical study (IHC) was performed using monoclonal mouse antibodies to SMA, BRG1, CD34, Chromogranin A, Synaptophysin, Desmin, S100, EMA, AE1/AE3, HMB45, Melan A, SALL4, SOX10, STAT6, TLE1, WT1, TTF1, PAX8, NTRK, Ki-67, PDL1 (22C3). Next-generation sequencing (NGS) was also used.
Results: A study of the medical data revealed that the patient had a cough and general weakness after COVID infection in May, 2023. Multi-slice computed tomography detected a large solid neoplasm of irregular shape and approximate size 171*103*123 mm in the left half of the thoracic cavity. Histological examination has shown the tumour tissue built from epithelial and spindle-shaped cells that formed solid clusters of intertwining bundles located in a loose stroma. The tumour positively expressed: BRG1, WT-1, STAT-6, NTRK, Ki-67 – 87%. Tumour cells were immune negative to: SMA, CD34, Chromogranin A, Synaptophysin, Desmin, S100, EMA, AE1/AE3, HMB45, Melan A, SALL4, SOX10, TLE1, WT1, TTF1, PAX8. Analysis of PDL-1 positive 15% of tumour and 3% of immune cells (CPS=18). A genetic study has confirmed NTRK1-KHDRBS1 fusion.
Conclusion: The accumulation of data about the clinical and morphological profile of patients with rare oncogenic mutations makes it possible for pathologists to gain knowledge about the diagnostics algorithm of rare tumours. The results of the study are discussed in terms of the necessary comprehensive genetic, immunohistochemical and pathomorphological studies for further successful targeted therapy.

E-PS-23-008

Histopathological changes in a mouse model exposed to fine particulate matter collected from Korean air

H. Oh[1], Y.J. Nam[2], H. Lee[2], S.H. Jeong[2], J.-H. Lee[1]
[1]Ansan Hospital, Korea University College of Medicine, Department of Pathology, Ansan-si, Republic of Korea, [2]Ansan Hospital, Korea University College of Medicine, Medical Science Research Centre, Ansan-si, Republic of Korea

Background & Objectives: PM2.5 exposure is widely studied for its association with lung cancer risk. However, most prior studies have relied on standardized commercial PM2.5 samples, which may not fully reflect real-world exposure conditions. To address this, we investigated the potential effects of PM2.5 collected directly from ambient air in South Korea on lung tissue alterations in a murine model. This study aimed to assess how regionally collected PM2.5 influences lung histopathology, focusing on neoplastic changes, inflammation, and fibrosis.
Methods: Male A/J mice (7 weeks old) were assigned to four experimental groups: saline control, urethane, PM, and urethane + PM. Following urethane injection (250 mg/kg intraperitoneally), PM2.5 (35 μL) or saline was intranasally administered twice per week for five weeks. PM2.5 samples were collected from ambient air in South Korea using a high-capacity air sampler, then processed and purified for experimental use. Lung tissues were harvested at 40 weeks and evaluated histologically for hyperplasia, adenoma, carcinoma, fibrosis, and inflammation severity. Statistical significance was determined using Kruskal-Wallis and Mann-Whitney tests ($p < 0.05$).
Results: Mice exposed to PM2.5, either alone or in combination with urethane, exhibited a greater tendency for adenoma formation compared to controls. The mean maximum adenoma diameter was larger in both the urethane + PM and PM groups than in the saline group, with the urethane + PM group showing the most pronounced increase. While these findings indicate a possible relationship between PM2.5 exposure and lung tissue alterations, additional studies are necessary to further explore these effects.
Conclusion: Our study highlights the potential impact of real-world PM2.5 exposure on lung tissue changes in a murine model. While the observed trends suggest a role for PM2.5 in early neoplastic processes, further validation with expanded sample sizes and mechanistic analyses will be essential for a more comprehensive understanding of its biological effects.

E-PS-23-009

Tumourlets in surgical lung specimens: an incidental finding with an unclear significance

Y. Dhouibi[1], W. Ajouli[1], A. Blel[1], R. Aloui[1], L. Bel Haj Kacem[1], M. Ksentini[1], A. Rais[1], A. Dahmane[1], S. Rammeh[1]
[1]Charles Nicolle Hospital, Department of Pathology, Tunis, Tunisia

Background & Objectives: Pulmonary tumourlets are benign neuroendocrine (NE) proliferations measuring ≤5 mm, often discovered incidentally in patients with various chronic lung diseases. This study aims to examine the histopathological features of tumourlets and their associated disorders.
Methods: A retrospective review of six cases collected over nine years (2016–2024) was conducted. Clinico- radiological, histopathological, and data for NE markers were analysed.
Results: The study included six patients (sex ratio F/M = 2) with a median age of 69 years (range: 55–85). One patient presented with massive haemoptysis. Three had a cystic lesion (left lower lobe, lingula). Two patients had a culmen mass, with ground-glass nodules observed in one of them. The last patient, with colorectal adenocarcinoma, had lung nodules on follow-up imaging. Tumourlets, discovered incidentally, measured between 2 mm and 5 mm. The associated lung conditions included bronchiectasis with secondary inflammatory or haemorrhagic changes (3 patients), emphysematous changes with pleural fibrosis (1 patient), pulmonary aspergillosis (1 patient), and colorectal adenocarcinoma with emphysematous changes (1 patient). In all cases, tumourlets appeared as small nests of NE cells expressing chromogranin A and synaptophysin.
Conclusion: This case series, in line with the literature, highlights the common association of pulmonary tumourlets with chronic lung damage, such as fibrosis, bronchiectasis, emphysema, and subacute or chronic inflammation. In most instances, tumourlets are considered a secondary tissue reaction to cellular hypoxia, although some studies suggest that multiple lesions may play a role in the pathogenesis of chronic obstructive pulmonary disease. It has been suggested that NE cells in tumourlets secrete VEGF, potentially contributing to lung tissue scarring, particularly fibrosis.

E-PS-23-010

Comprehensive analysis of PD-L1, ALK, and EGFR biomarker testing in lung carcinoma: insights from a five-year study at single centre

I. Petrovic[1], M. Jovanović[1], M. Denčić Fekete[1], M. Stjepanović[2], S. Popević[2], S. Janjić Dimić[2], S. Glumac[1]
[1]Institute of Pathology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia, [2]University Clinical Centre of Serbia, Clinic of Pulmonology, Belgrade, Serbia

Background & Objectives: Lung carcinoma is a leading cause of cancer-related mortality worldwide. Biomarker testing for PD-L1, ALK, and EGFR is essential for guiding targeted therapies and improving

patient outcomes. This study evaluates the prevalence and distribution of these biomarkers over a five-year period at the Institute of Pathology, Faculty of Medicine, University of Belgrade, a tertiary referral centre that handles consultation cases from secondary institutions across Serbia.
Methods: A retrospective analysis of lung carcinoma patients who underwent testing for PD-L1, ALK, and EGFR between 2020 and 2024. Patient demographics, histological subtypes, smoking status, clinical staging, and biomarker expression levels were collected and analysed. All results are cumulative over the five-year period.
Results: The cohort comprised 3,470 patients, with 2,222 males (64%) and 1,248 females (36%), aged between 19 and 90 years (mean age: 66.11 years). Histological subtypes included adenocarcinoma (64.2%), squamous cell carcinoma (23.3%), NSCLC-NOS (9.7%), and other types (2.8%). PD-L1 expression was <1% in 35.2% of patients, 1–49% in 30.7%, ≥50% in 29.1%, with 5% untested. ALK testing was positive in 1.6% of patients. EGFR mutations were detected in 8% of patients. Regarding smoking status, 2,739 patients (78.9%) were smokers, 276 (8%) were non-smokers, and 455 (13.1%) had unknown smoking status. Clinical staging indicated that most patients were in stage IV (2,768; 79.8%), followed by stage III (18.3%), stage II (1%), and stage I (0.9%).
Conclusion: The observed histological subtypes and biomarker prevalence align with international data. The lower-than-expected EGFR mutation rate may be due to reduced testing during the COVID-19 pandemic in 2020. The high smoking rates and late-stage diagnoses in Serbia underscore the need for comprehensive tobacco control and enhanced early detection programs. The initiation of a lung cancer screening program at the University Clinical Centre of Serbia in late 2024 is a promising step toward improving patient outcomes.

E-PS-23-011
Evaluation of prognostic clinicopathological parameters in non-small cell lung cancer: insights from a single-centre study
E.E. Çetiner[1], I.E. Çakır[1]
[1]Izmir Katip Celebi University Ataturk Training and Research Hospital, Department of Pathology, Izmir, Turkey

Background & Objectives: Non-small cell lung cancer (NSCLC) is one of the most common malignancies with high mortality rate. Aim of this study was to evaluate prognostic clinicopathological features in NSCLC patients.
Methods: 136 cases diagnosed with NSCLC from resection materials between 2017-2024 were retrospectively analysed for age, gender, tumour localisation, tumour size, histological type, grade, spread through airspaces (STAS), pleural invasion, lymphovascular invasion, perineural invasion, lymph node metastasis and PD-L1 status.
Results: Out of 136 cases, 74 were lung adenocarcinoma(LUAD), 60 were squamous cell carcinoma(SCC) and 2 were adenosquamous carcinoma. 105(77.20%) of the patients were male, 31(22.80%) were female. Mean age was 64.08(40-86) years. Mean tumour size was 3cm(0.5-10cm). Pleural invasion was present in 39(28.67%), LVI in 63(46.32%), PNI in 18(13.23%), lymph node metastasis in 32(24.24%) cases. Among LUAD cases, 68(91.89%) were non-mucinous, 3(4.05%) were mucinous and 3(4.05%) were mixed invasive mucinous non-mucinous adenocarcinoma. While 55.88% of non-mucinous adenocarcinoma cases were grade 3, most common dominant pattern was acinar (47.05%). STAS was observed in 63.5% of adenocarcinoma cases. Of the 60 SCC cases, 33(55%) were non-keratinizing, 23(38.33%) were keratinizing, 3(5%) were basaloid, 1(1.67%) was lymphoepithelial type. Furthermore, PNI was six times more frequent in SCC cases compared to LUAD cases. 38(27.94%) of the cases have died. 14 of these cases were adenocarcinoma and 24 were SCC. The calculated 1-year, 3-year, 5-year overall survival rates were 86.48%, 76.27%, and 67.85% respectively. PD-L1 immunohistochemistry was performed in 24 cases and 7 (LUAD=6, SCC=1) had a tumour proportion score (TPS) above 50%. While 2 PD-L1 positive cases died, all seven cases with a TPS>50% remained alive.
Conclusion: Lung cancer is one of the most lethal malignancies worldwide. Prognostic clinicopathological features play crucial role in patient survival. In addition, the higher survival rates of patients with high PD-L1 expression highlight the prognostic and therapeutic importance of immunotherapy.

E-PS-23-012
PD-L1 expression in non-small cell lung cancer: clinicopathological and theranostic implications study of 69 cases
S. Moussa[1,2], R. Badr[1,2], S. Sakly[1,2], M. Krifa[1,2], S. Mestiri[1,2], A. Bdioui[1,2], S. Hmissa[1,2]
[1]Sahloul University Hospital, Pathology Department, Sousse, Tunisia, [2]Faculty of Medicine of Sousse, Research Laboratory LR21 ES03, Sousse, Tunisia

Background & Objectives: Lung cancer is the leading cause of cancer death worldwide. Non-small cell lung cancer (NSCLC) accounts for most cases, with adenocarcinoma and squamous cell carcinoma being the main types. About 30% of cases are diagnosed at stage III, and the prognosis remains poor despite various treatments. Immunotherapy is an interesting new option for treating advanced NSCLC.
The objective of this study is to investigate the expression of PDL1 in NSLCC and to assess its clinic-pathological significance.
Methods: The present retrospective study examined 69NSLCC cases, assessing PDL1 expression through immunohistochemistry using the clones CAL10 and 22c3. The tumour proportion score (TPS) was used for quantitative analysis, with two positivity thresholds (TPS<1%, TPS1≥%). Expression was also investigated in lymph node metastasis in 7cases. The results of the two clones were compared. A statistical study of PDL1 expression and clinicopathological factors was performed.
Results: Most patients were between 55 and 65 (43.5%) and mostly male (91.3%). The main histological type was adenocarcinoma, with 33.3% classified as IASLC grade3. Surgical margins were clear in 94.3%, stage IIIB was reported in 21.2%, and 2patients had a cerebral metastasis.
Overall, 36.2% of tumours had TPS levels <1%, while 63.8% had PDL1 expression in at least 1% of cells. Of these, 14.5% had strong PDL1 expression (TPS ≥50%). The results of the PDL1 expression analysis remained consistent across the two clones, with TPS ranging from below 1% to ≥50%. PD-L1 expression remained stable between primary tumours and their lymph node metastasis. However, differences were observed in brain metastasis (case1: primary tumour TPS=10% versus brain metastasis TPS=90%; case2: primary tumour TPS=25% versus brain metastasis TPS=10%). A significant correlation was observed between PD-L1 expression and surgical margins (p=0.031).
Conclusion: The present study revealed variability in PD-L1 expression in NSCLC, with a significant proportion of tumours potentially eligible for PD-1/PD-L1 inhibitor therapies.

E-PS-23-013
Pulmonary dirofilariasis: diagnostic challenges in the presence of pulmonary tuberculosis and a history of colorectal cancer
A.I. Popescu[1], A.S. Marghescu[2,3], E.D. Magheran[2], O. Danaila[4], V. Grigorie[4], M. Solomon[5,6], A. Macri[7], G.L. Popa[8]
[1]University Emergency Hospital, Department of Pathology, Bucharest, Romania, [2]Marius Nasta Institute of Pneumophtisiology, Department of Pathology, Bucharest, Romania, [3]Faculty of Medicine, Carol Davila University of Medicine and Pharmacy, Department of Pathology, Bucharest, Romania, [4]Marius Nasta Institute of Pneumophtisiology, Department of Thoracic Surgery, Bucharest, Romania, [5]Faculty of Midwives and Nursing, Carol Davila University of Medicine and Pharmacy, Department of Microbiology, Parasitology and Virology,

Bucharest, Romania, [6]Marius Nasta Institute of Pneumophtisiology, Clinical Laboratory of Medical Microbiology, Bucharest, Romania, [7]Marius Nasta Institute of Pneumophtisiology, Department of Pneumology, Bucharest, Romania, [8]Faculty of Midwives and Nursing, Carol Davila University of Medicine and Pharmacy, Department of Parasitology, Bucharest, Romania

Background & Objectives: Pulmonary dirofilariasis, a rare parasitic infection caused by the filarial nematode Dirofilaria typically affects dogs but can incidentally infect humans as aberrant hosts. Pulmonary dirofilariasis is an uncommon condition that primarily involves the lungs, where it manifests as solitary pulmonary nodules or masses, often leading to diagnostic confusion due to its clinical similarity to malignancy or infectious diseases.
Methods: We report the only two cases of pulmonary dirofilariasis diagnosed at the Marius Nasta Institute of Pneumophthisiology, Bucharest, Romania between 2000 and 2025. All data was extracted from the digital archive of the Institute.
Results: **Case 1:** A 58-year-old male, with history of right hemicolectomy for colorectal cancer, presents for further investigations of a pulmonary nodule detected on chest radiograph. An atypical pulmonary resection was performed. On gross examination the specimen presented a well-defined nodule of 12mm diameter which microscopically revealed granulomatous inflammation and the presence of characteristic Dirofilaria larvae. 55
Case 2: A 36-year-old female presented with dry cough, dyspnea and weight loss. Chest radiograph showed multiple, bilateral pulmonary nodules. The laboratory received an atypical pulmonary resection specimen which, on gross examination, presented multiple grey-white nodules between 1 and 7mm diameter. Microscopic examination revealed a necrotizing granulomatous inflammation suggestive of pulmonary tuberculosis further confirmed by a Ziehl-Neelsen stain. One of the examined slides revealed the presence of Dirofilaria larvae inside one necrotizing granuloma.
Conclusion: Both cases demonstrate the importance of considering pulmonary dirofilariasis in patients presenting with solitary pulmonary nodules. Additionally, the co-occurrence of other pulmonary or systemic conditions, such as tuberculosis or a history of cancer, requires clinicians to maintain a broad differential diagnosis and avoid prematurely attributing pulmonary findings solely to the underlying disease. A careful and thorough workup, including biopsy or resection specimen and histopathological examination, is essential in providing an accurate diagnosis and ensuring appropriate management.

E-PS-23-014

Calcifying fibrous tumour of the pleura: a case report of an uncommon entity in an unusual location

I. Araújo[1], M. Zbronska[1], M. Caldas[1], X. Wen[1], A. Coelho[1]
[1]Unidade Local de Saúde de Santo António, Anatomic Pathology Service, Genetics and Pathology Clinic, Porto, Portugal

Background & Objectives: Calcifying fibrous tumour (CFT) is an uncommon, benign entity primarily associated with the gastrointestinal tract. It is an extremely rare finding in a pleural location, with only 42 cases reported in the literature.
Methods: We here present a case of a 42-year-old woman undergoing follow-up consultations after being diagnosed with hyperplastic intraductal papilloma of the breast. MRI revealed, as an incidental finding, an 18mm oval nodule in the left cardiophrenic field. The patient had no symptoms. The possibility of a solitary fibrous tumour was considered and a biopsy was performed. The histological findings of the specimen were consistent with the diagnosis of calcifying fibrous tumour of the pleura.
Results: The specimen was a 15mm filiform fragment, and the histological analysis revealed a paucicellular lesion composed of spindle-shaped cells without evident atypia, embedded in a collagenized stroma, accompanied by psammomatous calcifications and minor chronic inflammation. Immunohistochemical analysis revealed positivity for CD34 and negativity for STAT6.
Conclusion: Calcifying fibrous tumour of the pleura is an extremely rare presentation of a benign soft tissue lesion and, as seen in our case, it usually is an incidental finding. Biopsy specimens can impose a challenge when diagnosing CTF as the lack of specific genetic and immunohistochemical markers makes it mostly a morphological diagnosis and, in a limited biopsy sampling, it may mimic other entities with a higher risk of aggressiveness, such as the solitary fibrous tumour. Recognizing this entity can ultimately avoid overtreating patients, as it is a completely benign lesion.

E-PS-23-015

Giant solitary fibrous tumour of the thorax: an unusual presentation on a known thoracic neoplasm of uncertain malignant potential

N. Chiote[1], I. Araújo[1], G. Carrola[1], N.J. Lamas[1,2]
[1]Anatomic Pathology Service Genetics and Pathology Clinic Unidade Local de Saúde de Santo António (ULSSA)Largo Professor Abel Salazar, Porto, Portugal, [2]School of Medicine & Life and Health Sciences Research Institute (ICVS), University of Minho, Campus of Gualtar, Braga, Portugal

Background & Objectives: Solitary Fibrous Tumour (SFT) can occur in almost any part of the body, however, the thoracic region is among the most common locations. SFTs often have indolent growth, with larger tumours normally causing symptoms of cough, dyspnea or chest pain. Around 10% to 20% display an aggressive behaviour. In several cases, SFTs are asymptomatic and only discovered incidentally.
Methods: We report the case of a 77-year-old woman who had asthenia following a viral upper respiratory infection. The ensuing computed tomography (CT) study revealed a 17x16x15 cm right hemithorax mass. A biopsy was then performed and the presence of a neoplasm displaying SFT features was suggested. After surgical excision we received a 20x18x13,5cm tumour weighing 2538g. The external surface was smooth and, upon sectioning, there was a whitish, well-defined, vaguely multinodular neoplasm.
Results: The histological analysis revealed a mesenchymal neoplasm with mostly well-defined limits, made up of spindle-shaped to ovoid cells, with poorly defined cytoplasmic borders, scarce to slight eosinophilic cytoplasm and small to medium-sized hyperchromatic nuclei, sometimes with obvious nucleoli. The cells were slightly to moderately pleomorphic, mostly distributed in a disorganized manner around a rich vascular network and sometimes intertwined bundles could be seen. Occasional staghorn vessels could be observed. There were >2 mitotic figures/mm^2. Necrosis was absent. Images of vascular invasion or perineural invasion were not identified. Immunohistochemistry showed diffuse positivity for CD34 and STAT6. Based on the WHO critera, the metastatic risk was predicted to be elevated.
Conclusion: This case highlights the uncommon presentation of a 20 cm thoracic SFT, which was successfully treated with surgical resection. Larger SFTs are more likely to be malignant and are therefore associated with worse prognosis. Nearly 5 months have elapsed after surgery and the patient remains well, under a thorough CT scan surveillance scheme, without signs of disease relapse.

E-PS-23-016

SMARCA4-deficient thoracic undifferentiated tumour: the case report of a rapidly progressive malignancy at risk of diagnostic oversight

F. da Costa Jesus[1], R. Fonseca[1]
[1]Instituto Português de Oncologia de Lisboa Francisco Gentil, Pathology Department, Lisbon, Portugal

Background & Objectives: SMARCA4-deficient thoracic undifferentiated tumour is a rare and aggressive malignancy associated with biallelic inactivation of the *SMARCA4* gene. It typically presents as a rapidly growing thoracic mass, often with metastases at the time of diagnosis, carrying a poor prognosis.
Methods: We report the case of an 81-year-old man who presented with recent significant weight loss, dyspnea, and right-sided hemiparesis. Imaging studies revealed a 10 × 8 cm nodule in the upper lobe of the right lung, along with brain metastases. A transthoracic biopsy of the pulmonary nodule was performed. The patient was provided with the best supportive care, dying one week after the diagnosis was established.
Results: Microscopic examination revealed a predominance of large ovoid cells with vesicular nuclei, prominent nucleoli, and abundant basophilic cytoplasm, apart from rare dispersed rhabdoid cells. The tumour exhibited extensive necrosis and a mitotic rate of 36 mitoses per 10 high-power fields. Immunophenotypically, the tumour was negative for CKAE1/AE3, Cam5.2, CK20, p40, TTF-1, synaptophysin, chromogranin A, INSM1, SOX10, CD20, CD3, ERG, calretinin and WT1, with loss of SMARCA-4 expression.
Conclusion: SMARCA4-deficient thoracic undifferentiated tumour represents a rare and aggressive malignancy with a poor prognosis. Its diagnosis remains challenging due to histological overlapping features with other undifferentiated neoplasms.
This rare entity should be considered in the differential diagnosis of high-grade thoracic neoplasms, particularly in cases with challenging immunohistochemical characterization.

E-PS-23-017

Challenges in diagnosing pulmonary salivary gland-type tumours: a case study

S. Vakili[1,2], S. MacMahon[3], E. Beddow[4], J. Weir[5], K. Thway[5,6], A.G. Nicholson[1,7], Y.Z. Zhang[1,7]
[1]Royal Brompton and Harefield Hospitals, Guy's and St Thomas' NHS Foundation Trust, Department of Histopathology, London, United Kingdom, [2]Princess Royal University Hospital, King's College Hospital NHS Foundation Trust, Department of Histopathology, London, United Kingdom, [3]The Royal Marsden NHS Foundation Trust, Centre for Molecular Pathology, London, United Kingdom, [4]Royal Brompton and Harefield Hospitals, Guy's and St Thomas' NHS Foundation Trust, Department of Thoracic Surgery, London, United Kingdom, [5]The Royal Marsden NHS Foundation Trust, Department of Histopathology, London, United Kingdom, [6]Institute of Cancer Research, London, United Kingdom, [7]Imperial College London, National Heart and Lung Institute, London, United Kingdom

Background & Objectives: Salivary gland-type tumours (SGTs) of the lung are rare neoplasms arising from the submucosal glands of the tracheobronchial tree. While the majority of SGTs show specific morphological and genomic features, a subset of currently unclassifiable tumours are recognised, presenting diagnostic particularly in small biopsy setting. We present a case of unclassifiable SGT of the lung with likely pathogenic *BCOR* mutation and *APC* deletion.
Methods: This is a case report of resected pulmonary tumour at a tertiary thoracic centre. DNA next generation sequencing (NGS) was performed using a customised 200-gene panel, and RNA NGS was performed using Illumina Pancancer RNA fusion panel.
Results: The patient was a 70-year old male presenting with an incidental right middle lobe lesion with low grade FDG-avidity (SUVmax 2.7), together with right hilar and subcarinal nodal activity. A total of four biopsies were attempted, neither of which achieved a definitive pre-operative diagnosis with diagnostic opinions including SGT, bronchiolar adenoma, primary lung cancer and an inflammatory lesion. Right middle lobectomy reveals a low-grade biphasic neoplasm composed of epithelial and myoepithelial components within a fibromyxoid stroma. Immunohistochemistry (IHC) demonstrated AE1/3 and CK7 positivity in epithelial cells, while myoepithelial cells showed strong SMA, SOX10, multifocal S100, and focal p40 positivity, with largely negative TTF-1 expression. Definitive features of recognised SGT entities are not present. The tumour was classified as a low grade salivary gland-type neoplasm at this stage.
NGS revealed likely pathogenic *BCOR* p.H358fs* (c.1072del) mutation and *APC* deletion, without specific re-arrangements of SGTs. The consensus diagnosis was a salivary gland-type neoplasm without discernible features of atypia. The patient is currently under clinical follow-up.
Conclusion: This case underscores the diagnostic complexity of currently unclassifiable SGTs, representing an unmet clinical need in tumour classification. Our case could represent either a novel SGT entity, or an existing tumour subtype with non-canonical genomic profile.

E-PS-23-018

Histopathologic analysis of H69PR *in ovo* culture treated with *Carmona retusa* leaf extract: bridging basic sciences and clinical practice

V.D. Ramil[1], T.L. Tatlonghari[1], G.J. Cadena[1], S.C. Carlos[1], C.B. Bautista[1], G.A. Espiritu[2,1,3]
[1]De La Salle University, Department of Biology, Manila, Philippines, [2]Centro Escolar University, School of Medicine, Manila, Philippines, [3]Antipolo City Molecular Laboratory, Antipolo City, Philippines

Background & Objectives: Lung cancer is the second-most common cause of mortality in the Philippines. There have been instances that lung cancer developed resistance to chemotherapeutic agents, and one of the reasons is the overexpression of signalling molecules involved in angiogenesis. This study investigated the effects of an antiangiogenic leaf extract to H69PR *in ovo* culture.
Methods: H69PR was inoculated in the chorioallantoic membrane of duck embryos. These cultures were treated with 5 mg/mL and 10 mg/mL of *Carmona retusa* leaf extract. Isotretinoin (10 mg) was used as positive control. Tumour invasion, necrosis, and mitosis were assessed using haematoxylin & eosin staining. Microvascular density was determined using desmin immunohistochemical staining.
Results: Analysis of the H&E sections showed squamous cell carcinoma instead of small cell carcinoma (H69PR). Tumour invasion was absent in the culture treated with 10 mg/mL concentration of leaf extract. Necrosis was present in all set-ups except positive control. This may be attributed to apoptosis triggered by retinoic acid response elements. Mitosis (5 per high-power field) was only observed in the negative control. One-way ANOVA of the microvascular density showed significant difference among the groups with a 0.03 p-value suggesting inhibition of angiogenesis in the treated groups.
Conclusion: The metaplastic change of H69PR was an unexpected but interesting finding in this study, which emphasizes the importance of pathology in validating the cell line thus bridging basic sciences with clinical practice. *Carmona retusa* leaf extract was just as effective as isotretinoin in inhibiting angiogenesis. At higher concentration, *Carmona retusa* may possibly prevent tumour invasion warranting further investigation.

E-PS-23-019

Negative prognostic significance of primary cilia and cytoplasmic β-catenin expression in non-small cell lung cancer

B. Rosová[1], J. Dvorak[2], R. Matej[1]
[1]Third Faculty of Medicine Charles University and Thomayer University Hospital, Department of Pathology and Molecular Medicine, Prague, Czech Republic, [2]First Faculty of Medicine Charles University and Thomayer University Hospital, Department of Oncology, Prague, Czech Republic

Background & Objectives: The aim of this study was to investigate the prognostic significance of the frequency of primary cilia (PC) and cytoplasmic β-catenin expression in non-small cell lung cancer (NSCLC) (pts).
Methods: Ninety-three pts with histologically verified squamous cell carcinoma and 218 pts with adenocarcinoma of the lung were retrospectively studied. The frequency of PC and cytoplasmic β-catenin expression were immunohistochemically and immunoflourescence evaluated.
Results: In the whole group of 218 pts with NSCLC, overall survival (OS) was significantly inferior among pts with present PC than without PC (p=0.024) and with higher cytoplasmic β-catenin expression (25-75%) than with lower cytoplasmic β-catenin expression (<25%) (p=0.008). In the univariate Cox proportional hazard model, the hazard ratio was 1.653 in pts with present PC (p=0.026) and 1.851 in pts with higher cytoplasmic β-catenin (25-75%) (p=0.009). Multivariate testing of the whole group of 218 pts with NSCLC showed that the presence of PC was associated with a worse prognosis (p=0.018). In the subgroup of 125 pts with adenocarcinoma, OS was significantly improved in pts with higher membranous β-catenin expression (≥50%) than in pts with lower expression (<50%) (p=0.0300) and OS was significantly inferior in pts with higher cytoplasmic β-catenin expression (25-75%) than in pts with lower expression (<25%) (p=0.0004). Multivariate testing of the subgroup of pts with adenocarcinoma showed that cytoplasmic β-catenin (p<0.001) and pleural invasion (p=0.017) were associated with worse prognosis.
Conclusion: The present results indicate a negative prognostic significance of PC and cytoplasmic β-catenin expression in NSCLC and a negative prognostic significance of cytoplasmic β-catenin expression in adenocarcinoma.

E-PS-23-021
Bilateral lung transplantation in a patient with Clinically Amyopathic Dermatomyositis associated with rapidly progressive interstitial lung disease: a case report
M. Mollaee[1], A. Bombonati[1], A. Hernandez-Guzman[1]
[1]Temple University Hospital, Philadelphia, USA

Background & Objectives: Clinically amyopathic dermatomyositis (CADM) is a rare type of auto-immune disease within the dermatomyositis spectrum with cutaneous manifestations, which lack the typical muscle weakness. It has a high risk of developing interstitial lung disease (ILD), malignancy and other fatal complications. ILD associated with CADM is often refractory and rapidly progressive. In these patients, MDA-5 antibodies are associated with worse prognosis.
Methods: A 55-year-old man presented with fatigue, digital ulcers secondary to Raynaud's phenomenon, productive cough, shortness of breath, nailfold erythema and shawl sign with skin rash of back and neck. Chest CT showed bilateral ground-glass and cystic changes with lower lobe predominance. The diagnosis of CADM was made based on clinical assessment and immunological findings of PM-Scl, Anti-Ro and Anti-La autoantibodies. The MDA5 antibody was negative. The follow up wedge biopsy showed histological features suggestive of lymphoid interstitial pneumonia (LIP) pattern. Due to worsening of his symptoms and lack of response to immunosuppression, he underwent bilateral lung transplantation.
Results: Microscopically explanted lungs showed extensive areas of diffuse moderate interstitial fibrosis, chronic remodelling of small airways, patchy mild chronic interstitial inflammation, focal cystic parenchymal changes and old fibrous pleural adhesions, consistent with systemic connective tissue disease associated with CADM involving the lungs. Additionally, marked chronic pulmonary arteriopathy was also identified, consistent with his history of pulmonary hypertension, and likely representing a secondary complication of connective tissue disease. After transplant, the patient developed multiple respiratory infections and ultimately died 11 months post-transplant from acute respiratory failure.
Conclusion: CADM has been associated with progressive ILD. Due to the severity and low survival rate, accurate diagnosis is of utmost importance. Early detection, with early and aggressive combined immunosuppression, is key to better survival. Early screening for malignancy as well as presence of MDA-5 antibodies, which is associated with adverse prognosis and progressive ILD, is essential.

E-PS-23-022
Mediastinal Inflammatory Myofibroblastic Tumour mimicking a mediastinal cyst: a rare case
M. Mollaee[1], A. Bombonati[1], B. Fentaw[1]
[1]Temple University Hospital, Philadelphia, USA

Background & Objectives: Inflammatory myofibroblastic tumours (IMT) are rare mesenchymal neoplasm. It is common in children and young adults. It has been reported in many anatomical locations such as lung, liver, spleen, head and neck. The mediastinal IMT has been rarely documented. IMT has different morphological features ranging from benign to malignant. It is associated with ALK gene rearrangements as well as fusions of some kinase genes including ROS1, RET, etc. in ALK negative IMT.
Methods: We report a case of non-smoker 66-year-old male who presented for atrial fibrillation and found to have an incidental 7.4 cm middle mediastinal thin-walled cyst on chest CT scan. On chest CT angiogram, the cystic mass had partial effacement of the oesophagus and left atrium without any evidence of invasive or complex components.
Results: The patient underwent complete surgical excision of the mass. Morphology revealed bland spindle shaped cell proliferation devoid of atypia or mitotic activity admixed with inflammatory infiltrates including plasma cells and myxoid appearing background. Immunohistochemical stains showed positivity for S100, CD34, calretinin, SOX10. The ki-67 proliferation index was less than 3%. The ALK gene rearrangement by FISH analysis was detected, confirming the diagnosis.
Conclusion: IMT is a rare tumour and the mediastinal location has been reported very infrequent. The radiologic features are very nonspecific and variable, hence the diagnosis is solely based on tissue diagnosis and molecular studies. It should be considered in the differential diagnosis of mediastinal neoplasms. Complete surgical excision with close follow up after surgery is the definitive treatment. Overall IMT has an indolent behaviour.

E-PS-23-023
Endobronchial hamartoma, an extremely rare benign tumour involving the respiratory tract
R. Ayadi[1], R. Yaiche[2], O. Mnif[1], Y. Barbirou[1], S. Jedda[1], Y. Dhouibi[1], E. Braham[1], O. Ismail[1], N. Ben Jamaa[1], A. Ayadi[1]
[1]Abderrahmane Mami Hospital, Pathology, Tunis, Tunisia, [2]Abderrahmane Mami Hospital, Tunis, Tunisia

Background & Objectives: Hamartoma is the most common benign neoplasm involving the lung. Most hamartomas are located peripherally in the lung parenchyma and endobronchial hamartoma is a rare lesion. Their clinical presentation mimics obstructive lung diseases such as asthma and chronic obstructive pulmonary disease, or malignancy because of their obstructive character, leading to a delay in diagnosis and errors in treatment. Therefore, making precise diagnosis may be challenging.
To better understand this entity, we reviewed clinicopathological data of patients with endobronchial hamartoma.
Methods: We report a retrospective study of 18 cases of endobronchial hamartoma, diagnosed at our department of pathology and treated at our institution, with a hindsight of 30 years, from 1995 to 2024.
Results: There were 15 male and 3 female patients, aged between 3 and 68 years with a mean of 52,88 years. Chest pain and cough were the most commonly reported symptom. Bronchoscopy revealed well-defined submucosal endobronchial lesions (n=12) and the clinical impression was that of a benign neoplasm. Computed tomography of the chest showed an endobronchial lesions in all cases. Histologic diagnosis was obtained by endobronchial biopsy in 4 cases and surgical resection (lobectomy, pnemonectomy, bilobectomy, wedge) in 14 cases. All lesions showed similar morphology: showed the presence of nodules of hyaline cartilage admixed with variable amounts of fibrous adipose tissue, spindle cells, hypertrophic seromucous gland and myxoid stroma without signs of specificity or malignancy. The diagnosis of endobronchial hamartoma was established. No recurrence was observed after a follow-up period of 12 months.
Conclusion: Endobronchial hamartoma is an extremely rare benign lesion of the respiratory tract which may lead to obstructive complications if unresected. It should be distinguished from malignancy lesion. All endobronchial HC tumours in the present series behaved in a benign manner.

E-PS-23-024
A rare case of pulmonary alveolar adenoma mimicking metastatic breast carcinoma: radiologic, pathologic and molecular characterisation
J. Coelho Lima[1,2], G. Maggioni[1], F. Pezzuto[1], F. Calabrese[1]
[1]Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Padua, Italy, [2]Addenbrooke's Hospital, Department of Histopathology, Cambridge, United Kingdom

Background & Objectives: Alveolar adenomas are exceedingly rare benign epithelial lung neoplasms, accounting for <1% of all lung tumours. They usually present as incidental radiologic findings in asymptomatic patients. We present a case of alveolar adenoma that clinically and radiologically mimicked a metastatic breast carcinoma and describe its histologic, immunohistochemical, and molecular profiles.
Methods: Clinical, radiologic, and pathologic data were reviewed. Immunohistochemical and molecular investigations (Myriapod NGS 50 genes) were carried out. This case report adheres to the Declaration of Helsinki.
Results: A 55-year-old female with left breast carcinoma underwent a chest computed tomography (CT) for radiologic staging, which evidenced a 13mm hypodense solitary nodule in the left lower lobe (LLL) base. Following left breast quadrantectomy and adjuvant chemo-radiotherapy, 3-monthly radiologic surveillance of the solitary lung nodule was performed. The nodule showed no radioisotope avidity on positron emission tomography (PET)-CT, but increased 5mm in size within one year and a half. Thus, the patient underwent LLL segmentectomy and mediastinal lymphadenectomy. Histologically, this was a well-circumscribed, cystic and solid neoplasm. The cystic spaces contained abundant eosinophilic granular material and were lined by cuboidal to hobnailed cells resembling type II pneumocytes. The intervening solid areas comprised spindle cells admixed with lymphocytes, plasma cells, and conspicuous eosinophils. No nuclear pleomorphism, mitoses, necrosis, or lymph node metastases were present. On immunohistochemistry, the cyst-lining cells strongly expressed CK MNF116, EMA, and TTF-1 and did not express GATA3, ER or PR. The stromal spindle cells showed vimentin and CD34 expression only. Immunohistochemistry was crucial for distinction from differential diagnosis such as metastatic breast carcinoma and primary lung tumour mimickers (sclerosing pneumocytoma, bronchiolar adenoma, lymphangioma, adenocarcinoma). NGS did not reveal any gene alteration.
Conclusion: We report this case because of its rarity, good prognosis and to avoid misdiagnosis. Histological examination, including immunohistochemistry, is mandatory for precise diagnosis.

E-PS-23-025
Can murine influenza A-induced pneumonia serve to study human post-viral lung disease?
A. Ognjenović[1], I. Stražić Geljić[1], L. Mušak[2], O. Majstorović[2], S. Vidović Iviš[1], M. Antolić[1], V. Milutinović[1], H. Brzica[1], I. Glojnarić[1], S. Čužić[1]
[1]Selvita Ltd., In vivo Pharmacology and Toxicology, Zagreb, Croatia, [2]University of Rijeka, The Faculty of Medicine, Department of Histology and Embryology, Rijeka, Croatia

Background & Objectives: Influenza viruses are one of the most common pathogens causing respiratory infections in humans, with a wide spectrum of clinical symptoms and even mortality. The study aimed to characterize the alveolar repair response occurring in a murine model of sublethal pneumonia induced by the influenza A (PR/8/34) virus.
Methods: BALB/c female mice were intranasally infected with a sublethal dose of influenza A virus (PR/8/34). Lung tissue was collected at designated time-points from day 3 until day 31 post-infection (p.i.), formalin-fixed paraffin-embedded and stained by haematoxylin-eosin and immunohistochemistry (primary antibodies against surfactant protein C (SFTPC), cytokeratin 5 (KRT5), doublecortin-like kinase 1 (DCLK1) and collagen type I alpha1 (COL1A1). Slides were scanned using the AxioScan scanner (Zeiss).
Results: Intranasal infection with a sublethal dose of influenza A virus induced severe damage of alveolar epithelium, characterized by multifocal dropout of alveolar epithelial cells type II (SFTPC+ cells) that were replaced by clusters of KRT5+ stem cells, i.e., pods. Pods were observed from day 12 p.i. onwards and were still present on day 21 p.i. In addition, within KRT5+ regions in lung parenchyma, a differentiation into tuft cells occurred, which was recognized by the DCLK1 expression. Interstitial fibrosis was detected from day 12 p.i., and persisted until the end of the study on day 31 p.i.
Conclusion: Alveolar epithelial injury and repair process was studied in a murine model of post-viral lung remodelling induced by influenza A virus. At sites of severe alveolar epithelium injury, islands of KRT5+ pods were formed with ectopic tuft cell differentiation. By the end of the observation period, interstitial fibrosis developed. The lung repair process described in this model has been documented in human post-viral lung disease, among others post-SARS-CoV-2 infection. This opens the possibility for wider use of this murine model in translational respiratory research.

E-PS-23-026
Inflammatory myofibroblastic tumour of the lung: a diagnostic challenge in an asymptomatic adolescent
S. Yurtsever Inan[1], A. Tan[1]
[1]Manisa Celal Bayar University, Pathology, Manisa, Turkey

Background & Objectives: Inflammatory myofibroblastic tumour (IMT) of the lung is a rare lesion within the inflammatory pseudotumor spectrum, primarily affecting children and young adults. This

report details a case of pulmonary inflammatory myofibroblastic tumour (IMT) in an 18-year-old male. A 3 cm mass was incidentally detected on thoracic CT at 11 years of age, with no subsequent medical follow-up. The patient re-presented in 2024 for a pre-employment evaluation, where repeat thoracic CT revealed progression of the lesion. This case is presented to underscore the diagnostic challenges and clinicopathological correlations inherent to IMT.
Methods: Following detection of a left upper lobe mass (55×43 mm, lobulated, peripherally located with central calcification) on contrast-enhanced CT, a lobectomy specimen (299,5 g, 16,4 × 12,3 × 5,2 cm) was subjected to histopathological analysis.
Results: Gross examination revealed a well-circumscribed lesion (5,2×4,6×3,3 cm) adjacent to pleura with central calcification and peripheral solid components. Microscopy demonstrated alveoli entrapped within haphazardly distributed spindle-shaped fibroblasts and inflammatory cells rich in plasma cells. These alveolar cells exhibited hyperplasia, and focal calcifications were observed in scattered areas. No cytological atypia, mitotic activity, or necrosis was identified. Immunohistochemistry confirmed diffuse ALK positivity (ALK-1/D5F3+), polyclonal light chains, and a low Ki-67 index (1-2%), while excluding mimics (STAT6−, CD34−, p40−, TTF-1−). Surgical margins were tumour-free.
Conclusion: This case underscores the diagnostic complexity of IMT, requiring correlation of histomorphological features with immunohistochemical markers (particularly ALK positivity) to exclude malignancy and distinguish it from benign mimics, such as sclerosing pneumocytoma. Despite its benign classification, complete surgical excision is imperative to mitigate recurrence or local invasiveness. In the context of a well-circumscribed, incidentally detected pulmonary lesion, inflammatory myofibroblastic tumour (IMT) merits inclusion in the differential diagnosis.

E-PS-23-028
Autoimmune Pulmonary Alveolar Proteinosis and mantle cell lymphoma
P. Vlachou[1], A. Mellou[1], E.-A. Spiteri[1], A. Georgiou[1], E. Manali[2], C. Vourlakou[1]
[1]Evaggelismos General Hospital of Athens, Pathology Department, Athens, Greece, [2]General University Hospital 'Attikon', 2nd Pulmonary Medicine Department, Athens, Greece

Background & Objectives: Pulmonary alveolar proteinosis (PAP) is a rare lung disease with an incidence of 0.2 cases per million. It is characterized by the accumulation of lipoproteinaceous material within the alveoli due to impaired clearance by alveolar macrophages. PAP can be classified as congenital, secondary, or autoimmune. The objective of this abstract is to present an extremely rare case of autoimmune alveolar proteinosis occurring simultaneously with CD5(+) B-cell lymphoma.
Methods: An 80-year-old female smoker with a recent hospitalization in a pulmonary clinic due to bilateral lung infiltrates underwent a lung biopsy. Two lung specimens were excised and analysed using haematoxylin-eosin (H&E) staining, immunohistochemistry, and periodic acid–Schiff (PAS) histochemical staining. Following the pathology report, a serum sample was tested for anti-GM-CSF antibodies, and the patient was thoroughly evaluated for a possible hematologic malignancy.
Results: Microscopically, an amorphous, eosinophilic material was observed within the alveoli, which was PAS-positive, along with macrophages/histiocytes. The interstitial space showed a small number of lymphocytes and areas of mild fibrosis. Additionally, in other lung tissue sections, a neuroendocrine nodule (tumourlet) measuring 0.1 cm in diameter was identified near a terminal bronchiole, with the following immunohistochemical profile: CK8/18 (+), Chromogranin A (focal+), OTP (+), and TTF-1 (+). Furthermore, anti-GM-CSF antibodies were positive, and the bone marrow biopsy confirmed the presence of mantle cell lymphoma.
Conclusion: Although PAP is a rare entity, it should be considered in the differential diagnosis by pathologists, as its clinical course can range from complete resolution to respiratory failure and increased susceptibility to opportunistic infections. Additionally, thorough histological examination and comprehensive clinical and laboratory evaluation are crucial, as PAP may coexist with other pathological conditions.

E-PS-23-029
Confusion in the diagnosis of endobronchial tumours: not so obvious or are we too late?
R. Ayadi[1], R. Yaiche[1], O. Mnif[1], S. Jedda[1], Y. Barbirou[1], Y. Dhouibi[1], E. Braham[1], O. Ismail[1], N. Ben Jamaa[1], A. Ayadi[1]
[1]Abderrahmane Mami Hospital, Pathology, Tunis, Tunisia

Background & Objectives: Primary endobronchial tree tumours can be either malignant or benign. Benign tumours of the lung constitute a small minority of all lung tumours but they can cause clinical roentgenographic changes similar to those seen in malignant neoplasms. Most benign tumours are located peripherally in the lung parenchyma and endobronchial location a is an unusual lesion.
In this study, we aimed to present our experience with the diagnosis of endobronchial benign tumours in our clinic
Methods: We report a retrospective study of 36 cases of endobronchial tumour, diagnosed at our department of pathology and treated at our institution, with a hindsight of 30 years, from 1995 to 2024.
Results: There were 30 male and 6 female patients, aged between 3 and 80 years with a mean of 46,44 years. Chest pain and cough were the most commonly reported symptom. Bronchoscopy revealed well-defined submucosal endobronchial lesions (n=30) and the clinical impression was that of a suspected neoplasm in 11 cases. Additionally, the procedure led to the complete excision of the tumour in 7 cases. Computed tomography of the chest showed an endobronchial lesions in all cases. The diagnosis was obtained by endobronchial biopsy in 16 cases and surgical resection (lobectomy, pnemonectomy, bilobectomy, wedge) in 20 cases. Histologically, 50% of tumours were hamartomas (n=18), followed by papillomas in 30,55% (n=11), lipomas in 16,6% (n=6) and pleomorphic adenoma in 2,85% (n=1). No recurrence was observed after a follow-up period of 12 months.
Conclusion: Benign endobronchial tumours are uncommon location lesions. The course of the disease is unpredictable. It may regress spontaneously, but in other instances it may lead to serious complications ranging from airway obstruction up to malignant transformation.

E-PS-23-030
Case report: primary pulmonary extraskeletal osteosarcoma – a rare diagnostic challenge in thoracic tumours
G. Bal[1], E. Kul[1], R. Ucak[1], F. Kabukcuoglu[1]
[1]SBU Sisli Hamidiye Etfal Research and Training Hospital, Pathology, Istanbul, Turkey

Background & Objectives: Primary pulmonary extraskeletal osteosarcoma (ESOS) is an exceptionally rare and aggressive malignant mesenchymal tumour characterized by the production of osteoid matrix by tumour cells in the absence of skeletal involvement. In contrast to metastatic osteosarcoma, this tumour originates from the lung parenchyma, mimicking other high-grade thoracic sarcomas. The objective of this report is to underscore the hallmark features aiding accurate diagnosis and differentiate this entity from other tumours with sarcomatoid features.
Methods: Formalin-fixed, paraffin-embedded sections were stained with haematoxylin and eosin, and immunohistochemistry was performed with an antibody panel including Pancytokeratin (AE1/AE3), EMA, S100, Desmin, SMA, Myogenin, MyoD1, TLE1, SATB2, and

CD99. A literature review was conducted to compare this case to previously reported cases.
Results: A 73-year-old male presented with pleuritic chest pain. Imaging showed 10.9×8.5 cm heterogeneous mass with cystic areas in the left upper lobe. The specimens included left upper lobectomy, 2nd to 4th rib resection, regional lymphadenectomy, and separately submitted tumour tissue. Histology revealed a high-grade sarcoma with hyperchromatic nuclei, prominent nucleoli, occasional osteoblast-like cytoplasm, multinucleated giant cells, frequent mitoses, cytologic atypia, and necrosis. Malignant osteoid appeared as thin, lace-like or irregular trabecular deposits closely associated with tumour cells. The tumour was diffusely positive for CD99 and negative for all other tested markers. Although it extended into adjacent soft tissue, the resected ribs were uninvolved, confirming a primary pulmonary origin.
Conclusion: Primary pulmonary ESOS is a rare and aggressive neoplasm that requires a thorough histopathological assessment to distinguish it from other high-grade sarcomas and metastatic lesions. In this case, the diagnosis was established by identifying malignant osteoid and excluding mimickers through immunohistochemistry, while the absence of rib involvement further supported a pulmonary origin. This case adds to the current knowledge of pulmonary ESOS and serves as a reminder to include it in the differential diagnosis of thoracic sarcomas.

E-PS-23-031
Pulmonary oxalosis associated with Aspergillus niger infection: case report
S.K. Dursun[1], F. Cengiz[1], S. Bagbudar[2], Z. Tosuner Koçyiğit[1]
[1]Basaksehir Cam ve Sakura City Hospital, Department of Pathology, Istanbul, Turkey, [2]Istanbul University, Istanbul Faculty of Medicine, Department of Pathology, Istanbul, Turkey

Background & Objectives: *Aspergillus niger* is an opportunistic fungal pathogen that can cause invasive and non-invasive aspergillosis, particularly in patients with underlying lung disease or immunosuppression. Pulmonary oxalosis, characterized by calcium oxalate crystal deposition within lung tissue, is a rare but significant complication of *Aspergillus* infections, contributing to tissue destruction and disease progression.
Methods: We report a case of a 62-year-old male, a former heavy smoker with a 20-year history of chronic obstructive pulmonary disease (COPD), who underwent left lower lobectomy for moderately differentiated non-keratinizing squamous cell carcinoma (pT2aN1). Postoperatively, he developed a persistent dry cough, recurrent fever, and worsening respiratory symptoms. Bronchoscopy revealed a bronchopleural fistula, and microbiological cultures identified *Acinetobacter spp.*, *Corynebacterium spp.*, and *Escherichia coli*, leading to broad-spectrum antibiotic therapy. Despite treatment, he developed empyema and progressive respiratory failure, necessitating completion pneumonectomy.
Results: Histopathological examination of the pneumonectomy specimen revealed a necrotic cavitary lesion with extensive suppurative inflammation. Brown-black pigmented fungal hyphae and conidia, consistent with *Aspergillus niger*, were identified, along with birefringent calcium oxalate crystal deposition within necrotic lung tissue. Background changes included emphysematous lung parenchyma, fibrosis, anthracosis, and chronic inflammation. Fluconazole therapy was initiated postoperatively; however, the patient's condition deteriorated, and he succumbed to sepsis and multiple cardiac arrests on postoperative day 11.
Conclusion: Pulmonary oxalosis is an uncommon but serious manifestation of *Aspergillus niger* infection, resulting from fungal production of oxalic acid, which reacts with tissue calcium to form calcium oxalate crystals. This process exacerbates local tissue damage and may contribute to poor clinical outcomes. While *Aspergillus fumigatus* is the most common species in pulmonary aspergillosis, *Aspergillus niger* should also be considered, particularly in patients with persistent respiratory decline postoperatively. Recognition of calcium oxalate crystal deposition in lung tissue should raise suspicion for invasive fungal infection, emphasizing the need for early diagnosis and prompt antifungal treatment to improve outcomes.

E-PS-23-032
Clinicopathological analysis of EGFR mutation subtypes in lung adenocarcinoma
G. Aydogan[1], G. Serin[1], P. Gursoy[2], A. Ozdil[3], A. Veral[1], D. Nart[1]
[1]Ege University Faculty of Medicine, Department of Pathology, Izmir, Turkey, [2]Ege University Faculty of Medicine, Department of Oncology, Izmir, Turkey, [3]Ege University Faculty of Medicine, Department of Thoracic Surgery, Izmir, Turkey

Background & Objectives: EGFR mutations are the most common driver alterations in lung adenocarcinoma. Although their general clinical and pathological features are documented, the specific characteristics and outcomes of different EGFR mutation subtypes remain unclear.
Methods: We analysed retrospectively 60 lung adenocarcinoma cases with confirmed EGFR mutations at our centre between 2013 and 2023. Tumours were evaluated for histological pattern, grade, lymphovascular invasion (LVI), pleural invasion (PLI), lymph node metastasis (LNM), spread through air spaces (STAS), and survival outcomes. EGFR mutations were detected using the EGFR Pyro Kit.They were classified as typical (exon 19 deletions, exon 21 L858R), atypical (exon 18 G719, exon 21 L861), or compound. Overall survival(OS) and recurrence-free survival(RFS) were analysed using the Kaplan-Meier method.
Results: The cohort included 40 females (67%) and 20 males (33%), with a mean age of 60.8 years.The most common predominant morphological pattern was acinar, observed in 66.7% of cases, followed by lepidic in 21.7%, with papillary, micropapillary, and solid patterns each found in 3.3% of cases. STAS, PLI, LVI, and LNM were observed in 38%, 57%, 28%, and 23% of cases, respectively. Typical mutations were found in 78.3% of patients, atypical in 15%, and compound in 6.6%. The cases with predominant lepidic pattern were seen only in typical mutations, and 84.3% of these cases showed exon19 deletions.However, differences in histological patterns between mutation subtypes were not statistically significant (p=0.2).
Mean OS was 72.5 months, and mean RFS was 51.6 months. Although no statistically significant differences were found between mutation type and OS (p=0,093), patients with atypical mutations had 33.9% 5-year survival rate while those with typical mutations and compound mutations showed 68.5% and 66.7%, respectively.
Conclusion: Atypical EGFR mutations may show different pathological features and outcomes, but our findings are not sufficient to confirm this. Further studies are warranted to clarify the differences between EGFR mutation subtypes.

E-PS-23-033
Generation-age structured modelling of neuroendocrine lung tumours: a biopsy-calibrated approach to understanding small cell lung cancer dynamics
I. Vamvakaris[1], G. Evangelou[2], A. Bianchi[3], A. Chatzichristos[3], S. Makrogkikas[4], P. Gavriliadis[3], G. Lolas[5]
[1]Sotiria Hospital, Pathology, Athens, Greece, [2]National & Kapodistrian University of Athen, 3rd Dept of Internal Medicine & Laboratory, Athens, Greece, [3]InCELLia, Marousi, Greece, [4]National Technical University of Athens, Research Unit of Advanced, Composite Nano-Materials and Nanotechnology, School of Chemical Engineering, Zographos, Greece, [5]SAMRC Precision Oncology Research Unit (PORU), Pan African Cancer Research Institute (PACRI), University of Pretoria, InCELLIA - 3.Dep. Int. Med., Pretoria, South Africa

Background & Objectives: Small Cell Lung Cancer (SCLC), an aggressive neuroendocrine tumour of the lung, is characterized by rapid proliferation, early metastasis, and resistance to therapy. Despite advances in molecular profiling, its clinical management remains largely empirical. In this talk, we present a novel generation-age structured mathematical model that extends the Iwata framework of metastatic progression to account for clonal proliferation and generational age in primary and metastatic lesions.
Methods: The central innovation of our approach lies in modelling tumour growth as a process driven by successive generations of proliferating cells, where each generation carries distinct phenotypic characteristics and metastatic potentials—linking tumour "age" to aggressiveness and therapeutic response.
Results: A key aspect of our work is the direct calibration of the model using patient-derived tumour biopsies. By integrating histopathological data—such as Ki-67 proliferation indices, neuroendocrine marker expression, spatial distribution of clones—we aim to extract generational fingerprints that inform the distribution of cell division rates and clonal hierarchies. This biopsy-calibrated approach enables us to simulate patient-specific tumour evolution and predict the burden of occult micrometastases.
Conclusion: To our knowledge, this is the first effort to quantitatively link tumour age structure with real-world biopsy data in the context of neuroendocrine lung cancer. The model not only offers mechanistic insights into SCLC progression but also lays the foundation for computational tools that can stratify patients based on generational dynamics and forecast response to treatment.

E-PS-23-034
Serum protein - Omics of non-small cell lung cancer patients in Greece
I. Vamvakaris[1], E. Kopana[2], A.N. Kontouli Pertesi[2], I. Gkiozos[3], K.N. Syrigos[3], A.K. Anagnostopoulos[4]
[1]Sotiria Hospital, Pathology, Athens, Greece, [2]Biomedical Research Foundation of the Academy of Athens, Biotechnology, Athens, Greece, [3]Sotiria Hospital for Diseases of the Chest, National and Kapodistrian University of Athens, Oncology Unit, 3rd Dept of Medicine, Athens, Greece, [4]Biomedical Research Foundation of the Academy of Athens, Dep. Int. Med., Biotechnology, Athens, Greece

Background & Objectives: Lung cancer remains the leading cause of cancer-related mortality worldwide, demanding for revolutionary approaches to enhance accurate diagnosis and treatment. The study aimed to investigate proteins of serum samples from patients with lung cancer across various stages of the disease to identify prognostic biomarkers as well as elucidate molecular mechanisms underlying disease pathophysiology and progression.
Methods: Patients diagnosed with Non-Small Cell Lung Cancer (NSCLC) were prospectively recruited at the Oncology Unit of the 3rd Department of Internal Medicine, "Sotiria" University Hospital. Serum samples were obtained from Stage II, III, and IV patients, whilst their clinical and demographic data were also recorded. Serum from all patients was analysed by in-depth liquid chromatography–tandem mass spectrometry based on in-house developed protocols followed by rigorous statistical evaluation.
Results: Two proteins, haptoglobin (HP) and vitronectin (VTN), were found to be increasingly expressed in NSCLC advanced-stage patients compared to those of lower-grade disease. These biochemical alterations were pinpointed in parallel with marked disease progression. Overexpression of VTN and HP in cancer patients, is traditionally associated with increased tumour aggressiveness, a higher likelihood of metastasis, and overall poor clinical outcomes.
Conclusion: Serum protein -omics remains crucial in advancing precision medicine for lung cancer by facilitating earlier prognosis and tailored therapeutic approaches.

E-PS-23-035
Multinodular epithelioid haemangioendothelioma with intermediate grade of malignancy (G2) in combination with tuberculoma in the same lung lobe
Y. Slavova[1,2], D. Marinova[1,2], G. Ignatov[1,2]
[1]University of Ruse, Ruse, Bulgaria, [2]UMHAT Medika, Ruse, Bulgaria

Background & Objectives: Epithelioid haemangioendothelioma (EHE) of the lung is a rare low- to intermediate-grade vascular tumour composed of solid nests and short cords of epithelioid endothelial cells in a myxohyaline stroma. In 60% of the cases it presents as a multinodular mass, rarely diagnosed radiographically, clinically presented with chest pain or haemoptysis.
We present a clinical case of a 50-year-old man with recurrent haemoptysis for several months, with computer tomographic data for a nodular formation in the left upper lobe, in whom a lobectomy of the left upper lobe revealed a multinodular EHE and a tuberculoma in the same lobe.
Methods: Surgical resection material from left upper lobectomy was examined histologically by haematoxylin-eosin, and immunohistochemical markers - CD34, ERG, Vimentin, CK7.
Results: Macroscopically: encapsulated subpleural, nodular lesion measuring 16/21 mm, with an inhomogeneous yellow-whitish cut surface, friable.
Microscopically: nodular structure containing caseous necrosis, surrounded by expanded connective tissue, in places with hyalinization, in the periphery histiocytes with anthracotic pigment, lymphocytes, corresponding to tuberculoma. In the vicinity - multifocal proliferations of atypical endothelial cells with intracytoplasmic capillary lumens (pseudo signet-ring cells) with angiocentric location - in vascular walls of blood vessel lumens, perivascularly, along alveolar septa; intraalveolar spaces with nodular structures of atypical endothelial cells; myxoid stroma; irregularly shaped vascular channels filled with blood; remodelling of the lung parenchyma by tumour proliferations; blood in alveolar spaces, bronchiolar, bronchial lumens. Immunohistochemically, the atypical cells express CD34, ERG, Vimentin and focally CK7.
Conclusion: We present a rare neoplasm of the lung, and in a combination with tuberculosis in the same lung lobe. The lobectomy was performed for persistent haemoptysis and a nodular mass that proved to be a tuberculoma. The described case demonstrates that persistent haemoptysis can be due to EHE, which should be taken into consideration in clinical practice.

E-PS-23-036
The changing landscape of lung cancer diagnosis with emphasis on unusual histologies
R. Nasa[1], M. ElWakeel[2]
[1]NCIC NHS Trust, Cellular Pathology, Carlisle, United Kingdom, [2]NCIC NHS Trust, Medicine, Carlisle, United Kingdom

Background & Objectives: Advances in lung cancer biology have led to the development of targeted therapies. The need for accurate histological classification and guided molecular characterization highlights the continued role of the surgical pathologist in the multidisciplinary team. The emphasis has shifted towards diagnosis on endoscopic biopsies rather than resections. Preserving tissue for molecular studies is crucial. Minimal material may be sufficient to distinguish non-small cell lung cancer (NSCLC) from small cell lung cancer, however, additional tissue is needed to perform immunohistochemistry (IHC) for subtyping of NSCLC. Lack of accurate NSCLC subclassification could expose patients to unnecessary risks or deny them effective treatment. A diagnostic strategy for small biopsies lacking differentiation criteria relies on IHC markers, TTF1 and P63. These IHC markers lead to a specific diagnosis in over 80% of biopsies.

When there is no clear morphological or immunohistochemical evidence of lineage differentiation, it becomes imperative to classify the tumour as NSCLC-NOS. Pathologists are discouraged from using excessive IHC stains and should focus on saving tissue for molecular analysis. Searching for relevant mutations will direct the choice of targeted therapy. These new paradigms emphasize close communication between pathologists and clinical colleagues to ensure tissue adequacy and optimal triage for appropriate diagnostic studies.
Methods: All the lung cancer cases confirmed histologically between January 2023 and March 2025 were retrieved from the hospital information system. Demographic data, morphology, IHC and the molecular studies were collated for these cases.
Results: Of the 484 histologically confirmed cases, 13.4% were identified as small cell lung cancer, 37.2% as adenocarcinoma, 17.8% as squamous cell carcinoma, while 6.8% remained unclassified as NSCLC, NOS. The diverse morphology observed in NSCLC, NOS cases often necessitates multidisciplinary discussions to determine the optimal utilization of tissue.
Conclusion: Our study emphasizes the importance of preserving tissue for molecular studies to improve the diagnosis and treatment protocols.

E-PS-23-038
How does tumour spread through air spaces survive (STAS)? – An approach to the microenvironment of STAS and the role of extracellular matrix in airborne metastases
A.Y. Kang[1,2], J. Riese[1], H. Khalil[3,4], S.J. Mentzer[3,4], M.P. Kühnel[1], A. Walch[5], D.D. Jonigk[1,6,7], M. Ackermann[1,8,9], Experimental Lung Pathology Study Group
[1]University Hospital RWTH Aachen, Institute of Pathology, Aachen, Germany, [2]University Hospital RWTH Aachen, Department of Pneumology and Intensive Care Medicine, Aachen, Germany, [3]Harvard Medical School, Boston, MA, USA, Laboratory of Adaptive and Regenerative Biology, Brigham and Women's Hospital, Boston, USA, [4]Harvard Medical School, Boston, MA, USA, Department of Thoracic Surgery, Brigham and Women's Hospital, Boston, USA, [5]Helmholtz Institute Munich, Institute of Pathology, München, Germany, [6]German Centre for Lung Research, Hannover, Germany, Biomedical Research in Endstage and Obstructive Lung Disease Hannover, Hannover, Germany, [7]Hannover Medical School, Hannover, Germany, Institute of Pathology, Hannover, Germany, [8]Helios University Clinic Wuppertal, University of Witten/Herdecke, Wuppertal, Germany, Institute of Pathology and Molecular Pathology,, Wuppertal, Germany, [9]University Medical Centre of Johannes Gutenberg University Mainz, Mainz, Germany, Institute of Anatomy, Mainz, Germany

Background & Objectives: It is hypothesized that a novel form of airborne metastasis may be observed, involving the dissemination of tumours through air spaces. This phenomenon has been observed at the periphery of some pulmonary adenocarcinoma cases. The objective of the present study was to achieve a more profound comprehension of the survival mechanisms of STAS, with particular reference to the impact of hypoxia and extracellular matrix on progress, as well as PDL1-expression in STAS in comparison with the primary tumour.
Methods: The present study identified STAS using haematoxylin and eosin (HE) and immunohistochemistry (IHC). MALDI-TOF imaging was utilized for the analysis of the extracellular matrix. The NanoString GeoMx platform was used to perform high-plex profiling at the RNA level, thereby facilitating a comprehensive assessment of the microenvironment associated with STAS. Furthermore, the expression levels of PDL1 in the primary tumour and STAS were examined, as well as the levels of MUC-1 and MUC-5AC.
Results: It has been demonstrated that STAS exhibits heterogeneity with respect to spatial distribution and quantity, thereby demonstrating aberrant functional gene expression in tumours and inflammatory pathways.
Conclusion: Changes in the extracellular matrix and mucin levels appear to be significant in the development of STAS. Further investigation is required to characterize the various entities involved and to evaluate therapeutic options.

E-PS-23-040
Spontaneous haemothorax revealing a malignant solitary fibrous tumour in the postpartum period
O. Belkacem[1], M. Krifa[1], W. Majdoub[1], Z. Eleuch[1], S. Mestiri[1], S. Hmissa[1]

[1]Sahloul Hospital, Pathology, Sousse, Tunisia
Background & Objectives: Malignant Solitary Fibrous Tumours (SFTs) are rare tumours that develop from mesenchymal cells of the pleura. Their occurrence within the lung tissue itself is even more uncommon. By this case, we want to explore the differential diagnoses of malignant SFTs and highlight the importance of immunohistochemistry in confirming the diagnosis.
Methods: We report the case of a 33-year-old woman in her third trimester of pregnancy who underwent a caesarean section due to acute foetal distress. Shortly after delivery, she developed a spontaneous haemothorax. Thoracic imaging revealed a highly vascularized tumour located in the left lung apex.
Results: The macroscopic examination showed a firm tumour and whitish, measuring 8×7×5 cm, with areas of necrosis and haemorrhage. Microscopically, it showed a mix of cellular and fibrous regions interspersed with hyaline and necrotic areas. The low-cellularity regions contained hemangiopericytoma-like blood vessels, while the denser areas consisted of spindle-shaped cells with moderate nuclear atypia and a mitotic rate of 9 mitoses per 10 high-power fields. Immunohistochemical analysis showed positivity for CD99, CD34, and STAT6. While BCL2 and ERG were negative. These findings confirmed the diagnosis of a malignant solitary fibrous tumour of the lung.
Conclusion: Intrapulmonary SFTs are extremely rare and present a variable clinical and radiological picture that can resemble other intrathoracic lesions. These tumours are generally slow-growing but can exhibit malignant behaviour in 10–30% of cases. Histopathological examination, along with immunohistochemistry, is crucial to distinguish SFTs from other tumours such as monophasic synovial sarcoma, fibrosarcoma, or high-grade vascular tumours like angiosarcoma.

E-PS-23-041
Bronchopulmonary carcinoma: unusual subtypes A study of 11 cases
S. Moussa[1,2], A. Bdioui[1,2], O. Belkacem[1,2], M. Krifa[1,2], Z. Eleuch[1,2], S. Mestiri[1,2], S. Hmissa[1,2]
[1]Sahloul University Hospital, Pathology Department, Sousse, Tunisia, [2]Faculty of Medicine of Sousse, Research Laboratory LR21 ES03, Sousse, Tunisia

Background & Objectives: Primary malignant tumours of the pulmonary salivary gland type (PMTSG) are rare, accounting for 1% of all bronchopulmonary malignancies. They present distinctly, so it's crucial to distinguish them from other bronchopulmonary tumours to ensure optimal management.
This work describes the clinico-pathological features of 11cases of PMTSG.
Methods: This retrospective study reviewed 11cases of PMTSG over 29years, including seven mucoepidermoid carcinoma (MEC) and four adenoid cystic carcinoma (ACC) cases.
Results: Mean age was 47.4years and sex ratio was 1:0. Most common symptom included cough and thoracic pain. Diagnosis was made after 7.45months from symptom onset. Chest X-rays showed opacities in all cases. Chest CTscans were performed in 10patients showing proximal mass in all cases, involving stem bronchus in 4cases, lobar bronchus

in 4others, and the hilar region in two. The mean tumour size was 3.6cm. Tumour invasion of middle mediastinum was noted, as well as vascular structure invasion in one and lower lobe collapse in two. Hilar and mediastinal adenopathies were noted in 3cases. Extension assessment included abdominal CTscan, performed in all cases, showing adrenal metastasis in 1case of MEC. Histological examination of bronchial biopsies revealed 3cases of ACC, 2cases of MEC, and 3 negative cases that subsequently were found to be MECs. Eight patients had localized stage, 2 had locally advanced stages and 1 had metastatic stage. Eight patients underwent surgery. Two of them received adjuvant radiotherapy. Neoadjuvant and palliative chemotherapy were prescribed in 1case each. Radiotherapy was the only indicated treatment in 1case. One patient had locoregional relapse and two had metastatic relapse (ACC). Mean overall survival was 37.8months. One patient died after 24months. Seven patients are alive and progression free at 24-72months, two have relapsed. One patient is lost to progression.
Conclusion: PMTSGs have a more favourable prognosis than other bronchopulmonary carcinomas, but recurrence and metastasis are common, requiring long-term monitoring.

E-PS-23-042
Pulmonary adenoid cystic carcinoma in patient with history of breast cancer
I. Benedetti[1], E. Ferreira[1], P. Montes[2,1]
[1]University of Cartagena, Histopathology research group, School of Medicine, Cartagena, Colombia, [2]Clínica IMAT Oncomedica, Department of Pathology, Monteria, Colombia

Background & Objectives: Pulmonary adenoid cystic carcinoma (PACC) is one of the rarest (0.04–0.2%) and unexplored presentations of lung cancer. It is considered a slow-growing tumour with a low-grade malignancy. Diagnosis is typically confirmed through histological examination. This report aimed to highlight the importance of being aware of this pathology and reducing the risk of misdiagnosis.
Methods: A 68-year-old woman with a history of breast cancer twelve years ago, presented non-specific respiratory symptoms. A CT scan highlighted a bilateral pulmonary nodule. The patient underwent a right medial segmental lobectomy with mediastinal lymphadenectomy and biopsy. Histopathological examination showed two solid lesions, measuring 2.2 x 1.4 x 1.2 cm and 1 x 1 x 0.7 cm, respectively. Both exhibited lung parenchyma compromised by a malignant tumour lesion composed of intermediate-sized cells exhibiting little euchromic cytoplasm, nuclei slightly pleomorphic, some with prominent nucleoli, and low mitotic activity. These cells were arranged predominantly in solid nests interspersed with cribriform areas exhibiting intraluminal myxoid secretion. Immunohistochemical analysis revealed reactivity for Cytokeratin-AE1/AE3, Cytokeratin-7, CD117, and focal S100, and negativity for Cytokeratin-20, TTF1, GATA3 and GCDFP15.
Results: The morphologic features of PACC are not very distinctive to give a confirmed diagnosis in routine H&E stains. To improve diagnosis, the immunohistochemistry study is highly recommended, the expression of myoepithelial markers, such as Cytokeratin 7, Cytokeratin AE1/AE3, CD117, and S-100 protein, is a strong argument for PACC. In this case, the immunophenotypic findings were compatible with a diagnosis of PACC and the histological features were consistent with PACC grade III (solid-type mass).
Conclusion: Pulmonary adenoid cystic carcinoma (PAAC) represents a malignant neoplasm wherein diagnosis can be challenging both clinically and histologically. Hence, PACC should be well recognized by pathologist to avoid misdiagnosis. The microscopic characteristics may deceptively suggest a benign lesion; accordingly, techniques including immunohistochemical analysis remain imperative for establishing malignant differentiation.

E-PS-23-043
MicroRNA 21 (miR-21) expression in non-small cell lung carcinoma (NSCLC) among Filipinos
G.A. Espiritu[1,2,3], J. Aban[1], E.J. Calderon[1], D.A. Lat[2]
[1]De La Salle University, Department of Biology, Manila, Philippines, [2]Antipolo City Molecular Laboratory, Antipolo Rizal, Philippines, [3]Centro Escolar University, School of Medicine, Manila, Philippines

Background & Objectives: In the Philippines, lung cancer is the top cause of cancer-related deaths. This is worsened by the continuous incidence of resistance to *EGFR* tyrosine kinase inhibitors (TKIs). MicroRNA-21 (miR-21), because of its role in invasion, metastasis, and chemoresistance, is a good candidate for targeted therapy. This study seeks to determine the expression of miR-21 in non-small cell lung carcinoma (NSCLC) among Filipinos.
Methods: Five (5) formalin-fixed, paraffin-embedded (FFPE) primary lung tumour tissue samples and 5 FFPE non-neoplastic lung tissue samples were retrieved from Tondo Medical Centre's Department of Pathology and Laboratory. RNA was isolated and purified, which was then subjected to reverse transcription. The resulting complementary DNA (cDNA) was analysed through quantitative PCR using miR-21 primers. Expression of miR-21 between NSCLC and non-neoplastic lung tissues were compared.
Results: All non-neoplastic lung tissues were diagnosed with chronic granulomatous inflammation. Two of five non-neoplastic lung tissues expressed miR-21, which both had extensive fibrosis. Age ranges from 15 to 48 years with female predominance. Two of five NSCLC tissues similarly expressed miR-21, one of which demonstrated squamous cell carcinoma with vascular invasion. This also had the lowest C_T value (suggesting highest expression) across all non-neoplastic and NSCLC tissues. The other one was diagnosed as invasive adenocacinoma. Upon microscopic review, the remaining three without miR-21 expression had very minute foci of tumour cells that may have contributed to this qRT-PCR outcome. Age ranges of patients with NSCLC were 64 to 72 years with male predominance. Student t-test (p value = 0.9646) showed no significant difference in the miR-21 expression between non-neoplastic lung and NSCLC tissues.
Conclusion: The high expression of miR-21 in the squamous cell carcinoma with vascular invasion is consistent with the association of miR-21 to tumour aggressiveness. The results, however, were not statistically significant. A prospective study with larger cohort is warranted.

E-PS-23-044
High-grade adenoid cystic carcinoma: a case report
A.I. Popescu[1], A.V. Tudor[2], E.D. Magheran[2], M. Stoicea[3], M.G. Orghidan[4], M. Alexe[5]
[1]University Emergency Hospital, Department of Pathology, Bucharest, Romania, [2]Marius Nasta Institute of Pneumophtisiology, Department of Pathology, Bucharest, Romania, [3]Regina Maria Private Healtchcare Network, Department of Pathology, Bucharest, Romania, [4]Marius Nasta Institute of Pneumophtisiology, Department of Thoracic Surgery, Bucharest, Romania, [5]Marius Nasta Institute of Pneumophtisiology, Department of Bronchology, Bucharest, Romania

Background & Objectives: Adenoid cystic carcinoma (AdCC) is a rare malignant neoplasm that primarily affects the salivary glands but can also occur in other areas such as the respiratory tract, lacrimal glands and breast. When occurring in the lung it makes up less than 0.2% of all primary lung neoplasms. High-grade transformation of AdCC is a rare, progressive transformation associated with to poorer prognosis and aggressive behaviour.
Methods: We report the case of a patient diagnosed with high-grade AdCC of the lung which presented at the Marius Nasta Institute of Pneumophthisiology, Bucharest, Romania in 2024. All data was extracted from the digital archive of the Institute.

Results: A 17-year-old male presented with progressive shortness of breath over the course of several months. During initial examination a chest CT was performed which revealed a 50mm diameter mediastinal mass invading the trachea and cervical oesophagus raising suspicion for a malignant tumour. A second mass was identified in the right pulmonary hilum. During bronchoscopy multiple fragments were resected and sent for histopathological examination. The laboratory received multiple fragments with sizes varying between 2 and 4cm which were completely processed. Histopathologic examination led to the diagnosis of high-grade AdCC which was further confirmed by immunohistochemistry.
Conclusion: There are several challenges when diagnosing high-grade AdCC. Considering that AdCC mainly affects patients in their sixth decade, a potential challenge occurs when the diagnosis is made in paediatric populations given its rarity and nonspecific clinical presentation. Another challenge is the slow growing yet insidious progression with propensity for local recurrence and distant metastasis which underscore the importance of early recognition and a thorough workup particularly in young individuals where rare malignancies can be overlooked. High-grade transformation AdCC diagnosis is based on sufficient material for microscopic examination, a high index of suspicion and appropriate immunohistochemical studies.

E-PS-23-045
EGFR-driven nuclear retention of the proteasome in NSCLC, mediated via p38-MAPK signalling
I. Livneh[1,2], P. Stein[1], A. Cretu[3], A. Dahan[1], Y. Zohar[1]
[1]Rambam Health Care Campus, Institute of Pathology and Cytology, Haifa, Israel, [2]Technion - Israel Institute of Technology, Faculty of Medicine, Haifa, Israel, [3]Carmel Hospital, Pathology, Haifa, Israel

Background & Objectives: The proteasome, a central effector of protein degradation, exhibits dynamic subcellular localization that responds to cellular stress. Beyond its well-established role in proteostasis, proteasome localization has recently emerged as a marker of tumour biology, with evidence suggesting that proteasome dynamics, largely regulated by anabolic and catabolic stimuli, play a key role in cancer cell survival. Insights from animal tumour models further position proteasome dynamics not only as a functional mechanism, but also as a potential marker of tumour aggressiveness. In this study, we observed an unexpected pattern in non-small cell lung carcinoma (NSCLC), where many tumours displayed predominant nuclear proteasome localization. Given the frequent presence of activating mutations in the EGFR-KRAS pathway in NSCLC, we hypothesized that oncogenic signalling may modulate proteasome distribution.
Methods: Using immunohistochemistry, proteasome localization was evaluated in FFPE samples of NSCLC, stratified by EGFR molecular status. In vitro, cultured cells were treated with EGF to assess the pathway effects on proteasome localization under both basal and amino acid-starved conditions. Key components of the MAPK pathway were perturbed to identify downstream mediators of EGFR-dependent proteasome control.
Results: Tumours lacking driver mutations showed predominantly cytosolic proteasomes, similar to other malignancies. In contrast, EGFR-mutant NSCLC exhibited strong nuclear proteasome localization ($OR = 76.0$, $p = 2.2 \times 10^{-6}$). EGF stimulation in culture induced nuclear retention of the proteasome, even during nutrient stress. Further, p38-MAPK was identified as a critical mediator linking EGFR activation to proteasome translocation.
Conclusion: These findings uncover a mechanistic connection between EGFR signalling and proteasome localization in NSCLC, mediated by p38-MAPK. Results from perturbation studies strongly suggest a causative mechanistic relation between EGFR signalling and proteasome localization. This pathway may contribute to altered stress responses and tumour behaviour, and this work prompts an investigation into potential clinical and prognostic implications of proteasome localization in EGFR-driven lung cancers.

E-PS-23-046
Peribronchiolar metaplasia mimicking pulmonary masses: a case series about a worrisome differential diagnosis
O. Pedro[1], M. Honavar[1], T. Amaro[1]
[1]ULS Matosinhos, Matosinhos, Portugal
Background & Objectives: This abstract aims to present three cases of peribronchiolar metaplasia (PBM), also known as Lambertosis, that clinically manifested as pulmonary masses. Peribronchiolar metaplasia is an uncommon lesion characterized by fibrosis and bronchiolar epithelial cell proliferation, typically in response to bronchiolar and peribronchiolar injuries. It usually appears as ground-glass nodules or sub-solid nodules on computed tomography (CT).
Methods: We describe three patients with PBM. The first patient, an 83-year-old male, presented with multiple pulmonary masses suspected of metastases from a previously diagnosed clear cell carcinoma of the kidney. One of the masses, measuring 11 mm, exhibited a spiculated appearance on CT. The second patient, a 79-year-old male, was found to have two basal nodules, with the larger nodule measuring 12 mm. The third patient, a 64-year-old female, showed an sub-solid area of ground-glass opacity in the middle lobe of the right lung, with a maximum diameter of approximately 30 mm. They were all submited to transthoracic fine needle biopsy.
Results: Histologically, all cases showed growth of ciliated columnar epithelium replacing alveolar epithelium in the bronchioloalveolar wall. Lesions sometimes exhibited a bronchioloalveolar growth pattern, associated with dilated bronchioles. The epithelium ranged from cuboidal to columnar, often ciliated, without atypia.
Conclusion: PBM is a nonspecific reaction to bronchiolar and peribronchiolar injury. It is characterized by fibrosis and proliferation of bronchiolar epithelium along the peribronchiolar alveolar walls. While PBM typically presents as ground-glass opacity lesions on CT, it can uncommonly manifest as solitary solid nodules or sub-solid nodules, posing diagnostic challenges. Recognizing the variable clinical and radiological presentations of PBM is essential for accurate diagnosis and differentiation from primary lung cancer and metastatic lung tumours.

E-PS-23-047
Lymphangitic breast cancer spread in explanted lungs with fibrosing interstitial lung disease: an unexpected finding
G. Maggioni[1], J. Coelho Lima[1,2], E. Faccioli[1], M. Loy[3], C. Giraudo[1], F. Pezzuto[1], F. Lunardi[1], F. Calabrese[1]
[1]Università degli Studi di Padova, Department of Cardiac, Thoracic, Vascular Sciences and Public Health, Padova, Italy, [2]Cambridge University Hospitals NHS Foundation Trust, Department of Histopathology, Cambridge, United Kingdom, [3]Azienda Ospedale-Università Padova, Padova, Italy

Background & Objectives: Breast metastases in explanted lungs and hilar lymphnodes are an exceedingly rare event, with lymphangitic spread previously virtually unreported. We present a very rare case of lymphangitic carcinomatosis from a previously undiagnosed breast carcinoma, identified only through systematic examination of explanted lungs in a patient undergoing bilateral lung transplantation for unclassifiable lung fibrosis. This case underscores the importance of standardized sampling protocols and multidisciplinary evaluation in transplant pathology.
Methods: A 60-year-old woman with progressive unclassifiable lung fibrosis underwent bilateral lung transplantation. Explanted lungs and hilar lymph nodes were sampled according to our institutional protocol, which includes multiple tissue blocks from all lobes (at least 3 per

lobe), vascular and bronchial margins, and complete hilar node dissection. Histological evaluation was supported by a immunohistochemical stainings. Clinical and radiological data were retrospectively reviewed in a multidisciplinary discussion.
Results: Gross examination of the explanted lungs and lymph nodes was unremarkable. Histology revealed metastatic involvement of multiple hilar lymph nodes and extensive architectural fibrotic remodelling with widespread lymphangitic infiltration of interlobular septa and peribronchial spaces by malignant epithelial cells. Immunohistochemistry (CK AE1/AE3+, GATA3+, ER+, PR+, HER2 2+) confirmed breast origin. Retrospective review of prior mammography revealed a previously uninvestigated suspicious lesion. The patient was subsequently diagnosed with metastatic breast cancer and treated with hormone therapy. Despite all efforts, the disease progressed, and she died 12 months post-transplantation.
Conclusion: This is the first reported case of bilateral lymphangitic breast cancer discovered incidentally in explant lungs. Neoplastic infiltration can be easily masked by pre-existing architectural distortion in end-stage fibrotic interstitial lung disease. Therefore, we highlight the critical role of a generous sampling and a thorough, standardized pathological evaluation in lung explants as well as a multidisciplinary discussion. Establishing shared protocols across transplant centres could improve early cancer detection and optimize long-term outcomes.

E-PS-23-048

A lung adenocarcinoma "collision tumour": two distinct driver mutations in histologically divergent regions

C. Guinard[1,2], M. Carter[1,2], M. Castonguay[1,2]
[1]Queen Elizabeth II Health Science Centre, Pathology and Laboratory Medicine, Halifax, Canada, [2]Dalhousie University, Pathology, Halifax, Canada

Background & Objectives: In 2024, 13% of cancers diagnosed in Canada and 23% of cancer-related deaths were due to lung cancers. There is a strong association with smoking and pulmonary carcinogenesis, and multiple oncogene mutations have been identified in lung cancers. In some cases, drugs can target specific oncogene mutations to improve patient outcomes or predict prognosis. The two main oncogenes mutated in lung cancers at our site in 2024 were EGFR (14%) and KRAS (41%). We report a case of a lung adenocarcinoma biopsy with two histologically distinct morphologies that also each showed unique oncogene mutations.
Methods: We used histology, immunohistochemistry, and Next-Generation Sequencing to diagnose and identify the mutations.
Results: The patient is a 67-year-old female with a 35-pack-year smoking history. A core biopsy of her right upper lobe tumour showed a lung adenocarcinoma with lepidic and invasive distinct components. Next-generation sequencing (NGS) identified two clinically significant mutations, including a EGFR exon 19 deletion and a KRAS G12C mutation. Repeat NGS of each individual component isolated the EGFR mutation to the lepidic region and the KRAS mutation to the invasive region. The copy number profiles of the two components were strikingly similar, suggesting a clonal relationship between the two components. These results therefore indicate a single tumour with two molecularly and histologically distinct clones arising from the same progenitor.
Conclusion: The molecular findings in this case are unique given there is a single tumour composed of two separate clones from the same progenitor. Activating KRAS and EGFR mutations are thought to be mutually exclusive due to synthetic lethality. The most likely explanation for their co-occurrence in this case is that the original tumour clone separately acquired KRAS and EGFR variants in distinct cell populations. The patient recently had a lobectomy, which may help shed additional light on the tumour's evolution.

E-PS-23-049

EGFR p.Glu709Lys mutation in lung adenocarcinoma – case report

L. Carvalho[1,2,3], A. Alarcão[1,2], A.F. Ladeirinha[1,2], M.R. Silva[1,2], T. Ferreira[1], M. Viseu[1], R. Silva[1], J. Pimentel[1,3], G. Fontinha[1,3], V. Almeida[1,3], V. Sousa[1,2,3]
[1]Institute of Anatomical and Molecular Pathology, Faculty of Medicine of the University of Coimbra, Coimbra, Portugal, [2]CIMAGO – Research Centre for Environment, Genetics and Oncobiology, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, [3]Pathology Service, ULS Coimbra, Coimbra, Portugal

Background & Objectives: Classic activating mutations (exon 19 deletion and exon 21 L858R) make up the vast majority of *EGFR* mutations and are well defined as strong predictors of good clinical response. However, low-frequency mutations still raise questions, because despite the increased use of more sensitive detection methods to identify rare *EGFR* mutations in patients, our understanding of the biology of these rare *EGFR* mutations is poor compared to classic mutations.
Methods: We present a case of a 72-year-old woman with an adenocarcinoma with acinar, lepidic, papillary and micropapillary patterns from the right upper and middle lobes. It were detected TP53 c.833C>A;p.(Pro278His); *EGFR* c.2573T>G;p.(Leu858Arg) and c.2125G>A;p.(Glu709Lys) known to be oncogenic in NSCLC. It was performed mutation research by next-generation sequencing (Genexus, Oncomine Precision Assay Panel, Thermo Fisher Platform). Manual macrodissection was performed and nucleic acid extraction was carried out with the MagMAX FFPE DNA/RNA Ultra Kit.
Results: The *EGFR* exon 18 E709K mutation occurs in the *EGFR* tyrosine kinase domain. This mutation has been found in patients with non-small cell lung cancer. Cell line experiments demonstrate that is an activating and transforming mutation, sensitizing to *EGFR* tyrosine kinase inhibitors (TKIs), gefitinib and erlotinib, with superior sensitivity to second-generation inhibitors such as afatinib and neratinib. Studies shown that patients with NSCLC harbouring the *EGFR* E709K mutation in combination with other TKI-sensitizing mutations derived clinical benefit from treatment with erlotinib or gefitinib.
Conclusion: Patients with *EGFR* E709K mutant non-small cell lung cancer (NSCLC) have tumours that typically carry a coincident *EGFR*-tyrosine kinase inhibitor (TKI)-sensitizing mutation such as L858R *or* G719X. The EGFR TKIs erlotinib, afatinib, and gefitinib are FDA and EMA approved for the treatment of patients with NSCLC harbouring specified EGFR sensitizing mutations including L858R and exon 19 deletions.

E-PS-23-050

Cytological diagnosis of paracoccidioidomycosis in pleural fluid

F. Mundim[1,2], B. Domingues[3], A.J. Resende[3], D. Martins[4], N. Mundim[5], P. Mundim[5]
[1]UNIFAL, Pathology, Alfenas, Brazil, [2]UNIVAS, Pathology, Pouso Alegre, Brazil, [3]UNIVAS, Pouso Alegre, Brazil, [4]UNIVAS, Pulmonology, Pouso Alegre, Brazil, [5]UNIFENAS, Alfenas, Brazil

Background & Objectives: Paracoccidioides brasiliensis is a dimorphic fungus and the causative agent of paracoccidioidomycosis, an infectious disease also known as South American blastomycosis. This report highlights its diagnosis in pleural fluid cytology.
Methods: A 60-year-old female patient presented to the emergency department reporting chest pain. For two weeks, she had been experiencing flu-like symptoms, which progressed to a persistent dry cough, ventilatory-dependent pain in the left costal region, and dyspnea. She reported a fever lasting approximately three days and denied purulent expectoration, but reported decreased urine output (oliguria).

Results: The hospitalized patient initially received treatment with Koide D and Dipyrone. However, the patient's condition did not improve, and she began to experience pain in the left hemithorax. Subsequently, Amoxicillin and Clavulanate were prescribed. After seeking care at another hospital, Clarithromycin, Atrovent inhalations, and another course of corticosteroids were added to her treatment regimen. Despite these interventions, there was no improvement, and she returned to the hospital in Brazil, where she was hospitalized. A chest CT scan revealed consolidation with left-sided hydrothorax. Pleural aspiration was performed. Cytological analysis of the pleural fluid revealed blood components with frequent neutrophils, lymphocytes, and histiocytes, some of which were multinucleated. Round structures with birefringent membranes, consistent with Paracoccidioides brasiliensis, were also observed, along with mesothelial cells with homogeneous nuclei and cytoplasm.
Conclusion: Diagnosing paracoccidioidomycosis through pleural fluid cytology presents a significant challenge due to the rarity and complexity of identifying Paracoccidioides brasiliensis. This case underscores the importance of meticulous cytological evaluation, particularly in patients who do not respond to conventional treatments for respiratory symptoms. Accurate identification of the fungus is crucial for effective clinical management, highlighting the value of cytology as a vital, though sometimes underutilized, diagnostic tool in complex clinical scenarios.

E-PS-23-051
Regulators of actin cytoskeleton LIMK1 and SSH1 are implcated in human lung adenocarcinoma
V. Bravou[1,2], C. Geramoutsou[1], V. Tzimogianni[3], P. Bosgana[1,4], Z. Lygerou[3], V. Tzelepi[2], S. Nikou[1]
[1]Medical School, University of Patras, Department of Anatomy-Histology-Embryology, Patras, Greece, [2]Medical School, University of Patras, Department of Pathology, Patras, Greece, [3]University of Patras, Medical School, Department of General Biology, Patras, Greece, [4]Agios Andreas General Hospital of Patras, Department of Pathology, Patras, Greece

Background & Objectives: Cofilin phospho-regulation, which is mediated by LIM kinases (LIMKs) and Slingshot phosphatases (SSH), is important for actin filament turnover, cancer cell invasion and metastasis. However, little is known regarding the role of actin cytoskeleton regulators in human lung adenocarcinoma (LUADC). In this study, we aimed to assess expression and significance of LIMK1 and SSH1 in human LUADC.
Methods: Expression of LIMK1 and SSH1 was evaluated by immunohistochemistry in 105 human LUADC samples in relation to clinicopathologic parameters (grade, pTNM, lymph node metastasis). Correlation with epithelial-mesenchymal transition (EMT) markers E-cadherin and ZEB (data available from previous studies in the same cohort) was also assessed. In addition, cell proliferation of human lung cancer cell lines was examined by MTT assay upon pharmacologic inhibition of SSH1.
Results: We here show that LIMK1 and SSH1 are expressed in 95/97 (98%) and 105/105 (100%) cases of human LUADC. Immunostaining for LIMK1 and SSH1 in lung cancer cells is mainly cytoplasmic with mean H-scores 111.9±6.6 and 156.6 ±6.5 respectively. Statistical analysis showed no significant association with tumour progression parameters although there is a trend towards significant correlation of SSH1 with lymph node metastasis ($p=0.06$). Expression of SSH1 is also significantly correlated with EMT marker ZEB ($r=0.445$, $p<0.001$). Inhibition of SSH1 by sennoside inhibits A549 lung cancer cell proliferation.
Conclusion: Our results suggest that overexpression of F-actin regulator SSH1 is implicated in the pathogenesis of lung adenocarcinoma representing a promising tumour biomarker and therapeutic target in the disease.

E-PS-23-055
Pulmonary squamous cell carcinoma with a predominant lepidic growth pattern mimicking metastasis: a case report and review of the literature
A. Erbağci[1], A. Toksöz Yıldırım[2]
[1]Goztepe Prof. Dr. Suleyman Yalcin City Hospital, Istanbul Medeniyet University, Pathology, Istanbul, Turkey, [2]Istanbul Medeniyet University, Pathology, Istanbul, Turkey

Background & Objectives: Lepidic growth is classically associated with lung adenocarcinoma and is exceedingly rare in squamous cell carcinoma (SCC). To date, only **12 cases** of pulmonary SCC with a lepidic growth pattern have been reported in the literature. This unusual morphology can lead to diagnostic confusion, particularly in patients with a history of malignancy. We present a rare case of pulmonary SCC with a predominant lepidic growth pattern initially suspected to be metastatic urothelial carcinoma.
Methods: A 77-year-old male with a prior diagnosis of T2 high-grade urothelial carcinoma underwent PET imaging during follow-up, which revealed a 1.5 cm hypermetabolic nodule in the left lower lobe of the lung. Wedge resection was performed for diagnosis and treatment. Histopathologic and immunohistochemical analysis was conducted to determine the origin and nature of the tumour.
Results: Histologic evaluation showed a tumour with an 85% lepidic growth pattern and a 15% poorly differentiated invasive squamous component. Tumour cells were positive for p63, p40, and CK 5/6 and negative for CK-7, TTF-1, Napsin-A, and Uroplakin II. No lymphovascular or perineural invasion was identified. Based on morphology and immunoprofile, a diagnosis of primary pulmonary SCC with a lepidic growth pattern was made. The tumour was staged as pT1b. The patient was alive and free of disease at 6-month follow-up.
Conclusion: Pulmonary SCC with a lepidic growth pattern is an **extremely rare variant**, with only 12 reported cases in the literature. It may closely mimic adenocarcinoma or metastatic disease, especially in patients with known malignancies. Accurate recognition and classification of this pattern are crucial to avoid diagnostic errors and to guide appropriate management. Our case supports the inclusion of lepidic components in the pathological staging system for pulmonary SCC, similar to adenocarcinoma.

Axillary presentation of CIC-rearranged sarcoma: a diagnostic conundrum in soft tissue pathology
A. Walczak[1], J. Kubacki[1]
[1]Lower Silesian Oncology Centre, Department of Pathology, Wrocław, Poland

Background & Objectives: CIC-rearranged sarcoma (CIC-DUX4 fusion-positive sarcoma) is a rare, aggressive undifferentiated round cell tumour mimicking Ewing sarcoma. It typically occurs in young adults in deep soft tissue; lymph node or unusual site involvement is uncommon. We report a case of a healthy 57-year-old woman with an axillary mass, highlighting the diagnostic challenges of this tumour.
Methods: Clinical examination and imaging studies (MRI, Mammography and PET scan) were performed, followed by biopsies of the breast and axilla. Histopathological evaluation with H&E staining and an immunohistochemical panel was undertaken. FISH assessed SS18 and EWSR1 rearrangements, while targeted NGS detected gene fusions, confirming the diagnosis.

Results: Mammography revealed enlarged left axillary nodes (up to 6.5 cm) suggesting breast malignancy. Biopsy of a contralateral BIRADS3 breast lesion was benign, while core biopsy of the axillary mass showed an undifferentiated malignant small round cell neoplasm. The tumour was highly cellular with scant stroma, delicate "chicken-wire" vasculature, focal necrosis, and brisk mitotic activity (17/1.73 mm², including atypical mitoses). Differential diagnoses included lymphoma and perivascular epithelioid cell tumour (PEComa). However, the immunoprofile (WT1, BCL-2, cyclin D1, CD99, vimentin, TLE1 positive; negative for epithelial, melanocytic, and myogenic markers) supported a non-epithelial malignancy. FISH excluded SS18 and EWSR1 rearrangements, ruling out synovial and Ewing sarcoma; NGS detected a CIC-DUX4 fusion, establishing the diagnosis.
Conclusion: This case underscores the need to consider CIC-rearranged sarcoma in axillary masses with undifferentiated round cell morphology. Its unusual topography adds diagnostic challenge, as seen in similar reports. Molecular techniques, especially FISH and NGS, are essential for confirmation. Early, accurate identification is crucial to guide appropriate therapy in this aggressive malignancy.

E-PS-24-002
PEComa of the gastrointestinal tract: a case report in this exceedingly rare location
M. Arias[1], M.N. Villca Huayta[1], M.L. Fernández Vázquez[2], L. González Bayón[2], A.I. Poza Garcia[3], E.M. Pena Burgos[1]
[1]Hospital General Universitario Gregorio Marañón, Pathology, Madrid, Spain, [2]Hospital General Universitario Gregorio Marañón, General Surgery, Madrid, Spain, [3]Hospital General Universitario Gregorio Marañón, Radiology, Madrid, Spain

Background & Objectives: Perivascular epithelioid cell tumours (PEComas) are a family of mesenchymal tumours with a wide morphological variety that exhibit melanocytic and smooth muscle differentiation. They present a broad differential diagnosis. They can anise in any location, but less than 60 cases of gastrointestinal tract (GIT) have been reported.
Methods: A 52-year-old female patient with a prior history of low-grade uterine leiomyosarcoma surgically treated in 2012 was admitted at the hospital due to intestinal obstruction. A 9 cm mass occupying up to 70% of the ileum lumen was described in radiological studies. A surgical resection was performed.
Results: The tumour was composed of a densely cellular proliferation with a multinodular growth pattern. It was originated form the muscularis propria. The cells were large, with ample, clear and granular cytoplasm, round nuclei, and occasionally prominent nucleoli. The cells showed no significant atypia or pleomorphism. Seven mitoses were seen in 50 high-power fields. No evidence of lymphovascular or perineural invasion was found. No lymph node metastases were detected. The cells were positive for desmin, smooth muscle actin, calponin, caldesmon, HMB45, S100 protein and hormonal receptors. Cytokeratins, CD34, DOG1, MDM-2, MelanA and myogenin were negative. Ki-67 was 5%. Molecular studies (next generation sequencing) were negative.
Conclusion: PEComas exceptionally arise in GIT. The most frequent location within the GIT is the colon, and they usually present epithelioid morphology. The biological risk of GIT PEComas is assessed using the criteria established by Doyle et al. in 2013. They may develop an indolent or an aggressive course. Considering its morphological and immunohistochemical wide spectrum, this entity should be included in the differential diagnosis of mesenchymal tumours in the GIT.

E-PS-24-003
Histopathological and clinical evaluation of pleomorphic soft tissue sarcomas: a case series
F. Korkmaz Aydın[1], C. Comunoglu[1], O. Yalcin[1], R. Tanritanir[1]
[1]TC Saglik Bilimleri University Prof. Dr. Cemil Tascioglu City Hospital, Pathology, Istanbul, Turkey

Background & Objectives: Pleomorphic soft tissue sarcomas are highly malignant mesenchymal tumours with heterogeneous histogenesis, characterized by marked cellular pleomorphism, atypia, and high mitotic activity. Pleomorphism refers to significant variations in tumour cell size, shape, and nuclear morphology, which are associated with aggressive biological behaviour.
Methods: This study retrospectively analysed 47 patients (23 females, 24 males) diagnosed between 2016 and 2025, with a mean age of 50–61 years. The aim was to assess the histopathological features of the most common pleomorphic soft tissue sarcoma subtypes and correlate them with clinical findings.
Results: The cases included 14 undifferentiated pleomorphic sarcomas (UPS), 22 dedifferentiated liposarcomas (DDLPS), 5 malignant peripheral nerve sheath tumours (MPNST), 3 pleomorphic liposarcomas (PLPS), and 3 pleomorphic leiomyosarcomas (PLMS). Mean tumour sizes were 12.5 cm (UPS), 21 cm (DDLPS), 6 cm (MPNST), 13 cm (PLPS), and 10 cm (PLMS). The mean mitotic rate was 12/mm² in UPS, 6/mm² in MPNST and PLPS, and 31/mm² in PLMS. The mean necrosis rate was 20–25% in UPS, <50% in MPNST and PLPS, and 30% in PLMS. The Ki-67 proliferation index was 60% in UPS, 55% in PLMS, 25% in DDLPS, and 30% in PLPS. In 19 cases of dedifferentiated liposarcoma, the mean mitotic count was determined to be 4–5/mm². Necrosis was present in 13 cases, while it was absent in 6 cases. All cases were high-grade. One DDLPS case exhibited rhabdomyoblastic differentiation. Twenty one additional cases displayed undifferentiated non-lipogenic pleomorphic sarcoma morphology. Pleomorphic liposarcomas featured pleomorphic lipoblasts, while PLMS exhibited pleomorphic spindle cells in fascicular arrangements.
Conclusion: Pleomorphic soft tissue sarcomas constitute a heterogeneous group of high-grade tumours that can reach large sizes, exhibit high mitotic activity, and display diverse morphological features.

E-PS-24-004
Osteofibrous dysplasia, osteofibrous dysplasia like adamantinoma and adamantinoma: a small case series including tumours with late recurrences
N.E. Kore[1], C. Comunoglu[1], O. Yalcin[1], R. Tanritanir[1], B. Doğan[2]
[1]TC Saglik Bilimleri University Prof. Dr. Cemil Tascioglu City Hospital, Pathology, Istanbul, Turkey, [2]Metin Sabanci Baltalimani Bone Diseases Training and Research Hospital, Orthopedic, Istanbul, Turkey

Background & Objectives: Osteofibrous dysplasia (OFD) is a benign fibro-osseous tumour of the anterior cortex of the tibia and/or fibula. OFD-like adamantinoma (AD), contains small nests of epithelial cells with fibroosseous stroma. AD is a locally aggressive or malignant tumour that has epithelial cells within the osteofibrous component. In recent years, the clinical course of OFD and OFD-like AD has been debated for their similarities.
Methods: We evaluated 4 cases of OFD-like AD, 2 cases of AD, and 1 case of OFD diagnosed in our laboratory between 2015 and 2025, in terms of histopathological, immunohistochemical and clinical findings.
Results: The median age was 26 years (range: 8–68). The most common gender was female, and the most frequent location was the diaphysis of the left tibia. Recurrence was observed in 2 patients, after 8 and 9 years, respectively. One of these was OFD-like AD, the other AD. The core biopsy of the recurrent OFD-like AD showed only OFD areas. The number of nested epithelial cells stained with keratin in OFD-like AD ranged from 1 to 10. All tumours were treated by wide resection. Additionally, in one patient with AD and one with OFD-like AD, cement was also used. Recurrence occurred in

the OFD-like AD patient. In three patients with OFD-like AD, liquid nitrogen application and bone recycling were performed. One patient with classic AD treated by resection alone had recurrence. This tumour exhibited an Ewing-like pattern but did not contain EWSR1 rearrangement.
Conclusion: OFD, OFD- like AD and AD are tumours showing similar morphological findings and a predilection to cortex of the tibia. Although they do not show an aggressive clinical behaviour we have observed late recurrences in AD patients.

E-PS-24-005
A rare case of sinonasal primary aneurysmal bone cyst in a paediatric patient
J. Noury Rad Davaji[1], E.B. Kutsal[1], C. Meço[2], H. Başak[2], S. Kaynak Şahap[3], G. Kaygusuz[1]
[1]Ankara University Faculty of Medicine, Department of Pathology, Ankara, Turkey, [2]Ankara University Faculty of Medicine, Otorhinolaryngology, Ankara, Turkey, [3]Ankara University Faculty of Medicine, Paediatric Radiology, Ankara, Turkey

Background & Objectives: Aneurysmal bone cysts (ABCs) are benign lesions characterized by multiloculated blood-filled cystic spaces, fluid-fluid levels and well defined, lytic, expansile lesions on imaging. It has a broad skeletal distribution but primarily it is seen in metaphysis of long bones and vertebrae. Occurrence in the head and neck region, particularly in the paranasal sinuses, is exceedingly rare.
Methods: We present a case of an 8-year-old female with a history of Burkitt lymphoma diagnosed in 2020, with the maxillary sinus as the primary site of involvement. After her treatment, she presented with nasal congestion, snoring, and sleeping with her mouth open in December 2024, 4 years after initial diagnosis.
Results: CT scan revealed an expansile mass in the sinonasal cavity, which shows fluid-fluid levels and causes destruction in lamina papyracea. FESS was performed. Histopathological analysis revealed a giant cell-rich mesenchymal lesion containing cystic and solid areas with spindle cells in storiform fashion and blue-bone formation.
Conclusion: FISH study demonstrated USP6 gene rearrangement and confirmed the diagnosis of primary ABC. This case underscores the importance of considering ABC in the differential diagnosis of paediatric patients presenting with sinonasal masses, especially those with a history of malignancy, to ensure timely and appropriate management.

E-PS-24-006
Aggressive angiomyxoma of the vulva: a case report
C. So[1], R. Arias[1]
[1]Zamboanga City Medical Centre, Department of Pathology and Laboratory Medicine, Zamboanga City, Philippines

Background & Objectives: Aggressive Angiomyxoma of the vulva is a rare, locally invasive mesenchymal tumour that has a strong predominance amongst middle-aged women. Majority of the cases of this neoplasm are only discovered through case reports due to its rarity. Due to its propensity to increasingly grow in size, it may cause the patient and clinicians to be alarmed of its potential threat to the patient's quality of life. This is a case of a 50 year old female who came in with a 10 year history of gradually-enlarging vulvar mass. On physical examination, there is a noted fleshy, foul-smelling, nodulo-cystic mass hanging at the right labia approximately measuring 22 x 14 x 12 cm. The objective of this study is to understand the histopathologic nature of the identified mass.
Methods: Microsections of the mass show a myxoid, hypocellular stroma with spindle to stellate shaped cells with fine cytoplasmic processes, very mild nuclear atypia, numerous varisized vessels and extravasated red blood cells. To further support the diagnosis of aggressive angiomyxoma, immunohistochemistry studies were recommended.
Results: Further testing revealed a strong, diffuse positivity for SMA and desmin. There is weak, patchy positivity for ER and negative for PgR and CD34. Thus, a definite diagnosis of aggressive angiomyxoma was established. Tahere is no consensus regarding the pathogenesis of adgressive angiomyxoma. This hormonally responsive tumour is believed to arise from specialized mesenchymal cells of the pelvic–perineal region or multipotent perivascular progenitor cells, which often display variable myofibroblastic and fibroblastic features.
Conclusion: Despite of its rarity, Aggressive Angiomyxoma of the vulva should still be considered as one of the differential diagnoses for any painless swelling in the genitofemoral area. Patient education is vital most especially regarding the term "aggressive" which may be misunderstood for its malignant nature where in fact it actually denotes high risk for local recurrence.

E-PS-24-007
Deceptively pleomorphic, biologically indolent: a case of superficial CD34-positive fibroblastic tumour
B. Bekiroglu Ozcan[1], A. Yucesan[2], A.K. Ganiyusufoglu[3], N. Erdogan[1], A.K. Kolik[1]
[1]Basaksehir Cam and Sakura City Hospital, Department of Pathology, Istanbul, Turkey, [2]Basaksehir Cam and Sakura City Hospital, Department of Orthopaedics and Traumatology, Istanbul, Turkey, [3]Basaksehir Cam and Sakura City Hospital, Department of Radiology, Istanbul, Turkey

Background & Objectives: Superficial CD34-positive fibroblastic tumour (SCD34FT) is an uncommon mesenchymal neoplasm first described in 2014. It is characterized by pronounced nuclear pleomorphism, low mitotic activity, diffuse CD34 positivity, and focal cytokeratin expression. Despite its sarcoma-like morphology, most cases follow an indolent clinical course with minimal metastatic potential. Over 150 cases have since been reported, improving the understanding of its clinicopathological features. Here, we present a new case to further expand the literature and diagnostic familiarity with this rare entity.
Methods: Clinical, radiological, and pathological evaluations were performed to reach diagnosis.
Results: A 48-year-old male patient presented with a slowly enlarging, painless subcutaneous mass in the left gluteal region, present for approximately ten years. The medical history included partial nephrectomy 13 years earlier, with no other comorbidities or medications.
MRI revealed a well-defined, subcutaneous mass measuring 6.5 cm, showing T2-hyperintense and T1-hypointense signals. The lesion compressed but did not invade the gluteus maximus and extended toward the dermis.
Tru-cut biopsy showed a spindle cell neoplasm of intermediate cellularity with pleomorphism, eosinophilic cytoplasm, pseudo-inclusions, and rare vacuoles. CD34 was diffusely positive;
cytokeratin AE1/AE3 showed focal weak staining. INI1 and H3K27me3 were retained. Findings were suggestive of SCD34FT, but limited sampling precluded definitive diagnosis.
The excised mass measured $6.2 \times 3.7 \times 3.3$ cm and was located 0.4 cm below the skin. Grossly, it appeared soft and heterogeneous. Histology confirmed biopsy findings and showed more extensive pleomorphism, xanthomatous change, and hemosiderin. Mitoses were rare, necrosis absent. CD34 remained positive; cytokeratins (AE1/AE3, OSKAR) were focally positive. Other markers were negative. Ki-67 was 4%.
Integration of clinical, radiological, morphological, and immunohistochemical findings confirmed the diagnosis. The patient remains disease-free without adjuvant therapy.
Conclusion: SCD34FT is a rare, low-grade neoplasm with deceptive morphology. Accurate recognition is essential to avoid overtreatment.

Correlating clinical, histological, and immunohistochemical findings is key to avoiding misdiagnosis.

E-PS-24-008

A rare tumour of soft tissue: Angiomatoid Fibrous Histiocytoma

S.N. Sayır[1], G. Kaygusuz[1], S. Yüksel[1]
[1]Ankara University School of Medicine, Department of Pathology, Ankara, Turkey

Background & Objectives: Angiomatoid fibrous histiocytoma (AFH) is a rare soft tissue tumour of intermediate malignant potential, often seen in children and young adults, and typically arising in superficial extremities. It usually presents as a slow-growing, well-circumscribed mass with prominent haemorrhage and cystic change.
Methods: A 6-year-old male presented with a progressively enlarging subcutaneous mass in the right forearm. Microscopically, the tumour was located in the subcutaneous tissue and displayed extensive haemorrhagic/cystic regions, numerous vascular spaces, and a fibrous capsule with pigment-laden fibrohistocytic cells. Tumour nests were composed of spindle to polygonal cells with moderate, oval nuclei, abundant eosinophilic cytoplasm and inconspicuous nucleoli, showing 13 mitoses/ 10 HPFs. A marked lymphoid infiltrate, sometimes with germinal centres, was noted, along with metastatic focus in one nearby lymph node.
Results: Immunohistochemically, the tumour cells were diffusely positive for Desmin and CD99, with multifocal positivity for EMA and ALK. Ki67 proliferation index was 10–15%. EWSR1 gene rearrangement was obtained by FISH, supporting the diagnosis of AFH.
Conclusion: AFH has intermediate malignant potential with the capacity to recur or metastasize. Diagnosis can be challenging due to non-specific clinical, histological and immunohistochemical features compounded by rarity of this tumour. Wide surgical excision is essential, and thorough clinicoradiologic and pathologic correlation, including molecular testing for EWSR1, is critical. Prognosis can be favourable but long-term follow-up is mandatory, especially in paediatric cases. Consequently clinical observation is advised to detect possible recurrence or further spread.

E-PS-24-009

Lymphomas primarily diagnosed on bone biopsy: a tertiary centre's perspective over the last five years

A. Alves[1], S. Petronilho[1], R. Pina[1], A. Lai[1]
[1]ULS Coimbra, Coimbra, Portugal

Background & Objectives: The diagnosis of lymphoma can be preceded by various symptoms and signs depending, in part, on the primary lesion's location. Lymphomas primarily diagnosed in bone biopsies are sparse in the literature. In the absence of specific symptoms or signs, their identification can be challenging, often leading to delayed diagnosis due to a lack of clinical suspicion of hematolymphoid origin.
Methods: We collected all cases of lymphomas diagnosed in bone biopsies from 2020 to 2024 in ULS-Coimbra. Cases with prior lymphoma diagnosis were excluded.
Results: We identified six cases of lymphomas primarily diagnosed in bone biopsies. Most patients were female (5/6), with a median age of 65 years (range: 33–83). All presented with bone pain, mainly involving the iliac bone. Imaging studies showed lithic lesions, raising the diagnosis of metastasis/primary bone tumour. Flow cytometry analysis in the original biopsy was performed in only one case, as clinical suspicion of lymphoma was lacking in the remaining cases. A diagnosis of diffuse large B-cell lymphomas was retained in all cases, including both germinal centre and non-germinal centre subtypes, as well as one case with *MYC* and *BCL2* rearrangements.
All patients were Ann Arbor stage IVA or IVB at diagnosis. Five underwent R-CHOP treatment: four achieved a complete metabolic response after 6 cycles, being currently alive, with no evidence of disease, and one is still under treatment, presently with a partial response. The oldest patient was treated with 6 cycles of R-mini-CHOP, achieving a partial response.
Conclusion: Our findings highlight that lymphomas primarily diagnosed in bone biopsies are uncommon, with most patients presenting with non-specific findings and no prior clinical suspicion. We emphasize the importance of considering lymphoma in the differential diagnosis of bone lesions, even in clinically and radiologically improbable scenarios, as this leads to an accurate diagnosis and optimal patient management.

E-PS-24-010

Dedifferentiated soft tissue and bone neoplasms: a case series

G. Öztürk[1], C. Çomunoğlu[1]
[1]SBU Istanbul Prof. Dr. Cemil Taşcıoğlu City Hospital, Pathology, Istanbul, Turkey

Background & Objectives: Dedifferentiation is observed in a subset of mesenchymal neoplasms and generally signifies the emergence of a high-grade tumour that lacks differentiation characteristics of the original neoplasm. This phenomenon can occur de novo or within a recurrent, previously well-differentiated tumour, contributing to a more aggressive clinical course. Histopathologically, a distinct boundary is typically observed between the well-differentiated and dedifferentiated components.
Methods: A retrospective analysis was conducted on patients diagnosed in our clinic between 2016 and 2025. Tumours identified with 'dedifferentiated liposarcoma (DDL)', 'dedifferentiated chondrosarcoma (DCSA)' and 'dedifferentiated solitary fibrous tumour (DSFT)' were retrieved from our clinical archives for further evaluation.
Results: A total of 27 patients met the inclusion criteria, including 22 with DDL, 4 with DCSA, and 1 with DSFT. Among the 22 DDL patients, 14 were male and 8 were female. The average tumour size was 21.3 cm, and the mean mitotic count was 4-5/mm². Necrosis was present in 13 patients. DDL predominantly affected middle-aged adults, with a mean age of 60 years, and the retroperitoneum was the most common site of origin. Among the four DCSA cases, 3 were male and one was female, with a mean age of 54 years. Two of these tumours were located in the femur and two in the pelvis. Our DSFT patient was male, 65 years old, and had a tumour located in the inguinal region.
Conclusion: Dedifferentiated soft tissue and bone neoplasms constitute a morphologically and histologically heterogeneous group. Their aggressive clinical behaviour and diagnostic complexity, due to significant histologic and immunophenotypic overlap, necessitate an integrative diagnostic approach. A multidisciplinary evaluation incorporating clinical, histopathologic, immunophenotypic, and molecular characteristics is crucial for accurate diagnosis and optimal patient management.

E-PS-24-011

Incidental presacral myelolipoma in a patient with prostate carcinoma: a case report

A.N. Dalli Tunce[1], P. Engin Zerk[2]
[1]Istanbul Medeniyet University Goztepe Prof. Dr. Suleyman Yalcin City Hospital, Department of Pathology, Istanbul, Turkey, [2]National Cancer Institute, National Institutes of Health, Laboratory of Pathology, Bethesda, USA

Background & Objectives: Presacral myelolipoma is a rare, benign extra-adrenal tumour composed of mature adipose tissue and hematopoietic elements. It is usually asymptomatic and discovered incidentally during imaging. Due to its rarity and radiological similarity to other fat-containing lesions, such as liposarcoma or teratoma, histopathological evaluation is essential for accurate diagnosis. This study

aims to present a case of presacral myelolipoma and highlight its diagnostic features and clinical relevance.
Methods: A 72-year-old male with a history of prostate carcinoma underwent pelvic MRI, which revealed a 53×35 mm fat-containing lesion in the presacral space, suggestive of a lipomatous neoplasm. The case was referred as a pathology consultation. Haematoxylin and eosin-stained sections were reviewed. Additional immunohistochemical staining for S100 was performed to confirm adipocytic components. The findings were assessed in line with WHO criteria for soft tissue tumours.
Results: Histological examination showed a well-demarcated lesion composed of mature adipose tissue and trilineage hematopoietic cells, including myeloid, erythroid, and megakaryocytic elements. No cytologic atypia, necrosis, or mitotic activity was observed. The S100 stain confirmed adipocytic differentiation. These findings supported the diagnosis of presacral myelolipoma, a benign tumour requiring no further treatment in the absence of symptoms or growth.
Conclusion: Presacral myelolipoma is a rare but benign lesion that may mimic malignant fat-containing tumours on imaging. Accurate diagnosis relies on histopathological examination, supported by immunohistochemical studies such as S100. Recognition of this entity is important to prevent overtreatment, particularly in patients with an existing oncologic history. In this case, the combination of imaging features and confirmatory pathology allowed for a confident diagnosis and conservative clinical management.

E-PS-24-012
Morphology speaks louder than fusions: a fusion-negative mixed tumour in the scalp diagnosed by classic histopathological approach
M.A. Aydogdu[1], Ş. Dikici[2], N. Erdoğan[1], A.K. Kolik[1]
[1]Basaksehir Cam ve Sakura City Hospital, Department of Pathology, Istanbul, Turkey, [2]Basaksehir Cam ve Sakura City Hospital, Department of Neurosurgery, Istanbul, Turkey

Background & Objectives: Myoepithelial tumours of soft tissue are rare neoplasms that morphologically and immunophenotypically resemble their salivary gland counterparts. The benign end of the spectrum includes myoepithelioma and mixed tumour, the latter defined by the presence of ductal differentiation. Although recurrent gene fusions involving EWSR1 and PLAG1 have been reported in a subset of these tumours, not all cases display identifiable molecular alterations. We present a well-characterized case of a fusion-negative soft tissue mixed tumour with classical histomorphological and immunohistochemical features, underlining the diagnostic power of conventional morphology and the spectrum of presentations within this entity.
Methods: Clinical, histopathological, and immunohistochemical evaluations were performed.
Results: A 48-year-old female presented with a slow-growing, pruritic subcutaneous mass in the left frontal scalp. Examination revealed a firm lesion near the hairline, which was excised under local anesthesia with a preoperative diagnosis of sebaceous cyst.
Grossly, the mass measured $1.2 \times 0.7 \times 0.7$ cm and appeared solid and tan-white. Histologically, it was composed of epithelioid cells with clear, vacuolated cytoplasm arranged in nests within a predominantly chondromyxoid stroma. Micronodular areas within hyalinized stroma and focal ductal differentiation were evident.
Immunohistochemistry showed diffuse positivity for cytokeratin AE1/AE3, S100, and PLAG1. EMA was focally positive. GFAP, brachyury, calponin, and p63 were negative. INI1 expression was retained. Ki-67 proliferation index was approximately 2%. Archer FusionPlex assay revealed no detectable gene fusion.
Diffuse PLAG1 positivity supported the diagnosis of mixed tumour despite the lack of molecular confirmation. The immunoprofile and negative GFAP and brachyury expression excluded morphologically similar entities such as parachordoma. No recurrence was observed during six months of follow-up.
Conclusion: This case emphasizes that even in the absence of detectable genetic alterations, a confident diagnosis of mixed tumour can be established through integrated morphological and immunohistochemical evaluation. Molecular findings may be supportive, but are not essential when classical features are present.

E-PS-24-014
When glomus tumours appear in unexpected places: a report of two rare cases
R. Yaiche[1], R. Ayadi[1], S. Jedda[1], Y. Barbirou[1], E. Braham[1], O. Ismail[1], N. Ben Jamaa[1], A. Ayadi[1]
[1]Abderrahmane Mami Hospital, Pathology, Ariana, Tunisia

Background & Objectives: Glomus tumours are rare, usually benign vascular neoplasms. They typically occur in the subungual area of the fingertips. Their occurrence in atypical locations is as unusual as their malignant transformation. The present report describes two cases of glomus tumours in two unusual locations: the trachea and the sternal manubrium.
Methods: This study presents two rare cases of glomus tumours located at unusual sites: the endotracheal region and the sternal manubrium. The cases were identified through pathological reports from Abderrahmane Mami Hospital in Tunisia, between 2005 and 2024. Diagnosis was confirmed by histopathological examination and immunohistochemical analysis.
Results: The first case involves a 74-year-old male who presented with chronic cough and dyspnea. Bronchoscopy revealed a polypoid mass on the tracheal wall. Computed tomography (CT) showed an intra-luminal obstructive tracheal mass, measuring 30x20mm. Surgical resection was performed. Histological findings revealed a proliferation of oval-shaped glomus cells, arranged in clusters or sheets, surrounding blood vessels. The diagnosis of malignancy was based on high mitotic index (> 5 mitosis/10 HPF), deep location, and tumour size over 2cm. The second case si of a 52-year-old female with a palpable mass at the anterior chest. CT scans revealed a well-circumscribed mass in the manubrium, which was excised. Histopathology concluded to a benign glomus tumour. Immunohistochemical study showed in both cases a positive staining for smooth muscle actin and H-caldesmon, without expression of cytokeratin, CD34, S100 and neuroendocrine markers. Surgical outcomes were successful in both cases, with the first patient requiring ongoing monitoring for potential recurrence due to the malignant nature of the tumour.
Conclusion: Glomus tumours are rare and can arise in unusual locations. While the case of malignant transformation in the trachea emphasizes their potential aggressiveness, the second case highlights their usually benign nature. Therefore, awareness of these rare presentations is essential for accurate diagnosis and proper management.

E-PS-24-015
Clinicopathological analysis of solitary fibrous tumour patients: a single-centre study
H.İ. Saribiyik[1], A.H. Üstündağ[2], G. Esendagli[1]
[1]Gazi University Faculty of Medicine, Pathology, Ankara, Turkey, [2]Gazi University Faculty of Dentistry, Department of Oral Pathology, Ankara, Turkey

Background & Objectives: Solitary fibrous tumour (SFT) is a rare mesenchymal neoplasm that can exhibit diverse biological behaviour. Identifying prognostic factors is crucial for risk stratification and clinical management. This study aims to evaluate the relationship between tumour necrosis, mitotic activity, tumour size, gender, recurrence and metastasis in patients diagnosed with SFT.

Methods: We retrospectively analysed 83 SFT patients with documented data on tumour size, mitotic count, necrosis, grade, recurrence, metastasis and survival. Statistical correlations were assessed between pathological features and clinical outcomes. All cases re-evaluated by two pathologists.
Results: The mean age was 54.9 years (16-77). Gender and location differences were analysed, but no statistically significant impact on prognosis was observed. Among the patients, 20% developed recurrence, and 8.7% experienced metastasis. The presence of necrosis increased the risk of metastasis by 6.2 times (p-value: 0.008). Mitotic count was found to be one of the strongest predictive indicators of recurrence ($p < 0.001$) and metastasis ($p = 0.003$). Tumours over 15 cm alone carry a 40% risk of metastasis ($p = 0.026$). The four-variable model showed that high-risk patients had the highest recurrence rate (31.3%). The three-variable model also indicated high recurrence risk, but less prominently than the four-variable model. In terms of metastasis, the three-variable model showed that high-grade patients had a higher risk ($p = 0.09$). The four-variable model indicated that both intermediate and high- risk groups were at increased risk of metastasis, though not as distinctly as the three-variable model.
Conclusion: Mitotic activity, tumour necrosis and size appear to be key prognostic indicators in SFT. These findings highlight the importance of comprehensive histopathological evaluation in predicting patient outcomes and follow-up. Further large-scale studies are needed to validate these results and refine risk assessment strategies for SFT patients.

E-PS-24-016
Solitary fibrous tumour of the vena cava-case report: morphological and immunohistochemical insights
J. Stefanovic[1], L. Simic[1], J. Sopta[1], M. Zivotic[1], S. Radojevic-Skodric[1], G. Nikolic[1]
[1]Institute of Pathology Faculty of Medicine, Belgrade, Serbia

Background & Objectives: Intravascular solitary tumours of the vena cava are rare and often present diagnostic and therapeutic challenges. These tumours may be primary or represent intravascular extensions of adjacent neoplasms, most commonly of renal or adrenal origin. However, solitary growth confined to the vena cava without an identifiable primary source is exceedingly uncommon.
Methods: We present the case of a 57-year-old female patient with an intravascular solitary tumour localized within the inferior vena cava, discovered during physical examination due to abnormal swelling of the lower extremities. The lesion was well-defined, non-obstructive, and showed no continuity with surrounding organs. Imaging studies were followed by surgical resection and histopathological evaluation.
Results: Histological examination revealed tumour tissue composed of hypercellular areas consisting of medium-sized oval to spindle-shaped cells with scant, light eosinophilic cytoplasm and round to oval nuclei, exhibiting mild atypia within a myxoid matrix. Focal angiocentric growth was noted. Less cellular regions were characterized by strands and sheets of tumour cells embedded in a collagenized stroma. Mitotic activity was low, with 1 mitosis per 10 high-power fields (HPF). Blood vessels were moderately numerous, thin-walled, and displayed slit-like, irregular lumina, reminiscent of a "hemangiopericytoma-like" vascular pattern. No necrosis was observed. Immunohistochemically, the tumour was negative for cytokeratin AE1/AE3. Diffuse and strong positivity was noted for vimentin, STAT6, CD34, CD99, and BCL2. MDM2 showed nonspecific cytoplasmic positivity. The tumour cells were negative for CD31, ERG1, alpha-smooth muscle actin, desmin, D2-40, and inhibin. Ki-67 proliferation index was approximately 5%. Based on the morphological and immunohistochemical features, a diagnosis of mesenchymal neoplasm of fibroblastic/myofibroblastic differentiation—**intravascular solitary fibrous tumour**—was established.
Conclusion: Solitary intravascular tumours of the vena cava are rare entities that require thorough evaluation to exclude secondary extension from other primary tumours. Complete surgical excision remains the cornerstone of treatment, and histopathological analysis is essential for diagnosis.

E-PS-24-017
Epithelioid sarcoma of vulva: a rare presentation with molecular characterization
S. Girgin Sargaço[1], J.P. Maldonado[1], M. Varela Santos[1], M.A. Cipriano[1]
[1]Unidade Local de Saúde de Coimbra, Pathology, Coimbra, Portugal

Background & Objectives: Epithelioid sarcoma (ES) is a rare soft tissue malignancy, accounting for less than 1% of all adult soft tissue sarcomas, and vulvar involvement is extremely uncommon. ES is divided into two subtypes: classic (distal) and proximal-type, with the latter linked to adverse prognosis. Loss of SMARCB1/INI-1 expression is a hallmark of ES. Due to its non-specific clinical presentation, ES is frequently misdiagnosed, leading to delay in treatment and poor prognosis. We present a case of proximal-type vulvar ES, highlighting its histopathological, immunohistochemical and molecular findings.
Methods: A 25-year-old female presented with a painful nodule located on the mons pubis. Initially, imaging suggested a nonspecific inflammatory process. Persistence of symptoms and concomitant weight loss led to further investigation. MRI revealed a subcutaneous mass with 34x32x19mm, harbouring suspicious neoplastic features. Fine-needle aspiration showed atypical epithelioid and plasmacytoid cells, which motivated excisional biopsy and subsequent histopathological analysis.
Results: The excised lesion was whitish-coloured and partially encapsulated with haemorrhagic content. Histology revealed a multinodular and sheet-like growth of pleomorphic epithelioid and rhabdoid cells, with enlarged nuclei and prominent nucleoli, with abundant foci of necrosis and myxoid stroma. Mitotic figures were common and lymphovascular invasion was observed. Immunohistochemistry showed immunoreactivity for epithelial markers (CKAE1/AE3, CKCAM5.2, EMA, BerEp4) and CD34 (heterogeneous staining), and loss of nuclear expression of INI-1, endorsing the diagnosis of ES. Molecular testing (NGS) identified a pathogenic SMARCB1 c.686del mutation (variant allele frequency of 39%), suggesting a potential germline origin.
Conclusion: This case highlights the diagnostic complexity of vulvar ES and the importance of molecular analysis for diagnostic purposes and recognizing potential germline origin. Optimal management of vulvar ES has not been determined due to its rarity, but given the high risk of local recurrence and distant metastasis, early and wide surgical excision is mandatory. The role of adjuvant radiotherapy and/or chemotherapy remains to be established.

E-PS-24-018
Primary diffuse large B-cell lymphoma of the bone, a rare and challenging diagnostic entity
A. Orosz[1], N.-S. Orosz-Bogya[1], A. Vigdorovits[1], M.-M. Muresan[1], S.-A. Vese[1], A.-C. Pop[1], A. Camarasan[1], A.-V. Pascalau[1], O.-L. Pop[1]
[1]Bihor County Emergency Clinical Hospital, Anatomical Pathology, Oradea, Romania

Background & Objectives: In this study, we describe a case of primary diffuse large B-cell lymphoma of the bone. Primary bone tumours are uncommon diseases, representing only 0,2% of all neoplasms, primary bone lymphomas (PBL) being even more rare, constituting approximately 7% of all malignant bone tumours. They typically arise sporadically and rarely in HIV-positive patients or on the background of longstanding osteomyelitis.
Methods: The patient is a 44 year-old male with no known medical history. Radiologic imaging revealed a large osteolytic mass on the proximal humerus without periosteal reaction. After bone curettage, H&E and immunohistochemical analysis for CD45, CD20, CD3,

CD10, CD5, CD23, CD99, BCL6, MUM1, MYC, BCL2 and Ki-67 were performed.
Results: H&E examination revealed a diffuse proliferation of medium-to-large size cells infiltrating bone lamellae, with prominent necrotic areas, numerous atypical mitoses and crush artefact. The population of tumour cells were CD45, CD20, CD10 and BCL6 positive and CD3, CD5, CD23, CD99, MUM1, MYC and BCL2 negative with a Ki-67 index of 95% which pointed us toward a diagnosis of diffuse large B-cell lymphoma of germinal centre type (according to the Hans algorithm).
Conclusion: Primary bone lymphomas represent 5% of all extranodal lymphomas and <1% off all non-Hodgkin lymphomas. The majority of PBL are diffuse large B-cell lymphomas. Our case report highlights the diagnostic challenges associated with this entity as well as the need for proper patient management.

E-PS-24-019
Too spindly to be a fibrolipoma, too fibrous to be a spindle cell lipoma
K. Yilmaz[1], K. Kösemehmetoğlu[1]
[1]Hacettepe University, Ankara, Turkey

Background & Objectives: The morphologic overlap between fibrolipoma and spindle cell lipoma can pose diagnostic, and mainly academic, challenges, especially in tumours with ambiguous stromal features. Given the known association between spindle cell lipoma and *RB1* deletion, FISH-based evaluation may offer supportive data in diagnostically uncertain cases.
Methods: Seventy-four lipomatous tumours initially diagnosed as fibrolipoma were retrospectively reviewed. Following histologic reassessment, 68 cases were reclassified into three diagnostic categories: fibrolipoma (54), spindle cell lipoma (7), or indeterminate fibrolipoma/spindle cell lipoma (7). *RB1* deletion status was evaluated by FISH in 55 cases on 4-mm-diameter tissue microarray. Eight spindle cell lipomas were included as control and 10/100 signal loss is determined as a cut-off value.
Results: *RB1* FISH analysis revealed higher deletion levels in indeterminate fibrolipoma/spindle cell lipoma [3/6 (50%), losses: 11%, 14%, and 15%] and spindle cell lipoma [1/5 (20%), loss: 21%], while tumours retaining a fibrolipoma diagnosis showed no or minimal deletion [39/44 (89%), mean loss 1,5% range 0-8]. After FISH testing, the morphological diagnosis was changed in 13/68 (19%) of the cases.
Conclusion: In this cohort, *RB1* loss was observed in tumours that, upon clinic and morphologic re-evaluation, were no longer consistent with a fibrolipoma diagnosis. However, some clear-cut fibrolipomas also showed RB1 loss to a lesser extent. *RB1* FISH provides meaningful diagnostic support in lipomatous tumours with overlapping features. Although classification was based primarily on histology, the molecular findings retrospectively aligned with and reinforced the revised diagnoses. These results support the use of RB1 status as a confirmatory adjunct in resolving the diagnostic spectrum between fibrolipoma and spindle cell lipoma.

E-PS-24-020
A case of calcium pyrophosphate crystal deposition disease (CPPD) of the temperomandibular joint
L. Johnston[1], J. Stahle[1]
[1]NHS Tayside, Dundee, United Kingdom

Background & Objectives: We present a case of calcium pyrophosphate crystal deposition disease (CPPD) of the temperomandibular joint (TMJ) with osteoarthritis. Whilst this diagnosis is not uncommon, CPPD usually affects larger joints such as the knee, wrist, elbow or ankle. Only rarely does CPPD affect small joints such as the TMJ (1).
Methods: An 82 year old female with a one year history of left jaw pain, and with a CT scan demonstrating significant flattening of the articular surface of the left condylar process of the mandible with relatively reduced condylar neck height, underwent total joint replacement. The bone and soft tissue removed during surgery was submitted for histological assessment.
Results: H&E stained sections demonstrated vital bone, benign cartilage, fibrocollagenous tissue, skeletal muscle fibres and benign salivary gland tissue. There was vegetable matter impacted within bone, with associated necrosis and degeneration. The articular cartilage appeared ragged with surface cracks and fissures. Overall the features were in keeping with degenerative joint disease.
Additionally, within the fibrocollagenous tissue focal basophilic aggregates containing rhomboid shaped crystals were noted with scattered macrophages adjacent to these aggregates. The features were suggestive of a crystal arthropathy, in particular CPPD.
Conclusion: CPPD results from an immune response to the pathological presence of calcium pyrophosphate (CPP) crystals inside joints. This process leads to a CPP-crystal inflammatory arthritis, and can present acutely - previously known as pseudogout - or be chronic (1). There is a strong association between CPP crystal deposition and osteoarthritis, called CPPD with osteoarthritis, but the direction of causality is unknown (2). CPPD disease is common, especially in those over 60 years of age, but is underrecognised and undertreated (3).
This case highlights the need to look for CPPD, even at unusual sites. As it is often associated with osteoarthritis, it should be considered as a potential second diagnosis in such cases.

E-PS-24-021
When osteosarcoma takes a twist: a wrist tumour with focal BCOR sarcoma dedifferentiation
D. Proca[1], R.A. Hernandez Guzman[1], J. Nani[1], B. Fentaw[1], M. Jabbar[1], S. Wei[2]
[1]Temple University, Pathology, Philadelphia, USA, [2]Fox Chase Cancer Centre, Pathology, Philadelphia, USA

Background & Objectives: We report the first documented case of central low-grade osteosarcoma undergoing dedifferentiation into a sarcoma with BCOR internal tandem duplications (ITDs). Previously, BCOR ITD sarcomas have been almost exclusively identified in the non-appendicular soft tissues of children, with no documented association with osteosarcoma.
Methods: Clinical and pathological information was obtained from institutional EPIC and COPATH information systems, HE and immunohistochemical slides were reviewed by 3 pathologists, and Next-generation sequencing (NGS)DNA and RNA, as well as cytogenomic microarray analysis (CMA) were performed on tumour samples.
Results: We present a 22-year-old male with a progressively enlarging mass in the right thumb at a previous fracture site. The mass exhibited a significant and rapid increase in size two months before presentation. Initial biopsies suggested a low-grade osteogenic tumour. The patient subsequently underwent partial thumb amputation with reconstruction. Gross examination showed a 3.7 cm mass involving the metacarpal bone and invading into adjacent soft tissue. Microscopic evaluation showed low grade central osteosarcoma with transition to round blue cell tumour histology. NGS DNA&RNA and CMA testing showed amplifications of MDM2 and CDK4 genes, numerous other genomic alterations, gains and losses of various chromosome segments, as well as BCOR ITD alteration. The final diagnosis was that of central low-grade osteosarcoma with BCOR sarcoma dedifferentiation.
Conclusion: We present the first documented case of central low-grade osteosarcoma of appendicular bone with BCOR sarcoma dedifferentiation, occurring in the thumb of a young adult, supported by detailed histopathologic analysis and comprehensive genomic profiling,

including NGS (DNA & RNA) and CMA. BCOR ITD sarcomas have been reported exclusively in the non-appendicular soft tissues of infants and young children, with no known association with osteosarcoma. This case underscores the importance of employing NGS and CMA in the evaluation of sarcomas with atypical or heterogeneous histology to improve diagnostic accuracy and guide targeted therapy.

E-PS-24-022

Novel *SMARCA2*::*DDIT3* fusion in myxoid liposarcoma due to an unusual unbalanced chromosomal translocation

A. Shah[1], L. Marcelis[2], W. Sukov[1], A. Oliveira[1]
[1]Mayo Clinic, Department of Laboratory Medicine and Pathology, Rochester, USA, [2]UZ Leuven, Department of Pathology, Leuven, Belgium

Background & Objectives: Myxoid liposarcoma (MLS) accounts for 20–30% of all liposarcomas, with most cases harbouring the fusion gene *FUS::DDIT3*, while approximately 5% exhibit the *EWSR1::DDIT3* fusion. This report aims to describe a novel fusion, *SMARCA2*::*DDIT3*, identified in a 26-year-old male presenting with a right upper arm mass displaying the classic histologic features of MLS.
Methods: Fluorescence in situ hybridization (FISH) was employed to investigate rearrangements in the *DDIT3* locus. Next-generation sequencing (NGS) was conducted to identify fusion transcripts, and chromosomal microarray analysis was utilized to assess the structural nature of chromosomal alterations.
Results: The tumour displayed the classic histological features of MLS, including small spindle/ovoid cells, variable univacuolated lipoblasts, and a prominent myxoid stroma with delicate arborizing vasculature. Despite these characteristic features, fluorescence in situ hybridization (FISH) revealed no rearrangement of the *DDIT3* locus.
Next-generation sequencing (NGS) identified a novel fusion transcript in which *SMARCA2* exon 4 was fused in-frame with *DDIT3* exon 2. Chromosomal microarray analysis demonstrated the unbalanced nature of the rearrangement, with partial deletions of 0.243 Mb and 0.176 Mb flanking the centromeric end of the *DDIT3* locus on 12q13.3 (which also included *GLI*) and disrupting the *SMARCA2* locus on 9p24, respectively. The resultant chimeric fusion protein is predicted to lack the *SMARCA2* DNA-binding domains while retaining the *DDIT3* DNA-binding and leucine zipper dimerization domains.
Conclusion: These findings indicate an unusual and complex rearrangement, leading to the recruitment of a novel *DDIT3* partner gene through a promoter-swapping-like mechanism. Moreover, they emphasize that the functional aspects of myxoid liposarcoma fusion genes depend on the retention of key *DDIT3* protein domains. Finally, this case highlights the power of traditional morphologic assessment to uncover new molecular genetic discoveries.

E-PS-24-023

***CIC* rearranged sarcoma: a clinical and pathological study**

O. Jaber[1], W. Maaita[1], N. Hasasna[2], S. Yaser[3], Y. Saleh[3], R. Abu-Hijlih[4], W. Asha[4], H. Halalsheh[5], A. Shehadeh[6]
[1]King Hussein Cancer Centre, Department of Pathology and Laboratory Medicine, Amman, Jordan, [2]King Hussein Cancer Centre, Department of Cell Therapy and Applied Genomics, Amman, Jordan, [3]King Hussein Cancer Centre, Department of Medical Oncology, Amman, Jordan, [4]King Hussein Cancer Centre, Department of Radiation Oncology, Amman, Jordan, [5]King Hussein Cancer Centre, Department of Paediatrics, Amman, Jordan, [6]King Hussein Cancer Centre, Department of Surgery, Amman, Jordan

Background & Objectives: *CIC*-rearranged sarcoma is a rare and aggressive type of undifferentiated round cell tumour characterized by *CIC* gene fusion, most commonly *CIC::DUX4*. This study presents a series of eleven cases, highlighting their clinical-pathological features.
Methods: Pathology files (2019 to 2024) were searched using "sarcoma with *CIC*" identifying 11 cases, of which seven referred cases were initially misdiagnosed. Pathological and clinical analysis was conducted. Treatment was dictated upon multidisciplinary panel discussion based on tumour stage. Follow-up data (1–25 months) was available for all patients.
Results: The cohort included 6 males and 5 females, aged 14–53 years (median 43), nine in soft tissue and two in bone. Tumour size ranged from 3.5 cm to 20.0 cm (mean 9.8 cm). Most cases showed sheets of undifferentiated cells with focal short fascicles and 1 showed Ewing-like pattern. 1 case showed spindle cells in a fibrotic stroma transitioning to epithelioid cells. Necrosis was present in nine cases, and mitotic count ranged from 2 to 38 (mean=14.2). CD99 was positive in (10/11) cases and WT-1 in (6/9). NKX2.2, S100 and MDM2 were positive in rare cases. *CIC::DUX4* fusion was detected in 4 cases. FISH was positive in 7 cases, two of them confirmed by methylation analysis. Metastasis at diagnosis was common (n=8), primarily in the lungs, with later metastasis to the brain and bone. Eight patients died within 1–19 months (median 10 months), while three are alive, two with controlled disease (6 and 25 months) and one with progression after 10 months. No correlation was seen between overall survival and the presence of metastasis at diagnosis or tumour size (p value= 0.43 and 0.26, respectively).
Conclusion: *CIC*-rearranged sarcomas are rare, high-grade tumours with predilection for soft tissue. Misdiagnosis is frequent, necessitating molecular confirmation. These tumours are treatment-resistant, often present with lung metastasis, and carry a poor prognosis.

E-PS-24-024

Pulmonary epithelioid haemangioendothelioma – case report of a rare entity

M. Nguyen[1], V. Parra[1], M.-P. Montminy[1]
[1]Institut Universitaire de Cardiologie et de Pneumologie de Québec, Quebec City, Canada

Background & Objectives: Epithelioid haemangioendothelioma is a rare malignant tumour of vascular origin characterized mostly by a WWTR1-CAMPTA 1 fusion with an incidence rate of 0.230 per 1,000,000 person-years. Most lesions are found in the soft tissue and skin, followed by the abdomen, respiratory system, bones and joints. The presentation and prognosis are variable, ranging from asymptomatic incidentally found lesions to aggressive and symptomatic metastatic disease. A study by Zhen Liu and Shuting He found that age > 80, African American and American Indian/Alaska Native/Asian or Pacific Islander ethnicity and respiratory origin were linked to worse survival rate.
Methods: We report the case of a 61-year-old female who was referred to pneumology for incidentally discovered bilateral pulmonary nodules, the largest one being 8 mm of diameter, on imaging done for shoulder pain. Differential diagnosis on imaging included metastases and granulomatous disease. However, past medical history was negative for neoplasia, cardiopulmonary disease, smoking and recreational drugs.
Results: A cone-beam CT-guided lung biopsy was performed and only the cryobiopsy specimen yielded results. Histologic examination revealed epithelioid eosinophilic cells containing intracytoplasmic vacuoles “blister cells”, arranged in nests and cords on a background of myxoid to hyaline stroma. This resulted in the creation of multifocal and bilateral nodules that followed alveolar-filling pattern, characteristic of pulmonary lesions of this entity. IHC was positive for ERG and CAMTA1. Thus, the diagnosis of epithelioid haemangioendothelioma was confirmed and the patient’s management was transfered to hemato-oncology.
Conclusion: The pathological diagnosis for this rare entity can be challenging and a second opinion from an expert could be required.

The management requires a specialized centre and entails surveillance, surgery, chemotherapy or radiotherapy.

E-PS-24-025

An EWSR1::PBX3 fusion-positive intraosseous myoepithelioma in the clavicle

L. M[1], K. Sittampalam[1]
[1]Singapore General Hospital, Anatomical Pathology, Singapore, Singapore

Background & Objectives: Myoepitheliomas are uncommon benign tumours usually occurring in the soft tissue, but occasionally in an intraosseous location. We present a case of an intraosseous myoepithelioma occurring in the clavicle of a 40 year old male patient, with an EWSR1::PBX3 fusion, the first in this anatomical site. The patient presented to the orthopedics service with complaints of right shoulder pain. Imaging studies showed an radiolucent tumour within the clavicle, measuring up to 2.1cm.
Methods: The lesion was curetted and subsequent histological evaluation showed a tumour with interlacing fascicles of spindled cells with monomorphic cytological features and eosinophilic cytoplasm. There was mild nuclear atypia with very rare mitoses, and no necrosis. No surrounding bone or cartilage formation was noted. The tumour cells were immunopositive for EMA, SMA, S100 and caldesmon, supporting a myoepithelial lineage. The Ki-67 proliferation index was less than 1%. Immunohistochemical staining for keratins and SOX10 were negative.
Archer FUSIONPlex pan solid V2 assay showed an EWSR1::PBX3 fusion.
Results: EWSR1::PBX3 fusions have largely been reported in cutaneous syncytial myoepitheliomas, with less than 10 cases in intraosseous locations, preferentially in the long bones of the lower limb. As this fusion can be seen in both benign myoepitheliomas and malignant myoepithelial carcinomas, the low-grade histology confirms the benign nature in this case, with immunohistochemical studies remaining the cornerstone for diagnosis. No recurrence has been reported by the patient in the 36 months since the curetting.
Conclusion: This case illustrates the need to consider the diagnosis of myoepitheliomas as primary bone tumours that can occur outside the long bones, and lends support to the predilection of this fusion for skeletal involvement. While immunopositivity for myoepithelial markers in conjunction with the morphology may be sufficient for diagnosis in some cases, molecular studies are useful in supporting the diagnosis and appear suggestive of a morphological phenotype and presentation.

E-PS-24-026

A rare case of pleomorphic sarcoma arising in a background of regressive changes associated with giant cell tumour of bone. A diagnostic challenge in a core biopsy

V. Pant[1], A. Borges[1]
[1]Center for Oncopathology, Histopathology, Mumbai, India

Background & Objectives: The case illustrates the diagnostic challenge presented in a core biopsy of a pleomorphic sarcoma arising in a fibrohistiocytic background in the upper end of tibia of a 48yr old male. The WHO 5th edition of soft tissue and bone tumours has highlighted that tumours resembling benign fibrous histiocytomas in bone, which occur in sites not typical for non ossifying fibromas, often represent regressive changes in giant cell tumours of bone. Sarcomas in epiphyseal locations of long bones which express histone marker H3.3G34W possibly represent malignant giant cell tumours of bone even without an associated giant cell tumour component. This case illustates both these points.
Methods: A 48 year male presented with pain in his left knee of 2 years duration. His radiology at presentation showed ill defined lytic areas with soft tissue component involving upper end of left tibia. Two earlier biopsies were diagnosed as a histiocytic proliferation. Our lab received the third trucut biopsy.
Results: The biopsy cores showed variable cellularity and a variegated morphology with areas showing a fibrohistiocytic infltrate with a storiform pattern and admixed lymphocytic infiltrate. Also present were few areas showing pleomorphic polygonal to spindle cells with mitosis. The initial IHC work up with histiocytic and mesenchymal markers was non contributary. A review of his earlier radiology in 2024 showed an epiphyseal lytic lesion which prompted IHC for H3.3G34 which was diffusely positive in the spindle cell component of the tumour. There were no areas of classic giant cell tumour seen.
Post 4 cycles of chemotherapy the tumour was excised with a partial response to therapy.
Conclusion: The case highlights the importance of site in interpreting an unusal bone malignancy and illustrates regressive changes in giant cell tumour of bone as a differential diagnosis of fibrohistiocytic epiphyseal bone proliferations.

E-PS-24-027

Diagnostic pitfalls in splenic pathology: a case report

B. Anghel[1], L. Lozneanu[1,2], C. Ungureanu[1,3], I. Ungureanu[4]
[1]"Sf. Spiridon" Emergency County Hospital, Department of Pathology, Iași, Romania, [2]"Grigore T. Popa" University of Medicine and Pharmacy, Department of Morphofunctional Sciences I - Histology, Iași, Romania, [3]"Grigore T. Popa" University of Medicine and Pharmacy, Department of Morphofunctional Sciences I - Pathology, Iași, Romania, [4]"Grigore T. Popa" University of Medicine and Pharmacy, Iași, Romania

Background & Objectives: Splenic angiosarcoma is a rare and aggressive malignant vascular tumour with high metastatic potential, with a poor prognosis. Due to the nonspecific presentation, which may be splenomegaly or anaemia, it is frequently misdiagnosed. We present a case in which splenic and hepatic abscesses were initially suspected and later confirmed as splenic angiosarcoma, highlighting the diagnostic challenges and histopathological features.
Methods: A 60-year-old man with multiple comorbidities presented with diffuse abdominal pain and expiratory dyspnea. Initial imaging studies identified liver abscesses, which necessitated further evaluation. CT examination showed multiple hypodense nodular lesions localized to the spleen and liver. The patient decompensated, developing septic shock and multiple organ dysfunction, requiring splenectomy. The excision specimen was analysed in the pathology laboratory for gross, histopathological, and immunohistochemical analyses.
Results: Macroscopic evaluation describes the presence of multiple gray and haemorrhagic areas diffusely distributed in the splenic parenchyma. Histopathological examination of these areas revealed cellular proliferation with various growth patterns including solid areas and vasoforming regions. The solid areas were composed of spindle and epithelioid cells with amphophilic cytoplasm, large nuclei, and prominent nucleoli. The vasoforming areas presented anastomosing vascular channels lined by atypical, large, pleomorphic endothelial cells with high mitotic activity (23 mitoses/10 HPF). The tumour cells were positive for CD31 and CD34. Extensive areas of coagulation necrosis and haemorrhage were also observed. Despite intensive care, the patient developed multiple organ failure and died two days after surgery.
Conclusion: This case highlights the diagnostic challenges of splenic angiosarcoma, which can mimic abscesses radiologically. Histopathological examination, along with immunohistochemical examination, remain crucial for accurate diagnosis. Given the aggressiveness of the tumour, early recognition and treatment are essential for improving the prognosis.

E-PS-24-028

An atypical spindle cell/pleomorphic lipomatous tumour of the thigh with a difficult imaging diagnosis that mimicked a malignant lipomatous tumour

J. Ichikawa[1], T. Fujibuchi[2], K. Onohara[3], M. Wako[4], T. Kawasaki[5]
[1]University of yamanashi, Orthopedic Surgery, Chuo, Japan, [2]University of Ehime, Orthopedic Surgery, Toon, Japan, [3]University of Yamanashi, Radiology, Chuo, Japan, [4]University of Yamanashi, Orthopaedic Surgery, Chuo, Japan, [5]Saitama Medical University International Medical Centre, Pathology, Hidaka, Japan

Background & Objectives: Atypical spindle cell/pleomorphic lipomatous tumours (ASPLT) are categorized as benign lipomatous tumours. However, various MRI findings pose diagnostic challenges. In our case, MRI indicated the possibility of an atypical lipomatous tumour/well-differentiated liposarcoma (ALT/WDL) or a dedifferentiated liposarcoma (DDLPS).
Methods: A 74-year-old woman presented with a mass in her right thigh that had been present for 20 years but had begun to increase in size 1 year prior. MRI revealed a low-intensity signal on T1-weighted images, with scattered high signal and high-signal intensity on T2, with scattered low signal. Heterogeneous enhancement was observed on gadolinium-enhanced T1-weighted images, suggesting that the differential diagnosis was ALT/WDL or DDLPS. Needle biopsy suggested both benign and low-grade malignant lipomatous tumours. Overall, the preoperative findings did not definitively rule out malignant tumours, leading to the decision to perform a wide resection.
Results: A wide range of microscopic appearances and cellularity was observed based on the various proportions of atypical spindle cells, adipocytes, lipoblasts, and pleomorphic (floret-like) cells, as well as variable amounts of collagenous and/or myxoid extracellular matrix. The adipocytic component had predominantly mature morphologies with variations in adipocyte size and shape. Mitotic figures were scarce (0–1/10 HPF), and tumour necrosis was absent. Immunohistochemistry results were as follows: CD34 (+, focal), retinoblastoma (RB1) (−, lost), MDM2 (−), CDK4 (−), S100 (+, focally), and BCL-2 (+, weakly). Fluorescence in situ hybridization revealed no MDM2 amplification.
Conclusion: MRI findings for ASPLT vary due to differences in fat content, making the differential diagnosis broad, including ALT/WDL, DDLPS, and myxoid liposarcoma, suggesting that histopathological findings are crucial for ASPLT diagnosis. Although ASPLT have defined morphological and histopathological features, these findings overlapped with those of other tumours and were not consistently present. Caution should be exercised when distinguishing ASPLT from other lipomatous tumours.

E-PS-24-029

A rare case of malignant calcifying epithelial odontogenic tumour and large neurofibroma

R. Sawodny[1], S. Holawe[2], I. Noebauer-Huhmann[3], I. Sulzbacher[4]
[1]Medical University of Vienna, Clinical Insitute of Pathology, Vienna, Austria, [2]Medical University of Vienna, Department of Oral and Maxillofacial Surgery, Vienna, Austria, [3]Medical University of Vienna, Department of Radiology, Vienna, Austria, [4]Medical University of Vienna, Clinical Institute of Pathology, Vienna, Austria

Background & Objectives: Calcifying epithelial odontogenic tumour (CEOT), also known as Pindborg Tumour, is a rare benign odontogenic tumour with distinct histological features such as sheets and cords of polyhedral cells with nuclear pleomorphism and the presence of amyloid. Extraordinarily uncommon malignant transformation is often difficult to diagnose due to overlapping morphological criteria with benign and recurrent variants.
Methods: We describe the case of a malignant CEOT and a large neurofibroma in an adult female patient using immunohistochemistry and next generation sequencing.
Results: A female patient presented with a slowly expanding ulceration of the lower right alveolar mucosa, clinically giving the impression of oral squamous cell carcinoma. The x- ray and CT scan both showed an osteolysis of the right mandible spanning from regio 47 to the coronoid process with retained tooth 48. Biopsy revealed a CEOT with marked cellular pleomorphism, numerous mitoses and a high Ki-67 labelling index of 30%. Therefore, malignancy was diagnosed, and the patient was planned for partial jaw resection with fibular graft reconstruction. Coincidentally, during MR angiography of the leg vessels another large lesion was found inside the right adductor magnus muscle. Clinical diagnoses included a soft tissue tumour as well as a metastasis. Subsequent biopsy uncovered a neurofibroma with cellular atypia. Finally, jaw resection with additional neck dissection and scapular graft reconstruction was performed. The resection specimen exposed a small area of cortical destruction and mucosal invasion, but no lymph node involvement although a lymphatic vessel invasion was found. NGS of the tumour revealed no special genetic profile. The patient is currently at an eight-year follow-up without recurrence.
Conclusion: While squamous cell carcinoma may be one of the primary causes of progressively enlarging ulcerations in the oral mucosa, odontogenic tumours can also present with aggressive clinical behaviour. This case has been further complicated by the finding of a large neurofibroma.

E-PS-24-030

Case report: a 16-year old adolescent girl with fungal osteomyelitis mimicking malignant neoplasm of calcaneal bone

D. Borys[1], E. Borys[2], A. Aragao[3]
[1]Hospital for Special Surgery, New York, USA, [2]New York Medical College, Valhalla, USA, [3]Loyola University Chicago, Maywood, USA

Background & Objectives: Blastomycosis is a rare fungal infection caused by *Blastomyces dermatitidis*, typically affecting the lungs but occasionally disseminating to other tissues, including bone. This condition is most commonly reported in Canada and in the midwestern, south-central, and southeastern USA, with an annual incidence of approximately 1 to 2 cases per 100,000 individuals in endemic areas.
Methods: On physical examination, a painful, 6 cm diameter, oedematous, indurated lesion with yellow discharge was noted on the left lateral malleolus. An initial X-ray of the left ankle revealed soft tissue swelling, several areas of subtle lucency in the mid and anterior calcaneus, and a healing, non-displaced lateral malleolus. The X-ray findings raised suspicion of a possible underlying bone pathology, which led to further investigation.
An MRI was performed to evaluate for possible osteomyelitis, which showed destruction of the calcaneus and abnormal signals in the surrounding soft tissue. These findings were concerning for malignancy or a severe infectious process, necessitating further diagnostic workup.
Results: Ultrasound-guided and open biopsies led to the histological finding of acute and chronic inflammation, necrosis, granulomatous inflammation, and fungal organisms. Gomori methenamine silver (GMS) stain confirmed the presence of *Blastomyces dermatitidis*.
Conclusion: This case highlights an atypical presentation of Blastomycosis in an adolescent, mimicking a malignant process in the bone and soft tissue. Despite being a rare condition, Blastomycosis should be considered in the differential diagnosis of osteomyelitis, particularly in endemic regions, even in immunocompetent individuals. Early recognition and appropriate antifungal therapy are crucial to prevent misdiagnosis and delayed treatment complications. This case emphasizes the importance of awareness and consideration of fungal infections in

atypical presentations to ensure timely diagnosis and optimal patient management.

E-PS-24-031

A novel fusion gene EML4-NTRK3 in a case of metastatic infantile fibrosarcoma

B.G. Özamrak[1], G. Gül Uz[1], M. Ertekin[2]
[1]Izmir Provincial Health Directorate, Izmir City Hospital, Department of Pathology, Izmir, Turkey, [2]Izmir Provincial Health Directorate, Izmir City Hospital, Department of Paediatric Haematology and Oncology, Izmir, Turkey

Background & Objectives: Infantile fibrosarcomas (IFS) are locally aggressive non-rhabdomyosarcoma soft tissue tumours. These uncommon tumours usually occur congenitally, affecting 5 in 1 million infants under 1 year of age. The lesions usually involve the extremities, with the lower extremities being the most affected area. They can also be observed in the trunk, head and neck region, and retroperitoneum. Involvement of lymph nodes or metastases is rarely reported.
Methods: A 7-year-old male presented with shortness of breath, fever, and a decline in general condition. Thorax CT revealed an 11x10 cm mass lesion in his left lung. The parenchyma seemed collapsed; extensive pleural effusion filled the left hemithorax. Additionally, a 2 cm metastatic solid lesion at an upper posterior segment and a 7 mm subpleural solitary nodule at the mid-lateral segment of the right lung were observed. The patient had a history of IFS located on his right forearm 5 years prior, followed by receiving chemotherapy and radiotherapy and an amputation operation one year later after the initial diagnosis.
Results: The sign-out diagnosis of the lung mass biopsy was consistent with a malignant mesenchymal tumour of spindle cell morphology. A molecular diagnostic workup with NGS was performed, which resulted in EML4-NTRK3 fusion.
Conclusion: Most IFS cases show ETV6-NTRK3 gene fusions and are sensitive to chemotherapy with favourable clinical behaviour. A few IFS cases were reported to lack ETV6-NTRK3 fusion. Recently, novel fusions such as SEPT7-BRAF, EML4-NTRK3, and TPM3-NTRK1 have been identified in unclassified spindle cell sarcomas, showing morphological overlap to IFS and located at extremities and retroperitoneum. In the setting of unusual clinical presentations with shared tumour morphology, identifying the gene fusions would provide insight into the response to targeted therapy and neoadjuvant regimens in inoperable cases and a chance to avoid maybe morbid surgery and help to predict prognosis.

E-PS-24-033

Citation analysis of the 5th edition WHO classification of tumours soft tissue and bone tumours volume

C. Giesen[1], R. Cierco Jimenez[1], I. Indave Ruiz[1], H. Wijesinghe[1], P. Puspanathan[1], C. Monnier[1], I.A. Cree[1], D. Lokuhetty[1], WCT EVI MAP Work Group
[1]International Agency for Research on Cancer/World Health Organization, Evidence Synthesis Branch, Lyon [Rhône], France

Background & Objectives: Evidence-based pathology practice informs the WHO Classification of Tumours (WCT) and should be supported by analysis of the references cited in the previous WCT to guide future editions. Evidence Gap Maps (EGM) and Citation Maps (CM) use a visual approach to identify gaps in cited evidence and detect relations between scholarly articles that could point towards a biased assessment of evidence. We aimed to assess the references cited in the WCT Soft Tissue and Bone Tumours 5th edition (STB-5), summarising gaps and special interests in cited publications, to assist authors and editors during the development of the WCT STB 6th edition.
Methods: We developed an EGM and CM of STB-5 references and provided a descriptive analysis summarising gaps, networks of referenced publications and relations of interests among cited articles. A citation analysis network was developed using VOSviewer®. Two main criteria were applied: maximum number of authors per document (15) and minimum number of documents per author (15).
Results: The CM included 3,373 references from 11,399 authors for 349 tumour types. The EGM we identified gaps in the cytology and macroscopy. The CM showed seven distinct clusters dealing with soft tissue tumour classification, molecular genetics (focussing on sarcoma), bone and cartilage tumours and regional or rare tumour research. All but two showed strong intra and interconnections. Key researchers formed clusters, acting as bridges between them. Main authors in isolated clusters were frequently cited despite weaker interconnections.
Conclusion: Interdisciplinary connections and bridges were observed, indicating that a wide range of tumour characteristics by a variety of key authors in the field are covered. Identifying clusters confirms citations from major research groups, supporting WCT's evidence-based classification. The visual representation of relationships of citations in WCT-5 provides guidance on improvements that can be made in the 6th edition of WCT Soft tissue and Bone volume.

A chameleon tumour: unraveling the rare phenomenon of myxoid Liposarcoma with osteocartilaginous differentiation

A. Dumitru[1], M. Publik[2], B. Serban[3], B.S. Cretu[3], S.A. Iordache[3], M.A. Costache[3], A. Cursaru[4], M. Nica[3], A.-M. Ciongariu[1], C.F. Cîrstoiu[4]
[1]Carol Davila University of Medicine and Pharmacy, Pathology, Bucharest, Romania, [2]University Emergency Hospital Bucharest, Pathology, Bucharest, Romania, [3]University Emergency Hospital Bucharest, Orthopedics and Traumatology, Bucharest, Romania, [4]Carol Davila University of Medicine and Pharmacy, Orthopedics and Traumatology, Bucharest, Romania

Background & Objectives: Myxoid liposarcoma with osteocartilaginous differentiation is a rare variant of myxoid liposarcoma (MLPS) characterized by mature hyaline cartilage within the tumour. Fewer than 10 cases of this phenomenon have been documented in the literature.
Methods: We present the case of a 52-year-old male who presented with pain and functional impairment in his left thigh. A whole-body scintigraphy scan revealed a region with high vascularization in the middle third of the thigh, encompassing a hypercaptant area with intense heterogeneity. SPECT-CT imaging identified a soft tissue tumour in the anterior thigh compartment, measuring 20 x 9.5 x 6 cm, well-demarcated, hypodense, with superior calcifications. A surgical excision was performed, and tissue samples were sent for histopathological analysis and frozen-section examination.
Results: The frozen-section examination revealed a tumour composed of small cells with cytological atypia, arranged in a myxoid stroma. Macroscopic examination identified a well-encapsulated, darkly coloured tumour mass. Paraffin-embedded tissue analysis revealed mesenchymal tumour proliferation with round to oval or spindle-shaped cells with stellate processes. These cells exhibited relatively monomorphic, hypochromatic nuclei with occasional nuclear pseudoinclusions. The stroma surrounding the tumour was myxoid, weakly basophilic, with mucoid extracellular lakes. There were numerous stromal blood vessels with a plexiform appearance. Lipoblast clusters were frequently observed at the tumour periphery, demonstrating atypia and occasional atypical mitotic figures. Multiple areas of haemorrhage and necrosis were noted within the tumour. Notably, there was an area of osteocartilaginous differentiation with hyaline cartilage and a transition to mature bone tissue. Immunohistochemical analysis was positive for S100 (expressed in myxoid areas and lipoblasts), P16, and Ki67 (1-2%) but negative for MDM2 and CD34. These features support a diagnosis of low-grade myxoid liposarcoma.

Conclusion: Myxoid liposarcoma with osteocartilaginous differentiation is a rare tumour seldom reported in the literature. Precise histopathological and immunohistochemical analysis is crucial for ensuring optimal diagnosis, treatment and prognosis.

E-PS-24-035

PD-1&PD-L1 expression in sarcomas

A. Nalwa[1], V. Gowda[1], M. Rao[1], P. Elhence[1], J.R. Vishnoi[2], M. Badkur[3]
[1]All India Institute of Medical Sciences, Pathology & Lab Medicine, Jodhpur, India, [2]All India Institute of Medical Sciences, Surgical Oncology, Jodhpur, India, [3]All India Institute of Medical Sciences, Surgery, Jodhpur, India

Background & Objectives: Primary therapy regimen for sarcomas is surgical resection with adequate margins.Aim of study is to assess expression of PD-L1/PD-1 in soft itssue sarcoma(STS) to investigate rationale for immune-checkpint inhibition in patients with PD-L1 positive soft tissue sarcomas.
Methods: CPS was calculated for PD--L1: CPS≥1 positive & CPS<1 as negative. For PD-1 IHC: more than1% membranous staining in tumour & tumour infiltrating lymphocytes and intensity was graded as 1+(weak), 2+(intermediate), 3+(strong).
Results: Of the 167 cases, adequate tissue for IHC was available in 99 cases.Median age of presentation was 44 years (age range: 3 to 94 years), with male predominance.A diverse array of sarcoma types were noted distributed across various primary tumour sites, most common being Ewing sarcoma followed by pleomorphic sarcoma, synovial sarcoma, MPNST, LMS, etc.Evaluation of these markers revealed variable expression patterns in both tumour cells and tumour-infiltrating lymphocytes, which included cytoplasmic and membranous staining pattern, with higher expression noted in higher grade sarcomas with an exceptional lower to nil expression in synovial sarcomas.PDL1 was 170, suggesting a potential for variable immune checkpoint activity among sarcoma subtypes. Of 99 cases, positive CPS was seen in 38 cases with a maximum score of 170.
Conclusion: Evaluation of these markers revealed variable expression patterns in both tumour cells and tumour-infiltrating lymphocytes, with higher expression noted in higher grade sarcomas, with an exceptional lower to nil expression in synovial sarcomas. The diversity in TILS across samples suggests an immunological response gradient, which may correlate with prognosis and immune responsiveness.

E-PS-24-036

CD44-AKT-miR-146a axis targets apoptosis in tendinopathy

S.-Y. Chen[1,2], P.-T. Wu[3]
[1]Chung Hwa University of Medical Technology, Nursing, Tainan, Taiwan, [2]National Cheng Kung University, Tainan, Taiwan, [3]College of Medicine, National Cheng Kung University, Orthopaedics, Tainan, Taiwan

Background & Objectives: Tendinopathy is a debilitating condition characterized by pain and impaired tendon function, with its development linked to chronic inflammation, cellular senescence, and apoptosis. Previous studies suggest that inhibiting CD44 signalling aggravates apoptosis and inflammation in tendinopathic tenocytes. Additionally, microRNA-146a (miR-146a) has been shown to counteract IL-1β-induced senescence in these cells and is upregulated by CD44 in knee osteoarthritis. Given these findings, this study aims to explore the role of the CD44-miR-146a signalling axis in regulating apoptosis in tendinopathy.
Methods: To investigate this mechanism, lentiviral vectors (LVs) were employed to induce overexpression of CD44 cDNA (LVCD44) and the miR-146a precursor (LVmiR-146a) in primary rat tendinopathic tenocytes and tendon tissues. Apoptotic cell death was evaluated using TUNEL staining. To further delineate the involvement of the CD44-AKT-miR-146a pathway, we used the PI3K/AKT inhibitor LY294002 and the CD44-blocking antibody OX-50. Additionally, in situ hybridization (ISH) and immunohistochemistry (IHC) were performed to assess the impact of this pathway on Smad4 expression in tendinopathic cells and tissues.
Results: Overexpression of CD44 and miR-146a significantly reduced apoptosis in tendinopathic tenocytes compared to control cells. The CD44-AKT-miR-146a signalling cascade was found to exert a protective effect against apoptosis in IL-1β-stimulated tenocytes and in a rat model of collagenase-induced Achilles tendinopathy, primarily by downregulating Smad4 expression.
Conclusion: These findings underscore the protective function of the CD44-AKT-miR-146a signalling axis in tendinopathy. By modulating the AKT/miR-146a/Smad4 pathway, CD44 and miR-146a effectively suppress apoptosis in tenocytes and tendon tissues, highlighting their potential as therapeutic targets for tendinopathy management.

Localized form of tenosynovial giant cell tumour: a study of 38 cases

I. Noomen[1], M. Njima[1], S. Ben Hammouda[1], S. Mabrouk[1], A. Ben Mabrouk[1], A. Bellalah[1]
[1]Fattouma Bourguiba Hospital, Pathology department, Monastir, Tunisia

Background & Objectives: Tenosynovial giant cell tumour (TGCT) is a rare, benign fibrohistiocytic tumour that may be intra or extra-articular. It is divided into two subtypes: localized or diffuse. Our aim is to describe the clinical, histopathological and prognostic features of TGCT in its localized form.
Methods: This is a retrospective descriptive study collected over a period of 17 years from January 2005 to December 2022. The study included 38 patients who were diagnosed with a TGCT in its localized form at Fattouma Bourguiba Hospital in Monastir.
Results: The average age was 42. Thirty patients were women (sex ratio= 0.26). Fifty percent of patients presented with isolated swelling, in 44% of cases the swelling was associated with pain and restricted mobility. On gross examination, 36 cases presented as a well circumscribed nodular formation with yellowish (29%), off-white (26.3%), white (26.3%), or heterogeneous (18.4%) cut surfaces. The mean size was 2.3 cm. Microscopic examination of all cases showed a mesenchymal tumour composed of mononuclear and histiocyte-like cells with multinucleated giant osteoclastic cells. In 42,1% of cases, giant multinucleated cells were matching mononuclear cell density. They were abundant in 7 cases and scarce in 15 cases. There was no cytonuclear atypia. Mitosis were observed in 15,7% of cases. In 20 cases, the tumour was highly cellular, the other cases presented as a hypocellular lesion with an abundant fibrous stroma. Hemosiderin deposit was found in 55.3% of cases while xanthoma cells were observed in 52,3% of cases.
Conclusion: The localized form of tenosynovial giant cell tumour is a benign neoplasm with unclear pathogenesis. It exhibits characteristic clinical and histopathological features. Despite its benign behaviour, a significant recurrence risk exists.

E-PS-24-038

Angiogenic profiles in bone pathologies: an immunohistochemical comparative analysis

L. Winter[1], R. Schönmehl[1], A. Artinger[1], N. Walter[2], M. Karlikova[3], M. Rupp[4], C. Brochhausen[1]
[1]Institute of Pathology, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany, [2]University Hospital Regensburg, Trauma Surgery, Regensburg, Germany, [3]Central Laboratory for

Immunoanalysis, Faculty of Medicine in Pilsen, Charles University, Pilsen, Czech Republic, [4]University Hospital Giessen, Trauma, Hand and Reconstructive Surgery, Giessen, Germany

Background & Objectives: Angiogenesis plays a crucial role in fracture healing. However, its precise role in non-unions remains unclear and is addressed by the so-called "vascularization paradox" of non-union (NU) formation: Reduced vascularization can inhibit fracture repair, while its stimulation can facilitate regeneration. In contrast, excessive angiogenesis has been shown to impede fracture healing and contribute to the exacerbation of NU formations.To better understand the vascularization of non-unions, we evaluated the differences in blood vessel density among NU, bone metastases (BM), and femoral head necrosis (FHN), and examined the spatial distribution of blood vessels in these conditions.
Methods: An immunohistochemical analysis was performed using the vascular markers CD31, CD34, and Nestin on a total of 50 samples from three different bone pathologies, namely 15 BM, 15 FHN, and 20 NU. Blood vessel annotation was performed using a self-trained algorithm on whole slide images. The analysis included the examination of the spatial distribution of vessels, comparing vessel count between central and peripheral areas, as well as between fibrotic scar tissue and granulation tissue. Furthermore, comparative analyses across the three different pathologies were conducted.
Results: Significant differences in vascular distribution were observed between NU and FHN, as well as between BM and FHN (both $p<0.0001$). Specifically, NU and BM exhibited significantly higher blood vessel density compared to FHN, indicating distinct angiogenic profiles. Interestingly, no significant differences in vascular distribution were found between BM and NU, or between the central and peripheral areas within the examined tissues.
Conclusion: The similar vascular characteristics observed between NU and BM contrast sharply with those of FHN. These findings suggest common angiogenic profiles that could potentially be targeted with therapeutic intervention. The study underlines the importance of angiogenesis in bone pathologies and suggests directions for future research, including 3D reconstruction and image registration techniques to further assess vascular branching characteristics.

E-PS-24-039
Malignant gastrointestinal neuroectodermal tumour: case report of an ultra-rare mesenchymal neoplasm
H. Galindo-Guzmán[1], B.B. Ardaya López[1], J. Suárez González[2], A. Matilla Peña[3], E.M. Pena Burgos[1]
[1]Hospital General Universitario Gregorio Marañón, Pathology, Madrid, Spain, [2]Hospital General Universitario Gregorio Marañón, Genomics Unit, Madrid, Spain, [3]Hospital General Universitario Gregorio Marañón, Gastroenterology and Hepatology, Madrid, Spain

Background & Objectives: Malignant gastrointestinal neuroectodermal tumour (GNET) is a rare mesenchymal tumour affecting the gastrointestinal tract (GIT). It is known as a clear cell sarcoma (CCS)-like tumour of the GIT. Less than 70 cases have been reported worldwide.
Methods: We present the case of a 67-year-old woman with no relevant medical antecedents. She was admitted to the hospital for gastrointestinal complaints for two years and weight loss of 10 kg in the last few months. Endoscopical evaluation was normal. A mural jejunal thickening, an adjacent lymphadenopathic conglomerate and multiple hepatic nodules were detected in radiological studies. The jejunal segment and the lymphadenopathic conglomerate were surgically removed and a hepatic lesion was biopsied.
Results: The mass was composed of a densely cellular proliferation arranged in nests and cords separated by fibrous septa. The cells were monomorphic, with large clear cytoplasm, round nuclei, and prominent eosinophilic nucleoli. Scattered multinucleated giant osteoclasts-like cells and frequent mitotic figures were seen. Lymphovascular and perineural invasion were found. Lymph node and hepatic metastases were histologically confirmed. The cells were intense and diffusely positive for S100 and SOX10, non-intense and diffusely positive for synaptophysin, and focal positive for CD56. INI1 expression was preserved. Smooth muscle actin, h-caldesmon, melanA, HMB45, MDM4, CDK4, DOG1, STAT6, SS18 and ALK were negative. Molecular studies (Next Generation Sequencing, Archer® FusionPlex® Sarcoma V2) revealed a *EWSR1::CREB1* gene fusion.
Conclusion: GNET is an ultra-rare and aggressive GI mesenchymal tumour characterized by neural markers positivity and melanic markers negativity. The main differential diagnosis is mainly made with a metastatic CSS, but melanic markers are positive; and metastatic melanoma, that do not harbour a EWSR1 gene rearrangement. Other tumours such as gastrointestinal stromal tumour, neuroendocrine tumours, synovial sarcoma or alveolar rhabdomyosarcoma are included in the differential diagnosis. A correct diagnosis of GNET is crucial to early provide an accurate treatment.

E-PS-24-040
From morphologic overlap to molecular precision: VGLL2::NCOA2-fused spindle cell RMS in early infancy
A.K. Kolik[1], F. Cengiz[1], M.C. Dönmez[2], N. Erdoğan[1]
[1]Basaksehir Cam and Sakura City Hospital, Department of Pathology, Istanbul, Turkey, [2]Basaksehir Cam and Sakura City Hospital, Department of Paediatric Oncology, Istanbul, Turkey

Background & Objectives: Limited biopsy material, such as tru-cut samples in infants, may lead to diagnostic ambiguity when evaluating spindle cell sarcomas. We present a diagnostically revised case of SC/S RMS, initially labeled as infantile fibrosarcoma (IFS), to highlight the value of clinical, morphological, and immunohistochemical integration in accurate diagnosis and to contribute to the molecular annotation of VGLL2-fused RMS.
Methods: Histopathologic and immunohistochemical analyses were followed by targeted RNA sequencing using a sarcoma-specific fusion panel (ArcherDX Sarcoma Panel v2, Illumina NextSeq 500) for molecular confirmation.
Results: A 6-month-old male infant was referred following a tru-cut biopsy at an external centre, which had rendered a diagnosis of IFS. The clinical differential diagnoses included IFS and Ewing sarcoma. The lesion, initially presenting as a painless swelling in the left elbow, measured 6×3 cm and demonstrated destructive involvement of the distal humerus. MRI revealed a 5.5×3 cm mass extending to the proximal forearm with cortical erosion.
Microscopic reevaluation demonstrated fascicular and focally herringbone-like spindle cell infiltration within a hyalinized stroma. Tumour cells were diffusely MyoD1-positive, focally Myogenin-positive, and negative for desmin, actin, caldesmon, S100, and CD34. Twenty-one mitoses were identified per 10 high-power fields. Based on these findings and clinical context, a diagnosis favoring SC/S RMS was rendered prior to molecular testing.
RNA sequencing subsequently confirmed the diagnosis by detecting a VGLL2::NCOA2 fusion. No MYOD1 mutation or FOXO1 alteration was identified.
The patient received 12 weeks of IRS/IR VAC chemotherapy and two cycles of neoadjuvant radiotherapy. Surgery was deferred at our centre; wide excision is reportedly planned externally. The clinical course remains stable to date.

Conclusion: This case illustrates the diagnostic complexity of SC/S RMS in infancy and demonstrates that clinicopathologic integration can be sufficient in selected cases. Molecular confirmation provided additional diagnostic support and contributes to the genomic understanding of fusion-positive rhabdomyosarcoma.

E-PS-24-041

Small bowel MPNST in a NF1 patient: a case report

B. Toma[1,2], M. Danciu[1,2]
[1]"Grigore T Popa" University of Medicine and Pharmacy, Pathology, Iasi, Romania, [2]"Sf. Spiridon" Emergency County Hospital, Pathology, Iasi, Romania

Background & Objectives: Malignant peripheral nerve sheath tumours (MPNSTs) are aggressive sarcomas frequently associated with neurofibromatosis type 1 (NF1). Only 13 cases with gastrointestinal involvement have been reported. We present a high-grade MPNST in the small bowel, initially suspected as GIST.
Methods: A 48-year-old female with NF1 family history presented with numerous skin neurofibromas and symptoms of intestinal obstruction and peritoneal irritation. Contrast-enhanced CT revealed a heterogenous lesion with no clear demarcation from adjacent structures. Right hemicolectomy and right adnexal removal were performed. Histopathological examination and immunohistochemical tests (SOX10, CD117, DOG1, CD34, SMA, MUC4, EMA, S100, and HMB45) were used for diagnosis.
Results: Gross examination showed a relatively well demarcated tan mass with cystic areas, measuring 11 cm in the long axis, originating in the subserosa and progressively invading the full thickness of the small bowel wall, leading to luminal protrusion and mucosal ulceration. Histologically, we described a well-demarcated, unencapsulated, intramural tumour with fascicular architecture, spindle cells, high mitotic activity (50 mitoses/10 HPF), myxoid stroma, and widespread tumour necrosis. IHC revealed focal SOX10 with moderate intensity, while CD117, DOG1, CD34, SMA, MUC4, EMA, S100, and HMB45 were negative. Given the histological features and immunohistochemical profile with focal SOX10 expression, and medical history of NF1, a diagnosis of high-grade MPNST was confirmed.
Conclusion: Gastrointestinal involvement by MPNSTs is extremely rare, with few cases reported so far. Other soft tissue neoplasms such as GISTs are typically included in the differential, although knowing the setting of NF1 allows for a higher index of suspicion in diagnosing MPNST. Taken together with the clinical context, histopathological and IHC evaluation are essential for diagnosis. Given the aggressive nature of MPNSTs, early recognition and preemptive management of plexiform neurofibromas, before transformation, is essential, ideally in a multidisciplinary setting.

E-PS-24-043

Rare variant of fibrous dysplasia: fibrocartilaginous dysplasia

B.U. Durmus[1], A.N. Yüksel[1], S. Çetinkaya[2], S.A. Gümüştaş[3]
[1]Kartal Lütfi Kırdar City Hospital, Medical Pathology, Istanbul, Turkey, [2]Dr. İlhan Varank City Hospital, Medical Pathology, Istanbul, Turkey, [3]Acıbadem Hospital, Orthopedics and Traumatology, Istanbul, Turkey

Background & Objectives: Fibrocartilaginous dysplasia is a rare benign bone lesion seen in children. Our patient is a 10-year-old female who presents to the clinic with left hip pain that has been ongoing for 3 months. The X-ray examination revealed a radiolucent lesion with indistinct borders and areas of ground glass opacity located in the left femoral neck-shaft and left tibia. There is a reduction in the angle of the left femoral neck-shaft, along with outward angulation of the proximal femur (Shepherd's Crook deformity).
Methods: The patient underwent bone curettage biopsy for both lesions. For the lesion located in the left femoral head, histopathological examination of the H&E sections revealed massive cartilage tissue composed of both small fragmented and mostly large nodules in many regions. Focal areas exhibit spindle-shaped benign-appearing fibrous stroma containing disorganized immature bone lamellae fragments within the stroma. Notably, osteoblasts are not prominent around the immature bone tissue in the fibrous stroma. In the cartilage tissue, there is focal cellularity increase and moderate atypia, along with widespread enchondral ossification. Areas of continuity between the cartilage tissue and fibrous stroma are observed.
Results: This lesion is reported as fibrocartilaginous dysplasia. No cartilage tissue is detected in the concurrent curettage biopsy of the tibia, and this lesion is reported as Fibrous Dysplasia.

Conclusion: In the literature, cases where varying amounts of cartilage differentiation accompanying fibrous dysplasia have been reported, though these are very rare. These cases have been described as fibrocartilaginous dysplasia. In these instances, cartilage tissue may sometimes be very prominent. Since atypia may be observed in the cartilage tissue, chondrosarcoma should be considered in the differential diagnosis. In these cases, the identification of the classic fibrous stromal component is crucial.

E-PS-24-044

Correlating nuclear morphometric patterns with immunohistochemical p53 staining and Ki67 labelling index in sporadic primary and long-term recurring chordomas

S.R. Ullmann[1], J.M. Ullmann[2], J. Schreier[1], M. Georgiades[3], C. Lohmann[4], M. Röpke[4], F.S. Karras[1], D. Jechorek[1], A. Roessner[1]
[1]Medical Faculty/University Hospital Magdeburg, Otto-von-Guericke-University, Department of Pathology, Magdeburg, Germany, [2]University Hospital of Rostock, Department of Pathology, Rostock, Germany, [3]Medical Faculty/University Hospital Magdeburg, Otto-von-Guericke-University, University Clinic for Radiology and Nuclear Medicine, Magdeburg, Germany, [4]Medical Faculty/University Hospital Magdeburg, Otto-von-Guericke-University, Orthopedic University Hospital, Magdeburg, Germany

Background & Objectives: Pleomorphic nuclear changes as well as tissue architecture can be characteristic for tumour progression or recurrence in solid tumours. Chordomas are malignant bone tumours with a high recurrence rate and uncertain tumorigenesis. Evaluation of nuclear pleomorphism in chordoma recurrences could facilitate the understanding of recurrence development and add a prognostic factor in diagnosis of this rare tumour. This study compares histology, immunohistochemistry and nuclear pleomorphy of non-recurrent chordomas (NRTs) and chordomas with long-term recurrences (RCs) in order to investigate wether tumour progression in chordoma coincides with nuclear pleomorphic changes.
Methods: 26 FFPE tissue samples of 12 patients (eight primary cases and four cases with multiple long-term recurrences) were obtained and stained for: H&E, brachyury, Ki-67, p53, S100, Vimentin, E-Cadherin, EGFR, VEGF, Pancytoceratines, SMARCB1, PD-1 and PD-L1. Nuclear morphometry was assessed by hand-tracing 320 nuclei per sample on digitally captured images.
Results: NRTs display a heterogenous distribution of nuclear morphometric measurements.
A comparison of RCs and NRTs show significant differences in all size and density-parameters as well as three out of four shape parameters and increased variances over time. Primary tumours of RCs had slightly smaller nuclei with higher deviations from a circular shape and were denser than NRTs hinting at a progress in dedifferentiation.

The p53 positivity was generally lower in primary tumours with < 1% compared to recurrent tumours with > 10%. Partial loss of SMARB1 expression could be observed more frequently in recurrences. Remarkably the Ki67 proliferation index showed a significant increase with a labelling index of < 1% in primary tumours and > 5% in the recurrences.
Conclusion: Patients with multiple recurrences showed significant pleomorphic changes over time especially in size and density parameters hinting that changes in clinical presentation and biological aggressiveness can present morphologically. This nuclear heterogeneity can be a feature associated with genetic instability and tumour progression.

E-PS-24-045
Insights into benign bone tumours of the chest wall: a series of 21 cases in a single Tunisian institution
R. Yaiche[1], R. Ayadi[1], S. Jedda[1], Y. Barbirou[1], O. Ismail[1], E. Braham[1], N. Ben Jamaa[1], A. Ayadi[1]
[1]Abderrahmane Mami Hospital, Pathology, Ariana, Tunisia

Background & Objectives: Benign bone tumours of the chest wall are rare entities. The diagnosis of these tumours can be challenging due to their overlapping histological features with other subtypes of bone tumours, especially when biopsy material is limited. In this report, we outline the clinicopathological features of benign thoracic bone tumours, along with their surgical management and prognosis.
Methods: A retrospective review was conducted on 21 patients diagnosed with benign bone tumours of the chest wall between 2002 and 2024. Clinical data, imaging findings, histopathological results, treatment modalities, and follow-up outcomes were retrieved from pathological reports and surgical records at Abderrahman Mami Hospital in Tunisia.
Results: There were 9 men and 12 women. The median age was 36 years, ranging from 20 to 52 years. Chest pain and palpable masses on physical examination were the most common presenting symptoms, reported in 10 and 7 cases, respectively. In 4 patients, the lesions were asymptomatic and discovered incidentally on imaging. Chest radiographs showed well-defined costal opacities in 14 cases. Chest computed tomography revealed a lytic, well-limited medullary costal lesion (17 cases) and a corticalized overgrowth (4 cases). No periosteal reaction or soft tissue infiltration were noted.
Surgical resection was performed in all patients. Pathological examination revealed 13 cases of fibrous dysplasia, 4 cases of enchondroma, 2 cases each of osteochondroma and mesenchymal hamartoma.
No postoperative complications or recurrences were noted during a mean follow-up of 8 years.
Conclusion: Benign bone tumours of the chest wall are rare and usually exhibit a benign course. Surgical resection remains an effective treatment with excellent prognosis and low recurrence rates. Although, radiological imaging plays a crucial role in the initial identification of these tumours, diagnosis confirmation still requires histological examination which accurately differentiate between different tumour types.

E-PS-24-046
Novel and unusual USP6 fusion partners in aneurysmal bone cyst – an update
J. Balko[1], W. Golas[1], M. Strnadová[1], J. Kotiš[1], J. Zámečník[1]
[1]2nd Faculty of Medicine, Charles University and Motol University Hospital, Department of Pathology and Molecular Medicine, Prague, Czech Republic

Background & Objectives: Aneurysmal bone cyst (ABC) belongs to a heterogenous group of reactive and neoplastic processes collectively known as giant cell-rich lesions of bone. Regarding the histopathological diagnosis, morphological features should be accompanied by clinical data or molecular analysis. A useful diagnostic clue represents the fact that approximately 70% of ABC harbour rearrangements of *USP6* gene. The aim of our research is to identify and report previously unrecognized and rare *USP6* fusion partners in ABCs. These discoveries could aid in both routine diagnostic practices and the exploration of the underlying biology of *USP6*-associated disorders.
Methods: This retrospective, non-randomized study involved a cohort of 14 patients diagnosed with ABCs, who were examined between 2014 and 2025 at Motol University Hospital in Prague. The cases were evaluated through histopathological analysis, immunohistochemistry, and Anchored multiplex RNA methods. In addition, demographic and clinical data were also reviewed.
Results: We discovered four novel *USP6* fusion partners (*ZFX*, *IP6K2*, *DDX6*, and *MORF4L1*), six rare ones (*MEF2A*, *EIF1*, *COL1A2*, *RUNX2*, *PAFAH1B1*, and *FAT1*), and two common partners (*CDH11* and *OMD*) across the 14 ABC cases.
Conclusion: The cases in our study were diagnosed as ABCs based on their distinct clinical and morphological features. However, not all instances present so clearly, and molecular testing remains essential. Recognizing these genetic alterations can help differentiate true ABCs from ABC-like changes seen in a variety of benign and malignant bone tumours. Moreover, the majority of fusion partners identified in our study have been associated with tissue repair according to the literature, which could explain certain clinical peculiarities, such as their connection to trauma in the anamnesis and the self-healing course observed in some cases. We suggest that further exploration of this hypothesis may be desirable.

Epithelioid haemangioendothelioma: a case report and retrospective review of diagnosed cases in a surgical pathology laboratory
A. Georgiou[1], P. Vlachou[1], E.A. Spiteri[1], E. Gioti[1], C. Vourlakou[1]
[1]General Hospital of Athens "Evaggelismos", Pathology, Athens, Greece

Background & Objectives: Epithelioid haemangioendothelioma (EHE) is a rare malignant vascular neoplasm with variable clinical behaviour that can arise in diverse anatomical locations. Diagnosing EHE is challenging due to its histological overlap with other vascular and epithelioid neoplasms. This study aims to present an interesting case of EHE and provide a retrospective review of EHE cases diagnosed in our pathology laboratory. We emphasize the diagnostic challenges and highlight the importance of implementing molecular techniques in confirming the diagnosis.
Methods: A retrospective review of EHE cases diagnosed in our pathology laboratory from 2009 to 2025 was conducted. Patient data were collected from pathology reports and medical records, including age, gender, tumour location, histological characteristics, immunohistochemical findings, and molecular analyses when available. Additionally, we present a detailed report of a newly diagnosed EHE case, which served as the catalyst for this study.
Results: A total of 15 cases of EHE were identified, where the diagnosis was either strongly considered or molecularly confirmed. Patient mean age was 60.3 years, with a male-to-female ratio of 2:1. Anatomical sites included the pleura (33.3%), bone (26.7%), soft tissues (20.0%), liver (13.3%), and lungs (6.7%). All cases exhibited morphologic features of epithelioid cells within a myxohyaline stroma. Endothelial differentiation was confirmed through immunohistochemical staining using vascular markers. A definitive diagnosis of EHE was achieved in 4 of 15 cases, with molecular biology techniques utilized in 3 of these cases. We also present a

44-year-old female with a morphologically and mitotically low-grade tumour in the thoracic wall, illustrating the diagnostic complexity and the value of integrating pathology, immunohistochemistry, and molecular studies.
Conclusion: EHE is a rare and diagnostically challenging tumour with diverse clinical presentations. By presenting a unique case alongside a comprehensive institutional review, we aim to enhance awareness and facilitate the accurate diagnosis of this uncommon entity.

E-PS-24-048
***EWSR1-PATZ1* fusion sarcoma. A new case report and review of the literature**
J. Ryś[1], A. Kruczak[1], A. Adamczyk[1], M. Wesołowska[1], K. Mularz[1], M. Rozmus-Piętoń[1], K. Majchrzyk[1], A. Harazin-Lechowska[1]
[1]Maria Sklodowska-Curie National Research Institute of Oncology, Krakow Branch, Department of Tumour Pathology, Cracow, Poland

Background & Objectives: *EWSR1::PATZ1* sarcoma is a exceedingly rare malignant mesenchymal neoplasm with variable morphology and a heterogeneous immunohistochemical profile. So far, only 45 cases have been described in the literature, that is why we report an additional case of this tumour with complete clinico-morhological and molecular data.
Methods: Male, aged 55, was admitted to a hospital due to a subcutaneous tumour of the paravertebral region, growing for 2 months. CT examination showed unencapsulated mass, 23x20x41 mm, localized in the paravertebral soft tissues at the Th11 level. The tumour was radically removed and no adjuvant treatment was administered. The patient maintained free of disease for 13 months.
FFPE and HE stained tumour sections were reviewed by two pathologists. All immunohistochemical staining were made using DAKO Omnis autostainer.
FISH study was performed on FFPE tissue sections using the EWSR1-Dual Color Break Apart Rearrangement Probe set. At least 300 interphase nuclei were analysed. The most common fusion genes were assessed using Archer FusionPlex Sarcoma V2 assay and Illumina MiniSeq sequencer.
Results: **At low power microscopy**, the tumour was partially encapsulated by a variably fibrous tissue and skeletal muscles. **At high power** the tumour texture was consisted of small round cells with moderate polymorphism and moderate proliferative activity. The neoplastic cells formed solid and perivascular arrangements or gathered around pseudocystic spaces. Their immunophenotype was characterized by strong expression of desmin (DER11), S100 protein and MyoD1. The immunohistochemical reactions to cytokeratins, EMA, smooth muscle actine, myogenin, DOG1, and ERG gave negative results. EWSR1-FISH showed the split of two signals in more than 10% tumour cells. NGS study demonstrated EWSR1::PATZ1 gene fusion, with EWSR1 exon 8::PATZ1 exon 1.
Conclusion: Depending on histological texture and the immunofenotype, *EWSR1-PATZ1* sarcoma may histologically resemble rhabdomyosarcoma. The molecular studies (using both FISH or NGS methods) allow to establish the proper final diagnosis.

Retiform haemangioendothelioma of the index finger: a diagnostic challenge
Z. El euch[1,2], Z. Lajmi[1,2], S. Sakly[1,2], S. Moussa[1,2], A. Bdioui[1,2], S. Hmissa[1,2]
[1]Sahloul University Hospital Centre, Department of Anatomy and Pathological Cytology, Sousse, Tunisia, [2]Faculty of Medicine of Sousse, Research Laboratory LR21 ES03, Sousse, Tunisia

Background & Objectives: Retiform haemangioendothelioma (RH) is an uncommon vascular tumour of intermediate biological behaviour, which is prone to local recurrence but rarely shows metastasis to distant sites. It most frequently occurs on the limbs especially the lower extremities. Distinguishing RH from the aggressive angiosarcoma is challenging, as it may mimic well-differentiated angiosarcoma, especially on small biopsies. It is crucial to consider RH in the differential diagnosis of vascular lesions that present with angiosarcoma-like characteristics.
Methods: A 46-year-old woman, with no history, consulted for a painless swelling on the palmar side of her right index finger. The lesion caused mild discomfort without functional limitations. On examination, the nodule was firm, immobile and adherent to deep structures, initially raising suspicion of a tenosynovial giant cell tumour. Imaging findings were in line with this hypothesis. During surgery, unexpected skin adhesion suggested a more aggressive process.
Results: Gross examination revealed a nodule measuring 3.5 × 1.5 cm. Microscopically, the dermis was the site of poorly defined vascular proliferation, forming elongated and branching channels in a distinctive retiform pattern. The endothelial cells exhibited mild nuclear atypia and occasional protrusions into the lumen. Mitotic figures were rare. The surrounding stroma contained moderate lymphocytic infiltration and fibrosis. Immunohistochemical analysis showed ERG positivity and HHV-8 negativity. The diagnosis of RH was retained.
Conclusion: This case illustrates the diagnostic complexity of RH, which can clinically resemble both benign and more aggressive tumours. The unusual location on the finger, combined with its intraoperative and histological characteristics, highlights the need to consider RH in the differential diagnosis of vascular lesions. Given its high recurrence rate, complete surgical resection with negative margins is essential, along with long-term follow-up to monitor for potential regrowth.

E-PS-24-051
Histologic and clinical vagaries of Sclerosing Epithelioid Sarcoma: a series of 23 patients
M. Ramadwar[1], B. Rekhi[1], P. Panjwani[1], A. Kaushik[1], M. Bhandari[1], S. Dhande[1], M. Pruthi[2], N. Khanna[3], P. Bhargava[4]
[1]Tata Memorial Hospital, Pathology, Mumbai, India, [2]Tata Memorial Hospital, Surgery, Mumbai, India, [3]Tata Memorial Hospital, Radiation Oncology, Mumbai, India, [4]Tata Memorial Hospital, Medical Oncology, Mumbai, India

Background & Objectives: Sclerosing Epithelioid Fibrosarcoma (SEF) is a rare sarcoma with high local recurrence rates and metastatic potential. Histologically, it contains bland epithelioid cells within a dense fibrous stroma. Immunohistochemistry for MUC4 is highly specific for diagnosis of SEF. We studied 23 patients diagnosed with SEF in our institution from 2019 to 2025 with emphasis on the histologic spectrum, immunohistochemistry and clinical outcomes..
Methods: We obtained clinical data from hospital records and reviewed histopathology findings
Results: The age range of patients was 9 to 70 years; median 40 years. M:F ratio was 60:40. The most common site of occurrence was lower extremity followed by shoulder region, chest wall and paravertebral region. Primary bone involvement was seen in 2 patients. Conventional morphology was seen in most tumours. Areas with spindle cell morphology resembling low grade fibromyxoid sarcoma were seen in 3 cases, necrosis in 3 cases, mitoses in 1 case. Significant nuclear atypia was seen in 2 cases. 86% % of tumours were positive for IHC with MUC4. Molecular testing for EWSR1 gene rearrangement was performed in only 2 patients, both were positive. 11% patients presented with metastasis. 40% experienced local relapse and 16 % had distant metastasis later.

Conclusion: SEF occurred at varied sites and in wide age range, hence required a high index of suspicion. Typical morphology of bland epithelioid cells embedded in dense fibrous stroma was seen in 70% of patients. 30% cases showed unusual findings such as spindle cell areas, foci of necrosis, atypia and increased mitoses. Aggressive clinical behaviour of SEF was evident in spite of its low grade histological features. 40% patients experienced relapse, 27% had metastasis. Lungs, bones, soft tissue and lymph nodes were the commonest sites of metastasis. IHC for MUC4 proved to be specific which helped in ruling out a wide spectrum of differential diagnoses of SEF.

E-PS-24-052

Calcifying Fibrous Tumour of the stomach mimicking Gastrointestinal Stromal Tumour: a report of a rare case

A. Therapontos[1], A. Mellou[1], D. Efthymiou[1], E. Athanasiou[1], M. Lenos[1], C. Vourlakou[1]
[1]Evaggelismos General Hospital, Department of Pathology, Athens, Greece

Background & Objectives: Calcifying fibrous tumour (CFT) is a rare benign soft tissue mesenchymal neoplasm which can occur anywhere and pathogenesis was controversial. Although the gastrointestinal tract is the most common predilection site and often stomach. The histologic examination is the gold standard for the diagnosis. By definition has characteristic morphology thus immunohistochemistry might be of use in the differential diagnosis from other submucosal, more aggressive clinically mimickers and the principle consideration was gastrointestinal stromal tumours (GIST).
Methods: A 52-year asymptomatic woman with gastric lesion found incident in a screening esophagogastroduodenoscopy. Endoscopic ultrasonoscopy showed a mass derived from the muscularis propria and diagnosis of (GIST) was suspected. A laparoscopic wedge resection was preferred. The pathological findings showed grossly well circumscribed submucosal mass 15mm with white to gray cut surface. Microscopically was hypocellular, composed of bland spindle cells with fibroblastic differentiation in a hyalinized collagen stroma and dystrophic type calcifications. Necrosis and mitosis were absent.
Results: Immunostains were negative for the markers CD117, DOG-1, AE1/AE3, SMA, Desmin, S-100 STAT-6, CD34 although SDHB retained. A diagnosis of CFT was rendered. Coexisted a lot lymphoplasmacytic infiltration which are IgG4 positive with IgG4/IgG > 50% in immunohistochemistry. These lesions overlaps morphologically igG4 related disease however the long term follow up showed no evidence especially in patients without other inflammatory or autoimmune diseases and combination of serologic-radiologic findings.
Conclusion: Local resection with clear margins is the most chosen treatment option for CFTs and should be distinguished from other tumours due to their low risk of recurrence and benign biological behaviour with excellent prognosis. When CFT is suspected the patient should be tests for igG4 related disease. The relationship between them remains unclearand only a subset of CFTs may arise in the context of either systematic ig4 disease.

E-PS-24-053

Case series of giant cell rich bone lesions: a 10-year single-centre retrospective analysis of 68 cases

M. Ayyıldız Mercan[1], O. Mercan[2], C.B. Akbaş[3], E. Taştekin[1], U. Usta[1]
[1]Trakya University, Department of Pathology, Edirne, Turkey, [2]Trakya University, Department of Orthopaedics and Traumatology, Edirne, Turkey, [3]Trakya University, Department of Radiology, Edirne, Turkey

Background & Objectives: Giant cell-rich bone lesions encompass a spectrum of neoplastic and non-neoplastic disorders characterized by osteoclast-type giant cells, demonstrating diverse clinical and biological behaviours. A multidisciplinary approach incorporating clinical, radiological, pathological, and genetic features is essential to establish a definitive diagnosis and guide appropriate management.
Methods: Between 2014 and 2024, we retrospectively analysed clinical data from 68 patients diagnosed with giant cell-rich bone lesions. The evaluation included demographic characteristics (sex, age), lesion localization, clinical presentation (presence of pain, oedema, pathological fracture), and outcomes (recurrence, metastasis).
Results: In a cohort of 68 patients (35 female, 33 male; mean age 25.5 years, range 2–64) with histologically confirmed bone lesions, the most common diagnosis was aneurysmal bone cyst (ABC) (n=32, 47.1%), followed by giant cell tumour of bone (GCT) (n=17, 25%), chondroblastoma (n=6, 8.8%), non-ossifying fibroma (NOF) (n=4, 5.9%), and giant cell-rich osteosarcoma (n=4, 5.9%). Less frequent entities included reparative granuloma (n=3, 4.4%), chondromyxoid fibroma (n=3, 4.4%), brown tumour (n=1, 1.5%), benign fibrous histiocytoma (n=1, 1.5%), and osteoblastoma (n=1, 1.5%). The femur was the most frequently involved bone (32.4%), followed by the tibia (19.1%) and fibula (16.2%). Pelvic bones (pubis + sacrum) constituted 7.3% of cases (pubis 2.9%, sacrum 4.4%), while small bones of hands/feet (metacarpals + metatarsals) accounted for 8.9% (metatarsals 7.4% + metacarpals 1.5%). Rare sites included the scapula and ribs (1.5% each). Clinically, 92.6% (n=63) presented with pain, 27.9% (n=19) had oedema, and 14.7% (n=10) presented with pathological fractures. Recurrence occurred in 8.8% (n=6), including 3 ABC, 2 GCT, 1 osteosarcoma. Lung metastasis was identified in 1 osteosarcoma case.
Conclusion: The accurate diagnosis of giant cell-rich bone lesions requires comprehensive integration of histopathological characteristics with key clinical-radiological parameters, including patient age, anatomical location, and imaging findings, to distinguish between histologically similar but clinically distinct entities.

E-PS-24-054

EWSR1-PATZ1 fused sarcoma arising in chest wall: a case report

H. Jang[1], K.S. Lee[1]
[1]Seoul National University Bundang Hospital, Pathology, Seoul, Republic of Korea

Background & Objectives: Sarcomas with EWSR1-PATZ1 fusion are rare soft tissue tumour. In the WHO Classification 5th Edition of Soft Tissue and Bone Tumours, it has been classified as Round cell sarcoma with EWSR1-non-ETS fusion. It has been reported to occur across a broad age range (1–81 years) with an approximately equal male-to-female ratio. Notably, it was recently recognized as an entity and demonstrates variable morphology, ranging from low- to high-grade sarcomas, along with a heterogeneous immunohistochemical profile. Due to its low incidence and diverse histologic features, accurate diagnosis is challenging, requiring ancillary immunohistochemistry. Herein, we report an extremely rare case of EWSR1-PATZ1 fused sarcoma.
Methods: Immunohistochemistry and next-generation sequencing (NGS) were used for diagnostic purposes.
Results: A 58-year-old male with no specific symptoms was found to have a 6.5 × 4.3 × 3.6 cm mass in the chest wall on CT. He underwent surgical resection. Grossly, the tumour was well-circumscribed, solid, and fibrotic. Microscopically, it predominantly showed sclerotic areas with low cellularity, interspersed with regions of pleomorphic cells and notable microcystic changes. Most of the tumour cells were spindle-shaped or had a fibrohistiocytic appearance. Immunohistochemically, the tumour showed positivity for GFAP and Desmin, with focal positivity for Sox10, S100, EMA, SMA, and calponin. Based on these findings, EWSR1-PATZ1 fused sarcoma was suspected, prompting NGS analysis, which confirmed an in-frame fusion between EWSR1 exon 7 and PATZ1 exon 1, leading to the final diagnosis.
Conclusion: EWSR1-PATZ1 fused sarcoma is a very rare novel entity of undifferentiated small round cell sarcoma. This case underscores

the importance of considering EWSR1-PATZ1 fused sarcoma in the differential diagnosis of chest wall lesions and highlights the clinical significance of molecular testing in rare sarcomas.

E-PS-24-055

Sclerosing/spindle cell rhabdomyosarcoma. Case series of the last 5 years

I. Garcia Miranda[1], K.A. Gonzalves Villarreal[1], I. Orbegozo Arrizabalaga[1], D. Bravo Blanco[1], L. Zaldumbide Dueñas[1], L. Mosteiro González[1]
[1]H.U. Cruces, Barakaldo, Spain

Background & Objectives: Rhabdomyosarcoma (RMS) is a rare malignant neoplasm arising from undifferentiated mesenchyme. Head and neck and extremities are the most frequent locations. It was first classified as a variant of embryonal RMS but it´s been recently recognized as an independent entity.
Methods: A 58-year-old male patient with the complaints of left hand paresthesias. The radiologic studies showed a lesion that involved 3rd and 4th metacarpians and it caused cortical bone rupture.
A 65-year-old female patient assisted with a nodule in the back of the neck that was initially suspicious for sebaceous cyst and it was resected without posterior pathological examination.
Results: Slides of both lesions showed neoplastic proliferation consisting of spindle and epithelioid cells. They had marked cytological atypia, irregular nuclei, vesicular chromatin and prominent eosinophilic nucleoli. In the first case, numerous rhabdomyoblasts could be seen, with a variable cell density that alternates hypercellular and hipocellular zones with stromal sclerosis. The second case standed out with numerous mitosis figures and foci of geographic necrosis and, peripherally, a crown of lymphocytes was observed.
Immunohistochemical staining:
Positive: Smooth muscle actin, desmin, caldesmon, INI1 (nuclear), MyoD1, mioglobin, H3-K27me3, CK AE1/AE3, CK7.
Negative: neural markers, beta-catenin (nuclear), CD34, calponin, CK20, p40, CK5/6, GATA3, EBER.
After histological examination and immunohistochemical staining, both lesions were diagnosed as spindle cell rhabdomyosarcoma.
Conclusion: It`s important of preparing a broad IHQ panel that allows to elaborate a correct differential diagnosis with other spindle cell sarcomas (many of which may have rhadbomyoblastic differentiation).
The fact that a small percentage of spindle cell RMS can express citoqueratine could lead us to mistake with undifferentiated carcinomas, especially in head and neck region.
Spindle cell variant of RMS seems to be an aggressive lesion; despite it has a better prognosis than other adult RMS.

E-PS-24-056

Case report: primary breast soft tissue sarcoma with BCOR genetic alterations

A. Gradil[1], M. Pinho Fialho[1], J. Santos[1], D. López-Presa[1]
[1]Unidade Local de Saúde Santa Maria, Lisbon, Portugal

Background & Objectives: Primary breast sarcomas are rare, accounting for less than 1% of all breast malignancies. Angiosarcoma is the most common type of breast sarcoma but other types have limited clinical, histologic and molecular information, hindering optimal patient management.
Methods: We report a case of a previously healthy 20-year-old female that presented with a 3-week growing, painful breast nodule.
Results: After 2 biopsies inadequate for a histological diagnosis, the patient underwent a tumorectomy. Histological examination revealed a spindle and round cell neoplasm, non-encapsulated, infiltrative, of high malignancy grade with venous invasion and no necrosis. Neoplastic cells were immunoreactive for vimentin, CD10, pS100, CD56, cyclin D1, SATB2, BCL2, and focal SMA and CD99 staining; they were negative for cytokeratins, EMA, p63, GFAP, SOX10, HMB45, melan A, calponin, desmin, myogenin, CD34, ERG, STAT6, MUC4 and TLE1, with a Ki67 of 40%. Together with molecular and NGS ancillary techniques, a non CCNB3-BCOR fusion and a non-homozygotic CDKN2A gene mutation were identified. A diagnosis of primary breast soft tissue sarcoma with BCOR genetic alterations was made after ruling out metastatic endometrial stromal sarcoma. The patient underwent radical mastectomy and chemotherapy. The tumour was poorly responsive to treatment and the patient later developed lymph node and skin metastases and is currently awaiting further treatment.
Conclusion: Primary breast soft tissue sarcomas with BCOR genetic alterations are very rare, with around 200 reported cases, and are associated with a poor prognosis. Given the paucity of data, the management of these patients remains unclear; however, molecular and NGS profiling can identify potentially useful therapeutic targets, thus improving patient overall survival.

E-PS-24-057

Molecular decryption of sarcomas: a 6-year retrospective study revealing new diagnostic perspectives in Marrakech

S. El attar[1], M. El Ouazzani[1], F.E. Ghlalou[1], S. Sellami[2], B. Zinbi[3], J. Chouaf[3], H. Rais[1]
[1]Faculty of Medicine and Pharmacy, Cadi Ayyad University, Arrazi Hospital, Mohammed VI University Hospital Centre, Department of Pathological Anatomy, Marrakech, Morocco, [2]Faculty of Medicine and Pharmacy, Cadi Ayyad University, Arrazi Hospital, Mohammed VI University Hospital Centre, Immunohistochemistry Unit, Marrakech, Morocco, [3]Faculty of Medicine and Pharmacy, Cadi Ayyad University, Arrazi Hospital, Mohammed VI University Hospital Centre, Molecular Biopathology Unit, Marrakech, Morocco

Background & Objectives: **Background:** Soft tissue sarcomas are rare tumours whose classifications, based on their appearance and characteristics, often lack consistency. A better understanding of their molecular profiles is essential to improve diagnosis and management.
Objective: To explore the molecular characteristics of soft tissue sarcomas in comparison with their pathological features in patients at the Mohamed VI University Hospital.
Methods: A retrospective study was conducted from January 2019 to January 2025, examining 66 cases of sarcomas (19 PNET/Ewing, 19 synovial, 28 liposarcomas) at the pathology department. Diagnosis was based on standard histology, immunohistochemistry (anti-CD99, anti-cytokeratin, anti-EMA, anti-TLE, anti-MDM2, and anti-CDk4 antibodies) and FISH to detect EWSR1 and SS18 gene rearrangements, as well as MDM2 gene amplification.
Results: The average age of patients was 37 years (13-79 years), with a male predominance. 81% of cases were grade III according to the FNCLCC classification, mainly located in the lower limbs. PNET/Ewing tumours showed proliferation of small round cells, with 85% intense positivity for CD99 and 78.9% EWSR1 rearrangement. Synovial sarcomas presented spindle cells, with >80% positivity for cytokeratin, EMA, and TLE, and 26.3% SS18 rearrangement. Liposarcomas showed positivity for MDM2 and CDk4, with 17.8% MDM2 amplification.
Conclusion: This study underscores the importance of a diagnostic approach combining morphological evaluation and molecular analyses for soft tissue sarcomas. The diversity and complexity of these tumours require a comprehensive approach, allowing for accurate and informed clinical decisions in the management of sarcoma patients.

E-PS-24-058

Tumour necrosis shapes Ewing sarcoma intra-tumoral heterogeneity

F. Ruiz[1], E. Perez[2], K. Rubio[2], R. Dong[2], L. Broye[3], N. Chevalier[3], N. Druck[2], A. Villanueva[2], Y. P Hung[2], R. Renella[3], I. Letovanec[4], P. Gunnlaugur[2], N. Riggi[3], M. Rivera[2], M. Suvà[2]

[1]Geneva University Hospital, Clinical pathology, Geneva, Switzerland, [2]Massachusetts General Hospital and Harvard Medical School, Boston, USA, [3]Centre Hospitalier Universitaire Vaudois, University of Lausanne, Lausanne, Switzerland, [4]Central Institute, Valais Hospital, Sion, Switzerland

Background & Objectives: Ewing sarcoma (EwS) is the second most common bone malignancy in children and young adults. Most, if not all, EwS oncogenesis is driven by a chromosomal translocation between a member of the Erythroblast transformation specific *(ETS)* family of transcription factors and a member of the *FET* family of RNA binding proteins, most commonly resulting in the *EWS-FLI1* fusion. Despite multimodal therapy, EwS prognosis remains dismal in the presence of metastasis or recurrence, possibly due to its intra-tumoral heterogeneity (ITH). Ewing sarcoma displays one of the lower mutational burdens of all cancers, raising the question of the molecular mechanisms driving its ITH.
Methods: To better understand EwS ITH, we performed single-cell transcriptomics on seven freshly dissociated tumours using full-length single-cell RNA sequencing (SMART-Seq2) and further validated our findings with droplet-based single-nucleus RNA sequencing (10x) on four tumours. In addition, we utilized spatial transcriptomics (GeoMX) to investigate EwS cellular-states spatial distribution and *in-vitro* culture of primary EwS sarcoma cells to decipher molecular drivers of EwS cellular heterogeneity.
Results: We identified six malignant cellular states, including a mesenchymal program predictive of worse prognosis. Spatially, peri-necrotic tumoral cells exhibited a profoundly altered cellular landscape, with enrichment in meta-programs linked to inflammation and mesenchyme-related genes, alongside reductions in cell cycle and metabolic activity. Mechanistically, soluble factors from necrotic tumour cells increased the expression of Activating Protein 1 (AP1) family transcription factors, altering cell state distribution and modulating EWS-FLI1 activity.
Conclusion: Overall, our work provides an atlas of EwS malignant cells, underscores the critical role of tumour necrosis in shaping ITH, and identifies a cell population associated with poorer prognosis, offering potential therapeutic targets and highlighting the role of the mesenchymal cellular state markers in predicting EwS prognosis

Funding: Swiss National Science Foundation (SNSF); Project number P500PM_206713; Name of the project: Dissecting molecular mechanisms driving Glioblastoma heterogeneity

E-PS-24-059

Soft tissue sarcomas: epidemiological criteria and pronostic and predictive clinical and anatomopathological factors for recurrence in the centre of Tunisia

D. Chiba[1], A. Mdaoukhi[2], J. Saadana[2], I. Hadhri[3], A. Ben Abdelkader[3], M. Mokni[3], B. Sriha[3]
[1]Avicenne Hospital, Pathology, Paris, Tunisia, [2]Fattouma Bourguiba Hospital, Orthopedic, Monastir, Tunisia, [3]Farhat Hached Hospital, Pathology, Sousse, Tunisia

Background & Objectives: Soft tissue sarcomas (STS) are rare malignant tumours that arise from supportive mesenchymal tissue. Their etiopathogenesis is poorly understood, and several prognostic factors influence patient survival, which varies from 42% to 87% at 5 years. In addition to prognostic factors, it is crucial to identify and manage predictive factors for local recurrence in order to improve treatment outcomes.
The main objective of this study was to analyse the epidemiological, clinical, and pathological characteristics of soft tissue sarcomas, and to identify the predictive factors for tumour recurrence as well as the prognostic factors influencing overall survival.
Methods: This is a retrospective, descriptive, and analytical study based on data from the Cancer Registry of the Centre of Tunisia over a 25-year period (1997-2021). It included patients diagnosed and treated at the orthopedics departments of Monastir and Sahloul hospitals, with diagnoses confirmed by the pathology departments of Farhat Hached and Monastir hospitals.
Results: The study included 142patients,with an average age of 50.7years,ranging from 3 to 93 years.The male-to-female ratio was 1.15.The main symptom was swelling,observed in 85.2%of cases,with an average consultation delay of 20.6 months.The thigh was the most frequent location,involved in 45%of cases.Liposarcomas and fibrosarcomas were the most common histological types,each accounting for 26.8% of cases.The local recurrence rate at 3 years was 45.1%,and the 5-year overall survival rate was 47.9%.Univariate analysis showed that factors such as age,consultation delay,histological type,tumour location,and clinical and radiological characteristics significantly influenced local recurrence and overall survival.
Conclusion: Although rare,soft tissue sarcomas present a great histological and anatomical diversity.Analysis of clinical and therapeutic data allowed the identification of essential prognostic and predictive factors for better disease control and improved outcomes.These results highlight the importance of multidisciplinary management,including multidisciplinary tumour board meetings,in optimizing the treatment and follow-up of patients with soft tissue sarcomas.

E-PS-24-062

Intratesticular leyomioma with degenerative atypia: an unexpected diagnosis of an exceedingly rare benign testicular tumour

I. Araújo[1], S. Neves[1], N. Chiote[1], N.J. Lamas[1,2]
[1]Unidade Local de Saúde de Santo António, Anatomic Pathology Service, Genetics and Pathology Clinic, Porto, Portugal, [2]University of Minho, School of Medicine & Life and Health Sciences Research Institute (ICVS), Braga, Portugal

Background & Objectives: Mesenchymal tumours of the testis are extremely rare and they have a tendency to display malignant features. In addition, they are normally difficult to distinguish from other more common testicular tumours. Therefore, radical orchiectomy is the likely choice upon on the presence of a suspicious testicular nodule.
Methods: Here, we report the case of a 46-year-old man who sought medical care after noticing a nodule in his right testicle evolving for nearly 1 month. The ultrasound imaging study described a hypoechoic and highly vascularized nodule with 9 mm. A radical orchiectomy was performed.
Results: A 10 mm whitish well-circumscribed nodule was present in the upper pole of the 5,5x4x3 cm testicle. The histological analysis showed a neoplasm composed of spindle-shaped cells with indistinct cytoplasmic borders, eosinophilic cytoplasm, nuclei with tapered ends and small nucleoli; and epithelioid cells with eosinophilic cytoplasm and rounded nuclei with similar characteristics. There were also frequent cells of increased size, eosinophilic cytoplasm, with irregular nuclear contour, hyperchromasia and a "blurred nuclei" appearance, suggesting degenerative changes. Frequent nuclear pseudoinclusions and occasional multinucleated giant cells were also noted. Mitotic activity was not significant. Necrosis was absent. The immunohistochemistry study showed expression of SMA, Desmin, HHF35 and Caldesmon, while S100 protein and Inibin A were negative. TP53 had wild-type expression. The proliferative index (%Ki-67) was <1%. The diagnosis of a leiomyoma with degenerative nuclear atypia was advanced.
Conclusion: Leiomyomas are benign mesenchymal neoplasms commonly occurring in locations such as the uterus or small bowel. Leiomyomas affecting the male genitourinary tract are extremely uncommon. Of these, intratesticular leiomyomas are exceedingly rare. Given the benign nature of this neoplasm, is of utmost importance to identify

novel markers and imaging features that will prevent unnecessary orchiectomies for a benign testicular tumour.

E-PS-24-063

When rare meets young: paediatric presentation of desmoplastic fibroblastoma

M. Della Mura[1], J. Sorino[1], A. Colagrande[1], E. Cascardi[1], G. Ingravallo[1], G. Cazzato[1]
[1]University of Bari "Aldo Moro", Section of Molecular Pathology, Department of Precision and Regenerative Medicine and Ionian Area (DiMePRe-J), Bari, Italy

Background & Objectives: Desmoplastic fibroblastoma (DF) is a benign soft tissue tumour made up of stellate and/or spindle-shaped fibroblasts, embedded in an abundant collagenous or myxocollagenous stroma. DFs are rare neoplasms, predominantly affecting adults. Herein, we present a novel case of paediatric DF, with the aim to expand our knowledge about this entity in childhood.
Methods: The clinical history of the patient was retrieved. Tissue samples were formalin-fixed and paraffin-embedded, then haematoxylin-eosin as well as immunohistochemical staining for CD34, smooth muscle actin (SMA), actin muscle specific (HHF-35), and Ki-67 were performed.
Results: A 12-year-old boy presented with a 4-cm mass on his left thigh. Complete surgical excision was performed. Histology revealed a subcutaneous, well-circumscribed tumour consisting of scattered, stellate and spindle-shaped fibroblasts embedded within an abundant hypovascular, collagenous matrix. Cytologically, no atypia or mitotic activity were noted. CD34, SMA, and HHF-35 were negative; Ki-67% was <1%. After 2 years of follow-up, the patient did not show signs of recurrence.
Conclusion: To date, only 5 additional cases of DF have been reported in paediatric patients (age: 0–18 years), affecting predominantly in males and following a benign clinical course. Our report further confirms the occurrence of this entity in children, underscoring the importance of considering it in the differential diagnosis of benign fibroblastic/fibrocytic lesions even in paediatric population.

Paraganglioma of the mediastinum: a primary tumour or a metastasis – a case report

M. Bosanac[1], G. Samardžija[2,3], D. Tegeltija[2,4], B. Andrejić Višnjić[1]
[1]Faculty of Medicine, University of Novi Sad, Histology and Embryology, Novi Sad, Serbia, [2]Faculty of Medicine, University of Novi Sad, Pathology, Novi Sad, Serbia, [3]Institute for Cardiovascular Diseases of Vojvodina, Sremska Kamenica, Serbia, [4]Institute for Pulmonary Diseases of Vojvodina, Sremska Kamenica, Serbia

Background & Objectives: Paragangliomas of the mediastinum are rare, slow-growing tumours, associated with high morbidity and mortality.
Methods: 45-year old patient with phaeochromocytoma and mediastinal mass was admitted to tertiary care hospital for additional diagnostics and operative treatment. Pathohistological analysis was performed using haematoxylin&eosin (HE) and immunohistochemistry (CD56, chromogranin, synaptophysin, vimentin, GATA 3, TTF, CD31, calretinin, SMA, S-100, Ki67).
Results: CT and MR were consistent with paraganglioma – benign appearing hypervascular, heterodense soft tissue mass (48mm), located above right atria in close proximity to vascular structures, but without signs of infiltration. MIBG scintigraphy revealed accumulations in right adrenal gland and middle mediastinum. Complete surgical excision wasn't possible due to localization, but removed tissue consisted of tumour composed of eosinophilic, polygonal cells with round nuclei (some of which atypical). Cells were mostly arranged in round formations (Zellballen) and bands, separated by delicate stroma with a large number of small blood vessels. Immunohistochemically, the tumour cells were: CD56, chromogranin, synaptophysin, vimentin and GATA 3 positive, while they were negative for: TTF1, CD31, calretinin and SMA. Sustentacular cells were positive for S-100 while the Ki-67 proliferative index is low (less than 1% of tumour cells).
Conclusion: Typical immunoprofile, low Ki67, rare nuclear atypia and lack of locally invasive growth led to a conclusion of primary paraganglioma rather than metastasis of pheochromocytoma. However, metastatic disease can involve any organ, so immunophenotypes of both tumours must be compared to obtain final conclusion. In addition, possibility of hereditary predisposition and various syndromes and familial conditions must be considered.

E-PS-25-002

Thymectomy specimens: a ten-year review in a Canadian academic pathology department

C. Guinard[1,2], M. Castonguay[1,2]
[1]Queen Elizabeth II Health Science Centre, Pathology and Laboratory Medicine, Halifax, Canada, [2]Dalhousie University, Pathology, Halifax, Canada

Background & Objectives: Thymectomy specimens are infrequently encountered in the surgical pathology laboratory, usually as management of thymic tumours or of myasthenia gravis. Our institution is the main referral centre for the Canadian Maritime provinces (2.1 million population) and we receive most thymectomy specimens in the region. There has been a subjective increase in the number of thymectomy specimens in our department in the past year. Our objective is to review the annual number of thymectomy specimens obtained in our laboratory over the past decade, along with the indication for surgery and the associated histopathologic findings.
Methods: Our laboratory information system was retrospectively searched for thymic resection, obtained for management of thymic tumour or of myasthenia gravis, between 01/01/2016 and 31/03/2025. Surgical date, patient demographics, and histopathologic findings were collected.
Results: From 2016 to 2023, there were 6-14 thymectomy specimens annually (average, 10.4). There were 23 in 2024, and 7 in the first quarter of 2025 (a 145% increase). Thymic tumour is the most frequent indication, and thymoma is the most frequent tumour type. There has been a significant increase in the number of type AB thymomas in 2023 and 2024 (average 6/year) compared to 2016-2022 (average 0.9/year).
Conclusion: There has been a measurable increase in the number of thymectomy specimens and in the incidence of type AB thymoma in our institution in the past two years. This is not explained by a pandemic-related operational slow-down or by an obvious population shift, and has an impact on the laboratory given the specialized resources necessary for their proper evaluation.

E-PS-25-003

Thymic lipofibroadenoma with sebaceous metaplasia and striated myoid cells: a case report

S. Papadopoulou[1], I. Emmanouil[1], I. Dimitriadis[1], N. Pastelli[1], P. Eskitzis[2], K. Domvri[1], S. Papaemmanouil[1]
[1]General Hospital of Thessaloniki George Papanikolaou, Pathology, Thessaloniki, Greece, [2]Assistant Professor, Western Macedonia University, Obstetrics Department, Ptolemaida, Greece

Background & Objectives: Thymic lipofibroadenoma is a rare benign thymic tumour. While typically composed of adipose tissue, fibrous stroma, and residual thymic elements, unusual metaplastic changes

can occur. We report the rare instance of sebaceous and apocrine metaplasia and numerous myoid cells within a thymic fibrolipoadenoma.
Methods: **Case Report:** A 61-year-old male with aortic dilation underwent preoperative chest imaging, revealing an anterior mediastinal mass which was resected. Grossly, it was a well-circumscribed, encapsulated lesion measuring 11 cm. Microscopically, the tumour displayed the characteristic features of a lipofibtoadenoma, including mature adipose tissue, fibrous stroma, and thymic remnants. Notably, focal areas showed sebaceous gland differentiation, characterized by clusters of cells with foamy cytoplasm and central nuclei. Additionally, apocrine metaplasia was observed, with cells exhibiting abundant eosinophilic cytoplasm. Also the tumour showed a frequent occurrence of polygonal, striated myoid cells with abundant eosinophilic cytoplasm. The myoid cells were positive for SMA and desmin. They also lacked cytological atypia and mitotic figures. The findings were compatible with a lipofiroadenoma of the thymus gland. The patient recovered well.
Results: **Discussion:** Sebaceous and apocrine metaplasia within thymic lipofibroadenomas is an exceedingly rare phenomenon. The mechanisms driving these metaplastic changes are poorly understood. Differential diagnoses include thymolipoma with ectopic sebaceous glands, which is also rare. The presence of apocrine differentiation further distinguishes this case. The incidental discovery of this unusual metaplastic variant highlights the diverse histological spectrum of thymic lipofibroadenomas. It is important to recognize these rare variations to avoid misdiagnosis, particularly with malignant sebaceous or apocrine tumours, though these would rarely present in the thymus.
Conclusion: This case presents a rare thymic lipofibroadenoma with sebaceous and apocrine metaplasia and striated myoid cells, expanding the known histological variations of this benign thymic tumour. Pathologists should be aware of these unusual features to ensure accurate diagnosis and appropriate patient management.

E-PS-25-004

Castleman disease of the thorax: a single-centre case series

S. Jedda[1], Rahma Ayadi, Rahma Yaiche, Yasmine Barbirou, Emna Brahem, Olfa Ismail, Yasmine Dhouibi, Nadia Ben Jamaa, Aida Ayadi
[1]Abderrahmane Mami Hospital, Department of Pathology, Ariana, Tunisia

Background & Objectives: Castleman disease (CD) is a rare and heterogeneous complex lymphoproliferative disease. Most commonly, CD is classified clinically as unicentric (UCD) or multicentric (MCD) and pathologically as hyaline vascular variant (HVV) or plasma cell variant (PCV). The HVV is the most common, and is treated with surgical resection. It is most commonly found in the mediastinum, where it classically appears as a unicentric, avidly enhancing mass at computed tomography (CT). This appearance can mimic other avidly enhancing mediastinal masses.
With this report, sharing our experience with five cases of CD, aims to contribute to literature on diagnosing and treating this disease.
Methods: We performed a retrospective study of CD diagnosed at our department of pathology, from 2004 to 2024. Demographics, clinical variables, anatomical site, centricity, histopathology, immunochemistry, and surgical approach were reviewed.
Results: There were 3 females and 2 males. The mean age of the patients was 43 years, average from 24 to 59 years**.** All the patients show enlarging lymph node or mass (n=4) or systemic inflammatory manifestations including fever, anaemia, anasarca, generalized lymphadenopathy and hepatomegaly symptoms (n=1). The histopathological examination based on an excisional biopsy of an affected lymph node (n=2) or on a surgical specimen (n=3). The median mass size was 4.5cm (range 11cm-1.5cm). In our study, histologically, CD is characterized by an onion-skinning of follicular dendritic cells around hyalinized vessels and small, atrophic germinal centres with interfollicular expansion by vascular proliferation and lymphocytes. Helping exclude lymphoma, immunohistochemically (n=3), germinal centres on CD was positive for CD20 and the interfollicular territories was positive for CD3 and CD5.
Conclusion: Castleman disease is a rare, complex and underdiagnosed disorder requiring multidisciplinary management. While UCD is often curable, MCD remains challenging, necessitating ongoing research into targeted therapies.

E-PS-25-005

Thymic adenoid cystic carcinoma with yolc sac tumour pattern

P. Lewitowicz[1], A. Horecka-Lewitowicz[2]
[1]Jan Kochanowski University, Collegium Medicum Department of Clinical and Experimental Pathology, Kielce, Poland, [2]Jan Kochanowski University, Collegium Medicum, Kielce, Poland

Background & Objectives: Thymoma is the most common primary tumour of the thymus. Its occurrence is estimated at roughly 0.2%. To present day only singular cases of well documented thymic adenocarcinomas were reported. In this group were noted intestinal adenocarcinoma, pulmonary adenocarcinoma, mucinous adenocarcinoma and singular cases of adenoid cystic carcinoma.
Methods: We present a case of primary mediastinal tumour composed with residual thymoma AB and adenoid cystic carcinoma presenting an unusual yolc-sac like pattern.
Case description. A 65 years old male patient with dyspnoe was admitted to hospital. Computer tomography revealed solid tumour mass in anterior mediastinum measuring 11cm in greater dimension.
Results: Macroscopy presented a well circumscribed tumour mass measuring 11x7x4cm weighing 88g. On the cut surface the tumour was white and shiny with no cystic degeneration and necrosis.
Histologically, we noted infiltration by adenocarcinoma with predominance of adenoid cystic carcinoma. In addition, about 20% of the tumour was composed of a microcystic component lined with flattened atypical epithelium and slit-like spaces with spindle cells closely mimicking microcystic and myxomatous yolc sac tumour. At the periphery a remnant of thymoma AB was noted.
We noted positive steins as follows: PanCK, CK7, SMA, CD117, GFAP, S-100, alcian-pas, mucicarmine. Negative stains were as follows: CK20, TTF-1, GATA-3, OCT3/4, SOX-2, AFP.
Conclusion: The final diagnosis was thymic adenoid cystic carcinoma. The germinal tumour was excluded. Tumour areas presenting yolc-sac patterns were composed with myoepithelial cells.

E-PS-25-008

Primary mediastinal yolk sac tumour: case presentation with molecular study by sequencing

A.M. Montaña Ramirez[1], R. Rendon García[1], C. Alfonso Rosa[1], M.L. Sanchez Bernal[1]
[1]Hospital universitario Virgen Macarena, Pathology, Seville, Spain

Background & Objectives: Primary Mediastinal Yolk Sac Tumour is an extremely rare and highly aggressive extragonadal germ cell neoplasm. These tumours typically occur in the anterior mediastinum of young men, usually between the ages of 15 and 59.
Methods: We present the case of a 56-year-old male, a former smoker with a family history of lung cancer, who presented with chest pain. Imaging studies revealed three large tumours compressing the superior mediastinum. The largest tumour, measuring 94 mm in diameter, caused destruction of the left fifth rib and soft tissue involvement. A core needle biopsy was performed and sent to our pathology department for analysis.
Results: Histological examination revealed a high-grade solid neoplasm, positive for pancytokeratin, SALL4, Glypican 3, and CDX2, and negative for GATA3, synaptophysin, OCT4, CD117, CD30, NUT,

HepPar, B-HCG, and WT1. These findings supported the diagnosis of a mediastinal Yolk Sac Tumour, while excluding other differential diagnoses such as thymic carcinoma, large cell neuroendocrine carcinoma, seminoma, hepatocellular carcinoma metastasis, and NUT carcinoma. Next-generation sequencing (NGS) revealed pathogenic point mutations in TP53 and PTEN, as well as several copy number variations (CNVs), including deletions and gains of whole chromosomes or parts of them.
Conclusion: Primary Mediastinal Yolk Sac Tumour presents significant diagnostic complexity due to its rarity and its aggressive clinical behaviour, often leading to confusion with other mediastinal tumours. The molecular profile, including TP53 mutations, is distinct from that of testicular germ cell tumours and plays a key role in the prognosis. TP53 mutations are reported in up to 82% of cases and are considered a prognostic factor associated with resistance to cisplatin based therapies, adding another layer of complexity in the management of these tumours. This case highlights the importance of integrating histopathological, immunohistochemical, and molecular data to achieve an accurate diagnosis and guide treatment decisions for such rare and aggressive tumours.

E-PS-25-009
Uncommon extra-mediastinal bronchogenic cysts: two cases in the cervical and nasopharyngeal regions
Y. Dhouibi[1], R. Ayadi[1], R. Yaiche[1], Y. Barbirou[1], S. Jedda[1], E. Brahem[1], O. Ismail[1], N. Ben jemaa[1], A. Ayadi[1]
[1]Abderrahmen Mami Hospital, Department of Pathology, Ariana, Tunisia

Background & Objectives: Bronchogenic cysts are congenital malformations arising from abnormal budding of the foregut during embryogenesis. They are most commonly found in the mediastinum, while cervical and nasopharyngeal localizations are extremely rare. Due to their unusual locations, these cysts can pose a diagnostic challenge and may be mistaken for other cystic lesions.
Methods: We report two cases of extra-mediastinal bronchogenic cysts: one located in the cervical region and the other in the nasopharynx . Clinical presentation, imaging findings, and histopathological features were reviewed.
Results: Case 1: A 27-year-old male presented with a painless cervical mass. Radiological examination revealed a well-defined cystic lesion. Surgical resection identified a 4×2.5 cm cystic lesion with a 1.8 cm cystic cavity. Histopathological examination showed a cyst wall lined by pseudostratified ciliated columnar epithelium with focal squamous metaplasia, along with underlying skeletal muscle and mucous glands. Case 2: A 54-year-old female was evaluated for a nasopharyngeal mass. A biopsy of a 0.4 cm lesion from the posterior wall of the cavum showed a fibrous-walled cyst lined by regular pseudostratified ciliated respiratory epithelium.
In both cases, histopathological examination confirmed the diagnosis of a bronchogenic cyst. No signs of malignancy were observed.
Conclusion: Bronchogenic cysts in the cervical and nasopharyngeal regions are exceptionally rare and can be misdiagnosed as other congenital or acquired cystic lesions. A thorough histopathological evaluation is essential for accurate diagnosis. Recognizing these atypical locations is crucial for pathologists and clinicians to ensure appropriate management and avoid unnecessary interventions.

E-PS-25-010
A rare malignancy – thymic squamous cell carcinoma
A. Camarasan[1], M. Muresan[1], A. Vigdorovits[1], A. Pascalau[1], S. Vese[2], A.C. Pop[2], O. Pop[1]
[1]University of Oradea, Department of Morphological Disciplines, Oradea, Romania, [2]County Clinical Emergency Hospital of Oradea, Department of Morphological Disciplines, Oradea, Romania

Background & Objectives: Squamous cell carcinoma of the thymus is an extremely rare neoplasm that originates from epithelial cells. This malignancy is characterized by its aggressive clinical course and potential for local invasion and metastasis.
Methods: A 51 years old female, with no previous medical history, was hospitalized due to a presumed bronchopulmonary tumour. The CT scan revealed in the upper and middle mediastinum, a large mass of tissue, multilobulated that compresses and stenoses the mediastinal anatomical structures. Multiple bronchial biopsis was performed at bronchoscopy. H&E and immunohistochemical analysis for p40, TTF1, CD56, CD5, PAX8, c-KIT were performed.
Results: The videobronchscopy revealed the stenosis of the left upper lobar bronchus due to extrinsic compression, while the left subsegmental bronchus appeared completely stenosed due to extrinsic compression and tumour invasion.
H&E examination revealed multiple fragments of bronchial mucosa extensively infiltrated by a cellular proliferation with a diffuse distribution pattern. The neoplastic cells are of medium size, polygonal, with undefined cellular borders, eosinophilic cytoplasm, and enlarged nuclei, some with hyperchromatic in focal areas, with moderate nuclar atypia. Prominent nucleoli are visible. Immunohistochemical analysis revealed the following: p40 positive, CD5 positive, PAX8 positive and c-KIT positive, TTF1 negative, CD56 negative.
Conclusion: Thymic squamous cell carcinoma is a rare type of cancer, accounting for less than 5% of all thymic tumours. In this case, the immunohistochemical profile was highly suggestive for thymic squamous cell carcinoma. Accurate diagnosis of this entity facilitates further patient management and treatment.

E-PS-26 E-Posters Uropathology

E-PS-26-001
Case report of sperm cell granuloma presenting as a peritoneal nodule: a rare entity
A. Kret[1], T. Green[1]
[1]Sheffield Teaching Hospital NHS Trust, South Yorkshire and Bassetlaw Pathology, Sheffield, United Kingdom

Background & Objectives: A man in his 30s underwent a reversal of the colostomy procedure. During the surgery a peritoneal nodule was identified and resected for histological assessment.
Methods: The peritoneal nodule measured 12mm in diameter. Histology demonstrated fibroconnective tissue and a population of small-sized cells with hyperchromatic round-to-oval nuclei and scanty cytoplasm which were recognised to be mature spermatozoa. These were associated with a surrounding histiocytic response. The diagnosis of sperm granuloma was made.
Results: Sperm granuloma is a benign condition caused by extravasation of spermatozoa due to vas deferens damage, usually occurring in the epididymis. Sperm granuloma outside of the male reproductive system is very rare and has previously been described in patients with a history of surgery around the urological system.
The underlying aetiology of sperm granuloma development in this patient is unclear. The patient's clinical records revealed a history of previous surgery in the pelvis to correct an inflammatory process which involved the bladder and a suspected fistula formation. Presumably, the inflammation and anatomical distortion have resulted in damage to the vas deferens with subsequent extravasation of spermatozoa into the peritoneum.
Conclusion: Here we present a case of sperm granuloma with an unusual site of presentation as a peritoneal nodule. The diagnosis requires the recognition of mature spermatozoa with surrounding histiocytes, particularly in the setting of previous surgery, inflammation or infection in the proximity of the male reproductive system.

E-PS-26-002

Role of Epithelial-Mesenchymal Transition (EMT) markers SNAIL-SLUG, and TWIST in prognosis of urothelial carcinoma of the bladder: a retrospective study

A.A. Khan[1], S. Ahuja[2], C. Ahluwalia[1]
[1]Vardhman Mahavir Medical College & Safdarjung Hospital, Pathology, New Delhi, India, [2]Vardhman Mahavir Medical College & Safdarjung Hospital, National Organ and Tissue Transplant Organization, New Delhi, India

Background & Objectives: Bladder cancer, primarily urothelial carcinoma, is a significant global health issue, especially given its high recurrence and poor prognosis. Tumour invasion into the muscularis propria is a crucial prognostic indicator, distinguishing muscle-invasive bladder carcinoma (MIBC) from non-muscle-invasive types (NMIBC). Epithelial-to-mesenchymal transition (EMT) has been implicated in promoting tumour aggressiveness and metastasis, marked by key transcription factors (TFs) like SNAIL, SLUG, and TWIST. This study investigates the association between EMT markers' expression and histopathological features of bladder carcinoma.
Methods: This retrospective study included 36 newly diagnosed cases of urothelial carcinoma at a tertiary care centre. Immunohistochemistry (IHC) was conducted to assess SNAIL-SLUG, and TWIST expression, scored by staining intensity and extent. The statistical analysis evaluated associations between EMT markers, tumour grade, muscle invasion, and clinical stage.
Results: Out of 36 patients, 23 were male, and the age of the patients ranged from 36 to 73 years. Myo-invasive urothelial carcinoma (MIBC) was observed in 21 (58.3%) patients, whereas 15 (41.6%) of them were non-myo-invasive. 80.6% of cases were found to be high-grade invasive urothelial carcinoma. The expression of SNAIL+SLUG showed variable results with 62.1% of the high-grade urothelial carcinoma showing decreased expression. No significant association was observed between them. However, 52.38% of the myo-invasive cases showed an increased expression of SNAIL+SLUG and a strong association was also observed ($p = 0.005$). None of the epithelial-to-mesenchymal transition markers showed an association with lymphovascular invasion.
Conclusion: Increased expression of these transcription markers in advanced stage and grade demonstrates a possible role in identifying the molecular mechanism underlying EMT during urothelial carcinoma pathogenesis. Nuclear expression of SNAIL+SLUG and TWIST in bladder carcinoma was associated with poor outcome indicating the possibility of identifying aggressive lesions.

E-PS-26-003

Collision nodal metastasis of urothelial carcinoma of the bladder and prostatic adenocarcinoma with seminal vesicle involvement

A. Vidac[1,2], D. Herman[2], A. Dema[1,2,3], A. Jurescu[1,3], V. Dema[4], A. Cumpănaș[4,5]

[1]ANAPATMOL Research Centre, "Victor Babeș" University of Medicine and Pharmacy, Timișoara, Romania, [2]"Pius Brînzeu" Emergency County Hospital, Department of Pathology, Timișoara, Romania, [3]"Victor Babeș" University of Medicine and Pharmacy, Department of Microscopic Morphology, Timișoara, Romania, [4]"Victor Babeș" University of Medicine and Pharmacy, Department of Urology, Timișoara, Romania, [5]"Pius Brînzeu" Emergency County Hospital, Department of Urology, Timișoara, Romania

Background & Objectives: Simultaneous involvement of a lymph node by both urothelial carcinoma and prostatic adenocarcinoma, known as collision metastasis, is an exceptionally rare phenomenon. Additionally, concurrent involvement of the same seminal vesicle by both malignancies is also uncommon, with only a few cases documented in the medical literature. Here, we report the case of a 68-year-old male with a history of T2 high-grade urothelial carcinoma who presented to the hospital with macroscopic haematuria.
Methods: Ultrasonography revealed a thickened bladder wall and a 3 cm tumour mass located in the bladder neck. The prostate measured approximately 40 cm^3. A cystoprostatectomy with bilateral iliac and obturator lymphadenectomy was performed.
Results: Microscopic examination revealed a high-grade urothelial carcinoma extensively infiltrating the bladder wall, predominantly exhibiting a solid growth pattern with areas of squamous and glandular differentiation. It was intricately intermixed with an acinar prostatic adenocarcinoma, which displayed cribriform, trabecular, and solid patterns (Gleason score 9, 4+5). Both the CK7-positive urothelial carcinoma and the PSA-positive prostatic adenocarcinoma invaded the left seminal vesicle. Dual metastases were identified in a left ilio-obturator lymph node, with one component originating from the CK7-positive urothelial carcinoma and the other from the PSA-positive prostatic adenocarcinoma. Additionally, a small component of ductal adenocarcinoma (Gleason score 8, 4+4) with an intraductal growth pattern was present in the prostatic parenchyma.
Conclusion: This case highlights the rare occurrence of collision metastasis, where urothelial carcinoma and prostatic adenocarcinoma metastasized to the same lymph node while simultaneously invading the seminal vesicle. These findings underscore the complexity of diagnosing and managing synchronous genitourinary malignancies. Awareness of such rare presentations is crucial for accurate pathological assessment and appropriate therapeutic strategies.

E-PS-26-004

Secondary hypertension in a young patient: the hidden role of juxtaglomerular cell tumour

T. Santos Vieira[1], V.S. Pina Gonçalves dos Santos[1], A. Teixeira Alves[1], P. Borralho Nunes[1], R. Ilgenfritz[1]
[1]CUF Descobertas Hospital, Pathology Department, Lisbon, Portugal

Background & Objectives: Secondary hypertension (SH) is a common condition with multiple underlying causes, the most prevalent being primary aldosteronism. Adrenal gland adenomas and pheochromocytomas are the most frequently suspected tumoral causes, juxtaglomerular cell tumour (JGCT) is a rare but significant differential diagnosis. JGCT is a renin-secreting neoplasm that can lead to hypertension, and surgery is often curative, yet it remains underrecognized due to its rarity.
Methods: We report a challenging case of JGCT in a 29-year-old woman with a five-year history of hypertension, unresponsive to drug therapy, and without prior investigation for secondary causes. Gross examination reveals a well-demarcated brown and yellow tumour measuring 15x15x14mm, confined to the parenchyma. On morphological examination the stroma was prominent with hyalinized areas and rich in vessels displaying variably sized branches, some of them with thick walls. The tumour cells formed groups with an epithelioid pattern, regular nuclei and condensed chromatin, featuring scattered bizarre cells. No mitotic activity or necrosis were observed. Some peripheral entrapped renal tubules were also identified.
Immunohistochymestry (IHC) revealed strong and homogenous positivity for CD34, partial positivity for DOG1, BCL2 and CD99, while ERG, Calponin, Melan-A, HMB45, PAX8, WT1, CK AE1/AE3, Actin, CD31, S100, STAT6 were all negative. There was no loss of INI1 expression.
Results: JGCT is a rare mesenchymal tumour that should be considered in young patients with drug-resistant hypertension. Morphologically angiomyolipoma, solitary fibrous tumour, sarcomas and Nephroblastoma were initially considered, but with help of IHC and clinical features the correct diagnosis was reached.
Conclusion: This case underscores the importance of considering JGCT as a differential diagnosis in patients with unexplained hypertension, particularly in young adults. Raising awareness among clinicians can lead to earlier detection, appropriate surgical management,

and improved patient outcomes. Moreover, nephron-sparing surgery should be prioritized over radical nephrectomy to minimize long-term complications.

E-PS-26-005

An audit of reporting of HPV status in penile squamous cell carcinoma; adherence to current WHO and RCPath dataset recommendations

S. Bond[1], A. Haider[1]
[1]University College London Hospital, London, United Kingdom

Background & Objectives: Penile squamous cell carcinoma (SCC) has an HPV-associated aetiology in up to 50% cases. Both the WHO 2022 and Royal College of Pathologists (RCPath) 2024 guidelines specify that p16 immunohistochemistry should be performed to assess for HPV association, and morphological subtype be stated, with NOS-type reserved only when HPV testing is unavailable. We audited current reporting practices within our department – a supraregional referral centre for penile cancer in the UK – against these recommendations.
Methods: Electronic reports were searched to identify all cases of penile SCC diagnosed at our centre between December 2023- December 2024. The following data was collected: patient age, specimen site, specimen type, morphological subtype of SCC, whether p16 testing and/or HPV genotyping performed, and whether HPV association stated.
Results: 143 cases of penile SCC were diagnosed at our centre within this timeframe. Mean patient age was 69.8 years. 39% (56) cases were resections, (31%) 44 biopsies and 30% (43) excisions. Specimen site was: penis in 46% (66), glans in 37% (53), foreskin in 11% (16), foreskin/glans in 3% (4), glans/corpus cavernosum in 1% (2) and penoscrotal skin in 1% (2) cases. Morphological subtype of SCC was NOS in 52% (74), not stated in 20% (28), mixed subtype in 15% (22), HPV-independent subtype in 7% (10) and HPV-associated subtype in 6% (9) cases. p16 was performed in 90% (129) cases and HPV genotyping in 10% (14) cases. HPV association was reported in 48% (68) cases and HPV independence reported in 34% (49) cases. In 18% (26) cases HPV association was not reported.
Conclusion: Overall there was high compliance with p16 testing at our centre, but efforts should be made to clearly state HPV association in reports and to avoid over-use of the NOS morphological subtype. Recommendations have been made locally, and we plan to re-audit reporting practice at 12 months.

E-PS-26-006

Clinicopathological insights into fumarate hydratase-deficient renal cell carcinoma: a study of 12 Hungarian cases

A. Jakab[1], A. Jenei[1], G. Forika[1], T. Micsik[1], K. Dezső[1], A. Fintha[1], B. Pósfai[2], Á. Somorácz[3], K. Eizler[4], D. Semjén[5], H. Butz[6,7], Z. Melegh[8], K. Pivovarcikova[9], L. Kuthi[1,8,7]
[1]Semmelweis University, Department of Pathology and Experimental Cancer Research, Budapest, Hungary, [2]University of Szeged, Albert Szent-Györgyi Medical School, Department of Pathology, Szeged, Hungary, [3]Eurofins-Medserv Ltd., Budapest, Hungary, [4]Fejér County Szent György University Teaching Hospital, Pathology Unit, Székesfehérvár, Hungary, [5]University of Pécs, Faculty of Medicine and Clinical Centre, Department of Pathology, Pécs, Hungary, [6]National Institute of Oncology, Department of Molecular Genetics and the National Tumour Biology Laboratory, Budapest, Hungary, [7]National Institute of Oncology, HUN-REN-ONKOL-TTK-HCEMM Oncogenomics Research Group, Budapest, Hungary, [8]National Institute of Oncology, Department of Surgical and Molecular Pathology, Tumour Pathology Centre, Budapest, Hungary, [9]Charles University Hospital and Medical Facility Plzen, Department of Pathology, Plzen, Czech Republic

Background & Objectives: Fumarate hydratase-deficient renal cell carcinoma (FHd RCC) is a rare and aggressive subtype of renal cell carcinoma. It is characterized by complex histology, biallelic inactivation of the FH gene, frequent loss of FH expression, and accumulation of S-(2-succino)-cysteine (2SC).
Methods: We retrospectively analysed 12 cases of FHd RCC, reviewed by two pathologists (AJa and LK). Clinical data were obtained from electronic records, while pathological features were extracted from histopathology reports.
Results: Ten tumours were identified in nephrectomy specimens (mean size: 91.5 mm; median: 90 mm; range: 23-220 mm), one in a renal mass biopsy, and another in a biopsy of a metastatic infraclavicular lymph node. The cohort included seven males and five females (mean age: 52.8 years; median: 48.5 years; range: 22-78 years). Three female patients had undergone prior hysterectomy for leiomyomas. Histologically, the tumours exhibited eosinophilic cells with high-grade nuclear atypia, predominantly forming a tubulo-papillary pattern. CMV inclusion-like nucleoli were observed in nine cases. FH expression was lost in all but one tumour, and 2SC staining (performed in seven cases) showed strong nuclear and cytoplasmic positivity, including the FH-retained tumour. Genetic analysis (six cases) identified pathogenic FH mutations in all, with one confirmed as germline. Three patients had distant metastases at diagnosis, and five developed metastases during follow-up. Four patients died of cancer-related causes.
Conclusion: FHd RCC is a diagnostic challenge due to its rarity and lack of specific morphology. However, accurate diagnosis is crucial due to its aggressive nature and possible association with hereditary leiomyomatosis and renal cell carcinoma syndrome. We strongly advocate FH and 2SC immunohistochemical testing for all high-grade or large RCCs, particularly in younger patients or those with a history of uterine or cutaneous tumours, suggesting a syndromic link.

Inflammatory myofibroblastic tumours of the urinary bladder: 25-year single-centre experience

E. Sayar[1], Ö. Hürdoğan[1], S. Erdem[2], I. Kılıçaslan[1], Y. Özlük[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Pathology, Istanbul, Turkey, [2]Istanbul University, Istanbul Faculty of Medicine, Urology, Istanbul, Turkey

Background & Objectives: Inflammatory myofibroblastic tumour (IMT) is a rare mesenchymal tumour, rarely seen in the urinary bladder. We aimed to document our 25-year single-centre experience on the histopathological and immunohistochemical characteristics of IMTs of the urinary bladder.
Methods: A database search was performed on urinary system materials diagnosed as IMT between 2000 and 2025 in our institution. Clinical data, histopathological features, immunohistochemical characteristics and fluorescent in-situ hybridization results were retrieved from archival records.
Results: Among 14 cases, 11 (78%) were male. Mean age was 48.35±14.38 years (median:43, [range: 28-72]). All cases were localized in the urinary bladder and underwent transurethral resection. Seven were consultation cases, among which the primary diagnosis differed in only one. Six (42%) demonstrated atypia and pleomorphism, while none showed necrosis. Three (21%) cases showed infiltration into the muscularis propria. Myxoid stroma was seen in 3 (21%) cases. On immunohistochemical examination, 50% (6/12) showed at least focal expression for anaplastic lymphoma kinase (ALK D5F3), 58% (7/12) for pancytokeratin, 71% (10/14) for smooth muscle actin. Fluorescent in-situ hybridization for ALK gene rearrangement revealed positive in 2 among 3 cases that were analysed. Follow-up data of 9 (64%) patients were available. During a mean follow-up period of 64 ± 70 months (range 1-200), one patient, with muscularis propria invasion, had recurrence after five months.

Conclusion: Inflammatory myofibroblastic tumour is a mesenchymal tumour that should be considered in the differential diagnosis of spindle cell lesions of the urinary bladder. Ancillary tests such as immunohistochemistry and fluorescence in situ hybridization for ALK are helpful in diagnosis.

E-PS-26-008

Biphasic squamoid alveolar renal cell carcinoma: a report of three cases with immunohistochemical and FISH analysis

A. Üzümcü[1], Ö. Hürdoğan[1], M.A. Ahmed[2], I. Kılıçaslan[1], Y. Özlük[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Department of Pathology, Istanbul, Turkey, [2]Istanbul University, Institute of Oncology, Department of Medical Oncology, Istanbul, Turkey

Background & Objectives: Biphasic squamoid alveolar renal cell carcinoma (BSARCC) is a recently described rare morphological variant of papillary renal cell carcinoma (PRCC). Due to its rarity, limited data exist regarding its histopathological, immunohistochemical, and molecular features. Herein, we present three cases of BSARCC, aiming to further characterize its clinicopathological profile.
Methods: Immunohistochemistry(IHC) was performed using CK7, PAX8, AMACR, P63, Cyclin D1, and Ki-67. Additionally, MET/CCP7 FISH analysis was conducted to assess chromosomal alterations.
Results: The cohort included two male and one female patient, with a mean age of 63.3 years (range: 59–69). Two cases were partial nephrectomy, one was core biopsy. The mean tumour diameter was 33 mm (range: 25–38). Tumours were well-circumscribed with a whitish or pale yellow appearance.
All cases exhibited a biphasic architecture characterized by nests of larger squamoid cells surrounded by a single layer of smaller cuboidal cells in an alveolar pattern. Emperipolesis was noted in two partial nephrectomy specimens but was absent in the biopsy.
IHC analysis showed diffuse positivity for CK7, AMACR, and PAX8 in both cell populations, while P63 was negative. Cyclin D1 was expressed exclusively in large cells. The Ki-67 index was higher in large cells compared to small cells(5-30% vs. 1%).
FISH analysis revealed chromosome 7 polysomy in all three cases, while MET gene amplification was observed in one case, with no difference between large and small cells.
At a mean follow-up of 26 months (range: 4–68 months), all patients remained alive without evidence of recurrence or metastasis. One patient underwent cryoablation following biopsy and follow-up continues without surgical resection.
Conclusion: Chromosome 7 polysomy links BSARCC to PRCC, reinforcing its classification within the PRCC spectrum. Our findings support BSARCC as a distinct variant of PRCC, with consistent histopathological and immunohistochemical characteristics. Further studies are needed to clarify its molecular pathogenesis and clinical implications.

E-PS-26-009

***CTNNB1* mutations characterize a subset of testicular Adult Granulosa Cell Tumours**

Background & Objectives: Testicular adult granulosa cell tumour (AGCT) is a rare sex-cord stromal tumour (SCST) that, unlike its ovarian counterpart, rarely harbours *FOXL2 p.Cys134Trp* mutation. Previous analyses of cases originally diagnosed as AGCT have shown that their genomic features are heterogeneous. The aim of this study was to perform genomic analyses on an expanded series of testicular SCSTs diagnosed as AGCTs.
Methods: In total, 15 AGCTs were collected and selected slides were centrally reviewed (Indiana University) to confirm the diagnosis. Cases were analysed using two DNA-NGS panels comprising 34 genes, including those with alterations identified in previous studies of testicular AGCT (i.e. *FOXL2*, *NRAS*, and *TP53*).
Results: NGS was successfully performed in 9/15 (60%) tumours; the remaining 6/15 (40%) did not yield DNA suitable for sequencing. No alterations were found in 6/9 (66.6%) tumours. Three tumours (3/9; 33.3%) harboured *CTNNB1* alterations: *CTNNB1 p.Ser37Phe* (VAF:42%), *CTNNB1 p.Gln322_Trp338delinsArg* (VAF: 54%), and *CTNNB1 p.Gly34Arg* (VAF: 42%). Of note, 2/3 tumours with *CTNNB1* alterations showed a focal tubular architecture, a feature not seen in tumours without *CTNNB1* alterations. No tumours showed *FOXL2* alterations.
Conclusion: The results of this study suggest that a subset of AGCTs exhibit *CTNNB1* alterations, a genomic finding seen in other SCSTs (in particular Sertoli cell tumour, not otherwise specified) and associated with a focal tubular histology. Additionally, this study confirms that testicular AGCTs do not typically harbour *FOXL2* alterations. Further studies with β-catenin immunohistochemistry in selected cases is underway.

E-PS-26-010

GATA3 immunostaining and clear cell renal tumours with fibromyomatous stroma

M. Çağlayan[1], B. Sarsık Kumbaracı[1], B. Yaman[1], M.S. Kalemci[2], E. Güler[3], S. Şen[1]
[1]Ege University Faculty of Medicine, Department of Pathology, İzmir, Turkey, [2]Ege University Faculty of Medicine, Department of Urology, İzmir, Turkey, [3]Ege University Faculty of Medicine, Department of Radiology, İzmir, Turkey

Background & Objectives: There are limited number of studies investigating GATA3 expression in renal tumours with fibromyomatous stroma. We aimed to identify the GATA3 expression in carbonic anhydrase 9/cytokeratin 7 positive renal tumours with fibromyomatous stroma and tubulopapillary morphology.
Methods: We retrospectively re-evaluated expressions of GATA3, carbonic anhydrase 9, cytokeratin 7, CD10 and histopathological features of 13 renal tumours with fibromyomatous stroma/tubulopapillary morphology were diagnosed in our centre between 2012-2024 years.

Results: In this series of 13 patients, five patients (39%) were female and eight patients (61%) were male. The mean age of the patients was 55,3 years (range; 30-76 years). According to World Health Organization (WHO) 2022 renal tumours classification systems, eight (61%) tumours were clear cell papillary renal cell tumour (CCPRCT). Three tumours (3/8) showed nuclear reactivity for GATA3 diffusely and four (4/8) tumours stained with CD10 focally. The other five (39%) tumours were morphologically similar to *ELOC* mutant renal cell carcinoma. However, since molecular methods could not be applied, they were classified as "renal cell carcinomas with fibromyomatous stroma (FMS-RCC)". These tumours except one (4/5) tumour were GATA3 diffusely and CD10 focally positive.
Conclusion: According to the 2022 WHO classification, renal tumours with fibromyomatous stroma were classified as "*ELOC* mutated RCC" and "CCPRCT". However, there is no clear consensus on "*TSC/MTOR* mutated FMS-RCC", which has not yet been classified. Our study suggests that GATA3 expression can potentially be used in the differential diagnosis of FMS-RCC. Investigation of GATA-3 expressing fibromyomatous stroma renal tumours using molecular diagnostic methods will allow the classification of new tumour subtypes.

E-PS-26-011
Clinicopathologic and immunohistochemical features of oncocytic and chromophobe renal tumours: a single-centre retrospective study
K. Karaca[1], A. Yavuz[1], A.E. Caylan[2], B. Akkaya[1], H.S. Toru[1]
[1]Akdeniz University School of Medicine, Pathology, Antalya, Turkey, [2]Akdeniz University School of Medicine, Urology, Antalya, Turkey

Background & Objectives: Oncocytic renal tumours and chromophobe renal cell carcinoma (ChRCC) are low-grade renal neoplasms that often display overlapping histomorphological features. However, they differ significantly in biological behaviour. Oncocytic tumours are typically benign and do not require further treatment after surgical excision, while ChRCC is a malignant tumour with metastatic potential, necessitating distinct clinical management. Immunohistochemistry (IHC) serves as an important adjunct tool in distinguishing between these entities. This study aimed to evaluate the clinicopathologic and immunohistochemical characteristics of renal oncocytic and chromophobe tumours and to analyse their associations with capsule invasion, tumour multiplicity, and survival outcomes.
Methods: We retrospectively reviewed 45 renal tumour cases diagnosed between 2016 and 2021 at Akdeniz University, Türkiye, comprising oncocytic (n=10), hybrid (n=3), and ChRCC (n=32) tumours. Clinical and pathological data were collected. IHC markers (CD117, CK7, CK18, CD10, E-cadherin, AMACR, and Vimentin) were evaluated semi-quantitatively. Statistical analyses were performed using the Chi-square test in SPSS version 28.0.
Results: The mean patient age was 59.3 years (range: 28–80), and 55.6% were male. Most tumours were left-sided (60%), solitary (95.6%), and classified as stage I (91.1%). Capsule invasion was observed in 24.4%, and positive surgical margins in 8.9% of cases. Recurrence occurred in 2 cases, and 3 patients died due to unrelated causes. Common comorbidities included hypertension (40%) and diabetes mellitus (13.3%). CD117 and CK18 were the most frequently expressed markers. While most IHC markers showed no significant association with capsule invasion or multiplicity ($p > 0.05$), AMACR was significantly associated with tumour multiplicity ($p = 0.010$). No correlation was found between IHC profiles and overall survival.
Conclusion: This study highlights the importance of immunohistochemical evaluation in distinguishing oncocytic from chromophobe renal tumours. While AMACR expression may be more frequent in multifocal tumours, further studies with larger cohorts are needed to determine its potential clinical significance.

E-PS-26-012
PD-L1 expression in neuroendocrine urothelial and prostate tumours
M.L. Abascal Camacho[1], M.C. Ariño Palao[1], A. Nogales Moro[1], M. Gomez Marguez[1], N. Dimas Vazquez[1], M.V. Dominguez[1], M. Chao Crecente[1]
[1]Hospital Universitario Severo Ochoa, Surgical Pathology, Madrid, Spain

Background & Objectives: Small Cell Neuroendocrine Carcinomas (SCNECs) of the genitourinary tract are rare, with urothelial and prostate being the most common sites. These tumours are often diagnosed at advanced stages, leading to poor prognosis. Recent studies, including a phase 1b trial combining pembrolizumab with platinum-based chemotherapy, have shown promising results for stage III-IV SCNECs. This study aims to summarize the clinicopathological features of SCNECs and assess PD-L1 expression.
Methods: A retrospective study of genitourinary SCNECs at our hospital was conducted over a 10-year period (2015-2025), identifying 7 cases: 5 from the bladder (3 pure, 2 mixed with high-grade urothelial carcinoma) and 2 from the prostate (1 pure, 1 mixed with Gleason 9 acinar adenocarcinoma). PD-L1 expression was independently assessed by two pathologists using the combined positive score (CPS).
Results: The cohort consisted predominantly of men (5/7), with a mean age of 66 years (range 45-78). Four cases were diagnosed at stage IV, 2 at stage III, and 2 at stage II. Five patients received palliative chemotherapy, 1 underwent surgery followed by a clinical trial, and 1 case was monitored closely. Tumour cell PD-L1 positivity was observed with a mean of 0.8% (range 0-3%), while immune cell PD-L1 expression was positive with a mean of 8% (range 0%-25%). CPS scoring revealed PD-L1 positivity in four cases (all bladder-origin), with CPS scores ranging from 1-10, and three cases (1 bladder, 2 prostate) were negative with a CPS score of 0. The highest CPS score (5.2) was observed in the disease-free patient.
Conclusion: This study is the first to evaluate PD-L1 expression in genitourinary SCNECs. While expression varied, bladder-origin tumours showed higher PD-L1 positivity compared to prostate-origin tumours. These findings suggest that bladder-origin SCNECs may benefit from immunotherapy, though larger studies are needed to confirm these results.

E-PS-26-013
When clear cells turn dark: unraveling the aggressive nature of renal cell carcinoma with sarcomatoid differentiation
V. Pascu[1], B. Radu Mihai[1], A. Nicolae Alin[1], M. Diana Maria[1], N. Razvan[1]
[1]Colentina Clinical Hospital, Pathology, Bucharest, Romania

Background & Objectives: Renal cell carcinoma (RCC) with sarcomatoid differentiation represents a highly aggressive type of RCC. This study aims to characterize the clinicopathological features and the immunophenotypic profile of clear cell RCC with sarcomatoid differentiation diagnosed in our institution between 2016 and 2024.
Methods: A total of five cases of renal cell carcinoma with sarcomatoid differentiation between January 2016 and December 2024 were retrieved from the pathology archives of Colentina Clinical Hospital. The studied cohort comprised 3 male and 2 female patients. Immunohistochemical analysis was performed using the Leica BOND immunostaining system.
Results: In four of the five cases, the neoplastic process originated within the left kidney. All documented cases exhibited extensive areas of necrotic tissue, indicative of aggressive tumour progression. Immunohistochemically, carbonic anhydrase IX (CA IX) as well as CD10 demonstrated positive staining across all cases, with a patchy

distribution within the sarcomatoid component and a diffuse pattern within the clear cell component. PAX8 expression was absent in the sarcomatoid component across all cases while the clear cell component showed patchy positivity only in two cases. In contrast, cytokeratin 7 (CK7) was negative in four cases across both tumour components, while one case exhibited patchy CK7 positivity within the sarcomatoid component, particularly noteworthy for its marked pleomorphic features.
Conclusion: This findings enhance our understanding of the clinicopathological characteristics and immunophenotypic profile of this phenomenon. The different expression patterns of CA IX, CD10, PAX8 and CK7 highlight the distinct phenotypic divergence between the clear cell and sarcomatoid component. Such insights hold importance especially in metastasis wherein the renal origin remains ambiguous or in instances where the clear cell constituent presents atypical features.

E-PS-26-014
Renal hydatid cyst: diagnostic and treatment considerations
R. Gheorghe-Giurca[1], L.C. Daminescu[2], A. Rus[2], D. Anderco[1], A. Dema[3,1]
[1]"Pius Brinzeu" Emergency Country Clinical Hospital, Pathology, Timisoara, Romania, [2]"Pius Brinzeu" Emergency Country Clinical Hospital, Urology, Timisoara, Romania, [3]Anapatmol Research Centre, Victor Babes Univeristy of Medicine and Pharmacy, Timisoara, Romania

Background & Objectives: A renal hydatid cyst is a rare parasitic infection of the kidney caused by *Echinococcus granulosus* or *Echinococcus multilocularis*. It develops when hydatid larvae reach the kidney, forming fluid-filled cysts. Symptoms vary and may include flank pain, haematuria, or a palpable mass. Rupture can lead to severe complications such as anaphylactic shock or secondary infection. Diagnosis relies on imaging techniques (ultrasound, CT, MRI) and serological tests. Treatment options include surgery (partial or total nephrectomy), percutaneous drainage, and antiparasitic therapy with albendazole.
Methods: We report a case of a 40-year-old woman who presented to the Urology Department with a large multilocular tumour mass in the right kidney. The tumour was located at the lower pole of the kidney, extending into the renal sinus and protruding beyond the renal contour. It appeared heterogeneous on imaging, with fluid densities, septa, and microcalcifications. The CT findings suggested either a multilocular cystic nephroma or a multilocular cystic renal carcinoma.
Results: Gross examination of the nephrectomy specimen (14 × 9 × 6 cm) revealed a multilocular cystic cavity at the lower renal pole, containing multiple smaller cysts filled with citrine fluid. Histological analysis showed a multilocular cystic structure surrounded by a hyalinized and partially calcified fibrous pseudocapsule. A peripheral inflammatory response consisting of lymphoplasmacytes, histiocytes, and eosinophils was observed. Inside the cyst, multiple eosinophilic, acellular lamellar membranes with a distinct proliferative layer were present, along with ovoid structures resembling protoscolices, findings characteristic of a hydatid cyst.
Conclusion: This case underscores the rare presentation of renal hydatid cysts and emphasizes the importance of early diagnosis to prevent severe complications such as rupture or infection. Accurate identification through imaging and serological tests is crucial, and timely treatment significantly improves patient outcomes.

E-PS-26-015
Applications of 12p *Fluorescence in situ hybridization* (FISH) in testicular germ cell tumours (TGCTs)
P. Rodrigues Veiga[1], A. Lapa[1], R. Henrique[1], Â. Rodrigues[1], J. Lobo[1]
[1]Portuguese Oncology Institute of Porto (IPO-Porto), Department of Pathology, Porto, Portugal

Background & Objectives: Gains of the short arm of chromosome 12 (12p), often in the form of isochromosome 12p (i12p), are considered hallmarks of postpubertal-type GCNIS-derived TGCTs, being diagnostically useful. FISH is commonly used for detecting 12p gains. We aimed to review TCGT cases where this FISH assay was ordered and its diagnostic purpose.
Methods: All TGCT cases where 12p FISH was ordered in our institution between 2021 and 2024 were retrieved. Clinicopathological data and cytogenetic test results were collected.
Results: Our study included nine patients. The most frequent reason was for supporting the diagnosis of prepubertal-type teratoma (n=4) by showing absence of gains in 12p, which were diagnosed after puberty, in patients aged 20 to 28 years.
Two cases were ordered to support a diagnosis of somatic-type malignancy in the metastatic setting. One was a 47-year-old patient presenting with a retroperitoneal mass adherent to the duodenum, initially suspected to be a gastrointestinal-tract tumour. Confirmation of i12p, together with a personal history of a TGCT >20 years previously, confirmed the diagnosis of somatic-type adenocarcinoma arising from a TGCT.
The second was a 30-year-old patient presenting with a large retroperitoneal mass, mostly composed of carcinoma with solid and glandular pattern and unspecific immunophenotype, adjacent to teratoma foci. The detection of i12p led to investigation of the testis, which showed features of regressed TGCT with postpubertal-type teratoma.
The remaining three cases corresponded to spermatocytic tumours, with absence of 12p, in patients aged 36, 41 and 62.
Conclusion: The 12p FISH can be useful in three main settings: for the differential diagnosis between prepubertal-type and postpubertal-type teratoma, considering that both could occur at post-pubertal age; for supporting the diagnosis of spermatocytic tumour, which can occur at a wide age range; and for supporting the diagnosis of somatic-type malignancy arising in TGCT, especially at metastatic sites with limited clinical history.

E-PS-26-016
SMARCB1-deficient medullary-like renal cell carcinoma: report of two cases with emphasis on morphological spectrum and differential diagnosis
A. Lapa[1], P. Rodrigues Veiga[1], R. Henrique[1], Â. Rodrigues[1], J. Lobo[1]
[1]Portuguese Oncology Institute of Porto (IPO-Porto), Department of Pathology, Porto, Portugal

Background & Objectives: SMARCB1-deficient medullary renal cell carcinoma (RCC) is a very rare and aggressive tumour, considered within the group of molecularly defined RCC. It represents <0.5% of RCCs and often presents in patients with sickle cell trait. Even rarer, some tumours occur in patients without haemoglobinopathies, being considered SMARCB1-deficient medullary-like RCC. We reviewed two patients diagnosed at out institution.
Methods: Patient A (PtA) presented with a 9.3cm right renal mass, with extensive necrosis. The patient underwent a radical nephrectomy 5 months later. Patient B (PtB) presented with lumbar pain and haematuria and a 15cm right renal mass.
Results: Both showed a high-grade carcinoma with infiltrative features, invading peri-renal tissues and renal hilum, with extensive lymphovascular invasion, high mitotic index and necrosis. PtA showed a tumour with tubulo-papillary to solid architecture, raising the hypothesis of papillary RCC or MiTF-family RCC. PtB showed a mostly solid and poorly-differentiated tumour, with both epithelioid and spindle cell areas, which in some foci raised differential diagnosis of a small round cell tumour. The tumours were PAX8+, cytokeratin+, FH/SDHB/SMARCA4 retained, OCT3/4-, ALK-. FISH for TFE3/TFEB/gains in 7/17 were negative. FISH for EWSR1/CIC/SS18 in PtB were negative. Both tumours had complete loss of INI1

immunoexpression. DNA/RNA were extracted from both tumours, and NGS studies revealed no fusions and presence of SMARCB1 pathogenic variants as the single alteration.
Despite systemic therapy, both patients died at 1.5years and 8months post-resection with metastatic disease.
Conclusion: SMARCB1-deficient RCC with medullary-like features is a rare entity which lacks association with haemoglobinopathy. It can have variable morphological resemblance to "classical" SMARCB1-deficient medullary RCC, being often poorly differentiated and raising several differential diagnoses, but shows a similar INI1 loss and poor clinical behaviour.

E-PS-26-017
Langerhans cell histiocytosis in renal cell carcinomas: a multicentre case series
P. Rauseo-Aristigueta[1], T.D. Ayquipa Arrospide[2], P. Tornero-Piñero[1], A.F. Aguero[1], X. Bernal Escoté[3], E. Condom[2], M. Pané Foix[2], G. Ippoliti[2,1]
[1]Hospital del Mar, Pathology Department, Barcelona, Spain, [2]Hospital Universitari de Bellvitge, Pathology Department, Barcelona, Spain, [3]Hospital Universitari Joan XXIII de Tarragona, Pathology Department, Tarragona, Spain

Background & Objectives: Langerhans cell histiocytosis (LCH) is a rare neoplasm characterized by neoplastic Langerhans cells intermixed with reactive mononuclear cells and granulocytes, particularly eosinophils. LCH can be associated with non-hematologic neoplasms. This study compiles cases from three hospitals to describe the clinicopathological and molecular features of renal cell carcinomas (RCC) with LCH.
Methods: A retrospective, multicentre study including five cases of renal tumours with a Langerhans cell component.
Results: All patients were male, with a mean age of 61 years (range: 50–70). All cases presented as well-defined solid lesions, with a mean tumour size of 4.26 cm (range: 2–6.5 cm). Most (4/5) were clear cell RCC (ISUP grade 2 [3/4], grade 3 [1/4]), including one collision tumour with papillary RCC (ISUP grade 3). One case (1/5) was high-grade RCC with rhabdoid transformation (ISUP grade 4). The histiocytic component demonstrated epithelioid histiocytes (4/5), eosinophilic cytoplasm (5/5), histiocytes with prominent nucleoli (4/5), multinucleated giant cells (1/5), and eosinophilic infiltration (5/5). Immunohistochemistry showed positivity for CD68 (4/4), S100 (3/3), CD1a (3/4), Langerin (2/2), and Cyclin D1 (1/1). BRAF V600E mutation was detected in all tested cases (2/2). None of the three assessed patients had systemic histiocytosis, though one had monoclonal gammopathy of undetermined significance (MGUS). Another patient is pending systemic evaluation.
Conclusion: Recognizing LCH in renal neoplasms poses a diagnostic challenge, as these cells may be misinterpreted as part of the renal tumour, potentially leading to overestimation of grade and impacting prognosis. Eosinophils may serve as a diagnostic clue. Immunohistochemical or molecular testing for BRAF V600E helps confirm diagnosis. While our cases were renal-limited, systemic disease has been reported, highlighting the need for further evaluation.

E-PS-26-018
***FGFR3* and *PIK3CA* mutations in non-muscle invasive bladder cancer: novel variants and prognostic value**
A. Dahmane[1], M. Ben Rakaya[2], A. Ochi[2], E. Hamdeni[2], A. Blel[1], I. Ouzeri[3], H. Ayed[2], L. Bel Hadj Kacem[1], M. Ksentini[1], S. Rammeh[1]
[1]Charles Nicolle University Hospital, Department of Pathology, Tunis, Tunisia, [2]Faculty of Medicine of Tunis, LR23ES02, Tunis, Tunisia, [3]University of Tunis El Manar, LR03ES03, Tunis, Tunisia

Background & Objectives: Urothelial bladder cancer is a prevalent urological malignancy, particularly among Tunisian men. Non-muscle invasive bladder cancer (NMIBC) is characterized by heterogeneity and variable recurrence/progression risks. *FGFR3* and *PIK3CA* mutations are frequent in NMIBC. This study aimed to identify *FGFR3* and *PIK3CA* mutations in NMIBC and evaluate them with clinicopathological features.
Methods: Clinicopathological data from 42 NMIBC cases from the pathology department at Charles Nicolle Hospital (Tunis, Tunisia) were analysed. *FGFR3* (exons 7, 15) and *PIK3CA* (exon 9) hotspot regions were sequenced using Sanger sequencing.
Results: Cases were equally distributed between pTa and pT1 stages (50% each; pT1 substaged as pT1a [n = 4 (19%)] and pT1b [n = 17 (31%)]). Carcinoma in situ (CIS) was present in 3 cases (7%) of pT1 tumours. Thirteen distinct FGFR3 variants were identified in exon 7, including eight known (S249C, P250R, P250S, H251Q, S249S, S249Y, S249A, T264T) and five novel mutations (P250A, H251L, A257S, P253P, I254V). S249C was the most frequent alteration, observed in 22 cases (85% of FGFR3-mutated cases). FGFR3 mutations were found in 26 cases (68%) and correlated with tumour stage ($p = 0.03$).
Conclusion: *FGFR3* and *PIK3CA* molecular testing may complement cystoscopy and urinary cytology for NMIBC prognosis. Novel *FGFR3* mutations and their association with tumour stage suggest their potential as prognosis biomarkers. Further studies are needed to validate these findings.

E-PS-26-019
HPV-induced penile squamous cell carcinoma with subsequent CDKN2A (P16) deletion
B. Luu[1], S. Siegmund[2]
[1]Queen's University, Department of Pathology and Molecular Medicine, Kingston, Canada, [2]Brigham and Women's Hospital and Harvard Medical School, Department of Pathology, Boston, USA

Background & Objectives: The WHO classification of tumours currently recommends stratifying penile squamous cell carcinoma (pSCC) by HPV status. Studies investigating clinicopathologic and prognostic differences variably define HPV status by P16 immunohistochemistry (IHC) and/or HPV viral detection (e.g. polymerase chain reaction-restriction fragment length polymorphism [PCR-RFLP], in situ hybridization [ISH]). We present a case of P16-positive HPV-induced pSCC with subsequent loss of P16 protein expression secondary to biallelic inactivation of *CDKN2A*.
Methods: A patient with pSCC was seen at our institution, and all specimens (initial biopsy, penectomy and recurrence biopsy) were evaluated by HPV ISH, PCR-RFLP, P16 IHC, and next-generation sequencing (NGS).
Results: A 70-year-old man initially presented with gross haematuria and a groin mass. Cystoscopy revealed a papillary neoplasm arising from the distal penile urethra, and biopsy confirmed an invasive keratinizing squamous cell carcinoma. This initial biopsy was block-positive for P16 by IHC, positive for high-risk HPV by ISH, and positive for HPV subtype 16 by PCR-RFLP. He subsequently underwent partial penectomy and immune checkpoint inhibitor therapy. Unfortunately, his disease progressed, and repeat biopsy 5 months after surgery demonstrated pSCC with positive HPV ISH but negative P16 IHC. Genomic testing of the penectomy and post-penectomy biopsy revealed a homozygous *CDKN2A* deletion, explaining the acquired loss of P16 expression.
Conclusion: To our knowledge, this is the first case of HPV-induced pSCC with subsequent P16-loss reported in the literature. This case underscores the complexity of pSCC pathogenesis and the limitations of P16 as a surrogate for HPV status.

E-PS-26-021
Relevance of Von Hippel Lindau protein (pVHL) expression in biological behaviour of renal cell carcinomas in Indian subcontinent
S. Babu[1]
[1]King George Medical University, Pathology, Lucknow, India

Background & Objectives: Von Hippel Lindau (VHL) is tumour suppressor gene; alterations in gene product (pVHL) of which leads to development of Renal Cell Carcinoma (RCC). pVHL functions through transcription dependent nuclear-cytoplasmic trafficking for it's action. Present study is an aim to evaluate and correlate the frequency of pVHL expression with Renal Carcinoma subtypes, grades and stages.
Methods: Total 78 cases of RCC which included three subtypes viz. clear cell, papillary and Chromophobe were analysed for pVHL expression using polyclonal antibody to pVHL (pVHL30/ pVHL19). Age of the patients varied from 50 to70 years with mean age of 54.5±12 years. Of these 70 cases expressed positivity. Among these 55,11 and 04 were clear cell, papillary and Chromophobe respectively. Stage wise distribution of these cases was as 44% (I),28% (II),18% (III)and10% (IV).
Results: pVHL expression across tumour cells was predominantly nucleo-cytoplasmic (83%) followed by exclusive cytoplasmic (11%) and nuclear(06%) expressions. TNM staging wise, exclusive nuclear expression was confined to early stages (I and II) only, whereas cytoplasmic exclusivity showed a predominant predilection for advanced stages viz. 23% and29% for stages III and IV as against 6% in early stages (I and II). Nucleo-cytoplasmic expression also was skewed towards early stages (84%) as compared to locally metastatic(77%) and advanced metastatic(71%) stages. Fuhrman's nuclear grading in clear cell RCC cases too accounted for all the exclusive nuclear positive pVHL expression in grade I while the cytoplasmic alone expressive pVHL cases shared60% of grade IV labelled carcinomas. Statistical significance was achieved for most of the results.
Conclusion: To conclude, the results emphasize that VHL gene mutations leading to structural alterations in pVHL have significant relevance in biological profile of Renal Cell Carcinomas.

E-PS-26-022
Renal metastasis of sinonasal adenoid cystic carcinoma: a case report
Z.S. Chua[1], R.S.-E. Lau[2], H.Y. Tiong[2], T.P. Thamboo[1]
[1]National University Health System, Pathology, Singapore, Singapore, [2]National University Health System, Urology, Singapore, Singapore

Background & Objectives: Adenoid cystic carcinoma (ACC) is a malignant epithelial tumour which arises from salivary glands. They can present with metastases many years after the initial resection. We describe the clinical, radiological and morphologic features of a case of a patient with sinonasal ACC with metastasis to the kidney. Renal metastasis of ACC is uncommon and presents diagnostic challenges. Histological examination is key in confirming the diagnosis and excluding a primary renal tumour.
Methods: A 54-year-old female had previous sinonasal ACC, treated with resection and adjuvant radiotherapy. She presented with epistaxis 8 years later and was diagnosed with local recurrence of the tumour. Imaging revealed a tumour within the left kidney, with no other evidence of distant metastases. The tumour was hypo-enhancing on the arterial phase, with progressive enhancement on the portovenous phase. The radiological impression was that of papillary renal cell carcinoma. The patient opted for resection of the local tumour recurrence and surveillance for the kidney tumour. Surveillance imaging subsequently showed interval growth of the left kidney tumour and a radical nephrectomy was performed.
Results: The kidney contained a 6.0 cm tan-white tumour at the interpolar region. Microscopically, the tumour had a biphasic appearance, comprising basaloid luminal cells and clear abluminal cells with surrounding basement membrane material. On immunohistochemical staining, the luminal cells were positive for CD117, while the abluminal cells were positive for p40. The histologic features were those of ACC.
Conclusion: The clinical-radiological features of renal metastasis may resemble a primary renal tumour. Increased venous enhancement during a contrasted CT study has been suggested as a finding that favours metastasis over a primary renal tumour. The radiological features in our case support this observation.

E-PS-26-024
Next-generation sequencing (NGS) and PD-L1 immunohistochemistry in plasmacytoid urothelial carcinoma of the urinary bladder: a single institution experience
R. Dhir[1], L. Diamantopoulos[1], M. Mohebnasab[1], G. Quiroga-Garza[1], D. Korentzelos[1]
[1]University of Pittsburgh, Pathology, Pittsburgh, USA

Background & Objectives: Plasmacytoid urothelial carcinoma (PUC) of the urinary bladder is an aggressive urothelial carcinoma subtype characterized by single infiltrating cells with plasmacytoid appearance, and somatic CDH1 mutations leading to loss of E-cadherin expression. This variant has been previously described in limited case series and thus warrants further investigation.
Methods: 32 cases with this diagnosis and slides available for review were found in our pathology archives from 2018-2024. Next-generation sequencing (NGS) data were available in 18 cases, and PD-L1 immunohistochemistry in all 32 cases. Both tumour proportion score (TPS) and combined positive score (CPS) were calculated for PD-L1. Survival analysis was performed using Kaplan-Meier method and log-rank test.
Results: Median patient age was 72.5 years (IQR: 64.3-78.8). The cohort consisted predominantly of males (29/32, 91%). 25 patients (78%) underwent radical cystectomy (RC), while 7 (22%) had transurethral resection. Median tumour size was 5.2 cm (IQR: 3.6-8.0). Most RCs (22/25, 88%) were high-stage (pT3-4). Lymph node dissection was performed in 23/25 RCs, and of those 12 (52%) were pN1-2. Lymphovascular invasion was identified in 22/25 RCs (88%). 17/32 cases (53%) showed a PD-L1 TPS≥1% (6/17 received immune-checkpoint inhibitors – ICIs), while 21/32 (66%) exhibited a CPS≥1% (8/21 received ICIs). Recurrently mutated genes included TP53, TERT, RB1, CREBBP, and ERBB2, among others; our NGS panel does not cover CDH1. Most frequent copy number alterations were losses of RB1, CDKN2A, and CDKN1B. Median tumour mutational burden (TMB) was 10.3 mut/Mb (IQR 5.4-15.73). Median overall survival (OS) was 13.0 months (95% CI: 4.2-21.8). There was a trend for superior OS among patients with PD-L1 expression.
Conclusion: Our study shows that PUCs frequently feature a high TMB and/or PD-L1 expression, suggesting a potential for intervention with ICIs. Additionally, there is a strong rationale for NGS testing as actionable mutations are frequently present, including ERBB2 mutations.

E-PS-26-025
Collision metastasis of urothelial carcinoma and neuroendocrine tumour to para-aortic lymph node: a case report
E. Coskun[1], T. Wang[1], C. Davidson[1], K. Ren[1]
[1]Queen's University, Diagnostic and Molecular Pathology, Kingston, Canada

Background & Objectives: Collision tumours involve the simultaneous presence of two distinct malignant neoplasms. In nodal metastasis, this refers to the occurrence of metastatic deposits from two separate primary tumours within the same lymph node, a rare phenomenon. We present a case of collision metastasis in para-aortic lymph node, involving urothelial carcinoma of the renal pelvis and a neuroendocrine tumour from the small intestine.
Methods: A 63-year-old female with a history of high-grade urothelial carcinoma of the renal pelvis and well-differentiated neuroendocrine tumour of the small bowel (status post right nephroureterectomy and small bowel resection). Approximately one year after the operation, the patient presented with bilateral leg oedema and

abdominal/groin pain. A CT scan revealed a 3.6 x 6.1 cm conglomerate paraaortic lymph node, which was biopsied.
Microscopic examination of the biopsy revealed two distinct populations of epithelioid cells:
• Urothelial Carcinoma Component: Atypical cells with hyperchromatic, irregular nuclei and large cytoplasm, resembling the previously resected urothelial carcinoma.
◦ Immunohistochemistry: GATA-3 (+), p40 (+), CK7 (+), CK20(+), CK-pan (+)
• Neuroendocrine Tumour Component: Small, round cells with pink cytoplasm and speckled "salt-and-pepper" nuclei arranged in nests, similar to the previous neuroendocrine tumour from the small bowel resection.
◦ Immunohistochemistry: CK-pan (+), Synaptophysin(+), Chromogranin(+)
Results: The needle biopsy showed a collision of high-grade urothelial carcinoma and well-differentiated neuroendocrine tumour infiltrating fibrous tissue, with findings that were morphologically and immunohistochemically consistent with previous resected primary tumours.
Conclusion: In conclusion, collision metastases involve the co-occurrence of metastatic deposits from different primary tumours within the same lymph node. Accurate diagnosis requires close clinical-pathology correlation and detailed histologic examination to differentiate the individual tumour components. The recognition of collision tumours is crucial, as the individual components may necessitate different treatment strategies. Awareness of collision tumours is essential to ensure comprehensive evaluation of patients with multiple cancer diagnoses, appropriate management, and optimized patient outcomes.

E-PS-26-026
Machine learning-based integration of transcriptome and digital pathology for predicting chemoresistance in muscle-invasive bladder cancer
Y.M. Cho[1], J. Jeong[1], G. Jeong[2], Y. Kim[1], H. Ju[1], H.J. Im[1], H.J. Kim[1], J.-M. Park[1], S.U. Jeong[3], H. Kwon[1], S.W. Ha[1], S. Lee[1], D. Lee[1], E. Park[4], I. Park[1], J.L. Lee[1], G. Yoon[5], H. Lee[6], S. Lee[1], M.G. Jang[1], Y.J. Nam[1], B. Hong[1], D.-M. Shin[1]
[1]Asan Medical Centre, University of Ulsan College of Medicine, Seoul, Republic of Korea, [2]CJ Logistics, Seoul, Republic of Korea, [3]Kyung Hee University Hospital, Seoul, Republic of Korea, [4]AinB Inc, Seoul, Republic of Korea, [5]Kyungpook National University School of Medicine, Daegu, Republic of Korea, [6]Nowon Eulji Medical Centre, Seoul, Republic of Korea

Background & Objectives: Muscle invasive bladder cancer (MIBC) presents with variable clinical and pathological features, leading to inconsistent responses to standard treatments such as neoadjuvant chemotherapy (NAC). Although transcriptome profiling has shown differences in NAC response, reliable predictors of treatment outcome remain elusive.
Methods: Machine learning workflows analysed transcriptome data from four independent cohorts (n=376) to extract molecular classifiers associated with the response to NAC. Spatial protein expression was assessed by computational pathology using two in-house cohorts (n=91). The digital pathology datasets, encompassing 74 protein markers, were further interrogated using deep learning models to identify an optimal antibody panel for immunohistochemistry (IHC)-based diagnostics. Survival outcomes were assessed through computational pathology-driven prediction modelling. Functional assays evaluating gene expression, cell proliferation, and apoptosis were conducted to elucidate the role of the KEAP1/NRF2 pathway on modulating chemoresistance in MIBC.
Results: The machine learning analysis of multi-cohort transcriptome datasets, incorporating diverse gene classifiers, uncovered key molecular features associated with NAC response, which highlighted key genes involved in stress, immune responses, and cell adhesion. The clinical relevance of these markers was validated by digital pathology for analysing spatial protein expression. The machine learning frameworks reduced complex digital pathology datasets to a clinically manageable number of biomarkers for IHC-based diagnostic or therapeutic applications. Computational pathology-driven predictions of NAC response demonstrated a strong correlation with survival outcomes in MIBC patients, highlighting their potential clinical utility. Furthermore, targeting KEAP1 resensitized MIBC cells to cisplatin, highlighting a potential therapeutic approach for overcoming chemoresistance and enhancing treatment efficacy.
Conclusion: This study improves the predictive power of the NAC response by integrating machine learning-based transcriptome profiling to refine gene classifiers and applying digital pathology analysis to increase clinical relevance. This approach advances precision medicine in MIBC by offering a more personalized, predictive, and feasible framework for treatment decision-making.

Funding: This research was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (Ministry of Science and ICT) (RS-2024-00422023) and by grants (2023IP0034) from the Asan Institute for Life Sciences, AMC, Seoul, Korea

E-PS-26-027
Osseous metaplasia in kidneys
M. Wołowiec[1]
[1]Alab Plus Sp. z o.o., Pathology, Warsaw, Poland

Background & Objectives: Osseous metaplasia (OM) in kidneys is a relatively rare finding, which has only a few research studies, with less than 50 reported cases in English literature.
The objective of this study was to investigate the prevalence of OM in kidneys or parts of kidneys removed for any reason between 2020 and 2024 in one laboratory.
Methods: Routine pathological reports from partial or total nephrectomy, conducted for various reasons, were retrospectively evaluated for mentions of OM. These reports included side, patient's age, sex and for tumours: size, tumour type (WHO classification), pTNM classification and histological grade (WHO/ISUP).
Results: 44 cases of OM were detected:
- 40 in tumours (main mass or capsule),
- 4 outside of tumours (renal pelvis, wall of simple renal cyst, perirenal adipose tissue and renal blood vessel), but each of them occurred within a kidney, which contains neoplasm (2 papillary renal cell carcinoma, 2 urothelial neoplasm).

The sex distribution included 16 females and 28 males in scope of report.
The arithmetic mean patient's age was 65 (range of age 41-82).
Histological types of tumours were: 37 renal cell carcinomas /RCC/ (34 clear cell /CCRCC/, 2 chromophobe, 1 papillary /PRCC/) and 3 oncocytomas.
The mean tumour size was 5,2cm (1,7cm – 13cm).
In RCC distribution according to TNM classification was: pT1 - 22 (pT1a - 11 , pT1b - 11), pT2b – 1, pT3a - 14.
Histological grade (CCRCC and PRCC) was: G1– 8, G2– 19, G3– 6, G4- 2 (1 with rhabdoid features, 1 with sarcomatoid features).
5 tumours contained necrosis (1-30%).
There was no confirmed case of OM in the kidney removed due to non-tumour conditions.
Conclusion: OM in the kidney occurred within benign and malignant renal neoplasms as well as it was detected outside of renal tumours.

E-PS-26-028

A pleomorphic rhabdomyosarcoma, arising from spermatic cord

A. Fatima[1], A. Hennessy[1], M. B Casey[1]
[1]Galway University Hospital, Histopathology, Galway, Ireland

Background & Objectives: Rhabdomyosarcoma is a malignant tumour of mesenchymal origin. Pleomorphic rhabdomyosarcoma is an uncommon subtype that affects older adults and is characterized by aggressive behaviour and poor prognosis. Spermatic cord tumours are rare and rhabdomyosarcomas arising from spermatic cord are extremely uncommon. Here we present a case of a 76 year old male diagnosed with pleomorphic rhabdomyosarcoma of the spermatic cord.
Methods: A 76 year old male presented to the emergency department with left inguinal pain, swelling for one year along with elevated Beta-HCG. Physical examination revealed a firm, non-testicular 9 x 5 cm mass extending into the scrotum without overlying skin changes. Imaging studies including MRI pelvis, ultrasound of the testis and CT abdomen-pelvis identified a suspicious mass in the left inguinal soft tissue raising suspicion for a spermatic cord tumour. The patient underwent left radical orchiectomy.
Results: Gross examination of the specimen revealed a 9 x 5.3 cm tan white tumour with areas of necrosis and haemorrhage. Microscopic evaluation showed sheets of high grade malignant cells with abundant atypical mitosis, necrosis, spindle cell morphology and plasmacytoid features. The adjacent testis was uninvolved. Immunohistochemistry demonstrated diffuse desmin positivity, weak focal positivity for SMA and MYOD1 and negativity for epithelial, melanocytic and vascular markers. A diagnosis of pleomorphic rhabdomyosarcoma was made. After multi disciplinary meeting discussion no chemotherapy was required, the patient is being followed and is doing well.
Conclusion: Paratesticular rhabdomyosarcoma can occur at any age. Histopathology and immunohistochemistry play a crucial role in distinguishing it from other paratesticular tumours. In our patient aggressive surgical management was the mainstay of treatment.

E-PS-26-029

Mesothelioma of the tunica vaginalis: report of a rare entity and lights on differential diagnosis from 5th WHO classification of urinary and male genital tumours

C. Taverna[1,2], A.G. Bonadio[1], F. Bonini[3], F. Montefiore[3], S. Orecchia[4], S. Delfanti[5], F. Grosso[5]
[1]Local Hospital ASLAL, Ospedale san Giacomo, Pathology Unit, Novi Ligure, Italy, [2]University of Eastern Piedmont "Amedeo Avogadro" UNIUPO, Department of Health Sciences, Novara, Italy, [3]Local Hospital San Giacomo, Urological Unit, Novi Ligure, Italy, [4]University Hospital SS Antonio e Biagio e Cesare Arrigo, Pathology Unit, Alessandria, Italy, [5]University Hospital SS Antonio e Biagio e Cesare Arrigo, Oncology Unit, Alessandria, Italy

Background & Objectives: Mesothelioma of the tunica vaginalis (MVT) is rare, with less than 300 cases reported since the first description in 1957. It accounts for less than 1% of pleural and peritoneal mesotheliomas and of testicular neoplasms.
In Italy, the mean standardized incidence rate of MTVT is 0.095 per million person-years, with a peak incidence in the sixth decade.
Herein we report a rare case of mesothelioma of the tunica vaginalis with immunohistochemical and molecular assessment.
Methods: An 83-year-old patient, with no history of trauma came to our urological unit in January 2024, for left testicular swelling.
He worked as a railway station systems technician.
Clinically the mass resembled a cyst and a routinary ultrasound was performed. Results were consistent with a cyst with associated thin papillary projections on tunica vaginalis.
The patient underwent orchiectomy.
Results: Macroscopically, the tunica vaginalis was covered by multiple white thin papillae, measuring from 2 to 0,1 cm. Testicular parenchyma did not present macroscopical alterations.
Microscopically, a proliferation of epithelioid elements with marked atypia and pleomorphism covered tunica vaginalis, forming papillae and pseudoglandular structures, with invasive foci.
Psammomatous bodies were present. Necrosis was absent.
Atypical cells expressed calretinin, WT1, CK5/6, BAP1 (pathcy) and were negative for BEREP4, CEA, CK20 and ER.
Molecular test showed deletion of CDKN2A in 30% of cells (cut off 15%) with FISH.
For all these features, a diagnosis of epithelioid MVT was made.
Conclusion: MVT is rare and aggressive, with no AJCC/IUCC classification nor standard treatment available.
The diagnosis is challenging, as it must be distinguished from other mesothelial lesions (well-differentiated papillary mesothelial tumour), ovarian type epithelial tumours, tumour originated from the collecting duct and rete testis and metastases.
A combination of immunohistochemistry and FISH analysis showing deletion of CDKN2A is mandatory.

E-PS-26-030

Coexistence of low-grade oncocytic tumour (LOT) and multifocal angiomyolipomas: a unique case report

F. Aknar[1], G. Kir[1]
[1]Istanbul Medeniyet University Goztepe Prof. Dr. Suleyman Yalcin City Hospital, Department of Pathology, Istanbul, Turkey

Background & Objectives: LOT is an emerging renal neoplasm recently delineated in the 2022 WHO classification as part of a heterogeneous group of oncocytic tumours not fitting into conventional categories. LOT characteristically shows diffuse CK7 positivity, absent CD117 expression, and frequently harbours mutations in mTOR pathway genes. In addition, angiomyolipomas (AMLs) – tumours that may be associated with tuberous sclerosis complex (TSC) – often display similar mTOR dysregulation. We report a unique case of a 61-year-old male that combines LOT with multifocal AML foci in radical nephrectomy specimen, raising strong suspicion for an underlying TSC/mTOR-driven pathology.
Methods: The patient presented with urinary symptoms and imaging studies identified a left renal mass and incidental hepatic AML. The radical nephrectomy specimen underwent thorough gross and microscopic examination. Immunohistochemical studies were performed to distinguish LOT from other oncocytic renal tumours and to characterize the AML components.
Results: Gross examination revealed a well-circumscribed, cream-colored tumour measuring 5.2 cm in the upper pole of the kidney, with cystic and haemorrhagic areas. Histologically, the lesion exhibited uniform low-grade nuclei eosinophilic voluminous cytoplasm, a solid nested architecture, and a prominent perinuclear halo – features consistent with LOT. Immunohistochemistry confirmed diffuse CK7 and PAX8 positivity and lack of CD117 expression. In addition, random sampling of the apparently normal renal parenchyma uncovered multiple, scattered AML foci (largest 1.5 cm) that displayed a classic triphasic pattern and robust expression of melanocytic markers (HMB45, MelanA, Cathepsin K) alongside SMA positivity.
Conclusion: This case illustrates the rare coexistence of LOT and multifocal AML, suggesting a shared TSC/mTOR-driven molecular basis. Despite the patient's demise due to non-neoplastic causes precluding genetic consultation, the morphological and immunohistochemical findings align with literature implicating mTOR pathway dysregulation and underscore the importance of considering TSC. Recognizing this association may have significant implications for genetic counselling and potential targeted therapeutic strategies.

E-PS-26-031

Metanephric stromal tumour of the kidney: a case presentation

A. Miroshnichenko[1], M. Urezkova[2], A. Gogolev[2], S. Bolsynbekova[2], R. Belyayev[1]

[1]Karaganda Medical University, Karaganda, Kazakhstan, [2]National Research Oncology Centre, Department of Cytopathology, IHC and Translational Oncology, Astana, Kazakhstan

Background & Objectives: Metanephric stromal tumour (MST) is a rare, benign renal tumour found primarily in children, typically diagnosed at the average age of around 2 years. It's very uncommon in adults, which can complicate diagnosis.

Methods: A 23-year-old male noticed right abdominal enlargement and underwent an ultrasound, which revealed a space-occupying lesion in the right kidney. A contrast-enhanced CT scan showed a large lesion in the right kidney with right-sided hydronephrosis. The patient underwent right radical nephrectomy.

Results: On gross examination was presented the kidney weighed 3024g and measured 22x20x15 cm, with most of it replaced by tumour mass (18x21x14 cm). Macroscopically the tumour was grayish-pink, flabby, and solid-cystic, with predominant solid components and smooth-walled cysts (0.5 to 4.5 cm) containing yellowish fluid. The renal pelvis was compressed but not infiltrated. On microscopic examination the tumour was mainly spindle-shaped, with monomorphic cells forming multidirectional bundles around stromal vessels. There were minimal fat components, pronounced degenerative changes (sclerosis, necrosis), and unlined cysts. The mitotic count was 1 per 10 hpf. No infiltrative growth into the renal capsule or pelvis was noted, and the tumour's morphology resembled angiomyolipoma. Immunohistochemical results revealed negative status of tumour cells for PanCK, Desmin, SMM, S100, MelanA, HMB45, and CD99. CD34 showed focal expression in spindle cells around vessels and renal tubules. The patient was diagnosed with metanephric stromal tumour, and molecular testing for BRAF p.V600E was recommended.

Conclusion: Surgery is the main treatment for MST, with preoperative diagnosis often requiring differentiation from other renal conditions. While CT, ultrasonography, and CEUS are commonly used, recent studies suggest BRAF mutation detection may provide a valuable diagnostic tool. MST is primarily diagnosed through exclusion, with imaging techniques playing a crucial role in distinguishing it from other renal tumours.

E-PS-26-033

A primary well-differentiated neuroendocrine tumour of the bladder in a young male: a case report of a rare entity

C. Wraith[1], A. Sridhar[1], N. Magdy[1]

[1]University College London Hospitals NHS Foundation Trust, London, United Kingdom

Background & Objectives: Neuroendocrine neoplasms are a diverse group of tumours that can arise in any organ system. They are much rarer in the genitourinary (GU) system, constituting around 1% of bladder neoplasms, with the least common subtypes is well differentiated neuroendocrine tumour (NET). We present a case of a young man, presenting with hypertension and renal impairment who was diagnosed with a primary well- differentiated NET of the bladder.

Methods: A 29- year-old man underwent an USS KUB to investigate symptoms of hypertension and renal impairment. Further CT and MRI imaging showed an organ- confined bladder tumour with no nodal disease or distant metastasis. A transurethral resection of the bladder tumour (TURBT) was performed.

Results: Microscopically, the initial TURBT showed a tumour consisting of bland, monotonous cells with mild nuclear pleomorphism and speckled chromatin with scarce mitoses. Immunohistochemistry was positive for AE1/AE3, synaptophysin, CD56 and chromogranin A but negative for NKX3.1 and GATA3. Ki67 labelling index was low (5-10%). This was consistent with a well- differentiated NET. Correlation with clinical and radiological findings were recommended to exclude metastases from elsewhere before considering the rare primary bladder origin. Following his initial diagnosis, the patient underwent a partial cysto-prostatectomy with ureteric reimplantation. Analysis of the resected specimen concurred with that of the initial TURBT with a diagnosis of a grade 2 well- differentiated NET of the bladder.

Conclusion: A range of neuroendocrine neoplasms have been described in the GU tract including large and small cell carcinomas, paragangliomas and well- differentiated NET. The latter is exceedingly rare in the bladder, with fewer than 30 having been described in the literature. These tumours share architectural and cytological features with similar tumours from other sites. Metastases to other organs has been known. Given its rarity, there is no current standard of care for patients presenting with these tumours.

E-PS-26-034

Association of intertubular growth pattern with prognosis and prognostic parameters in pure seminomas

B. Timur[1], A.E. Sarikaya[2], V. Sen[3], H. Ellidokuz[4], E.B. Tuna[1]

[1]Dokuz Eylul University School of Medicine, Pathology, Izmir, Turkey, [2]Usak Training and Research Hospital, Urology, Usak, Turkey, [3]Dokuz Eylul University School of Medicine, Urology, Izmir, Turkey, [4]Dokuz Eylul University Institute for Oncology, Preventive Oncology, Izmir, Turkey

Background & Objectives: Testicular cancers are the most common solid neoplasms among young adults aged 20–40, with germ cell tumours accounting for approximately 95% of cases. About 55–60% of germ cell tumours are pure seminomas. Intertubular seminoma(ITS) is an entity that has been described in recent years, and its prognostic significance remains not fully established.

Methods: 81 patients diagnosed with stage 1 seminoma between 2007 and 2023 were identified at Dokuz Eylül University Hospital. Haematoxylin and eosin (H&E) stained slides of these patients were examined for the presence of ITS and other prognostic parameters.

Results: The median patient age was 33, and the median tumour size was 45 mm. The presence of an intertubular pattern was significantly associated with younger age($p=0.025$), smaller tumour size($p=0.009$), necrosis($p=0.001$), intratubular pattern ($p=0.014$), and rete testis invasion ($p<0.001$). In multivariate logistic regression, only rete testis invasion remained an independent predictor of intertubular pattern. Tumour size was not significantly associated with rete testis invasion ($p=0.163$), and no significant associations were found with vascular invasion or tumour localization. The distance between the main tumour mass and an ITS focus, measured in high power fields (HPFs), was inversely correlated with tumour size (Spearman $\rho=-0.35$, $p=0.033$). ITS were observed in association with germ cell neoplasia in situ (GCNIS) and/or tubular atrophy in 27/37 cases, with seminiferous tubules showing normal spermatogenesis in 3/37 cases, and with both ITGCN-positive and histologically normal tubules in 7/37 cases.

Conclusion: It is not yet clear whether ITS is associated with a more aggressive course; however, the presence of rete testis invasion should be considered in terms of the disease's potential for spread. The association of ITS with GCNIS and tubular atrophy may provide insights into the tumour's development process. Further research is needed to determine whether ITS can be used as a biological marker in early-stage seminomas.

E-PS-26-036

Recurrent clear cell adenocarcinoma in the urethral diverticulum: a case report

E. Lee[1,2], G. Yoon[1,2]

[1]School of Medicine, Kyungpook National University, Department of Pathology, Daegu, Republic of Korea, [2]Kyungpook National University Chilgok Hospital, Department of Pathology, Daegu, Republic of Korea

Background & Objectives: We report a case of recurrent clear cell adenocarcinoma (CCA) in the urethra following an initial occurrence involving the urethral diverticulum. CCA of urethra is a rare and aggressive malignancy, with only about 250 cases reported in the English literature.
Methods: A 43-year-old female presented to the hospital with abdominal pain. Imaging studies demonstrated a periurethral mass in urethral diverticulum. A urethral diverticulectomy was performed and clear cell adenocarcinoma was identified. Three and half years later, a residual mass was observed in the urethra inferior to the bladder. Finally, a total urethrectomy was performed.
Results: Gross finding of urethral diverticulectomy specimen shows a gray-white soft polypoid mass. Histologic examinations demonstrate a combination of solid, papillary and tubulocystic growth pattern. The atypical cells show clear to eosinophilic abundant cytoplasm and luminal hobnailing of nuclei with moderate nuclear atypia. In immunohistochemical staining, PAX8, CK7, p53 and Napsin A were positive and GATA3 was focal and weak positive. Three and half years later, the patient visited the hospital with complaints of haematuria and dysuria. In imaging studies, there was about a 3cm mass confined into urethra inferior to the bladder. Total urethrectomy was done. The pathologic findings were similar to those of the previous urethrectomy specimen. Following the diagnosis of recurrent CCA of the urethra, the patient is undergoing palliative chemotherapy.
Conclusion: CCA of urinary tract, especially urethra is a rare malignancy with a relatively poor prognosis compared to non-CCA cancers. This case presents a rare disease of recurrent CCA originating in the urethral diverticulum, highlighting the importance of pathological and immunohistochemical findings in diagnosing CCA.

E-PS-26-037

High-grade urothelial carcinoma of the renal pelvis with trophoblastic differentiation and micropapillary subtype: a rare case report

A. Türkmen Dedeoğlu[1], I.K. Taşdemir[2], H. Dedeoğlu[3], Y. Yuyucu Karabulut[1]
[1]Mersin University, Pathology, Mersin, Turkey, [2]Mersin University, Urology, Mersin, Turkey, [3]Mersin University, Radiology, Mersin, Turkey

Background & Objectives: Urothelial carcinomas (UC) typically exhibit classic transitional cell morphology, but some cases may present with distinct histological features. Trophoblastic differentiation is rare and warrants detailed evaluation due to its prognostic significance. The aim of presenting this case is to emphasize the clinical and histopathological characteristics of rare variants and contribute to existing literature.
Methods: A 73-year-old male with a history of prostate adenocarcinoma presented with left flank pain. Imaging revealed grade 4 hydronephrosis in the left kidney and a soft tissue density filling the lumen of the left ureter. Left ureteronephrectomy was performed.
Results: Macroscopic examination identified a tumour in the proximal ureter and papillary lesions filling the renal pelvis. Histopathological evaluation showed high-grade UC areas alongside syncytiotrophoblastic cells with abundant eosinophilic cytoplasm, pleomorphic nuclei, and micropapillary structures. Extensive necrosis and haemorrhage was present, with faint cytoplasmic staining for β-hCG and SALL4 in syncytiotrophoblasts.
Conclusion: UC originates from the uroepithelial cells lining the urinary system. While most cases involve transitional cells, approximately 25% exhibit squamous, glandular, sarcomatoid, or micropapillary features, which are often aggressive. Trophoblastic differentiation in UC is rare and can range from syncytiotrophoblasts to choriocarcinoma. Only 7 cases of UC with trophoblastic differentiation of the renal pelvis have been reported in the literature. Syncytiotrophoblasts are giant cells with eosinophilic cytoplasm and large nuclei, observed in 28–35% of UCs and associated with β-hCG production. This differentiation is linked to high-grade, advanced stages, poor therapy response, and early hematogenous spread, indicating a poor prognosis. Immunohistochemically, β-hCG is expressed in trophoblastic/syncytiotrophoblastic cells and frequently in malignant urothelial cells. Elevated serum β-hCG levels independently correlate with poor prognosis. SALL4 is focally positive in <50% of cases but negative in syncytiotrophoblasts. To date, there have been no other reported renal pelvis UC case with micropapillary and trophoblastic differentiation other than our case in the literature.

Immune landscape alterations in renal cell carcinoma under transplant-related immunosuppression: clinical implications for personalized therapy

T. Holler[1], J. Schmitz[1], N. Vasileiadis[1], D. Christensen[1,2], G. Grabert[3,4], M. Müller[2], H. Tezval[5], M.A. Kuczyk[5], W. Gwinner[6], K. Schmidt-Ott[6], L. Neubert[7], C. Darr[8], V. Grünwald[8], P. Ivanyi[9], S. Halle[10,11], T. Kacprowski[3,4], J.H. Bräsen[1]
[1]Hannover Medical School, Nephropathology Unit, Institute of Pathology, Hannover, Germany, [2]MetaSystems Hard & Software GmbH, Altlussheim, Germany, [3]Peter L. Reichertz Institute for Medical Informatics of TU Braunschweig and Hannover Medical School, Division Data Science in Biomedicine, Braunschweig, Germany, [4]TU Braunschweig, Braunschweig Integrated Centre of Systems Biology (BRICS), Braunschweig, Germany, [5]Hannover Medical School, Department of Urology and Urologic Oncology, Hannover, Germany, [6]Hannover Medical School, Department of Nephrology and Hypertension, Hannover, Germany, [7]Hannover Medical School, Institute of Pathology, Hannover, Germany, [8]University Clinic Essen, Department of Urology, Department of Medical Oncology, Essen, Germany, [9]Hannover Medical School, Clinic for Haematology, Hemostaseology, Oncology and Stem Cell Transplantation, Hannover, Germany, [10]Hannover Medical School, Institute of Immunology, Hannover, Germany, [11]Hannover Medical School, Institute of Clinical Chemistry and Laboratory Medicine, Hannover, Germany

Background & Objectives: The tumour microenvironment (TME) plays a critical role in renal cell carcinoma (RCC) progression and response to immunotherapy. However, the impact of long-term immunosuppression in transplant recipients on immune cell composition in RCC subtypes remains poorly defined. This study aimed to characterize immune differences between immunocompetent and immunosuppressed post-transplant (post-Tx) patients in both clear cell RCC (ccRCC) and papillary RCC (pRCC), and to explore their clinical relevance.
Methods: Tumour samples from 81 RCC patients (49 ccRCC, 32 pRCC) were analysed, including 43 post-Tx patients under systemic immunosuppression (glucocorticoids, calcineurin and mTOR inhibitors, MMF). Immune cell infiltration and checkpoint expression were assessed using histology, immunohistochemistry, mRNA expression profiling (PanCancer IO360™ panel), mRNA-FISH, and AI-assisted digital pathology. Clinical and pathological data and prognostic scores (MSKCC, IMDC, UISS) were correlated with molecular findings.
Results: PD-L1 expression positively correlated with tumour grade, stage, size, and UISS classification in the whole cohort.
In ccRCC, immunosuppressed patients exhibited markedly reduced densities of $CD4^+$, $CD8^+$, $FOXP3^+$ T cells and $CD20^+$ B cells, with corresponding downregulation of *PDL1*, *CTLA4*, and *LAG3* at the mRNA level. PD-L1 protein expression was consistently lower across tumour cells, immune cells, and combined scoring systems. These immune alterations correlated with impaired renal function and higher clinical risk profiles.

In pRCC, post-Tx patients showed decreased macrophage density and lower PD-L1 protein expression, but only minimal differences in T or B cell infiltration compared to controls. Overall, immune activity was lower in pRCC than ccRCC, regardless of immune status.
Conclusion: Transplant-related immunosuppression significantly reshapes the immune microenvironment in ccRCC, while pRCC appears inherently less immunogenic. These findings underscore the clinical value of immune profiling and support PD-L1 as a potential biomarker to guide risk stratification and personalized therapy in RCC.

E-PS-26-039
Prognostic, clinical and pathological significance of HER-2 expression in urothelial carcinoma: a retrospective study
G. Arslan[1], İ. Oğuz[2], V. Erçolak[3], Y. Yuyucu Karabulut[1]
[1]Mersin University, Pathology, Mersin, Turkey, [2]Mersin University, Internal Medicine, Mersin, Turkey, [3]Mersin University, Oncology, Mersin, Turkey

Background & Objectives: HER-2 (Human Epidermal Growth Factor Receptor 2) is an emerging biomarker of interest in various solid tumours, including urothelial carcinoma (UC). The current study aims to evaluate HER-2 expression and its association with clinicopathologic characteristics and patient outcomes in UC.
Methods: This retrospective cohort study included 100 patients diagnosed with urothelial carcinoma. HER-2 expression was assessed immunohistochemically and scored as negative/(+1), (+2), or (+3). Clinicopathological variables including tumour subtype, grade, stage, metastatic profile, invasion patterns, and survival outcomes were analysed with respect to HER-2 status.
Results: HER-2 overexpression (+3) was observed in 32% of patients and was significantly more frequent in patients with micropapillary (18.8%) and nested (12.5%) histological subtypes (p=0.018). Patients with HER-2 (+3) had higher rates of advanced-stage disease and distant metastasis, particularly bone (28.1%) and liver (12.5%) involvement. Although not statistically significant, HER-2 (+3) cases showed trends toward poorer overall survival and higher rates of perineural and lymph node invasion. Patients with HER-2 (+2) expression had lower survival and progression-free survival, though numbers were limited. Mean event-free survival was shorter in HER-2 (+2) patients (16.0±16.4 months) compared to HER-2 negative/(+1) (24.5±23.3 months), and HER-2 (+3) (23.4±25.3 months), albeit without statistical significance. Progression-free survival similarly varied across HER-2 categories but did not reach statistical significance.
Conclusion: HER-2 overexpression, especially at the (+3) level, is associated with adverse histologic subtypes, higher rates of invasion and metastasis, and a trend toward worse clinical outcomes. Although HER-2 was not an independent prognostic marker in multivariate models, its strong association with aggressive disease features supports further investigation into its role as both a prognostic biomarker and a potential target for anti-HER-2 therapies in urothelial carcinoma.

E-PS-26-040
The value of the tumour-stroma ratio as a prognostic marker is low in clear cell renal cell carcinomas
D. Bayçelebi[1], F.N. Uygun[1], Z. Kiraz[1], E. Koç[2]
[1]Ondokuz Mayis University, Pathology, Samsun, Turkey, [2]Ondokuz Mayis University, General Medicine, Samsun, Turkey

Background & Objectives: The tumour-stroma ratio (TSR) is of interest as a new prognostic factor in many tumours. In clear cell renal cell carcinoma (CRCC), the aim was to investigate the relationship between TSR measured using image analysis and tumour prognosis.
Methods: Seventy patients diagnosed with CRCC who underwent nephrectomy between 2017 and 2021 were included in the study. TSR was calculated by marking the slides scanned on the digital scanning device. Patients were divided into 2 groups as stroma-poor and stroma-rich from the TSR median value of 86%. Differences between variables evaluated with the Chi-square test, T test and One Way Anova. Kaplan-Meier method were used for comparison of survival curves.
Results: Fifty-two males (74.3%) and 18 females (25.7%) were included in the study. The mean age was 58.5 ± 12.2, and tumour size was 6.5 ± 3.3. The effect of TSR on OS and MFT was examined using Kaplan-Meier log-rank analysis. It was determined that there was no significant difference between the TSR groups. When OS and MFT, grade groups were compared with the log-rank test, a significant difference was found (p:0.046, p:0.038, respectively). No statistically significant difference was found between TSR groups and overall survival (OS) and metastasis-free survival (MFS) (respectively, p=0.29, p=0.47). When the grade groups were compared with OS (p=0.32), MFT (p=0.01), and stage (p=0.01), a statistically significant difference was found; however, no significant difference was found with diameter groups (p=0.053), TSR groups (p=0.48), and lymphovascular invasion (p=0.06). When the stage groups were compared with diameter groups (p=0.02) and lymphovascular invasion (p=0.01), a statistically significant difference was found; when compared with OS (p=0.72), MFT (p=0.12), and stage (p=0.59), no significant difference was found.
Conclusion: In CRCCs, diameter criteria are associated with prognosis, while TSR, which has been reported as a new prognostic marker in other studies, is not associated with prognosis.

E-PS-26-041
Clear cell renal cell carcinoma with extremely cystic changes presents diagnostic challenges for pathologists and clinicians
J. Zhao[1]
[1]The University of Texas MD Anderson Cancer Centre, Department of Anatomical Pathology, Houston, USA

Background & Objectives: Clear cell renal cell carcinoma (ccRCC) is the most common type of RCC in adults. The classic ccRCC shows golden-yellow, variegated cut surface with focal haemorrhage, fibrosis, or necrosis. Cystic change is frequent especially in low-grade ccRCC, and most of them are focal. In rare cases, however, the cystic changes can be extensive or to extreme extent make the tumour resemble a renal cyst or multilocular cystic renal neoplasm of low malignant potential (MCNLMP) based on radiology, histology, or intraoperative appearance. This can pose diagnostic challenges for pathologists and clinicians. It may be misdiagnosed or mistreated as benign renal cyst or indolent MCNLMP, significantly affecting patient care.
Methods: Here we presented a 50 year-old female patient with bilateral multifocal ccRCCs, two of which show extremely cystic changes.
Results: The biggest tumour is a 10.6 cm, unilocular, smooth-walled cystic mass containing haemorrhagic and necrotic material. The cystic wall is thickened and grossly adherent to adjacent organs including pancreas, spleen, and adrenal gland. Histologically, cystic wall shows extensive fibrosis, focal chronic inflammation, and scattered small foci of tumour cells with clear cell features. Immunohistochemical stains show that tumour cells are positive for Pax 8, AE1/AE3, and CA IX, confirming the diagnosis of ccRCC. The second tumour was excised as a simple renal cyst after confirming with intraoperative ultrasound, but the histology showed small clusters of ccRCC cells in the cystic wall.
Conclusion: This case demonstrates ccRCC with extensive cystic changes as an important differential diagnosis for renal cystic lesions.

Non-urothelial tumours of the urinary bladder: a decade-long single-centre retrospective study

M. Nanu[1], D. Herman[1], D. Anderco[1], M. Iacob[1], A. Croitor[2,3], T.R. Bardan[2,3], A.-A. Cumpanas[2,3], A. Dema[4,1]
[1]"Pius Brînzeu" County Clinical Emergency Hospital, Pathology, Timisoara, Romania, [2]Pius Brînzeu Emergency County Hospital, Urology, Timisoara, Romania, [3]"Victor Babes" University of Medicine and Pharmacy, XV, Discipline of Urology, Timisoara, Romania, [4]ANAPATMOL Research Centre, "Victor Babes" University of Medicine and Pharmacy, Microscopic Morphology-Anatomic Pathology, Timisoara, Romania

Background & Objectives: Non-urothelial tumours of the urinary bladder are rare but clinically significant, including primary tumours, secondary extensions from adjacent organ malignancies, and distant metastases. These tumours present diagnostic and therapeutic challenges due to their diverse origins and pathological features. This study aims to analyse their clinicopathological characteristics, prevalence, and distribution to improve understanding and management strategies.
Methods: This retrospective observational study reviewed histopathologically diagnosed non-urothelial bladder tumours at Timișoara County Hospital from January 2015 to December 2024. Data were collected from electronic medical records, including patient age at diagnosis, gender, histological subtype, microscopic features, and tumour staging. Tumours were categorized into three groups: (1) primary bladder tumours, (2) secondary extensions from adjacent malignancies (e.g., prostate, cervix, rectum), and (3) distant metastases from extravesical primary tumours (e.g., breast cancer, melanoma).
Results: A total of 176 cases were identified, distributed as follows: primary bladder tumours - 59 cases (33.14%); secondary extensions from neighbouring tumours - 115 cases (64.60%); distant metastases to the bladder - 4 cases (2.24%). The mean age at diagnosis was 67 years (range: 36–90), with a slight male predominance (54.81%). Among primary bladder tumours, squamous cell carcinoma (11.23%) and sarcomatoid carcinoma (8.42%) were the most common histological subtypes. Among secondary extensions, colorectal adenocarcinomas were the most frequent (26.70%). Among the four cases of distant metastases, one stemmed from invasive lobular breast carcinoma, another from gastric adenocarcinoma, a third from non-Hodgkin lymphoma, and the final one from metastatic melanoma.
Conclusion: Although rare, non-urothelial bladder tumours present significant diagnostic and therapeutic complexities. Most cases involve secondary extensions from adjacent organs, while distant metastases are less common. These findings underscore the importance of early detection and personalized treatment approaches to improve patient outcomes. Further research is needed to better understand the clinical behaviour and optimal management of these tumours.

Low grade mucinous tubular and spindle cell renal cell carcinoma (MTSCC): a case report of a quite rare, newly described entity

C. Gouta[1], C. Yfanti[1], N. Antoniadis[2], E. Sakellariou[1], K. Gianna[1]
[1]Hippokration General Hospital, Department of Histopathology, Thessaloniki, Greece, [2]Hippokration General Hospital, Department of Transplantation, Thessaloniki, Greece

Background & Objectives: Mucinous, tubular and spindle cell renal cell carcinoma (MTSCC) is a quite rare subtype of renal cell carcinoma that was first included in the WHO classification of renal tumours in 2004. To our knowledge, up to now, there are fewer than 100 reported cases of MTSCC in scientific literature.
Methods: We report the case of a 44-year-old female, with no relevant medical history, who was referred to the surgical department of our hospital due to a renal mass found incidentally during an ultrasound examination. Additional imaging tests were performed that verified the presence of a 5,5 cm tumour in the parenchyma of the left kidney. Subsequently, the patient was subjected to laparoscopic partial nephrectomy and oncectomy and the specimen was sent for further histopathological examination.
Results: In our histopathological laboratory we received a specimen of partial nephrectomy of 6,5 cm in maximum diameter. At dissection a well-circumscribed, solid, white-tan mass of 5,5 cm was observed. Microscopic examination showed a low-grade epithelial neoplasm that consisted of elongated, tightly packed, anastomosing epithelial tubules of cuboid cells and a spindle cell component embedded in a mucinous stroma. The neoplastic cells were positive for AE1/AE3, vimentin, PAX-8 and CK7, while CD10, CK20 and 34βE12 were negative. Consequently, the diagnosis of MTSCC was established.
Conclusion: MTSCC accounts only for 1% of renal cell carcinomas and shows a predilection for women of middle age. The prognosis is very good, with very low rates of recurrence and metastasis after surgical treatment with no additional chemotherapy/radiotherapy. The microscopical diagnosis is based almost exclusively on its characteristic 3-element morphology. Our case report presents a case of a quite rare and newly described entity and poses questions with regards to its immunohistochemical and molecular profile.

E-PS-26-044

Establishing non-HPV induced penile squamous cell carcinoma cell lines to advance research in rare urogenital tumours

M. Koller[1], M. Seles[2], U. Bele[2], S. Ahyai[2], V. Holzer[3], B. Rinner[3], S. Regauer[1], K. Kashofer[1]
[1]Medical University of Graz, Diagnostic and Research Institute of Pathology, Graz, Austria, [2]Medical University of Graz, Department of Urology, Graz, Austria, [3]Medical University of Graz, Core Facility Alternative Biomodels and Preclinical Imaging, Graz, Austria

Background & Objectives: Rare urogenital tumours, including penile squamous cell carcinoma (PSCC) are significantly understudied which partly explains the lack of major treatment options beyond surgery. There is a critical need for models to facilitate further research and develop novel therapies. Here, we present preliminary data on cell culture establishment of three patients with HPV-independently induced PSCC, each exhibiting distinct biological characteristics.
Methods: All cell lines were enzymatically isolated from surgical specimens of primary PSCC operated at Medical University of Graz, Austria.
Results: Cell line PeniCA1 is derived from a 49-year-old patient with a pT2, G3 PSCC featuring pathogenic *CDKN2A* missense and *TP53* missense mutations. PeniCA2 was isolated from a pT3, N1, G2 PSCC of a 78-year-old man featuring a disruptive *CDKN2A* mutation, and missense mutations in *TP53*, *HRAS*, and *FBXW7*. PeniCA3 was obtained from a 75-year-old man with pT2, G2, N1 PSCC with a missense *TP53* mutation. Additionally, HPV6 DNA was detected despite a morphological lack of a productive HPV infection. PeniCA1 exhibited a medium maturation rate while PeniCA2 displayed the lowest maturation rate, but highest doubling time. PeniCA3 cell culture showed a low proliferative activity but high maturation rate with large mature squamous cells and individual koilocytes. Despite the lack of morphological criteria of HPV infection in the primary SCC, cultured keratinocytes were able to differentiate into a stratified epithelium with koilocytes.
Conclusion: All three cell lines match their primary tumour histologies. We postulate that the mutation profiles influence the doubling time and growth rate of the cells in culture. They can serve as a functional model of HPV-independent PSCC in vitro and in vivo. We postulate that basal keratinocytes serve as a reservoir for HPV in latent infections, and that in a supportive culture environment allows virus production and assembly.

E-PS-26-045

HRR testing in Croatia; metastatic castrate-resistant prostate cancer; target for potential PARPi therapy

I. Franin[1], I. Čelap[2], I. Tomašković[3], J. Murgić[4], M. Ulamec[5]
[1]Sestre Milosrdnice University Hospital Centre, Ljudevit Jurak Department of Pathology and Cytology, Zagreb, Croatia, [2]Sestre Milosrdnice University Hospital Centre and University of Zagreb, Department of Clinical Chemistry and Faculty of Pharmacy and Biochemistry, Zagreb, Croatia, [3]Sestre Milosrdnice University Hospital Centre and Catholic University of Croatia, Department of Urology and School of Medicine, Zagreb, Croatia, [4]Sestre Milosrdnice University Hospital Centre, Department of Oncology and Nuclear Medicine, Zagreb, Croatia, [5]Sestre Milosrdnice University Hospital Centre and University of Zagreb and Scientific Centre of Excellence for Reproductive and Regenerative Medicine, Ljudevit Jurak Department of Pathology and Cytology and Department of Pathology, School of Medicine, Zagreb, Croatia

Background & Objectives: Homologous recombination repair (HRR) mutations, including those in key genes such as BRCA1/2, play a significant role in DNA repair mechanisms. Defective HRR pathways, especially in advanced cancers like metastatic castrate-resistant prostatic adenocarcinoma (mCRPC), make tumours susceptible to targeted therapies such as poly ADP-ribose polymerase inhibitors (PARPi). This study aims to start evaluating the prevalence of HRR gene mutations in mCRPC patients in Croatia and assess their potential for guiding PARPi-based therapeutic strategies.
Methods: A total of 30 mCRPC patients were selected for HRR mutation testing using formalin-fixed paraffin-embedded (FFPE) tissue samples. The HRR gene panel included full-length sequencing of the following genes: ATM, BARD1, BRCA1, BRCA2, BRIP1, CDK12, CHEK2, FANCD2, MRE11, NBN, PALB2, PPP2R2A, RAD51B, RAD54L, and TP53. Patohistological findings (GG, pTN, tumour volume) and clinical data (age, stage, therapy,OS) were compared to molecular testing results.
Results: Of the 30 patients, 25% (n=7) displayed pathogenic mutations in HRR-related genes. The most frequently mutated genes were BRCA2 (10%), followed by ATM (6%), and CDK12 (3%). Mutations in CHEK2 and PALB2 were observed in a smaller subset of patients. No cases of co-occurring mutations in multiple HRR genes were found. These genetic alterations were strongly associated with poor prognosis, indicating aggressive disease and an accelerated progression to metastatic castration resistance. Mutations were find in patients with higher GG and stage, often within cribriform pattern.
Conclusion: HRR gene testing is pivotal for identifying mCRPC patients who could benefit from PARPi therapy. A significant proportion of patients in our study carried mutations in BRCA2 and ATM genes, highlighting the potential of personalized treatment approaches. Targeted PARPi therapies offer promising therapeutic opportunities, especially in HRR-deficient tumours. Further clinical validation is essential to refine therapeutic strategies and expand the use of PARPi in clinical settings.

E-PS-26-046

The association of tertiary lymphoid structures and benign lympho-epithelial lesions in human prostate: their role in high grade chronic asymptomatic prostatitis NIH category IV

M. Koleva[1], A. Mollova-Kysebekirova[1], K. Simitchiev[2], D. Dikov[3]
[1]Medical University, Plovdiv, Bulgaria, [2]University of Plovdiv ''Paisii Hilendarski", Plovdiv, Bulgaria, [3]Jossigny Hospital, Jossigny, France

Background & Objectives: NIH-category IV prostatitis (histologic prostatitis, HP) is an asymptomatic chronic inflammation of the prostate. Chronic inflammation has been associated with the most frequent socially important prostate diseases like benign prostatic hyperplasia (BPH) and prostate cancer (PCa). Tertiary lymphoid structures (TLS) develop within the inflamed tissue, but changes in adjacent prostatic ducts are poorly studied. It remains unclear if these modifications are part of organized immune structures, leading to the hypothesis that they may represent benign lympho-epithelial lesions (LEL).
Methods: We investigated TLS and ductal epithelial cell changes (LEL presumably) in 110 different cases of prostatic inflammatory and normal specimens, in the context of basic prostate pathology – benign prostatic hyperplasia (BPH) and prostatic adenocarcinoma (PCa). HP is scored in low and high grade (LG and HG) using the severity of inflammation.
Results: We observed an association between TLS and LEL in the investigated 110 patients from the basic group with HP. A combination between both TLS and LEL was found in 45/110 cases (40.9%). Statistical analysis shows a significant correlation of the presence of both LEL and TLS examined separately or together, with HG-HP ($p<0.001$). There is lack of significant correlation between the presence of LEL and TLS with BPH and PCa.
Conclusion: The study is the first attempt to examine qualitatively and quantitative LEL and TLS in normal an inflammatory human prostate. Their presence, triggered by antigenic stimuli and external factors, reflects a chronic inflammatory microenvironment. The strong association between LEL/TLS and their link with HG-HP reflects HP aggressiveness. The data from this study suggest that LEL and TLS may be key players in the pathophysiology and morphogenesis of NIH-category IV prostatitis. LEL/TLS formation can be considered as a hallmark of tissue autoimmunity and probably reflects the immune/autoimmune phase of NIH category IV prostatitis.

E-PS-26-047

L1CAM expression defines low-grade oncocytic tumours among eosinophilic renal neoplasms

A. d'Amati[1,2], L. Scuccimarri[3,4], F. Pierconti[1], A. Santoro[1], L. Ciampi[3], T. Montrone[5], F.A. Zito[6], G. Lucarelli[7], G. Rindi[1], G.F. Zannoni[1], M.G. Mastropasqua[4]
[1]Anatomic Pathology Unit, Fondazione Policlinico Universitario "A. Gemelli" IRCCS, Università Cattolica S. Cuore, Rome, Italy, [2]PhD Programme in Applied Neuroscience, Department of Translational Biomedicine and Neuroscience (DiBraiN), University of Bari "Aldo Moro", Bari, Italy, [3]Pathology Unit, Regional General Hospital "A. Miulli", Acquaviva delle Fonti, Italy, [4]Pathology Unit, Department of Precision and Regenerative Medicine - Ionian Area, University of Bari, Bari, Italy, [5]Pathology Unit, Santissima Annunziata Hospital, Taranto, Italy, [6]Pathology Unit, I.R.C.C.S. Istituto Tumori "Giovanni Paolo II", Bari, Italy, [7]Urology, Andrology and Kidney Transplantation Unit, Department of Precision and Regenerative Medicine and Ionian Area, University of Bari, Bari, Italy

Background & Objectives: The classification of renal eosinophilic tumours has expanded with the recognition of new entities, including Low-Grade Oncocytic Tumour (LOT). Differentiating LOT from eosinophilic chromophobe renal cell carcinoma (E-chRCC), renal oncocytoma, and eosinophilic vacuolated tumour (EVT) may sometimes be complex due to shared morphological and immunohistochemical characteristics, particularly in small bioptic samples. This study aimed to assess the diagnostic utility of L1 cell adhesion molecule (L1CAM), a transmembrane glycoprotein involved in neural development and oncogenesis, as a marker for LOT.
Methods: A retrospective, multicentre study was conducted on a cohort of 50 eosinophilic renal neoplasms, including morphologically and immunophenotypically confirmed cases of low-grade oncocytic tumour (LOT), renal oncocytoma, eosinophilic chromophobe renal cell carcinoma (E-chRCC), and eosinophilic vacuolated tumour (EVT). All cases underwent centralized histopathological re-evaluation by expert uropathologists to assess architectural and cytological features. Immunohistochemical analysis was performed using antibodies against

L1CAM, keratin 7 (KER7), GATA3, CD117, and cathepsin K. The specificity and sensitivity of L1CAM for the identification of LOT were analysed in comparison to other eosinophilic renal tumours.
Results: LOT cases commonly displayed a "small nested" growth pattern, along with perinuclear halos and irregular nuclear contours—features occasionally shared with other eosinophilic renal tumours. Their immunophenotype (KER7 and GATA3 positive; CD117 and cathepsin K negative) was not consistently definitive for diagnosis. Notably, L1CAM expression was observed as strong and diffuse membranous staining in 100% of LOTs, but was entirely absent in oncocytoma, E-chRCC, and EVT. These findings highlight the superior sensitivity and specificity of L1CAM in identifying LOT.
Conclusion: L1CAM is a highly specific and sensitive marker for distinguishing LOT from other eosinophilic renal neoplasms, offering valuable support in challenging differential diagnoses. These results support the integration of L1CAM immunostaining into diagnostic workflows. Further investigations are warranted to assess its expression across the broader spectrum of oncocytic renal tumours.

E-PS-26-049
Paratesticular smooth muscle hyperplasia imitating malignancy: a possible link to epididymitis – a case report
A. Rozo[1,2], M.A. Palau-Lázaro[1]
[1]University Hospital Fundación Santa Fe de Bogotá, Pathology Department, Bogotá, Colombia, [2]Universidad de Los Andes, Bogotá, Colombia

Background & Objectives: Paratesticular smooth muscle hyperplasia (PT-SMH) is a rare benign mass-forming lesion, primarily affecting the epididymis but also the spermatic cord and tunica albuginea. Its resemblance to malignant neoplasms poses a significant diagnostic challenge, often resulting in unnecessary orchiectomies. Differential diagnoses include leiomyoma, leiomyosarcoma, and other mesenchymal tumours, requiring thorough histopathological evaluation. While its exact aetiology remains unclear, some evidence suggests an association with obstructive processes like epididymal or vas deferens duct ectasia. Epididymitis, a common inflammatory condition, may contribute to ductal obstruction and reactive smooth muscle proliferation; however, a direct causal relationship has not been established. This study presents a case of SMH-TA with concurrent epididymitis, highlighting their potential association.
Methods: A 66-year-old male presented with an incidental intrascrotal mass, clinically suspected to be a neoplasm, leading to a radical orchiectomy. Histopathologic examination showed a proliferation of smooth muscle bundles arranged in interstitial and perivascular patterns, lacking atypia, mitotic activity, or necrosis. The lesion surrounded dilated epididymal ducts, some containing spermatozoa. Adjacent testicular parenchyma exhibited severe tubular atrophy and extensive chronic and acute epididymitis with microabscess formation. Immunohistochemistry confirmed smooth muscle origin (SMA+, desmin+), ruling out neural and vascular neoplasms (S100-, CD34-).
Results: Findings support a hyperplastic rather than a neoplastic process, confirming the diagnosis of PT-SMH, likely secondary to chronic inflammation and obstruction.
Conclusion: PT-SMH remains an extremely rare entity and should be considered in the differential diagnosis of epididymal masses. The coexistence of PT-SMH with severe epididymitis may provide insight into a possible causal relationship, though further studies are needed to establish a definitive link. While few cases of PT-SMH have been reported, even fewer have highlighted this association. Increased clinical and pathological awareness, along with thorough histopathological evaluation, is crucial to avoid misdiagnosis and unnecessary surgical intervention.

E-PS-26-050
Eosinophilic vacuolated tumour: a case report of an emerging entity in uropathology
A. Rozo[1,2], M.A. Forero Rivera[1,2], M.A. Palau-Lázaro[1]
[1]University Hospital Fundación Santa Fe de Bogotá, Pathology Department, Bogotá, Colombia, [2]Universidad de Los Andes, Bogotá, Colombia

Background & Objectives: Eosinophilic vacuolated tumour (EVT) is a rare, emerging entity recently acknowledged in the 2022 WHO classification. It poses significant diagnostic challenges due to overlapping features with oncocytic, clear cell, and other eosinophilic renal neoplasms. Despite high-grade nuclear features, EVT generally demonstrates an indolent behaviour and favourable prognosis. However, limited data regarding its long-term clinical course necessitate further studies and extended follow-up to better elucidate its biology and prognostic implications. We present a case of EVT to detail its pathology, highlight diagnostic hurdles, and emphasize its rarity.
Methods: A 68-year-old female presented with a 2 cm exophytic lesion in the lower pole of the right kidney, initially suspected as clear cell renal carcinoma, papillary variant, based on MRI findings. A partial nephrectomy was performed. Histopathologic examination revealed a neoplasm composed of cells with abundant oncocytic cytoplasm and focal intracytoplasmic vacuoles, along with prominent nucleoli. The tumour exhibited a solid and nodular architecture, with trapped renal tubules and areas of sclerosis. Immunohistochemistry showed PAX-8 positivity, focal CK7 and CD117 reactivity, and negativity for CD10 and Carbonic Anhydrase IX.
Results: The morphological findings and immunoprofile supported the diagnosis of an oncocytic renal tumour, yet its features did not align definitively with either oncocytoma or chromophobe carcinoma. Instead, the tumour's characteristics were most consistent with EVT.
Conclusion: This case highlights a diagnostically challenging oncocytic renal tumour that defies conventional classification and stands as a testament to the evolving landscape of renal neoplasm classification. Classifying EVT within the 2022 WHO "Other Oncocytic Tumours" category marks a significant advancement in our understanding, yet it also reveals the gaps in our knowledge. This case exemplifies the importance of meticulous pathological evaluation for accurate diagnosis and classification of emerging renal neoplasms, paving the way for future research and clinical advancements in uropathology.

E-PS-26-051
Expression of Programmed Death-ligand 1 (PD-L1) in urothelial carcinoma of bladder
J. Kini[1], J. Ann George[1], S. Jayasheelan[1], H. Kini[1], P. K Suresh[1], S. Sreeram[1], G. Kini[1]
[1]Kasturba Medical College Mangalore, Manipal Academy of Higher Education, Karnataka, Manipal, India, Pathology, Mangalore, India

Background & Objectives: Bladder cancer is the second most common cancer in the genitourinary tract with urothelial carcinoma (UC) being the commonest histologic subtype. PD-L1 is used for selecting patients with urothelial bladder cancer for immunotherapy. The objective of our study was to evaluate the immunohistochemical expression of PD-L1 in UC of bladder and to study its association with the clinicopathological characteristics of UC.
Methods: A retrospective study was conducted of 65 patients who underwent transurethral bladder resection for UC from January 2020 to December 2024. The tumour was graded as per WHO classification. Immunohistochemistry staining for PD-L1 was done on the archived blocks. The expression of PD-L1 (SP 263) (membranous positivity) was analysed using the standard combined positive score (CPS) scoring system. A CPS equal to or greater than 10 was considered positive.

PD-LI positivity was compared with morphological features such as grade, tumour infiltrating lymphocytes and muscle invasion.
Results: PD-L1 expression was categorised as positive (41/65) and negative (24/65). The cases included 39 muscle invasive and 26 non-muscle invasive tumours. Of these, 53 (82%) were high grade and 12 (18%) were low grade. Tumour infiltrating lymphocytes (TILs) in the stromal compartment were calculated based on the stromal tissue occupied by mononuclear inflammatory cells relative to the total area of the stroma within the tumour and grouped as low (0–10%), intermediate (15–50%) and high (55–100%) grade of stromal lymphocytic infiltration. 75% of the cases showed the grade of TILs to be in the low category. There was a significant relationship between PD-L1 positivity, TILs grade and muscle invasive status of bladder UC. There was no significant association between tumour grade and PD-L1 positivity.
Conclusion: PD-L1 expression correlates with increased TILs and muscle invasive status, suggesting that PD-L1 as a potential biomarker for tumour aggressiveness and guide immunotherapy for advanced UC.

E-PS-26-052
Staining patterns of cancer-associated fibroblast markers and CD8+ T-cell distribution in the stroma of bladder cancers
I. Sycheva[1], N. Oleynikova[2]
[1]Lomonosov Moscow State University (MSU), Moscow Scientific Educational Institute (MSEI) Oncourology clinic, Moscow, Russia, [2]Lomonosov Moscow State University (MSU), Faculty of Medicine, Moscow, Russia

Background & Objectives: The components of the mesenchymal environment of the tumour stroma are significant. Investigating tumour-infiltrating lymphocytes and cancer-associated fibroblasts (CAF) is important for bladder cancers. Finding markers of these cells that can be used in future drug therapy is vital.
Methods: Immunohistochemistry was performed on material from 27 BCG-treated patients (1) and 40 non-treated patients (2). A study used CD8 T-lymphocyte markers. The evaluation was done quantitatively, determining the mean by counting cells in 10 high-power fields. FAP (fibroblast activate protein) and FSP1 (fibroblast specific protein 1/S100A4) were used to identify CAF. The evaluation employed a mark method for staining intensity, ranging from 0 for negative staining to 3 for maximum intensity.
Results: Group (1) had 1.2-fold more CD8+ T-cells in cases without relapses after BCG therapy than in cases that relapsed, confirming the protective function of the peritumoral inflammatory infiltrate. There is a higher rate of CD8-T cells in high grade MIBC (1.2-fold greater infiltration in comparison to low grade MNIBC). FAP reaction was exclusively observed in invasive bladder cancers and high-grade BC in both groups. In FAP+ urothelial carcinomas, CAFs were associated with poor CD8+ T-cell infiltration ($p<0.001$), indicating a lack of tumour cytotoxic potential. FSP1 showed reduced intensity and area of staining in tumour cells and the invasive margin of recurrence specimens compared to primary tumours ($p < 0.001$). In group (2) there was a positive correlation of FSP1 marker and FAP in the stroma of the invasive margin ($p < 0.001$).
Conclusion: Research into using more different CAF markers combined with other components of the mesenchymal environment in the context of bladder cancer is required. Analysing the markers' association with clinical data in large groups will help update tests and genetic markers for urothelial carcinomas, which is important for refining the criteria for BCG therapy in a Russian cohort.

E-PS-26-053
A rare collision: seminoma and teratoma coexisting in a young male's testis
A.-V. Tudorache[1], E.-I. Marinescu[1], Y.-C. Zosmer[1], A. Dumitru[1], O. Bratu[1]
[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania

Background & Objectives: Testicular germ cell tumours (TGCTs) are the most common malignancies in young men, with seminomas and non-seminomatous germ cell tumours (NSGCTs) as the primary subtypes. Collision tumours, defined as two histologically distinct neoplasms coexisting within the same testis without intermixing, are exceptionally rare. We report a rare case of a 21-year-old male diagnosed with a right testicular collision tumour composed of seminoma and teratoma.
Methods: A 21-year-old male presented with a palpable right testicular mass. Scrotal ultrasound revealed a hypoechoic, non-homogenous tumour with a multilobulated contour. The patient underwent right orchiectomy via an inguinal approach. The excised specimen underwent histopathological and immunohistochemical evaluation.
Results: Gross examination revealed a whitish, nodular tumour occupying 85% of the testicular parenchyma. Histologically, the tumour was composed of two distinct, colliding tumours: one with an epicentre in the testicular parenchyma and the other originating from the epididymal region, separated by a fibrous pseudocapsule. The seminomatous component was characterized by a monomorphic malignant germ cell proliferation, with large, atypical, mostly uninucleated germ cells arranged in nests and sheets. The cells had prominent nucleoli and eosinopholic cytoplasm.The teratoma consisted of well-differentiated elements from all three germ layers (including glandular, neural, and mesenchymal structures), alongside primitive neuroectodermal, rhabdoid and lipoblastic elements. Immunohistochemical staining confirmed the dual nature of the tumour, with seminoma cells expressing CD117, OCT4, Glypican3, SALL4, S100, while teratomatous elements demonstrated variable differentiation markers SALL4, P63, GFAP, Desmin, Synapthophisin and S100, reflecting its complex differentiation.
Conclusion: Testicular collision tumours, though rare, should be considered in the differential diagnosis of complex, heterogenous testicular masses in young males. Comprehensive histopathological and immunohistochemical evaluation is essential for accurate diagnosis and individualized treatment strategies.

E-PS-26-054
Immunomorphology of Post-Atrophic Hyperplasia of the Prostate
A. Fakirova[1], B. Ilcheva[1], V. Pavlov[1], I. Donev[2], S. Draganova[2], D. Dikov[1]
[1]Military Medical Academy, Department of Pathology, Sofia, Bulgaria, [2]MHAT Nadezhda, Department of Medical Oncology, Sofia, Bulgaria

Background & Objectives: The post-atrophic hyperplasia (PAH) of the prostate is a precancerous lesion, whose morphogenesis is insufficiently clarified. The histological components of an immune inflammation are diverse, but the most important elements that are also relatively easy to evaluate are as follows- the presence of lymphoid follicles (tertiary lymphoid structures: TLS) and benign lymphoepithelial lesions (BLEL). We examined TLS and BLEL in PAH.
Methods: We studied the combination of TLS and BLEL with PAH quantitatively and qualitatively in 165 prostatic biopsy, surgical and autopsy specimens.
Results: 37.3% of the cases show a combination of PAH and TLS. The statistical analysis of the results does not show any significant relationship between the presence of PAH and TLS ($\chi^2 = 2,38$; $p = 0,126$).
A combination of PAH and BLEL can be found in 44.9% of the patients. The statistical analysis of the results shows there is a significant link between the presence of PAH and BLEL ($\chi^2 = 20,95$; $p < 0.001$). In 75% of the cases the two lesions show a close topographic assiciation, with a distance between them <2mm. 85% of these cases involve residual BLEL. PAH is often shown as a proliferative lesion developing in the wall of prostate canalicules with BLEL. It is clearly visible on longitudinal histological sections.

Conclusion: This study represents the first effort to quantitatively and qualitatively analyse the immunopathologic patterns of PAH. PAH is a lesion, which represents an extension and an end stage of the prostate duct damage (BLEL) and reflects the chronic inflammatory prostate microenvironment.

E-PS-26-055

Heterogeneity of expression of potential CAF markers in prostate cancer

I. Sycheva[1], A. Vasiukova[1], E. Sokolova[1], N. Oleynikova[1]
[1]Lomonosov Moscow State University (MSU), Faculty of Medicine, Moscow, Russia

Background & Objectives: Cancer associated fibroblasts (CAF) are an important component of the tumour microenvironment. No universal marker has been identified for CAF due to their subpopulation division. Multiple substances are being considered for the role of potential CAF markers in tumours. However, there is evidence for heterogeneity in the expression of these markers.
Methods: We performed immunohistochemical staining of 75 samples with antibodies to periostin (POSTN) and 34 samples with PDGFRa+β from patients with prostate cancer. PDGFRα+β and POSTN staining in the prostate were assessed in the stroma around tumour glands. The aim of our study was to investigate the staining patterns of these CAF markers and their correlation with clinical and morphologic parameters and survival of patients.
Results: Immunohistochemical staining of both markers was distributed from no staining (0) to significant staining (3+). A significantly higher number of recurrences was shown in the group with a high PDGFRa+β (3+) reaction (p=0.0018). No relationship was found between grade (p=0.21112), invasion level (p=0.2757) and PDGFRα+β intensity. There was also no correlation between intensity of POSTN expression and clinical and morphologic parameters and recurrence.
Conclusion: Th1e obtained data confirm the heterogeneity of CAF markers in prostate tumours, as well as their potential to be used as prognostic markers. PDGFRa+β may be a significant diagnostic marker for predicting prostate cancer recurrence. The role of POSTN staining remains the subject of further study.

E-PS-26-056

L1 Cell Adhesion Molecule (L1-CAM) expression in oncocitomas scars

M. Pané-Foix[1,2], D. Fernández-Calvo[1,2], I. Blázquez[1,2], M.d.R. Taco[1,2], M. Gomà[1,2], M.Á. Lopez-Costea[3], A. Vidal[1,2]
[1]Hospital Universitari de Bellvitge, Pathology, L' Hospitalet de Llobregat, Spain, [2]Insititut d'Investigació Biomèdica de Bellvitge -IDIBELL, L' Hospitalet de Llobregat, Spain, [3]Hospital Universitari de Bellvitge, Urology, L' Hospitalet de Llobregat, Spain

Background & Objectives: Renal oncocytomas (RO) often present with a central scar. Cell groups adjacent to or encompassed by the scar often exhibit a morphology distinct from the rest of the tumour: tubular or cord-like pattern, cells with ovoid-spindle-shaped nuclei, clear cytoplasm, and absence of typical oncocytic features. Several previous studies have shown that these morphological changes are accompanied by immunophenotypic changes. Some of the observed markers, such as racemase or Napsin A, suggested an adaptive change reminiscent of renal tubules. Recently, it has been shown that the marker L1CAM (CD171), a type 1 multidomain transmembrane glycoprotein of the immunoglobulin superfamily, is differentially expressed in P-cells of the normal renal collecting duct, as well as in nephrogenic adenomas. Our main objective is to study L1CAM expression in RO scar areas with morphological changes such as those described previously.
Methods: We selected 25 RO cases diagnosed between 2016 and 2025 that contained a central scar area along with morphological changes in clusters of cells within it. Immunohistochemical staining for L1CAM was performed.
Results: Twenty-five cases that contained areas of tubular morphology within the fibrous scar were studied. These areas, unlike the rest of the tumour, showed intense positivity for L1CAM in 22/25 cases and weak positivity in 3/25. Positivity was observed in normal distal tubules of the non-tumour parenchyma. The remainder of the tumour was negative.

Conclusion: Scarred areas in RO often encompass groups of cells with a morphology and immunohistochemical profile distinct from the rest of the tumour. These include intense immunoreactivity for CK7 and Vimentin, negativity for CD117, and weak-irregular staining for AMACR and Napsin. The expression of L1CAM in the scar area in all cases, along with the expression of other renal tubule markers, reinforces the hypothesis that this morphology could be an adaptive change similar to nephrogenic metaplasia.

E-PS-26-057

Molecularly defined tumour microenvironment ecosystems enhance prognostic stratification in low- and intermediate-risk prostate cancer

G.N. Fanelli[1,2], F. Pederzoli[2], L. Queiroz[2], H. Garcia[2], H. Pakula[2], S. Rodrigues[2], P.V. Nuzzo[2], S. Bleve[2], E. Imada[2], C. Scatena[1], E. Belcastro[1], L. Marchionni[2], F. Khani[2], B.D. Robinson[2], A.G. Naccarato[1], M. Loda[2], Pan Prostate Cancer Group (PPCG)
[1]University of Pisa, Department of Translational Research and New Technologies in Medicine and Surgery, Pisa, Italy, [2]Weill Cornell Medicine, Pathology and Laboratory Medicine, New York, USA

Background & Objectives: Tumour progression in prostate cancer (PCa) is shaped by complex interactions between epithelial cancer cells and the surrounding tumour microenvironment (TME). While some relations are evident on haematoxylin and eosin (H&E) slides, transcriptomic profiling offers deeper functional insights. This study aimed to integrate RNA-seq and histopathological data to identify TME-defined tumour ecosystems (Ecotypes) and functional cell states, assessing their association with pathological features and clinical outcome.
Methods: On a clinicopathological well-annotated multi-institutional cohort of 400 prostate tissue samples (179 benign and 221 malignant) with matched bulk RNA-seq, we applied EcoTyper, a computational framework that deconvolutes transcriptomic data into distinct cell types with unique transcriptional states ("cell states") and assigns to each PCa an overall TME molecular profile called "Ecotype" (E). Associations between Ecotypes, cell states, Grade Groups (GG), and morphology were assessed. A graph neural network was trained to predict Ecotypes from H&E images.
Results: A predominant Ecotype was identified in 181/221 (82%) PCa cases. Interestingly, GG1 PCa (n=62) were enriched in E6 (*normal-like TME*), however GG1 patients lacking E6 showed a markedly higher recurrence rate with nearly fivefold increased odds (OR= 4.76, 95% CI: 0.83–40.0). Whereas in GG2-3 PCa (n=70), E10 (*longer overall survival*) showed a negative correlation with the percentage of Gleason pattern 4 (p=0.02). Moreover, specific cell states (e.g., myofibroblasts, chymase-positive mast cells) were enriched in low-grade tumours. Finally, distinct H&E patterns predictive of Ecotypes were identified.
Conclusion: Characterizing the TME using transcriptome-based, ecosystem-level tools provides relevant biological and clinical information beyond conventional clinicopathological features. Ecotype E6 may help identify truly GG1 indolent PCa suitable for active surveillance, while Ecotype E10 could refine prognostic stratification in intermediate-risk cases. Integrating these molecular ecosystem signatures with standard

histopathological evaluation has the potential to enhance diagnostic accuracy and shape tailored treatment strategies.

E-PS-26-058

Predictive influence of phenotypic characteristics in upper urothelial carcinoma to expression of CD44

L. Jankovic Velickovic[1], A. Ristic Petrovic[1], S. Stojnev[1], M. Andjelkovic Matic[2], M. Krstic[1], F. Velickovic[3]
[1]Medical Faculty, University of Nis, University Clinical Centre Nis, Serbia, Pathology, Nis, Serbia, [2]University Clinical Centre Nis, Serbia, Pathology, Nis, Serbia, [3]Medical Faculty, University of Nis, University Clinical Centre Nis, Serbia, Nuclear Medicine, Nis, Serbia

Background & Objectives: CD44 acts as a cell adhesion molecule and is involved in regulation of the malignant biological behaviour of tumour cells. Objective of this study was to determine the predictive influence of phenotypic characteristics - histological grade, pathologic stage, growth pattern, lymphovascular invasion, presence of necrosis and divergent differentiation in upper tract urothelial carcinoma (UTUC) to expression of CD44.
Methods: This study included 92 patients with UTUC who had undergone open type nephroureterectomy. H&E-stained slides were used to assess phenotypic characteristics. Immunohistochemistry was performed to detect membranous expression of CD44 which was categorized as normal or altered. Monoclonal antibody against CD44 (Dako, Glostrup, Denmark) at dilution 1:50 with a standard En Vision system was used. Slides were reviewed independently by three researchers (LJV, ARP, SS) and areas with greater positivity were selected.
Results: Pathological stage, growth pattern and lymphovascular invasion have significant influence to expression of CD44 in UTUC ($p<0.0001$; 0.05; 0.005, respectively), however, differentiation, necrosis and divergent differentiation have no significant influence. In regression analysis, parameters with predictive influence to expression of CD44 in UTUC included stage ($p=0.001$) and lymphovascular invasion ($p=0.024$).
Conclusion: This investigation detected that the loss of CD44 was determined with high stage and presence of lymphovascular invasion.

E-PS-26-059

Somatic-type malignancies in testicular germ cell tumours: a diagnostic challenge

T. Aydemir[1], B. Sarsık Kumbaracı[1], S. Şen[1], F. Kızılay[2], E. Güler[3]
[1]Ege University, Pathology, Izmir, Turkey, [2]Ege University, Urology, Izmir, Turkey, [3]Ege University, Radiology, Izmir, Turkey

Background & Objectives: The most common group of testicular tumours is germ cell tumours (GCTs). Somatic-type malignancies (STMs), which are more common after chemotherapy, arise from teratomas and yolk sac tumours. Diagnosing and managing STMs can be highly complex and challenging.
Methods: We retrospectively re-evaluated the morphological and immunohistochemical features of eight cases diagnosed with STM in metastases after GCT treatment and the molecular characterization of one patient.
Results: The median age of the cases at the time of STM diagnosis was 33 years. The median time from the initial diagnosis of GCT to the development of metastatic STM was 45.6 months. Adenocarcinoma was the most common STM in metastases (n=5), followed by sarcoma (n=1) and embryonic-type neuroectodermal tumour (ENT) (n=1). One tumour previously classified as STM was re-diagnosed as an epithelioid trophoblastic tumour (ETT). Among five adenocarcinoma cases, three (3/5) were SALL4 positive. Sarcoma case was SALL4 and Glypican-3 positive. ENT cells expressed synaptophysin, while ETT cells were positive for GATA3 and p63. NGS was performed only in one STM case (adenocarcinoma) and revealed a pathogenic variant in the PTEN gene that caused loss of function.
Conclusion: Most STMs associated with GCT are found in association with teratomas, leading to the assumption that teratomas are the tissue of origin. As in our metastatic sarcoma and testicular tumour YST case, SALL4 and glypican-3 positivity support that SMT may also originate from YST. The developmental origin of STM formation and the underlying molecular mechanisms remain unclear. Although there is no standard treatment for STM, treatment is generally tailored according to the stage of disease and histology (e.g. sarcoma, carcinoma). The existence of patients who are refractory to treatment suggests that despite the morphological similarity between STM and true somatic malignancy there are molecular differences. We believe that elucidation of the etiopathogenesis of STM will contribute to patient management.

E-PS-26-060

Defining the molecular profile: histomorphological evaluation and a sporadic somatic TSC2 mutation in fibromyomatous RCC

D. Gül[1], A. Aydin[1]

[1]Istanbul Medeniyet University Goztepe Prof. Dr. Suleyman Yalcin City Hospital, Department of Pathology, Istanbul, Turkey
Background & Objectives: Renal cell carcinoma (RCC) with fibromyomatous stroma is a rare subtype characterized by distinctive histopathological features. Here, we present a case where the diagnosis was established based on histomorphological criteria, subsequently supported by the identification of a novel somatic TSC2 variant through genetic analysis. This case expands the molecular spectrum of RCC and underscores the role of integrative diagnostics.
Methods: A 60-year-old male underwent partial nephrectomy for a 3×3×2 cm right renal mass. Given the unusual morphology, additional genetic analysis was performed using peripheral blood. Somatic variant analysis identified the TSC2 NM_000548.5:c.984A>G variant.
Results: Histopathological examination revealed a well-circumscribed tumour composed of elongated, branching tubular structures lined by clear to lightly eosinophilic cells, set within a dense fibromyomatous stroma. There was no evidence of perirenal fat, lymphatic, or vascular invasion, and the surgical margins were clear with a 2 mm parenchymal clearance. Immunohistochemically, tumour cells were positive for PAX8, HMWCK, and CK7, with focal CAIX positivity and a low Ki67 index (1-2%). AMACR and c-kit were negative. The surrounding stroma exhibited SMA positivity with focal desmin staining.
Conclusion: The combination of histomorphological features, immunophenotypic findings, and somatic TSC2 variant analysis supported the diagnosis of RCC with fibromyomatous stroma. The tumour displayed bland nuclear features (ISUP 2013/Fuhrman grade I) and a low proliferation index, indicating a likely indolent clinical course despite the presence of a novel genetic alteration. This case emphasizes the critical role of histopathology in diagnosing RCC with fibromyomatous stroma while highlighting the utility of targeted somatic genetic analysis for refining classification. Further studies are needed to elucidate the clinical implications of TSC2 variants in this rare RCC subtype.

E-PS-26-061

Correlation of serum prostate-specific antigen with Gleason's score/ grade group in prostate carcinomas

S. Kanoun[1], I. Helal[1], F. Khanchel[1], N. Dhawedi[2], M.A. Oueslati[3], R. Jouini[1], A. Chadli Debbiche[1]
[1]Habib Thameur University Hospital, Department of Pathology, Tunis, Tunisia, [2]Habib Thameur University Hospital, Department of Preventive and Community Medicine, Tunis, Tunisia, [3]Habib Thameur University Hospital, Department of Urology, Tunis, Tunisia

Background & Objectives: Prostate-specific antigen (PSA) is a key screening tool for prostate cancer, despite its high sensitivity and low specificity. Gleason's grading remains a strong predictor of tumour

aggressiveness. We studied the correlation between PSA levels and Gleason's score/grade group.
Methods: A retrospective study was conducted on prostatic adenocarcinoma cases diagnosed at Habib Thameur Hospital (January2021–February2025).
Pathologic reports were reviewed to extract data including: PSA levels, specimen type (needle biopsy, transurethral resection of the prostate [TURP], or radical prostatectomy), Gleason score/Grade group and histological type.
The relationship between PSA levels and Gleason score/Grade group was evaluated using linear regression modelling to assess correlations and trends.
Results: Of 83 prostate specimens received in the selected period, 51 (61.4%) were needle biopsies, 17 (20.5%) TURPs, and 15 (18.1%) radical prostatectomies. Mean age was 70.5 years (range: 52–85). Median PSA was 28ng/ml. With extremes of 5.2 ng/ml (Gleason 7(3+4)) and 6021ng/ml (Gleason 10(5+5)). Gleason Group 5 was the most frequent (28.9%), followed by Group 2 (21.7%). The most common Gleason scores were 7(3+4) (21.7%) and 6(3+3) (16.9%). A significant positive correlation (p=0.047) of moderate strength (r=0.218) was observed between PSA levels and Gleason scores. Acinar adenocarcinoma predominated (97.6%), with 1 case each of ductal and mucinous adenocarcinoma.
Conclusion: A significant positive correlation (p=0.047, r=0.218) was found between PSA levels and Gleason grades. Patients with high serum PSA concentrations are likely to have high tumour grade group. Our findings demonstrate that Gleason's score is one of the factors determining serum PSA concentration in patients with prostate carcinoma and its part is 21.8%.

E-PS-26-062
Interobserver reproducibility of PD-L1 interpretation in urothelial carcinoma
S. Kanoun[1], I. Helal[1], N. Dhawedi[2], I. Guesmi[1], F. Khanchel[1], R. Jouini[1], A. Chadli Debbiche[1]
[1]Habib Thameur University Hospital, Department of Pathology, Tunis, Tunisia, [2]Habib Thameur University Hospital, Department of Preventive and Community Medicine, Tunis, Tunisia

Background & Objectives: Programmed death-ligand 1 (PD-L1) expression by tumour cells suppresses anti-tumour T-cell responses, making it a key immunotherapy target. Accurate PD-L1 assessment is critical in urothelial carcinoma. It is essential for optimizing immunotherapy decisions and improving clinical outcomes but interobserver variability may impact its clinical utility. This study evaluates the reproducibility of PD-L1 interpretation in urothelial carcinoma.
Methods: A retrospective study was conducted on urothelial carcinoma cases diagnosed at Habib Thameur Hospital (2017–2021). PD-L1 immunohistochemical staining using the Tissue MicroArray (TMA) technique for the 22C3 clone was independently assessed by a senior pathologist (P1) and a pathology resident (P2). Based on the Combined Positive Score (CPS), cases were classified as positive (CPS >10) or negative (CPS ≤10). Interobserver agreement was analysed using Cohen's kappa coefficient.
Results: 105 specimens of urothelial carcinoma were received during the 5-year selected period, out of which 4 cases (3.8%) were classified as PD-L1 positive (CPS >10). Pathologist P1 identified 4 positive and 101 negative cases, while P2 identified 3 positive cases. Only one case showed discordance (P1: CPS=19; P2: CPS=9.2). The interobserver agreement, assessed using Cohen's kappa coefficient, was $\kappa = 0.852$, indicating strong reproducibility between the two pathologists.
Conclusion: PD-L1 evaluation play a pivotal role indetermining eligibility for immunotherapy in urothelial carcinoma. The high agreement among pathologists, regardless of experience, demonstrates strong interobserver reproducibility using the 22C3 clone. In cases of discordance, retesting may be required to confirm treatment suitability, thereby optimizing outcomes. Standardized training and protocols are crucial to minimize variability and ensure accurate patient selection for anti-PD-L1 therapy.

E-PS-26-063
MTSCC: insights into morphological variability and differential diagnosis with papillary RCC
G. Miranda[1], R. Henrique[1], Â. Rodrigues[1], J. Lobo[1]
[1]Portuguese Institute of Oncology - Porto FG, EPE, Pathology, Porto, Portugal

Background & Objectives: This study aims to characterize the morphological features of mucinous tubular and spindle cell carcinoma (MTSCC) and highlight diagnostic pitfalls with papillary renal carcinoma (PRCC).
Methods: A retrospective clinicopathological analysis was conducted on MTSCC cases diagnosed at the Portuguese Oncology Institute-Porto (IPO-Porto). Clinical and pathological parameters were assessed and relevant literature was reviewed.
Results: Six cases of MTSCC were identified, corresponding to three female and three male patients, aged 41 to 73 years. Mean tumour size was 8.3 cm (range: 3.1-14.5cm). Macroscopically, only one case showed extension to the pelvicalyceal system. Three cases were pT1b, one pT2a, one pT2b and pT3a. Microscopically, three cases had a predominant tubular pattern, two had a predominant spindle cell pattern, and one had equal proportions of both. Mucinous areas were abundant in three cases, moderate in two and focal in one tumour. All tumours exhibited haemorrhage, areas of cytoplasmic clarification, and no mitotic figures were found nor sarcomatoid or rhabdoid features. Other findings included psammomatous calcifications (three cases), hyalinized stroma (two), cholesterol clefts (five), xanthogranulomatous macrophages (five), and hemosiderophages (two). CD10 was negative/focal in 4/2, respectivelly. One case was studied with FISH and showed no gains in 7/17.
Conclusion: MTSCC is a rare renal tumour which can mimic PRCC, as mucinous areas may be present in both entities. Presence of more than focal papillary features favours PRCC. Immunohistochemistry may be overlapping, although CD10 is reported to be negative or focal in MTSCC, as verified in all MTSCC cases of our study. In difficult cases, the demonstration of gains in 7/17 in PRCC may be of help, since these are not observed in MTSCC. Upon review, we identified such a case, which had focal mucinous stroma, but showed gains in 7/17 being diagnosed as PRCC. These molecular differences, combined with thorough histopathological evaluation, are crucial for accurate diagnosis.

E-PS-26-064
Neuroendocrine differentiation in prostate cancer: clinical and pathological insights from a case series
M. Nanu[1], D. Herman[1], M. Iacob[1], D. Anderco[1], S. Dema[2,3], A. Croitor[4,5], A. Cumpanas[4,5], V. Dema[4,5]
[1]"Pius Brînzeu" County Clinical Emergency Hospital, Pathology, Timisoara, Romania, [2]Emergency Clinical City Hospital, Radiotherapy Service, Timisoara, Romania, [3]"Victor Babes" University of Medicine and Pharmacy, Oncology, Timisoara, Romania, [4]Pius Brînzeu Emergency County Hospital, Urology, Timisoara, Romania, [5]"Victor Babes" University of Medicine and Pharmacy, Dept XV, Discipline of Urology, Timisoara, Romania

Background & Objectives: Neuroendocrine proliferations in prostate cancer range from focal neuroendocrine differentiation within conventional adenocarcinomas to aggressive neuroendocrine carcinomas. Although rare, these entities display distinct biological behaviours and have significant therapeutic implications. This case series explores the pathological and clinical characteristics of patients diagnosed with neuroendocrine differentiation in prostatic malignancies.

Methods: A retrospective analysis was conducted using the electronic database of Timişoara County Hospital to identify male patients diagnosed with prostatic malignancies exhibiting non-focal neuroendocrine differentiation between January 2020 and February 2025. Clinical data, including age at diagnosis, sample type, treatment details (where available), histologic classification, Gleason score/grade group, and stage (if applicable), were collected. Histopathological assessment and immunohistochemical analysis using markers such as chromogranin A and synaptophysin were performed to evaluate neuroendocrine differentiation.
Results: Seven cases of prostate cancer with neuroendocrine differentiation were identified, with a median patient age of 71 years (range: 60–81). The sample types included biopsies (n=2), transurethral resection specimens (n=4), and radical prostatectomy specimens (n=1). These cases were classified as follows: prostatic adenocarcinoma with extensive neuroendocrine differentiation (n=5), prostatic adenocarcinoma with Paneth cell-like change (n=1), and small cell neuroendocrine carcinoma (n=1). Among cases of conventional prostatic adenocarcinoma with extensive neuroendocrine differentiation, the most common Gleason score was 9 (Grade Group 5). The patient with Paneth cell-like change had undergone hormonal therapy before prostatectomy and was staged as pT3a.
Conclusion: Neuroendocrine differentiation in prostatic malignancies is rare and encompasses a diverse morphological spectrum. A thorough histopathological evaluation using standard staining techniques, combined with immunohistochemical analysis, is essential for accurate classification. Further research is necessary to determine the clinical significance of these findings and to develop optimized treatment strategies.

E-PS-26-065

Dermal nerve sheath myxoma of the penis: the first histopathologically confirmed case

F. Aknar[1], G. Kir[1], S.S. Ozkanli[1]
[1]Istanbul Medeniyet University Goztepe Prof. Dr. Suleyman Yalcin City Hospital, Department of Pathology, Istanbul, Turkey

Background & Objectives: Dermal nerve sheath myxoma (DNSM) is a rare benign peripheral nerve sheath tumour, classically involving the distal extremities. Penile localization has never been reported. We present the first histopathologically confirmed DNSM in the penis, with clinical correlation to a prior incompletely excised lesion.
Methods: A 58-year-old male presented with a 2 cm ventral penile nodule at the site of a lesion excised 10 years earlier without pathological examination. Excisional biopsy was performed. Histomorphologic evaluation and comprehensive immunohistochemistry (S100, Ki67, CD34, PanCK, desmin, calponin) were conducted.
Results: Histopathological examination revealed a hypercellular, multilobular tumour composed of bland spindle cells arranged in interconnecting cords and syncytial clusters within a prominent myxoid stroma, devoid of nuclear atypia or mitotic activity. Immunohistochemical analysis demonstrated diffuse strong S100 positivity, confirming Schwann cell lineage, and a low proliferative index (Ki67 <1%). The tumour was negative for CD34 (excluding cutaneous myxoma), PanCK, and desmin. Additional markers were uniformly negative, further excluding vascular, smooth muscle and other mesenchymal differentials. These findings aligned definitively with the WHO diagnostic criteria for dermal nerve sheath myxoma.
Conclusion: This report presents the first documented case of DNSM in the penis, expanding the anatomic spectrum of this rare tumour. The diagnosis relied on histomorphology (cord-like/syncytial architecture) and S100 positivity, with CD34 negativity excluding cutaneous myxoma. The clinical history suggests this likely represented recurrence after incomplete excision a decade prior, emphasizing the necessity of pathological evaluation for all penile masses, even those clinically deemed benign.

E-PS-26-066

Investigation of concordance between prostate core biopsy and prostatectomy tumour grade over one year at MMUH, Dublin

R. Murphy[1], C. Barrett[1]
[1]Mater Miscericordiae University Hospital, Histopathology, Dublin, Ireland

Background & Objectives: Prostate cancer grading is persistently the most important predictor of overall outcome in localized disease. In 2014, the ISUP modified the Gleason score system to reduce the degree of upgrading from biopsy to radical prostatectomy specimens and improve reproducibility. The objective was to investigate the correlation of prostatectomy specimen and prostate core biopsy Gleason score and grade group.
Methods: Between September 2023 and September 2024 89 prostatectomy specimens were processed at MMUH. Reports were reviewed and compared to reports of correlating prostate core biopsy. Report deemed concordant if there was no difference in tumour grade between prostate core biopsy and prostatectomy specimen using the Gleason score system or grade group.
Results: The most common Gleason grade on prostatectomy and prostate core biopsy was 3+4 (n=60). Concordance was identified in 85% of the cases (n=77). Of the disconcordant Gleason grades, 8 (66%) were upgraded on prostatectomy specimen, 4 (33%) were downgraded. The highest rate of upgrading was seen in biopsies with Gleason score 3+3 (66%) and downgrading was seen in 50% of biopsies with Gleason score 3+5. Grade Group 2 was the lowest grade a prostatectomy specimen was downgraded to
Conclusion: The concordance of 85% is relatively high compared to previous studies which have demonstrated concordance of 54.8%-68%. Under grading is frequently seen when evaluating Gleason scores at biopsy. However, there are many factors which impact Gleason score correlation, for example, smaller prostate glands and higher percent tumour volume. Recommendations to expand this study include; a follow-up study to compare concordance, to identify and review clinical details which may demonstrate predictive factors, such as Prostate Specific Antigen and timing of the prostatectomy and identify number of core biopsies and percentage of tumour seen on core and to assess whether they are contributing factors in the upgrading or downgrading of the tumour grade.

E-PS-26-067

Expression and prognostic value of PD-L1 in urothelial bladder carcinomas: a retrospective study

S. Kanoun[1], I. Helal[1], I. Guesmi[1], F. Khanchel[1], M.A. Oueslati[2], E. Ben Brahim[1], R. Jouini[1], A. Chadli Debbiche[1]
[1]Habib Thameur University Hospital, Department of Pathology, Tunis, Tunisia, [2]Habib Thameur University Hospital, Department of Urology, Tunis, Tunisia

Background & Objectives: PD-L1 expression serves as both a predictive biomarker for immunotherapy response and a potential prognostic indicator in advanced bladder cancer. While its predictive role is well established, its prognostic significance remains controversial.
We evaluated PD-L1 expression in urothelial bladder carcinomas (UBC) and its associations with survival outcomes and clinicopathological features in Tunisian patients.
Methods: We retrospectively studied UBC patients treated surgically at Habib Thameur Hospital between 2016 and 2021. PD-L1 status was assessed by immunohistochemistry (clone 22C3) using the Tissue MicroArray (TMA) technique, with positivity defined as Combined Positive Score (CPS) ≥10. Comprehensive clinicopathological data were collected, and survival analyses were performed using Kaplan-Meier and Cox proportional hazards regression models.

Results: This study included UBC 142 patients. The mean patient age was 67.4 years (range: 29–90), with a male-to-female ratio of 8.46. The Tumours were classified as low-grade in 47.88% and high-grade in 52.12%.The most frequent pathological stage was pTa (35.21%). PD-L1 positivity (CPS ≥10) was identified in 10 cases (7%), showing predominant immune cell staining patterns. With a median follow-up of 54 months, PD-L1+ patients exhibited significantly reduced overall survival compared to PD-L1- cases (60.86 vs. 86.79 months; p=0.04). Multivariate analysis confirmed PD-L1+ as an independent predictor of poor prognosis (HR=4.42, 95% CI: 1.41-13.86; p=0.011), along with nodal metastasis (p=0.05) and increasing age (p=0.009). PD-L1+ tumours demonstrated significant associations with advanced stage (p=0.032) and concomitant carcinoma in situ (p=0.006).
Conclusion: Our findings demonstrate that PD-L1+ (CPS ≥10) represents an independent prognostic marker in UBC, associated with worse survival and aggressive characteristics (CIS, advanced stage). These results underscore the need for expanded research on PD-L1's prognostic role in bladder cancer and warrants further investigation of its biological mechanisms and clinical implications.

E-PS-26-068

Has CK20 alone the power to improve pT1 urothelial carcinoma stratification? Molecular phenotypes meet sub-staging

M. Valeri[1], R. Contieri[2], A. Salvati[3], M. Trasforini[3], M. Cieri[3,4], G.M. Elefante[3], C. De Carlo[3,4], R. Hurle[5], M. Lazzeri[5], L.M. Terracciano[3,4], P. Colombo[3,4]
[1]ASST Bergamo Est, Department of Pathology, Seriate (Bergamo), Italy, [2]IRCCS Istituto Nazionale Tumori "Fondazione G. Pascale", Department of Urology, Napoli, Italy, [3]IRCCS Humanitas Research Hospital, Department of Pathology, Rozzano (Milano), Italy, [4]Humanitas University, Department of Biomedical Science, Pieve Emanuele (Milano), Italy, [5]IRCCS Humanitas Research Hospital, Department of Urology, Rozzano (Milano), Italy

Background & Objectives: The classification in molecular phenotypes (MP) is still poorly understood in non-muscle-invasive bladder urothelial carcinoma. We characterized with immunohistochemistry the MP of a cohort of pT1 high-grade urothelial carcinomas (HGUC) to investigate MP correlation with extension of lamina propria (LP) invasion and predictive value for progression and recurrence.
Methods: Immunohistochemical markers (CD44, CK5/6, CK20, P-PARg) and a simple score system were employed as a surrogate of molecular analysis to stratify into Luminal and Basal phenotypes a series of pT1 HGUC diagnosed between 2013 and 2021 on TUR specimens. ROL system was adopted to quantify LP invasion, and classified cases were classified in ROL1 (<1mm) and ROL2 (>1mm).
Results: A total of 192 confirmed pT1 HGUC were analysed. Mean age was 73yrs, with male predominance (74%); 83 cases were ROL1 (43%) and 109 ROL2 (57%). Luminal and basal phenotype was present in 141 (73%) and 10 cases (5%); 32 showed a Mixed phenotype (17%) and 9 were Null (4,7%). Of the 156 pts with FUP, most cases were Luminal (117, 75%), only 9 Basal (6%), 27 Mixed (17%) and 3 Null (2%); at a median FUP of 24 months (IQR: 12.3-40), 24 patients had progression (15%) and 52 recurrence (33%). At multivariate Cox regression analysis, CK20 expression showed a protective effect for progression on all cases (HR=0.40, 95% CI 0.17-0.94; p=0.036); on the contrary, no correlation was found between ROL and MP, and no significant predictive role was detected when stratifying for ROL categories.
Conclusion: Clinical management of pT1HGUC patients is often challenging and relatable tools for risk stratification are still needed. Our results suggest that MP with immunohistochemistry is not able to stratify patients risk of progression, nor to improve sub-staging predictive value; interestingly CK20 expression alone might be protective, independently from MP, but further validation is needed.

E-PS-26-069

Immunohistochemical evaluation of potential prognostic and predictive markers in bladder transitional cell carcinoma

P. Babal[1], S. Kern[2], K. Mikus Kuracinova[1], L. Krivosikova[1], S. Ziaran[3], B. Trebaticky[3], P. Janega[1]
[1]Comenius University in Bratislava, Institute of Pathology, Bratislava, Slovakia, [2]Comenius University in Bratislava, Bratislava, Slovakia, [3]Comenius University in Bratislava, Urology, Bratislava, Slovakia

Background & Objectives: Urinary bladder carcinoma belongs to the most common cancers and represents the ninth leading cause of death in men. Diagnosis is based on histological evaluation of tumour surgical specimens, which is classified into several subtypes, the most frequent being the urothelial carcinoma, subdivided into low-grade and high-grade papillary lesions, non-invasive or invasive. The diagnosis of the different subtypes is then supported by detection of certain protein-expression profiles. In the presented work, prognostic value of several such proteins expression is evaluated in a retrospective study.
Methods: Over 250 cases of urothelial bladder carcinoma were diagnosed according to the WHO 2022 criteria. Expression of CK 5/6, CK7, CK20, p63, E-cadherin, AIF (apoptosis inducing factor), survivin and Ki67 were evaluated by immunohistochemistry. Products of staining intensity (0-3) and percentage of positive cells (1-10) were calculated for cytoplasmic/membrane expressions, nuclear expressions were evaluated as percentage only. Correlation of expression profiles with tumour stage and grade were statistically evaluated.
Results: Except for AIF, staining intensity did not show any significant differences between the different stages and the grades of the tumours. Evaluation of cytokeratin positive cells percentages showed significant differences between stage pTa and pT1 or pT2. Cytokeratin expression was not significantly different between low grade and high-grade carcinomas. The percentage of AIF, survivin and Ki67 -positive cells was significantly increased in high-grade versus low-grade tumours, the expression of p63 showing the opposite difference. The percentage of survivin and Ki67 -positive cells was significantly increasing from stage pTa through pT1 to pT2.
Conclusion: Evaluation of cytokeratins 5/6, 7 and 20 is of limited diagnostic or prognostic significance. The number of AIF-positive cells correlate with the grade of the tumour. Expression of survivin and Ki67 was increasing with both, the stage and the grade of bladder carcinomas, providing useful prognostic and predictive factors of the tumour.

E-PS-26-070

miRNA-371 in testicular germ cell tumours

M. Ulamec[1], S. Mašić[1], I. Čelap[2], B. Vrhovec[3], I. Tomašković[3], M. Jazvić[4]
[1]University Hospital Centre Sestre milosrdnice, Pathology and Cytology, Zagreb, Croatia, [2]University Hospital Centre Sestre milosrdnice, Clinical Chemistry, Zagreb, Croatia, [3]University Hospital Centre Sestre milosrdnice, Urology, Zagreb, Croatia, [4]University Hospital Centre Sestre milosrdnice, Oncology and Nuclear Medicine, Zagreb, Croatia

Background & Objectives: Patients with testicular tumours require adequate diagnostics and follow-up, currently done through classic protein serum biomarkers evaluation: lactate dehydrogenase, alpha fetoprotein and beta chorionic gonadotropin. However, research of miRNA's, especially miRNA-371 as more specific and sensitive biomarker has emerged.
Methods: Serum levels of lactate dehydrogenase, alpha fetoprotein, beta chorionic gonadotropin and miRNA-371 were measured in 16 patients with testicular tumours (seminoma or non- seminoma) during initial disease presentation and post-orchidectomy in order to evaluate

and compare miRNA-371 to classical markers. miRNA- 371 values were analysed and compared to different histological components. miRNA value was expressed in relation to referent sample (<5 as negative with small probability of tumour, 5-10 as indetermined, >10 as positive with great tumour probability).
Results: All sixteen cases were initially grouped according to the type of testicular tumour and stage of the disease, there were 9 pure seminomas and 7 mixed germ cell tumours. All patients had positive miRNA values (far higher than 10) before orchiectomy, while number of cases with other 3 positive markers was significantly lower. The lowest percentage of miRNA levels had cases with smaller tumour size. Depending on the stage there were positive cases after surgery as well.
Conclusion: Testicular tumours affect great number of patients, especially those of younger age, therefore research of new, more reliable markers is necessary in order to enable better diagnostics and follow-up. miRNA's as potential biomarkers have a role in carcinogenesis, as oncogenes or tumour suppressors. According to current findings regarding miRNA-371 in testicular tumours, it appears to be more sensitive and specific biomarker compared to the ones routinely used.

E-PS-26-071
Same stage, different fate: pelvic fat invasion independently identifies high metastases risk in pT3a RCC. A call for subclassification
M. Vescovo[1], S.E.M. Gelardi[1], F. Prata[1], R. Papalia[1], G. Perrone[1]
[1]Fondazione Policlinico Universitario Campus Bio-Medico, Roma, Italy

Background & Objectives: Pathologic T3a renal cell carcinoma (RCC) includes tumours with extension into perirenal fat, renal sinus fat, or renal vein; however recent evidences have shown that these distinct invasion patterns may have different prognostic implications, supporting the need to reconsider the current classification to better reflect the different biological behaviour of p T3a tumours. The aim of our study is to evaluate the prognostic impact of specific infiltration patterns and pathological features (grade, necrosis and lymphovascular invasion) of pT3a RCC patients.
Methods: We retrospectively analysed 102 patients with clear-cell pT3a RCC. Tumours were classified by site of extra-renal extension: pelvic vs. perirenal fat invasion. Metastatic events were taken into account, and both univariate and multivariate analyses were performed to identify independent predictors of metastases.
Results: Metastatic progression occurred in 69 of 102 patients (67.7%). Pelvic invasion was present in 53 cases (52%), and perirenal invasion in 49 (48%). Metastases occurred more frequently in patients with pelvic fat invasion (43/53, 81.1%) than in those with perirenal invasion (26/49, 53.1%) ($p = 0.002$, chi square test). At multivariate analysis, pelvic fat infiltration was an independent predictor of metastases (OR: 2.19, 95% CI: 1.08–5.91, $p = 0.04$), along with lymphovascular invasion (OR: 4.56, 95% CI: 1.16–17.9, $p = 0.03$). Necrosis and tumour grade were not significantly associated (all $p > 0.3$).
Conclusion: Pelvic fat invasion is associated with a significantly higher risk of metastasis compared to perirenal fat invasion in pT3a RCC, regardless of tumour grade and necrosis. These findings reinforce the need for redefining subclassification of pT3a disease to enhance prognostic accuracy and inform postoperative surveillance strategies.

E-PS-26-073
Adult Wilms tumour: a rare case of epithelial-predominant nephroblastoma mimicking renal cell carcinoma
G. Nikolic[1], J. Stefanović[1], M. Zivotic[1], L. Cukovic[1], S. Radojevic-Skodric[1]
[1]Institute of Pathology Faculty of Medicine, Belgrade, Serbia

Background & Objectives: Wilms tumour (nephroblastoma) is a malignant renal neoplasm that typically affects children, while its occurrence in adults is exceptionally rare, representing less than 1% of all adult renal tumours. Due to its rarity, adult Wilms tumour is often misdiagnosed as renal cell carcinoma, posing a significant diagnostic and therapeutic challenge.
Methods: We present the case of a 40-year-old male with a renal mass identified during imaging. A total nephrectomy was performed under clinical suspicion of renal cell carcinoma. Gross examination revealed that the entire kidney was replaced by tumour tissue measuring up to 180 mm, with nodular architecture and focal myxoid degeneration.
Results: Microscopic analysis showed that the tumour was composed predominantly (over 90%) of epithelial cells, round to cuboidal in shape, with scant basophilic cytoplasm, hyperchromatic nuclei, and prominent nucleoli. These cells formed glandular, cribriform, and occasional rosette structures. The blastemal component accounted for less than 10%, while the stromal component was sparse to nearly absent. Focal necrosis was present in less than 10% of the tumour. The tumour infiltrated the renal capsule and extended into the renal sinus. Immunohistochemically, tumour cells showed diffuse positivity for TLE-1, CD99, Bcl-2, CD56, CK AE1/AE3, and CAM5.2, and focal positivity for Chromogranin A, CK8/18, MyoD1, Vimentin, Cyclin D1, NSE, WT-1, and p63. INI1 was retained. The tumour was negative for a broad panel of other markers including RCC, CAIX, EMA, and CD34, excluding other types of tumours. Based on morphology and immunoprofile, the diagnosis of Wilms tumour was confirmed.
Conclusion: Adult Wilms tumour is a rare but aggressive malignancy and should be considered in the differential diagnosis of renal masses in young adults. Accurate histopathological identification and prompt multimodal therapy are critical for improving outcomes.

E-PS-26-074
The discrepancy between Gleason score in prostate biopsies and radical prostatectomy specimens: predictive factors
O. Belhadj[1], S. Makni[1], M. Mellouli[1], M. Zghal[1], M. Triki[1], O. Boudaouara[1], T. Boudaouara[1], M. Bouhamed[1]
[1]Habib Bourguiba University Hospital, Pathology, Sfax, Tunisia

Background & Objectives: Prostate cancer (PCa) is one of the most common malignant tumours in men worldwide and in Tunisia. Diagnosis confirmation relies on prostate biopsy (PB) with Gleason score (GS) assessment, a key element in therapeutic decision-making. However, discrepancies in GS between PB samples and corresponding radical prostatectomy (RP) specimens have been reported. This study aimed to evaluate the concordance of GS between PB and RP specimens and identify predictive factors for these discrepancies.
Methods: A retrospective study was conducted on patients with prostate adenocarcinoma confirmed by PB and treated by RP in pathology department of Sfax University Hospital over 11 years (January 2013–December 2023). Two pathologists reevaluated GS on both PB and RP specimens. Epidemiological, clinical, biological, radiological, and histological variables were collected. GS and ISUP grade concordance was assessed using Cohen's Kappa coefficient. Logistic regression analyses identified independent predictive factors of GS discordance. ROC curves determined optimal thresholds for significant quantitative variables. Statistical significance was set at $p \leq 0.05$.
Results: Forty-nine patients were included. Concordance rates for GS and ISUP grade between PB and RP were 69.39% and 57.14%, respectively, with weak agreement (Kappa = 0.39 and 0.29 respectively). PB underestimated GS in 30.61% of cases, without overestimation. Univariate analysis showed that a low percentage of grade 4 on PB and low-risk D'Amico classification were significantly associated with GS discordance ($p < 0.001$ and $p = 0.004$). The optimal threshold for grade 4 percentage was 2.5%, with 73.5% sensitivity and 93.3% specificity. Multivariate analysis identified the percentage of grade 4 on PB as the only independent predictor of GS discordance between PB and RP ($p = 0.021$; OR = 1.608; 95% CI [1.073–2.411]).

Conclusion: The concordance of GS between PB and RP is crucial in PCa management. Identifying predictive factors of GS discordance enhances prognostic accuracy and therapeutic strategy.

E-PS-26-075

Molecular subtyping of non-muscle invasive urothelial carcinoma by immunohistochemical analysis

N. Kakkar[1], B.B. Bhardwaj[2], P. Rastogi[3], M. Rohilla[4], U. Gorsi[5], A. Sharma[6]

[1]Post Graduate Institute of Medical Education and Research (PGIMER), Dept of Histopathology, Chandigarh, India, [2]PGIMER, Dept of Pathology, Chandigarh, India, [3]PGIMER, Dept of Haematology, Chandigarh, India, [4]PGIMER, Dept of Cytology and Gynaecopathology, Chandigarh, India, [5]PGIMER, Dept of Radiodiagnosis and Imaging, Chandigarh, India, [6]PGIMER, Dept of Urology, Chandigarh, India

Background & Objectives: Non-muscle invasive urothelial carcinoma (NMIUC) has a heterogenous outcome and is a challenge to treat. The aim of this study was to categorize NMIUC's into basal, luminal and p53 like categories, using surrogate immunohistochemical (IHC) markers and to correlate with prognosis.
Methods: A retrospective study with a sample size of 100 NMIUC's (Ta,Tis,T1). Tissue microarray slides were stained with nine markers. Tumour cell scores (TCS) for each antibody was evaluated either as intensity of staining or percentage of positive cells or both as designed by Hardy et al. After obtaining TCS normalised scores, Hardy et al's IHC Classifier tree algorithms were applied.
Results: Only three IHC markers ie Gata3 (cutoff 0.21), CK5/6 (cutoff 0.09) and P16 (cutoff 0.42) were found useful in the molecular subtyping. In cohort A (all cases), Gata 3 was positive (value > 0.21) in **94 cases** which fell in the luminal category (Ta 64, T1-30, Rec 34) and in **3 cases** with a value of <0.21 with CK5/6 <0.09 taking it again towards the luminal category. No case fell in the basal category. Of the 94 luminal cases, p16 divided these cases with a cutoff value of < 0.42 ie the **URO group** (n=41) and >0.42 ie the **GU (genomically unstable) group** (n=49). In the URO group 16/41 cases recurred and one case upstaged (Ta to T1). In the GU group , 18/49 recurred and 3 cases upstaged (T1 to T2). No case upgraded.
Conclusion: By using three antibodies (GATA3, CK5/6 and p16), NMIUC's can be divided into luminal (URO &GU) and basal groups on a routine basis. More cases upstaged in the GU group concluding that GU group performs worse than the URO group. DFS was more in the URO group.

E-PS-26-076

Bilateral epididymal papillary cystadenoma and metastatic clear cell renal cell carcinoma: differential diagnosis

T. Fadljević[1], I. Mićović[1], M. Murković[1], G. Đorđević[1]

[1]Clinical Hospital Centre Rijeka, Clinical Institute for Pathology and Cytology, Rijeka, Croatia

Background & Objectives: Von Hippel-Lindau (VHL) syndrome is an autosomal dominant, multisystem, inherited disorder caused by germline genetic variants of the VHL gene. It is characterized by the occurrence of highly vascularized tumours such as hemangioblastomas of the central nervous system and retina, visceral tumours such as clear cell renal carcinoma, pheochromocytoma, epididymal cystadenomas, pancreatic neuroendocrine tumours, and cysts.
Methods: We present a case report of von Hippel-Lindau disease associated with multiple cerebellar hemangioblastomas, clear cell renal cell carcinoma, pancreatic cysts, ocular disturbances and the presence of a bilateral epididymal mass. A 57-year-old man presented with hard, painless lumps in the area of both testicles, measuring up to 2 cm. Ultrasonography and radiographic examinations showed multilocular tumours in the bilateral epididymis, which were surgically resected.
Results: Histopathological examination revealed cystadenomas in both epididymides. In the right epididymis, in addition to the cystadenoma, there was a relatively well-circumscribed nodule with morphological and immunohistochemical characteristics of metastasis of clear cell renal cell carcinoma (CCRCC). Cystadenocarcinoma of the epididymis was also considered in the differential diagnosis. The patient has not received adjuvant therapy and is continuing to experience further complications related to VHL syndrome.
Conclusion: In this case, based on the immunohistochemical expression of markers for CCRCC, we cannot rule out epididymal metastasis from this carcinoma.

E-PS-26-077

Pathological challenges in frozen section examination for excisional biopsy of testicular masses: insights from a large retrospective cohort study

R. Choiniere[1], W.P.A. Boellaard[2], G.J.L.H. van Leenders[1]

[1]Erasmus MC Cancer Institute, University Medical Centre, Department of Pathology, Rotterdam, The Netherlands, [2]Erasmus MC Cancer Institute, University Medical Centre, Department of Urology, Rotterdam, The Netherlands

Background & Objectives: Frozen section examination for excisional biopsy (FSEB) of testicular lesions is an underused pathological & surgical approach considering the increasing number small testicular lesions that are found to be benign on radical orchidectomy specimens. This study aims to address existing gaps in the literature regarding pathology issues that may discourage practicing pathologists from performing FSEB for testicular masses.
Methods: We describe a large retrospective cohort of FSEB in our academic institution to assess its accuracy and discuss its pathological challenges and pitfalls. The algorithm determined by FSEB diagnosis was that radical orchidectomy would be carried out for malignant diagnoses only.
Results: From 2005 to 2024, 137 FSEB (median of 10 FSEB per year) were performed in 133 patients with a median tumour size of 0.9 cm (range 0.2-4 cm). The most common diagnoses on FSEB were Leydig cell hyperplasia/tumour and seminoma, both diagnosed in 37 (27%) and 37 (27%) cases. On FSEB, benign diagnoses represented 58% of cases which allowed 79 testis to remain in situ. The sensitivity and specificity of FSEB for malignancy were 100% and 96.3%, respectively. There were no false negatives and no delayed radical orchidectomy was required. One cause of false positive was the impossibility of immediate ancillary testing for mature teratomas without germ cell neoplasia in situ. Some histological pitfalls including regression changes and morphological changes of Leydig cell tumours became particularly challenging for non-uropathologists on FSEB. Immunohistochemistry was mostly unaffected by previously frozen tissue with the exception of the less precise, but still positive OCT3/4.
Conclusion: Our experience has proven that FSEB is accurate and safe for distinguishing benign from malignant testicular lesions if one is aware of the common pitfalls of testicular pathology. We hope this study will help pathologists become more familiar with testicular frozen sections and serve as a useful resource for routine practice.

E-PS-26-078

Survivin and Ki-67 co-expression: a potential prognostic indicator in urothelial cancer

K. Mikus Kuracinova[1], A. Janegova[1], I. Wilsinska[2], P. Babal[1]

[1]Institute of Pathological Anatomy, Faculty of Medicine, Comenius University and University Hospital Bratislava, Bratislava, Slovakia,

[2]Faculty of Medicine, Comenius University, Urology, Bratislava, Slovakia

Background & Objectives: Urothelial carcinoma is one of the most common malignancies in Europe, with invasive urothelial carcinoma ranking as the fourth most prevalent cancer. Non-invasive forms are notable for their high recurrence rates, highlighting the need for reliable prognostic markers. Survivin, an anti-apoptotic protein, and Ki-67, a cell proliferation marker, are associated with tumour progression across various cancer types. This study evaluates the correlation between these markers in urothelial carcinoma, providing insights into tumour behaviour and potential prognostic significance.
Methods: We analysed 145 formalin-fixed, paraffin-embedded tissue samples from patients with low-grade and high-grade papillary urothelial carcinoma. Following deparaffinization, immunohistochemical staining was performed to detect nuclear expression of Survivin (rabbit monoclonal antibody) and Ki-67 (mouse monoclonal antibody). Immunofluorescence microscopy was conducted to confirm co-localization of these markers. Statistical analyses (Pearson correlation coefficient, Spearman's correlation coefficient) were performed to assess their correlation.
Results: Statistical analyses revealed a significant correlation between Ki-67 and Survivin expression across all 145 urothelial carcinoma samples ($p < 0,01$). Immunofluorescence confirmed the presence of both markers within the identical cell nuclei, with differences in expression patterns corresponding to the degree of cytological atypia.
Conclusion: The significant correlation between Survivin and Ki-67 expression underscores their potential as combined prognostic markers in urothelial carcinoma. Elevated levels of these proteins have been individually associated with poor clinical outcomes, including reduced survival rates and increased recurrence. Their combined assessment may offer valuable insights into tumour aggressiveness and therapeutic targeting strategies, aiding in identifying high-risk patients.

HER2 expression in urothelial neoplasms

S.S. Kim[1,2], K.-H. Lee[1,3], J.Y. Lee[1,3], N.-I. Kim[1,2], E.C. Hwang[4,5], S.H. Yu[4,6]
[1]Chonnam National University Medical School, Department of Pathology, Gwangju, Republic of Korea, [2]Chonnam National University Hospital, Department of Pathology, Gwangju, Republic of Korea, [3]Chonnam National University Hwasun Hospital, Department of Pathology, Hwasun, Republic of Korea, [4]Chonnam National University Medical School, Department of Urology, Gwangju, Republic of Korea, [5]Chonnam National University Hwasun Hospital, Department of Urology, Hwasun, Republic of Korea, [6]Chonnam National University Hospital, Department of Urology, Gwangju, Republic of Korea

Background & Objectives: The clinical significance of HER2 expression in urothelial cancer is increasing in line with the application of antibody-drug conjugates in advanced or metastatic urothelial cancer. In this study we aimed to define the clinicopathologic significance of HER2 expression in non-muscle invasive (NMIBC) and muscle-invasive urothelial carcinomas (MIBC) using immunohistochemical stain and silver in situ hybridization.
Methods: A cohort of 60 non-invasive papillary urothelial carcinoma and 54 muscle-invasive urothelial carcinoma was used. They were immunostained with HER2 using the whole section. HER2 protein expression was interpreted using FDA criteria (0,1+, 2+, 3+), and categorized into negative (0, 1+) and positive (3+). When the HER2 expression was 2+, we underwent silver in situ hybridization and interpreted using FDA criteria. Clinicopathologic features were also investigated.
Results: HER2 expression is observed in 6/60 NMIBC (10%), whereas MIBC showed positive results in 23/54 (43%). There is a significant regional heterogeneity of positive area in both NMIBC and MIBC. HER2 expression was found to be associated with progression-free survival in MIBC, and was associated with recurrent free survival in NMIBC.
Conclusion: It is suggested that HER2 expression is associated with tumour progression or recurrence. The HER2 expression rate is higher than in other studies, which is thought to be the result of staining of whole sections rather than tissue microarray to overcome regional heterogeneity.

Clinicopathological features of Testicular Sex-cord Stromal Tumours (TSCSTs) - Institutional experience

B. Rancic[1], B. Kovacevic[1], S. Cerovic[1], I. Nikolic[2], A. Lazic[2]
[1]Institute of Pathology and Forensic Medicine, Military Medical Academy, Belgrade, Serbia, [2]Clinic of Urology, Military Medical Academy, Belgrade, Serbia

Background & Objectives: Testicular sex-cord stromal tumours (TSCSTs) represent a group of rare primary testicular tumours, originating in the supporting tissue of the testis. TSCSTs are neoplasms mostly with benign clinical behaviour. We analysed clinicopathological features of TSCSTs diagnosed in our Institute.
Methods: A surgical pathology archive from 2009 to 2024 has been searched for cases of TSCSTs in the final diagnosis. Patients' age, tumour subtype, tumour size, lymphovascular invasion, mitosis, necrosis, and immunophenotype were analysed. In cases with the presence of clinicopathological characteristics suggestive of malignancy, patients' follow-up were analysed.
Results: Radical inguinal orchiectomy as a surgical treatment of testicular tumours was performed in 384 patients. TSCST was diagnosed in 10 patients (2.6%) with an average age of 35.60 ± 10.55. The mean tumour size was 19.80 ± 9.41mm. Benign Leydig-cell tumour was the most common, and diagnosed in seven patients (70%). In one case each, a malignant Leydig cell tumour, malignant TSCST not otherwise specified and Large cell calcifying Sertoli cell tumour with uncertain behaviour were diagnosed. None of the patients disclose disease progression during follow-ups from 15 to 120 months. In each TSCST, immunopositivity for at least two of the following antibodies: Melan A, Calretinin, Inhibin A, and Vimentin was detected.
Conclusion: TSCSTs are a rare group of neoplasms, most commonly comprised of cells resembling nonneoplastic Leydig cells. It is a heterogeneous group of tumours with diverse morphology, cell origin and biological behaviour. Some cases occur only sporadically or disclose unspecific morphology and immunophenotype. Correct recognition of morphology, knowledge of diagnostic criteria, and immunohistochemical analysis are required for tumour typing and determination of its malignant potential. All of our malignant TSCTs revealed favourable clinical outcomes.

E-PS-26-085

Loss of glutamine synthetase expression may support a diagnosis of urothelial carcinoma in situ

M. Öz[1], O. Ertunç[1], B. Öğüt[1], E.B. Tuna[2], İ. Işık Gönül[1]

[1]Gazi University Faculty of Medicine, Department of Pathology, Ankara, Turkey, [2]Dokuz Eylul University Faculty of Medicine, Department of Pathology, İzmir, Turkey

Background & Objectives: Glutamine synthetase (GS) is a critical enzyme that is responsible for the synthesis of glutamine from glutamate and ammonia and hence is involved in glutamine metabolism. Glutamine plays an important role in maintaining the function of many cells as a nucleotide and a main source of energy for rapidly dividing cells. The aim of this study was to investigate the immunohistochemical expression of GS in the flat urothelial lesions of the bladder posing a diagnostic challenge (Urothelial carcinoma in situ? /Non-tumoral urothelium?)
Methods: This study included 50 patients diagnosed with urothelial carcinoma in situ (UCAIS) between 2022 and 2025 in our department. Paraffin blocks containing UCAIS areas with surrounding non-neoplastic urothelium were selected from the H&E-stained sections of the patients. Immunohistochemical staining was performed with GS antibody. The presence or absence of cytoplasmic expression in UCAIS and non-neoplastic urothelium were noted and results were statistically compared.
Results: 6 cases were excluded from the study because of sub-optimal staining results. Non-tumoral epithelium was not observed in the immunohistochemically stained sections of 18 patients. However, GS was not expressed in the UCAIS areas in these cases. In the remaining 26 cases, which included both UCAIS and non-tumoral urothelium, we observed that GS expression was maintained in non-tumoral urothelial areas, however it was lost in UCAIS areas. This difference was statistically significant ($p<0.001$).
Conclusion: To the best of our knowledge, this is the first study to evaluate GS expression in urothelial tumours, in which we showed that GS expression is maintained in non-tumoral urothelium, however its expression is lost in UCAISs. This difference may aid in the differential diagnosis of UCAIS in routine pathology work up. However, the molecular mechanisms underlying GS homeostasis and glutamine metabolism in UCAIS and other urothelial tumours need further effort to be discovered in the future.

E-PS-26-086
Tumour heterogeneity and prognostic significance of PD-L1 expression according to the durvalumab companion VENTANA (SP263) assay in metastasizing urothelial bladder carcinoma
A. Fleischmann[1], V. Genitsch[2], M. Blum[3], A. Perren[4], G.N. Thalmann[5], A. Rodriguez-Calero[1]
[1]Institute of Tissue Medicine and Pathology, University of Bern and Inselspital, Switzerland and Institute of Pathology, Muensterlingen, Switzerland, Bern, Switzerland, [2]Institute of Tissue Medicine and Pathology, University of Bern and Inselspital, Switzerland, Bern, Switzerland, [3]Cancer Registry East Switzerland, St. Gallen, Switzerland, [4]Institute of Tissue Medicine and Pathology, University of Bern and Inselspital, Bern, Switzerland, [5]University of Bern and Inselspital, Department of Urology, Bern, Switzerland

Background & Objectives: To determine the distribution of the therapeutic target programmed cell death 1 ligand 1 (PD-L1) in metastasizing muscle-invasive urothelial bladder carcinoma and assess its impact on overall survival (OS).
Methods: A total of 124 patients without any neoadjuvant therapy underwent radical surgery with curative intent and were followed prospectively. We constructed tissue microarrays with multiple samples from their primary tumours (PTs) and 1–3 corresponding lymph node metastases (LNMs; $n = 241$) and determined PD-L1 expression in all samples using the VENTANA (SP263) Assay. Differences in PD-L1 expression between various tumour components and OS were assessed using appropriate statistical tests.
Results: On average, 2.9 tumour foci per patient were analysed. The mean PD-L1 staining rate was significantly higher in tumour cells (TCs) than in immune cells (ICs) in the PTs (12.5% vs. 6.4%, $p < 0.05$) but not in the metastasizing tumour components (MTCs; 10.3% vs. 9.3%, $p = 0.67$). The frequency of high PD-L1 scores (TC/IC25%) was similar in PTs and MTCs (16.9% vs. 21.0%, $p = 0.23$). Additionally, 10.5% of patients presented with homogeneously high PD-L1 scores in all tumour foci, while 20.2% presented with high and low scores. Intermetastatic heterogeneity in PD-L1 scores was observed in 20.3% of the 69 patients with multiple LNMs. A high PD-L1 score in the PT independently predicted a favourable OS.

Conclusion: Primary-to-metastatic conversion of the PD-L1 score occurred in 20.2% of patients, and testing both components might improve patient selection for immune checkpoint therapies. A favourable OS for patients with high PD-L1 scores is compatible with tumour suppressive effects, as recently described for this biomarker.

Paratesticular well-differentiated liposarcoma with osseous metaplasia presenting as in indirect inguinal hernia: a case report
J. Alves[1], F. Nogueira[1], J. Oliveira[1], D. Gomes Pinto[1,2]
[1]ULS Almada-Seixal - Hospital Garcia de Orta, Department of Pathology, Almada, Portugal, [2]Nova Medical School, Lisbon, Portugal

Background & Objectives: Liposarcomas are the most common type of spermatic cord sarcomas in adults. We report on a case of well-differentiated liposarcoma with metaplastic ossification, an unusual finding within these tumours.
Methods: We report on a case of a 77-year-old male patient, presenting with an inguinal mass, initially diagnosed as an indirect inguinal hernia. During follow-up, the mass showed rapid growth and with the onset of pain, hernioplasty was performed. During the procedure, a large multinodular spermatic cord mass was identified and partially resected. A CT scan also revealed extensive areas of fat tissue and calcifications. The patient subsequently underwent radical orchiectomy.
Results: Gross examination of the specimen revealed an extensive spermatic cord mass, measuring 10x6x4,5cm, composed of large areas of adipose tissue with multifocal haemorrhagic tissue and hard consistency areas. Microscopic evaluation showed a heterogeneous proliferative lesion composed of mature adipocytes containing fibroblastic bands and extensive areas of osseous metaplasia. In the fibrotic component, spindle-shaped, atypical, and pleomorphic cells with hyperchromatic nuclei were observed. Among the mature adipocytes, rare lipoblasts were noted. Immunohistochemical study for MDM2 and p16 was positive, and a diagnosis of a well-differentiated liposarcoma/ atypical lipomatous tumour was made.
Conclusion: Liposarcomas of the spermatic cord can be clinically asymptomatic in the absence of rapid growth and may mimic indirect inguinal hernias. Surgical resection with widely negative margins is generally curative, although late recurrence can occur. Excluding benign lipomatous tumours, as well as differentiating well-differentiated from dedifferentiated tumours, is important as it affects prognosis — the latter being associated with a risk of metastatic disease. We highlight the importance of maintaining a high level of clinical suspicion for malignant disease in the presence of a painful inguinoscrotal mass, as well as the relevance of the pathological examination of these specimens.

E-PS-26-088
Comparative analysis of the efficacy between MRI lesion-targeted or combined versus standard prostate needle core biopsies in detecting prostatic adenocarcinoma
M. Khudadad[1,2], L. Leite-Kasaboski[2], J. Merrimen[1,2], C. Wang[1,2]
[1]Queen Elizabeth II Health Science Centre, Department of Pathology and Laboratory Medicine, Halifax, Canada, [2]Dalhousie University, Halifax, Canada

Background & Objectives: Prostate needle core biopsies (PNBs) are the gold standard for diagnosing prostatic adenocarcinoma, the most prevalent malignancies in men in North America. The NSH Central Zone processes a high volume of prostate biopsies. Recently, the integration of MRI in detecting prostate nodules into the diagnostic workflow has led to more lesion-targeted biopsies. This study compares the performance indicators of PNBs obtained in 2016 (pre-MRI era) and in 2022/23 (post-MRI era) to assess the impact of MRI-targeted biopsies on the diagnostic yield and quality control benchmarks.
Methods: We retrospectively analysed 1,345 PNB cases during the two years. Biopsy cases were classified into systematic, MRI lesion-targeted, or combined biopsy (MRI lesion-targeted and systematic) types. The cases were further broken down by diagnoses and grade group (GG) if the results were positive for prostatic adenocarcinoma. Statistical analyses using chi-square tests were performed to compare trends in biopsy usage, positive detection rates, and quality control markers such as atypical small acini proliferation (ASAP) diagnoses.
Results: Chi-square analysis ($p < .00001$) revealed a significant increase in MRI-targeted and combined biopsies from 2016 to 2022/23. However, the positive case rates between the systematic and MRI-targeted/combined biopsies were not significantly different ($p \approx 0.12$). The rate of atypical gland diagnoses was 4.98% (67/1345), meeting the established quality benchmark of <5%. Notably, no ASAP cases were identified in MRI-targeted or combined biopsy groups.
Conclusion: The number of MRI lesion-targeted and combined biopsies for diagnosing prostate cancer has significantly increased in NSH Central Zone. Despite this shift, positive case rates remain comparable between systematic and MRI-targeted/combined biopsy approaches. Additionally, the atypical gland diagnosis rate remains within the accepted <5% benchmark, reinforcing the region's consistency and quality of diagnostic practices. These findings highlight the growing role of MRI in biopsy guidance while maintaining diagnostic reliability.

E-PS-26-089

A rare case of low-grade oncocytic fumarate hydratase-deficient renal cell carcinoma

E. Omerogullari Sener[1], O. Bozkurt Ozturk[1], A. Yalcin[2]
[1]Ataturk University, Faculty of Medicine, Department of Pathology, Erzurum, Turkey, [2]Ataturk University, Faculty of Medicine, Department of Radiology, Erzurum, Turkey

Background & Objectives: Fumarate hydratase (FH)-deficient renal cell carcinoma (FH-deficient RCC) is a rare and typically high-grade, aggressive subtype of renal cell carcinoma (RCC) characterized by alterations in the FH gene.
The 2022 World Health Organization (WHO) classification introduced a subset of FH-deficient RCC cases exhibiting low-grade eosinophilic oncocytic morphology, which appears to be associated with a relatively favourable prognosis. However, such cases remain exceedingly rare, with only a limited number reported in the literature.
Methods: Herein, we present a case of FH-deficient RCC with rare low-grade eosinophilic cytology. The patient was a 21-year-old male who was admitted to the hospital with abdominal pain. Abdominal computed tomography (CT) revealed a mass located in the lower and medial poles of the right kidney. Histopathological and immunohistochemical analyses confirmed FH deficiency, with findings consistent with low-grade eosinophilic morphology.
Results: In macroscopic examination the focus in the mid-pole of the kidney appeared solid and gray-white in colour, whereas the focus in the lower pole was dark brown and contained cystic areas.
Histopathological evaluation revealed tumour cells are composed of oncocytic cells with, prominent nucleoli, and occasional perinuclear halos. The cystic component, tubulucystic component is also observed in the lower pole focus, Importantly, no evidence of necrosis, mitotic activity, or high-grade morphological features was identified.
Tumour cells were negative for CK7, CK20, Carbonic Anhydrase IX (Ca-IX), and TFE3. In contrast, AMACR and SDHB showed positive immunoreactivity. Loss of FH expression was confirmed by immunohistochemical analysis, with FH staining being negative in both distinct foci of the tumour.
These findings support the diagnosis of FH-deficient renal cell carcinoma with low-grade eosinophilic morphology.
Conclusion: This case contributes to the understanding of the clinicopathological spectrum of FH-deficient RCC and highlights the importance of recognizing this rare morphological variant in clinical practice.

E-PS-26-090

Leydig tumour microenvironment induces T-lymphocyte recruitment and tubular epithelial testicular atrophy

S. Stifter-Vretenar[1], M. Jürgens[1]
[1]Aarhus University Hospital, Department of Pathology, Aarhus, Denmark

Background & Objectives: We report a patient, a 56-year-old male, with right testicular atrophy with a simultaneous occurrence of Leydig cell hyperplasia (LCH) and Leydig cell tumour (LCT).
The objective of the presented study was to explore both lesions' morphology and their contribution to atrophy and fibrosis.
Methods: Immunohistochemical analysis was performed, including a standard diagnostic antibody panel (PLAP, inhibin, WT-1, calretinin, Melan-A/MART-1, vimentin, and Ki-67). Immunophenotyping of the inflammatory cells differentiated between mononuclear cells, using primary antibodies for macrophages (CD68 and CD163) and B- and T-lymphocyte subgroups (CD20, CD8, CD5, CD4, and CD3).
Results: Physical examination revealed an above-average size of the left testicle, bilateral gynecomastia, and normal routine blood tests. Testicular ultrasonography showed an atrophic right testicle with hypoechoic masses measuring up to 6×9 mm. The right orchiectomy specimen appeared inconspicuous, with a single whitish nodule measuring 9 mm in diameter.
Leydig cell hyperplasia and atypical Leydig cell tumour with different morphology were diagnosed. Both LCH and LCT displayed the same immunoprofile. Additional immunophenotyping of the inflammatory cells was performed. Decreased spermatogenesis was observed, with sclerotic and hyalinized tubules. Lymphocytic aggregates were visible in the peritubular interstitium, and focal intraepithelial lymphocytes were noted. Peritubular lymphocytic cuffing was observed, indicating the early phase of a chronic inflammatory process with consequent destruction of the epithelium.
Conclusion: The B-lymphocyte cell population resided in areas surrounding the LCT, accompanied by the remaining mononuclear cells identified as macrophages. T-lymphocyte distribution suggested epithelial tropism and pronounced both peritubular and pericapillary cuffing. Based on these observations, the testis affected by LCH and LCT shows progressive germ cell epithelial destruction mediated by T-lymphocyte recruitment. Therefore, a mechanism of inflammatory mononuclear immune cell recruitment mediated by Leydig cell paracrine and endocrine stimulation has been proposed as a testicular microenvironment milieu shifter.

E-PS-26-091

Primary ASPS of kidney mimicking translocation RCC: a diagnostic conundrum

S. Kaushal[1], S.S. Adhikari[1], B.B. Nayak[2], M.C. Sharma[1]
[1]All India Institute of Medical Sciences, Pathology, New Delhi, India, [2]All India Institute of Medical Sciences, Urology, New Delhi, India

Background & Objectives: **Background:** Alveolar soft part sarcoma (ASPS) is an uncommon and unique tumour, typically affecting

young individuals. It has been sparsely reported to affect kidney with only 3 cases reported in published literature. ASPS shares the molecular and immunohistochemical overlap with Translocation associated RCC and distinction of the two can be a diagnostic challenge.
Objective: To present the morphological, immunohistochemical and ultra structural features of primary ASPS of kidney.
Methods: Here we report a case of a 19-year-old female who presented with discomfort in the left flank region since last one year. On examination, a firm mass of 10*10 cm was palpated in the left hypochondrium with indistinct upper margins, CECT of the same showing mass arising from the kidney, pushing the pancreas anteriorly and abutting the spleen. With a clinical diagnosis of RCC, a left radical nephrectomy was performed. We performed histological, immunohistochemical and ultrastructural analysis on the primary tumour of kidney.
Results: Sections from the mass showed a tumour arranged predominantly in nested and alveolar pattern comprising of large, polygonal, highly pleomorphic tumour cells having abundant granular eosinophilic cytoplasm, vesicular chromatin, and prominent nucleoli. Necrosis, haemorrhage, tumour giant cell reaction and foci of dystrophic calcification were also noted.
On immunohistochemistry these tumour cells were immunopositive for TFE3 and Cathepsin K. SDH-B was retained. PAS positive diastase resistant intracytoplasmic needle shaped granules were seen.
Ultrastructural examination showed numerous intracytoplasmic needle to rhomboid shaped crystals. Based on the histological, immunochemical and ultrastructural findings a diagnosis of ASPS was rendered.
Conclusion: ASPS has morphological and molecular similarity to translocation associated RCC and poses diagnostic difficulty in kidney. Awareness and recognition of ASPS as one of primary renal sarcoma is important to avoid this pitfall. Ultrastructural examination is helpful for definitive diagnosis.

E-PS-26-092
Prostatic elastosis: a morphological feature to distinguish atrophy from adenocarcinoma in prostate needle biopsies
L.F. Arias-Ruiz[1], K. Herrera-Perdomo[1], R. Dorantes-Heredia[1]
[1]Médica Sur, Anatomic Pathology, Mexico City, Mexico

Background & Objectives: Prostatic atrophy is a frequent mimic of adenocarcinoma, making their distinction in needle biopsies challenging. Atrophy incidence increases with age, and ischemia appears to be important in its pathogenesis. A correlation has been described between local prostatic arteriosclerosis and atrophy.
Elastosis has been found in 65–85% of prostates at autopsy and, like atrophy, is linked to ischemia and arteriosclerosis. Despite its frequency, its significance remains unclear and is often overlooked. Some morphological features help rule out adenocarcinoma in benign glands, known as "features against cancer," including atrophic cytoplasm, corpora amylacea, merging with benign glands, and inflammation. Elastosis may serve as an additional morphological feature supporting benignity, as an inverse correlation has been observed between elastosis and neoplastic lesions.
We aimed to determine the frequency of elastosis in prostate needle biopsies, assess its association with atrophy and cancer, and evaluate its potential as a histopathological marker.
Methods: We conducted a retrospective observational study at Médica Sur's Department of Anatomic Pathology, reviewing all prostate needle biopsies from January 1st to July 31st, 2024. Two residents and one senior pathologist reviewed each case, recording elastosis and the gland type it surrounded (atrophic or malignant). Atrophy was subclassified into hyperplastic, simple, cystic, sclerotic, and partial. In difficult cases, p63 immunohistochemistry confirmed basal cells.
Results: We reviewed 92 biopsies: 90.0% (80/92) showed atrophy, 56.5% (52/92) adenocarcinoma, and 35.9% (33/92) elastosis. Elastosis was exclusively observed around atrophic glands. Among atrophy cases, 41.3% (33/80) had elastosis, while none of the adenocarcinoma glands exhibited elastosis (0/52). Fisher's exact test showed a significant association between elastosis and atrophy ($p = 0.0036$), and a strong inverse association with carcinoma ($p < 0.00001$).
Conclusion: Elastosis correlates strongly with benign atrophic glands and may aid in ruling out carcinoma in prostate biopsies, as only atrophic glands exhibited elastosis.

E-PS-26-093
Spatial transcriptomics in bladder cancer: insights into tumour heterogeneity
P. Janega[1], A. Janegova[1], T. Kuracinova[1], M. Bollova[1], K. Mikus Kuracinova[1], S. Ziaran[2], T. Sedlackova[3], P. Babal[1]
[1]Comenius University, Faculty of Medicine, Institute of Pathology, Bratislava, Slovakia, [2]Comenius University, Faculty of Medicine, Urology, Bratislava, Slovakia, [3]Comenius University, Science Park, Bratislava, Slovakia

Background & Objectives: Urinary bladder carcinoma is a common malignancy with increasing incidence, occurring six times more often in high-income countries. It exhibits significant intratumoral heterogeneity, posing diagnostic challenges and contributing to variability in grading. Accurate differentiation of dysplastic changes and understanding their genetic basis are essential, alongside the clinical distinction between low- and high-grade lesions and analysis of mutational, transcriptomic, and proteomic profiles. Research in this field represents an important challenge for the future.
Methods: Using the 10X Visium Spatial Gene Expression technology, we focused on molecular profiling of selected urinary bladder tumours. This technology enables effective spatial analysis and visualization of the whole transcriptome within the morphological context of FFPE samples. We analysed bladder tumour specimens with low-grade and high-grade dysplasia, including cases without signs of invasion as well as tumours exhibiting invasive growth patterns, aiming to better understand the spatial transcriptomic landscape associated with tumour progression.
Results: In our analysis, we identified transcriptomic changes in genes involved in cell signalling and growth regulation (P2RY2, KIAA1324), extracellular matrix remodelling and cell adhesion (FBLN1, CLIC3), and epithelial cell differentiation and development (MAL, MALL), specifically within tumour areas with and without invasive growth. Spatial analysis provided new insights into tumour heterogeneity, including the ability to detect cells artificially damaged during sampling, which exhibited altered transcriptomic profiles.
Conclusion: Spatial transcriptomics has proven to be an effective approach for identifying distinct cell populations, particularly in the context of tumour heterogeneity. Through this method, we have identified potential transcriptomic alterations linked to the diverse biological behaviour of tumour cells. Interestingly, noteworthy changes were also observed in the transcriptomic profiles of surrounding non-epithelial supportive tissues. Moreover, the ability to reliably distinguish potentially false transcriptomic changes caused by sampling artifacts is of significant importance for ensuring accurate data interpretation and clinical relevance in cancer research.

E-PS-26-094
p53 mutation phenotype and its correlation with ki67 and Her2 in metastasizing urothelial bladder carcinoma
L. Boesch[1], A. Rodriguez-Calero[2], A. Fleischmann[1,2]

[1]Spital Thurgau AG, Kantonsspital Münsterlingen, Pathologie Institut, Münsterlingen, Switzerland, [2]University of Bern and Inselspital, Institute of Tissue Medicine and Pathology, Bern, Switzerland

Background & Objectives: To assess the Ki67 proliferation marker and the Her2 amplification status in urothelial bladder carcinoma with and without p53 mutational phenotype.

Methods: Tissue microarrays with 978 samples of 1 mm in diameter from 124 primary tumours (PTs) and corresponding lymph node metastases (LNMs) were evaluated for p53 immunophenotype, Ki67 expression and Her2 gene status (VENTANA HER2 Dual ISH DNA Probe Cocktail).

Results: Of the evaluated tumour samples, 434 reveal a p53 mutational phenotype, 455 a p53 wild type and 30 could not be assigned to a category. In spot-by-spot analyses, tissues with p53 mutational phenotype have a significantly higher mean Ki67 staining than p53 wild type tissues (39.7% vs. 25.2%; $p < 0.05$). In addition, the frequency of Her2 amplification was significantly higher in tissues with p53 mutational phenotype (15.1% vs. 8.7 %; $p < 0.05$). The p53 phenotype of the PT is highly conserved in the LNM.

Conclusion: The increased Ki67 proliferation and Her2 amplification rate in urothelial carcinoma samples with p53 mutational phenotype are in line with a loss of tumour suppressor function and genomic stability. p53 status in the PT is highly conserved in the LNMs facilitating tissue testing for drugs targeting p53 mutations.

E-PS-26-095

p63 and HER2 expression patterns in plasmacytoid variant of urothelial carcinoma: immunohistochemical analysis and comparison with literature

B. Yaprak Bayrak[1], B. Ozbek[1], Y. Yuyucu Karabulut[2], L. Cheng[3], M. Akgul[4]

[1]Kocaeli University School of Medicine, Pathology, Kocaeli, Turkey, [2]Mersin University School of Medicine, Pathology, Mersin, Turkey, [3]Brown University Warren Alpert Medical School, the Legorreta Cancer Centre at Brown University, and Brown University Health, Providence, Pathology and Laboratory Medicine, Rhode Island, USA, [4]Brigham and Women's Hospital, Room AL.360E, Pathology and Laboratory Medicine, Boston, USA

Background & Objectives: Plasmacytoid urothelial carcinoma (PUC) is a rare and aggressive variant of urothelial carcinoma characterized by discohesive tumour cell. It harbours CDH1 mutations, resulting in loss of e-cadherin expression, similar to lobular breast carcinoma or signet ring gastric cancer. Immunohistochemical (IHC) markers such as p63 and GATA3 may assist in confirming the diagnosis, while HER2 overexpression by IHC may provide potential therapeutic targets, particularly in the emerging era of antibody-drug conjugates.

Methods: A retrospective analysis was conducted on PUC diagnosed between 2015 and 2024. Tissue specimens were evaluated using IHC for p63 (clone BC4A4, Dako) and HER2 (clone SP3, Cell Marque). Staining intensity and proportion were scored using standard criteria; HER2 interpretation was performed using accepted guidelines on gastrointestinal system malignancies. Clinical and demographic data, including age, gender, metastasis status, and follow-up outcomes, were analysed.

Results: The study included 16 cases of PUC, with a male predominance (75%) and a mean age of 68 years (range: 50–83 years). 62.5% (10/16) of the cases presented with advanced-stage tumours (pT3/pT4), and metastasis was detected in 43.7% (7/16), primarily involving the liver and peritoneum. The average follow-up period was 18 months (range: 7–28 months), and 56.2% (9/16) of the patients died during follow-up. p63 expression was observed in only 50% (8/16) of the cases. HER2 overexpression (3+) was detected in 37.5% (6/16) of the cases. Cases with HER2 positivity were associated with higher stages (pT3/pT4) and worse outcomes. E-cadherin loss was noted in 70% of cases.

Conclusion: Lack of p63 expression may be challenging in the diagnosis of PUC, since it is expected to be negative in top differential diagnoses. Increased HER2 overexpression may provide alternative therapeutic options in patients with PUC.

E-PS-26-096

Urothelial carcinoma with chordoid features: a rare diagnostic pitfall illustrated by three cases

D. Enneli[1], H. Aknar[1], S. Kiremitci[1]

[1]Ankara University Medical School, Department of Pathology, Ankara, Turkey

Background & Objectives: Urothelial carcinoma (UC) with chordoid features is an exceptionally rare histological subtype that shows significant morphological overlap with various myxoid neoplasms, posing diagnostic challenges. We present three cases to highlight the clinicopathological and immunohistochemical features of this subtype and to emphasize the difficulties in differential diagnosis.

Methods: The patients included a 58-year-old woman and two men aged 55 and 65, all presented with macroscopic haematuria. In two of the cases, tumours were located in the left ureteral orifice region of the bladder and measured 4 cm and 6 cm in diameter. All tumours were sampled by transurethral resection. Histologically, each tumour showed conventional urothelial carcinoma with variable proportions of chordoid features characterized by tumour cells arranged in reticular or cord-like patterns within a myxoid stroma. All cases displayed extensive and deep lamina propria invasion. In the female patient, tumour also exhibited extensive muscularis propria invasion, widespread lymphovascular invasion, and areas of sarcomatoid differentiation. Immunohistochemical markers of urothelial lineage showed variable expression in the chordoid areas.

Results: All tumours demonstrated deep lamina propria invasion and adverse prognostic features such as lymphovascular and perineural invasion. Notably, one case revealed a clear morphological transition between chordoid areas and sarcomatoid differentiation, suggesting that this pattern may represent a precursor or transitional stage toward sarcomatoid transformation—a hypothesis previously proposed in the literature.

Conclusion: Only a limited number of cases of this histological subtype have been reported. Greater awareness is essential for pathologists—primarily to avoid misdiagnosis due to its morphological overlap with various tumour types, and secondarily to understand its potential prognostic relevance. Further multicentre studies are required to clarify the clinical implications of chordoid features in urothelial carcinoma.

A methylation-based diagnosis of an intracranial MPNST with unusual morphological and immunophenotypical features case report

F. Váňa[1], P. Pokorná[2,3], P. Pospíšil[4], Z. Mackerle[5], M. Hermanová[1], I. Staniczkova Zambo[5], M. Barák[5], R. Jančálek[5], O. Slabý[2,3], M. Hendrych[1]

[1]Faculty of Medicine, Masaryk University and St. Anne´s University Hospital Brno, First Department of Pathology, Brno, Czech Republic, [2]Faculty of Medicine and Central European Institute of Technology (CEITEC), Masaryk University, Department of Biology, Brno, Czech Republic, [3]University Hospital Brno, Centre for Precision Medicine, Brno, Czech Republic, [4]Masaryk Memorial Cancer Institute Brno and Faculty of Medicine, Masaryk University, Department of Radiation Oncology, Brno, Czech Republic, [5]Faculty of Medicine, Masaryk

University and St. Anne´s University Hospital Brno, Department of Neurosurgery, Brno, Czech Republic

Background & Objectives: Malignant peripheral nerve sheath tumour (MPNST) is a rare, aggressive spindle-cell tumour that seldom develops intracranially. This study aims to report a case of this rare location and provide new insights into its clinical presentation in various stages.
Methods: We integrated clinical and imaging data with histopathology and molecular analysis. Retrospective DNA methylation profiling of the first three biopsies was performed using EPICv2 BeadChip arrays and classified by the Heidelberg classifier v12.8. Therapy targets were assessed with the TruSight Oncology 500 panel.
Results: The primary tumour did not align with any known peripheral sheath tumour by immunophenotype, nor did it correspond to any methylation category defined by the Heidelberg classifier with a sufficiently high classification score. On the contrary, its further recurrences were all classified as MPNST by accepted histopathological criteria and methylation profiling. Additionally, the tumour harboured the same NRAS gain-of-function variant in all the tumour samples strongly supporting its shared origin.
Conclusion: We present a rare case of intracranial MPNST with abundant myxoid stroma, broadening the recognized morphological spectrum of these tumours. Moreover, this case provides evidence for a potentially novel precursor lesion of intracranial MPNST, a finding not previously described in the literature. In routine diagnostic practice, MPNST should be considered in the differential diagnosis of myxoid tumours, regardless the proximity to a peripheral nerve.

Revolutionizing sepsis diagnosis: assessing the Genes2Me 'Sepsis-Q' Point-of-Care Test for rapid detection of 32 sepsis pathogens from whole blood in just 90 minutes
B.S. Gurjar[1], S. Mehra[1], N. Kumar[1], N. Erande[1]
[1]GENES2ME Pvt Ltd, Research and Development, Gurgaon, India

Background & Objectives: Traditional sepsis detection via blood cultures is slow, delaying treatment. The Genes2Me Sepsis-Q RT-PCR Kit enables rapid, accurate detection of 32 pathogens (bacteria, viruses, fungi) directly from whole blood. Using multiplex PCR with five fluorescence channels, it delivers results within 90 minutes (total ~2 hours). Optimized for OnePCR POCT & Rapi-Q POCT platforms.
Methods: 1. OnePCR POCT – A compact, sample-in-result-out platform designed for single-sample rapid testing. Using a four-tube assay and five fluorescence channels, it detects 20 high-priority sepsis pathogens, covering 94% of sepsis cases. Fully automated from extraction to results, it's ideal for point-of-care settings requiring quick clinical decisions.
2. Rapi-Q POCT with Rapi-X16 – A high-throughput system integrating the Rapi-X16 automated extraction unit, capable of processing 1 to 16 samples simultaneously. The eight-tube assay ensures comprehensive detection of 32 sepsis pathogens (100% prevalence coverage), making it ideal for batch processing in labs without compromising accuracy.
Both platforms use Genes2Me's Direct Blood Kit, featuring CellCrack Buffer & GeneErase Enzyme for efficient nucleic acid extraction directly from whole blood. These solutions provide high sensitivity, streamlined workflows, and rapid turnaround times, improving sepsis detection and patient outcomes in both POC and high-throughput settings.
Results: The Sepsis-Q Kit demonstrated analytical sensitivity at 100 copies/reaction and achieved 100% specificity, with no cross-reactivity observed with pathogens such as Chlamydia pneumoniae and Mycoplasma pneumoniae. Interference testing with human DNA, haemoglobin, NaCl, and BSA confirmed no impact on assay performance. Precision testing showed CV < 2%, and the kit exhibited an overall accuracy of 98%.
Conclusion: The Sepsis-Q Real-Time RT-PCR Kit offers a reliable, rapid solution for sepsis detection, with high sensitivity and specificity. Its integration with OnePCR and Rapi-Q platforms provides end-to-end automation for both point-of-care and high-throughput settings, significantly improving diagnostic speed and enabling timely, targeted treatment, ultimately reducing sepsis-related mortality.

Background & Objectives: Previously, a 22C3 antibody-based LDT protocol was validated on the Ventana BenchMark XT and BenchMark ULTRA platforms, showing high concordance between the LDT and the FDA-approved, CE-marked, PD-L1 IHC 22C3 pharmDx (Agilent) in several solid tumour types, except for gastric cancer (GC) (Vainer G. *PLOS One*. 2023). Here, we report on the correlation between the previously validated 22C3 antibody-based LDT and PD-L1 IHC 22C3 pharmDx in GC and an updated pan-tumour analysis.
Methods: PD-L1 expression by continuous combined positive score (CPS) was analysed in tumour samples obtained from participants with multiple tumour types, including GC, using both the 22C3 antibody-based LDT on Ventana BenchMark XT or BenchMark ULTRA and PD-L1 IHC 22C3 pharmDx, which served as the gold standard. Correlation between assays by CPS was assessed using interclass correlation coefficient (ICC) and Spearman correlation coefficient (ρ) in the GC samples and in a pan-tumour cohort including GC samples. Assay agreement rates at prespecified cutoffs (CPS ≥1 or ≥10) were reported as overall percentage agreement (OPA), positive percentage agreement (PPA), and negative percentage agreement (NPA).
Results: PD-L1 expression was evaluable in 129 GC samples by LDT and PD-L1 IHC 22C3 pharmDx. ICC was 0.93 (95% CI, 0.91-0.95) and ρ was 0.95 in GC. For PD-L1 CPS ≥1, OPA was 98% (95% CI, 93-100), PPA was 96% (87-100), and NPA was 99% (93-100). For PD-L1 CPS ≥10, OPA was 98% (95% CI, 95-100), PPA was 93% (66-100), and NPA was 99% (95-100). In 681 pan-tumour samples, ICC was 0.96 (95% CI, 0.95-0.96) and ρ was 0.94.
Conclusion: In GC samples, a 22C3 antibody-based LDT on the Ventana BenchMark XT or BenchMark ULTRA platforms yielded comparable results to PD-L1 IHC 22C3 pharmDx. In the updated pan-tumour analysis, a strong correlation was observed between the two assays.

Improved L252P *MYD88* mutation detection by Droplet Digital™ PCR
K. Matute Molina[1], L. Arnaldo[1], A.M. Muñoz-Mármol[1], A. Hernández[1], M. Tierno[1], R. Martínez[1], A. Urbina[1], J.L. Mate[1], G. Tapia[1], C. Sanz[1]

Background & Objectives: The L252P (formerly L265P) mutation in the *MYD88* gene is a characteristic alteration of lymphoplasmacytic lymphoma (LPL), making its detection essential for differential diagnosis with other lymphomas. This mutation is frequently analysed in formalin-fixed paraffin-embedded (FFPE) biopsies including bone marrow samples, often with a low percentage of neoplastic cells or with degraded DNA. Therefore, it is crucial to have a highly sensitive method. In our laboratory, pyrosequencing is routinely used to detect this mutation, with a limit of detection (LOD) of 3.5%. To increase sensitivity, droplet digital PCR (ddPCR) was set up, and its sensitivity was compared to pyrosequencing by analysing cases with prior wild-type (WT) results.
Methods: The L252P *MYD88* mutation was detected by ddPCR (Bio-Rad) in 21 FFPE samples with *MYD88* mutations previously characterized by pyrosequencing. Additionally, 16 normal tissue samples were analysed to establish the cut-off for the technique. A total of 17 samples with lymphoproliferative processes requiring a differential diagnosis of plasmacytic lymphoma and WT by pyrosequencing were also analysed. Furthermore, the sensitivity (LOD) of ddPCR was established in the wt cases taking in account that this value is experiment and sample depenent. Variant allele frequency (VAF) was also evaluated in the mutated cases.
Results: The L265P mutation was confirmed by ddPCR in all 21 *MYD88* mutated cases detected by pyrosequencing once the ddPCR cut-off was established using normal tissues. Additionally, *MYD88* mutation was detected by ddPCR in 5 of the 17 wt cases by pyrosequencing, with VAFs ranging from 0.4% to 3.11%. Negative results were confirmed with an sensitivity ranging from 0.09% to 0.89%.
Conclusion: The results of this study confirm that ddPCR offers greater sensitivity than pyrosequencing for detecting the L252P *MYD88* mutation, making it a highly valuable tool in the diagnosis of LPL, particularly in cases with low neoplastic cell representation and degraded genetic material.
